VOLUME 1 EIGHTH EDITION

Miller's Anesthesia

Edited by

RONALD D. MILLER, MD, MS
Professor Emeritus of Anesthesia and Perioperative Care
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
San Francisco, California

ASSOCIATE EDITORS

NEAL H. COHEN, MD, MS, MPH
Professor
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
San Francisco, California

LARS I. ERIKSSON, MD, PhD, FRCA
Professor and Academic Chair
Department of Anaesthesiology and Intensive Care Medicine
Karolinska University Hospital, Solna
Stockholm, Sweden

LEE A. FLEISHER, MD
Robert Dunning Dripps Professor and Chair
Department of Anesthesiology and Critical Care
Professor of Medicine
Perelman School of Medicine
University of Pennsylvania
Philadelphia, Pennsylvania

JEANINE P. WIENER-KRONISH, MD
Anesthetist-in-Chief
Massachusetts General Hospital
Boston, Massachusetts

WILLIAM L. YOUNG, MD
Professor and Vice Chair
Department of Anesthesia and Perioperative Care
Professor of Neurological Surgery and Neurology
Director, Center for Cerebrovascular Research
University of California, San Francisco, School of Medicine
San Francisco, California

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods, they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence, or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

www.elsevier.com • www.bookaid.org

To all of the residents, faculty, and colleagues who have helped advance the practice of anesthesiology and who serve as the foundation upon which the eighth edition has been completed

Contributors

ANTHONY R. ABSALOM, MBChB, FRCA, MD
Professor
Department of Anesthesiology
University of Groningen
University Medical Center Groningen
Groningen, Netherlands

OLGA N. AFONIN, MD
Former Assistant Clinical Professor
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
San Francisco, California

PAUL H. ALFILLE, MD
Assistant Professor of Anaesthesia
Harvard Medical School
Director, Thoracic Anesthesia Section
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

PAUL D. ALLEN, MD, PhD
Adjunct Professor
Department of Molecular Biosciences
School of Veterinary Medicine
Adjunct Professor of Anesthesia
School of Medicine
University of California, Davis
Davis, California
Professor of Anaesthesia Research
Leeds Institute of Biomedical & Clinical Sciences
School of Medicine
University of Leeds
Leeds, United Kingdom

J. JEFFREY ANDREWS, MD
Professor and Chair
Department of Anesthesiology
University of Texas Health Science Center at San Antonio
San Antonio, Texas

CHRISTIAN C. APFEL, MD, PhD, MBA
Associate Adjunct Professor
Departments of Epidemiology and Biostatistics
University of California, San Francisco, School of Medicine
San Francisco, California

JEFFREY L. APFELBAUM, MD
Professor and Chair
Department of Anesthesia and Critical Care
University of Chicago
Chicago, Illinois

CARLOS A. ARTIME, MD
Assistant Professor
Associate Director, Operating Rooms
Department of Anesthesiology
University of Texas Medical School at Houston
Houston, Texas

ARANYA BAGCHI, MBBS
Clinical Fellow in Anesthesia
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Harvard Medical School
Boston, Massachusetts

DAVID J. BAKER, DM, FRCA
Emeritus Consultant Anesthesiologist
SAMU de Paris and Department of Anesthesia
Necker Hospital
University of Paris V
Paris, France

ANIS BARAKA, MB, BCh, DA, DM, MD, FRCA (Hon)
Emeritus Professor
Department of Anesthesiology
American University of Beirut Medical Center
Beirut, Lebanon

ATILIO BARBEITO, MD, MPH
Assistant Professor
Department of Anesthesiology
Duke University Medical Center
Anesthesia Service
Veterans Affairs Medical Center
Durham, North Carolina

STEVEN J. BARKER, PhD, MD
Professor Emeritus
Department of Anesthesiology
University of Arizona College of Medicine
Tucson, Arizona

SHAHAR BAR-YOSEF, MD
Assistant Consulting Professor
Department of Anesthesiology and Critical Care Medicine
Duke University Medical Center
Durham, North Carolina

BRIAN T. BATEMAN, MD, MSc
Assistant Professor of Anaesthesia
Harvard Medical School
Attending Physician
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

CHARLES B. BERDE, MD, PhD
Chief, Division of Pain Medicine
Department of Anesthesiology, Perioperative, and Pain Medicine
Boston Children's Hospital
Professor of Anaesthesia and Pediatrics
Harvard Medical School
Boston, Massachusetts

D.G. BOGOD, MB, BS, FRCA, LLM
Honorary Senior Lecturer
University of Nottingham
Consultant Anaesthetist
Nottingham University Hospitals
NHS Trust
Nottingham, United Kingdom

DIPTIMAN BOSE, MS, PhD
Assistant Professor
Department of Pharmaceutical and Administrative Sciences
College of Pharmacy
Western New England University
Springfield, Massachusetts

EMERY N. BROWN, MD, PhD
Warren M. Zapol Professor of Anaesthesia
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Harvard Medical School
Edward Hood Taplin Professor of Medical Engineering
Institute for Medical Engineering and Science
Professor of Computational Neuroscience
Department of Brain and Cognitive Sciences
Massachusetts Institute of Technology
Boston, Massachusetts

RICHARD BRULL, MD, FRCPC
Professor
Department of Anesthesia
University of Toronto
Site Chief
Department of Anesthesia
Women's College Hospital
Staff Anesthesiologist
Toronto Western Hospital
University Health Network
Toronto, Ontario, Canada

DAVID W. BUCK, MD, MBA
Department of Anesthesiology
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

MICHAEL K. CAHALAN, MD
Professor
Chair of Anesthesiology
Department of Anesthesiology
University of Utah
Salt Lake City, Utah

ENRICO M. CAMPORESI, MD
Professor Emeritus
Department of Surgery
University of South Florida
Tampa, Florida

JAVIER H. CAMPOS, MD
Executive Medical Director of Operating Rooms
Professor
Vice Chair of Clinical Affairs
Director of Cardiothoracic Anesthesia
Medical Director of the Preoperative Evaluation Clinic
Department of Anesthesia
University of Iowa Hospitals and Clinics
Iowa City, Iowa

XAVIER CAPDEVILA, MD, PhD
Professor of Anesthesiology
Department Head
Department of Anesthesia and Critical Care Unit
Lapeyronie University Hospital
Montpellier, France

ROBERT A. CAPLAN, MD
Medical Director of Quality
Seattle Staff Anesthesiologist
Virginia Mason Medical Center
Clinical Professor of Anesthesiology
University of Washington Medical Center
Seattle, Washington

MARIA J.C. CARMONA
Professor, Doctor
Division of Anesthesia of ICHC
University of São Paulo Medical School
São Paulo, Brazil

LYDIA CASSORLA, MD, MBA
Professor Emeritus
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
San Francisco, California

NANCY L. CHAMBERLIN, PhD
Assistant Professor
Department of Neurology
Harvard Medical School
Assistant Professor
Beth Israel Deaconess Medical Center
Boston, Massachusetts

VINCENT W.S. CHAN, MD, FRCPC, FRCA
Professor
Department of Anesthesia
University of Toronto
Head, Regional Anesthesia and Acute Pain Program
Toronto Western Hospital
University Health Network
Toronto, Ontario, Canada

LUCY CHEN, MD
Associate Professor of Anaesthesia
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Harvard Medical School
Boston, Massachusetts

HOVIG V. CHITILIAN, MD
Assistant Professor of Anesthesia
Harvard Medical School
Staff Anesthesiologist
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

CHRISTOPHER G. CHOUKALAS, MD, MS
Assistant Clinical Professor
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
Staff Physician
Department of Anesthesia and Critical Care
San Francisco Veterans Affairs Medical Center
San Francisco, California

CASPER CLAUDIUS, MD, PhD
Department of Intensive Care
Copenhagen University Hospital
Copenhagen, Denmark

NEAL H. COHEN, MD, MS, MPH
Professor
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
San Francisco, California

RICHARD T. CONNIS, PhD
Chief Methodologist
Committee on Standards and Practice Parameters
American Society of Anesthesiologists
Woodinville, Washington

CHARLES J. COTÉ, MD
Professor of Anaesthesia
Harvard Medical School
Director of Clinical Research
Division of Pediatric Anesthesia
MassGeneral Hospital for Children
Department of Anesthesia Critical Care and Pain Management
Massachusetts General Hospital
Boston, Massachusetts

[†]CHAD C. CRIPE, MD
Instructor of Anesthesiology and Critical Care
Department of Anesthesiology and Critical Care Medicine
Perelman School of Medicine
University of Pennsylvania
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

CHRISTOPHE DADURE, MD, PhD
Professor of Anesthesiology
Head of Pediatric Anesthesia Unit
Department of Anesthesia and Critical Care Unit
Lapeyronie University Hospital
Montpellier, France

BERNARD DALENS, MD, PhD
Associate Professor
Department of Anesthesiology in Laval University
Clinical Professor
Department of Anesthesiology
University Hospital of Quebec
Quebec City, Quebec, Canada

HANS D. DE BOER, MD, PhD
Anesthesiology and Pain Medicine
Martini General Hospital Groningen
Groningen, The Netherlands

GEORGES DESJARDINS, MD, FASE, FRCPC
Clinical Professor of Anesthesiology
Director of Perioperative Echocardiography and Cardiac Anesthesia
Department of Anesthesiology
University of Utah
Salt Lake City, Utah

CLIFFORD S. DEUTSCHMAN, MS, MD, FCCM
Department of Anesthesiology and Critical Care
Perelman School of Medicine
University of Pennsylvania
Philadelphia, Pennsylvania

PETER DIECKMANN, PhD, Dipl-Psych
Head of Research
Capital Region of Denmark
Center for Human Resources
Danish Institute for Medical Simulation
Herlev Hospital
Herlev, Denmark

RADHIKA DINAVAHI, MD
Anesthesiologist

[†]Deceased.

D. JOHN DOYLE, MD, PhD
Professor of Anesthesiology
Cleveland Clinic Lerner College of Medicine
Case Western Reserve University
Staff Anesthesiologist
Department of General Anesthesiology
Cleveland Clinic
Cleveland, Ohio

JOHN C. DRUMMOND, MD, FRCPC
Professor of Anesthesiology
University of California, San Diego
Staff Anesthesiologist
VA Medical Center San Diego
San Diego, California

RICHARD P. DUTTON, MD, MBA
Executive Director
Anesthesia Quality Institute
Chief Quality Officer
American Society of Anesthesiologists
Park Ridge, Illinois

RODERIC ECKENHOFF, MD
Vice Chair for Research
Austin Lamont Professor
Department of Anesthesiology and Critical Care
Perelman School of Medicine
University of Pennsylvania
Philadelphia, Pennsylvania

DAVID M. ECKMANN, PhD, MD
Horatio C. Wood Professor of Anesthesiology and Critical Care
Professor of Bioengineering
University of Pennsylvania
Philadelphia, Pennsylvania

MARK R. EDWARDS, BMedSci, BMBS, MRCP, FRCA, MD(Res)
Consultant in Anesthesia and Perioperative Research
University Hospital Southampton
Southampton, United Kingdom

CHRISTOPH BERNHARD EICH, PD DR MED
Department Head
Department of Anaesthesia, Paediatric Intensive Care, and Emergency Medicine
Auf der Bult Children's Hospital
Hannover, Germany

MATTHIAS EIKERMANN, MD, PhD
Associate Professor of Anaesthesia
Harvard Medical School
Director of Research
Department of Anesthesia, Critical Care, and Pain Medicine
Critical Care Division
Massachusetts General Hospital
Boston, Massachusetts

LARS I. ERIKSSON, MD, PhD, FRCA
Professor and Academic Chair
Department of Anaesthesiology and Intensive Care Medicine
Karolinska University Hospital, Solna
Stockholm, Sweden

NEIL E. FARBER, MD, PhD
Associate Professor of Anesthesiology, Pharmacology and Toxicology & Pediatrics
Departments of Anesthesiology and Pediatrics
Children's Hospital of Wisconsin
Department of Pharmacology and Toxicology
Medical College of Wisconsin
Milwaukee, Wisconsin

MARC ALLAN FELDMAN, MD, MHS
Staff Anesthesiologist
Department of General Anesthesiology
Director, Cole Eye Institute Operating Rooms
Cleveland Clinic
Cleveland, Ohio

LEE A. FLEISHER, MD
Robert Dunning Dripps Professor and Chair
Department of Anesthesiology and Critical Care
Professor of Medicine
Perelman School of Medicine
University of Pennsylvania
Philadelphia, Pennsylvania

PAMELA FLOOD, MD, MA
Professor
Department of Anesthesiology, Perioperative, and Pain Medicine
Stanford University
Palo Alto, California

STUART A. FORMAN, MD, PhD
Associate Professor of Anaesthesia
Harvard Medical School
Associate Anesthetist
Anesthesia Critical Care and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

KAZUHIKO FUKUDA, MD
Professor
Department of Anesthesia
Kyoto University Faculty of Medicine
Kyoto, Japan

DAVID M. GABA, MD
Associate Dean for Immersive and Simulation-Based Learning
Stanford University School of Medicine
Stanford, California
Codirector
Simulation Center Anesthesiology and Perioperative Care Service
VA Palo Alto Health Care System
Palo Alto, California

SARAH GEBAUER, MD
Assistant Professor
Department of Anesthesiology and Palliative Care
University of New Mexico
Albuquerque, New Mexico

SIMON GELMAN, MD, PhD
Chairman Emeritus
Department of Anesthesiology, Perioperative, and Pain Medicine
Brigham and Women's Hospital
Boston, Massachusetts

DAVID B. GLICK, MD, MBA
Associate Professor
Department of Anesthesia and Critical Care
University of Chicago
Chicago, Illinois

LAWRENCE T. GOODNOUGH, MD
Professor of Pathology and Medicine
Stanford University
Director, Transfusion Service
Stanford University Medical Center
Stanford, California

SUMEET GOSWAMI, MD, MPH
Associate Professor of Anesthesiology
Cardiothoracic Anesthesiology and Critical Care
Columbia University Medical Center
New York, New York

SALVATORE GRASSO, MD
Section of Anesthesia and Intensive Care
Department of Emergency Organ Transplantation
University of Bari
Bari, Italy

ANDREW T. GRAY, MD, PhD
Professor of Clinical Anesthesia
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
San Francisco General Hospital
San Francisco, California

WILLIAM J. GREELEY, MD, MBA
Chair and Anesthesiologist-in-Chief
Department of Anesthesiology and Critical Care Medicine
The Children's Hospital of Philadelphia
Professor of Anesthesia and Pediatrics
Perelman School of Medicine
University of Pennsylvania
Philadelphia, Pennsylvania

THOMAS E. GRISSOM, MD
Associate Professor
Department of Anesthesiology
R Adams Cowley Shock Trauma Center
University of Maryland School of Medicine
Baltimore, Maryland

MICHAEL P.W. GROCOTT, BSc, MBBS, MD, FRCA, FRCP, FFICM
Professor of Anesthesia and Critical Care Medicine
Integrative Physiology and Critical Illness Group
Division of Clinical and Experimental Science
Faculty of Medicine
University of Southampton
Anaesthesia and Critical Care Research Unit
University Hospital Southampton
Southampton, United Kingdom
The Royal College of Anaesthetists
London, United Kingdom

MICHAEL A. GROPPER, MD, PhD
Professor and Acting Chairman
Department of Anesthesia and Perioperative Care
Professor of Physiology
Investigator, Cardiovascular Research Institute
University of California, San Francisco, School of Medicine
San Francisco, California

WENDY L. GROSS, MD, MHCM
Vice Chair, Anesthesia for Interventional Medicine
Division of Cardiac Anesthesia
Department of Anesthesiology, Perioperative, and Pain Medicine
Brigham and Women's Hospital
Boston, Massachusetts

[†]FOUAD SALIM HADDAD, MD, FACA, DABA
Clinical Associate
Department of Anesthesiology
American University of Beirut Medical Center
Beirut, Lebanon

CARIN A. HAGBERG, MD
Joseph C. Gabel Professor and Chair
Department of Anesthesiology
University of Texas Medical School at Houston
Houston, Texas

C. WILLIAM HANSON, MD, FCCM
Professor of Anesthesiology and Critical Care
Professor of Surgery and Internal Medicine
Chief Medical Information Officer and Vice President
University of Pennsylvania Health System
Perelman Center for Advanced Medicine
Philadelphia, Pennsylvania

GÖRAN HEDENSTIERNA, MD, PhD
Professor in Clinical Physiology
Uppsala University
Uppsala, Sweden

EUGENIE S. HEITMILLER, MD, FAAP
Professor
Departments of Anesthesiology/Critical Care Medicine and Pediatrics
Division of Pediatric Anesthesiology/Critical Care Medicine
Johns Hopkins University School of Medicine
Baltimore, Maryland

[†]Deceased.

THOMAS M. HEMMERLING, MD, DEAA
Associate Professor
Department of Anesthesia
McGill University Health Center
Associate Director
Arnold and Blema Steinberg Medical Simulation Center
McGill University
Associate Director
Institute of Biomedical Engineering
Director, ITAG Laboratory
University of Montreal
Montreal, Quebec, Canada

HUGH C. HEMMINGS, Jr., MD, PhD, FRCA
Joseph F. Artusio, Jr., Professor and Chair of Anesthesiology
Professor of Pharmacology
Weill Cornell Medical College
Attending Anesthesiologist
New York Presbyterian Hospital
New York, New York

ZAK HILLEL, MD, PhD
Professor of Clinical Anesthesiology
Department of Anesthesiology
College of Physicians and Surgeons
Columbia University
Director of Cardiothoracic Anesthesiology
St. Luke's-Roosevelt Hospital Center
New York, New York

NAOYUKI HIRATA, MD, PhD
Instructor
Department of Anesthesiology
Sapporo Medical University School of Medicine
Sapporo, Japan

TERESE T. HORLOCKER, MD
Professor of Anesthesiology and Orthopaedics
Department of Anesthesiology
Mayo Clinic
Rochester, Minnesota

STEVEN K. HOWARD, MD
Staff Anesthesiologist
Anesthesiology and Perioperative Care Service
VA Palo Alto Health Care System
Associate Professor of Anesthesiology, Perioperative, and Pain Medicine
Stanford University School of Medicine
Stanford, California

YUGUANG HUANG, MD
Professor and Chairman
Department of Anesthesiology
Union Medical College Hospital
Beijing, China

MICHAEL HÜPFL, MD
Consultant
University Clinic for Anaesthesia, Intensive Care, and Pain Therapy
Head of Medical Simulation
Medical University Vienna
Emergency Physician
Chair of European Trauma Course Austria
Vienna, Austria

ROBERT W. HURLEY, MD, PhD
Professor of Anesthesiology
Vice Chairman of Pain Medicine
Department of Anesthesiology
Medical College of Wisconsin
Milwaukee, Wisconsin

FUMITO ICHINOSE, MD, PhD
Professor of Anaesthesia
Harvard Medical School
Attending Physician
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

SAMUEL A. IREFIN, MD, FCCM
Associate Professor
Anesthesiology and Intensive Care Medicine
Cleveland Clinic Lerner College of Medicine
Case Western Reserve University
Cleveland, Ohio

YUMI ISHIZAWA, MD, MPH, PhD
Instructor of Anaesthesia
Harvard Medical School
Assistant Anesthetist
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

VESNA JEVTOVIC-TODOROVIC, MD, PhD, MBA
Harold Carron Professor of Anesthesiology and Neuroscience
Department of Anesthesiology
School of Medicine
University of Virginia
Charlottesville, Virginia

KEN B. JOHNSON, MD
Professor
Department of Anesthesiology
University of Utah
Salt Lake City, Utah

OLUWASEUN JOHNSON-AKEJU, MD
Instructor in Anaesthesia
Harvard Medical School
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

DAVID W. KACZKA, MD, PhD
Associate Professor
The University of Iowa Hospital and Clinics
Department of Anesthesia
Iowa City, Iowa

BRIAN P. KAVANAGH, MB, FRCPC
Chief, Department of Anesthesia
Departments of Anesthesia and Critical Care Medicine
University of Toronto
Toronto, Ontario, Canada

JENS KESSLER, MD
Department of Anaesthesiology
University Hospital
Division Center for Pain Therapy and Palliative Medicine
Heidelberg, Germany

TODD J. KILBAUGH, MD
Assistant Professor of Anesthesiology, Critical Care Medicine, and Pediatrics
The Children's Hospital of Philadelphia
Department of Anesthesiology and Critical Care Medicine
Perelman School of Medicine
University of Pennsylvania
Philadelphia, Pennsylvania

TAE KYUN KIM, MD, PhD
Associate Professor
Department of Anesthesia and Pain Medicine
Pusan National University School of Medicine
Busan, South Korea

JAMES D. KINDSCHER, MD
Professor of Anesthesiology
Department of Anesthesiology
Kansas University
Director, Liver Transplant Anesthesiology
Kansas University Hospital
Director, Kansas Society of Anesthesiologists
Kansas City, Kansas

BENJAMIN A. KOHL, MD, FCCM
Chief, Division of Critical Care
Program Director, Adult Critical Care Medicine Fellowship
Medical Director, Penn eLert Telemedicine Program
Department of Anesthesiology and Critical Care
Perelman School of Medicine
University of Pennsylvania
Philadelphia, Pennsylvania

ANDREAS KOPF, MD
Department of Anesthesiology and Critical Care Medicine
The Free University of Berlin
Charité Campus Benjamin Franklin
Berlin, Germany

SANDRA L. KOPP, MD
Associate Professor of Anesthesiology
Department of Anesthesiology
Mayo Clinic
Rochester, Minnesota

PRIYA A. KUMAR, MD
Professor of Anesthesiology
University of North Carolina School of Medicine
Chapel Hill, North Carolina

ARTHUR M. LAM, MD, FRCPC
Medical Director
Neuroanesthesia and Neurocritical Care
Swedish Neuroscience Institute
Swedish Medical Center
Clinical Professor
Anesthesiology and Pain Medicine
University of Washington
Member, Physician Anesthesia Services
Seattle, Washington

GIORA LANDESBERG, MD, DSc, MBA
Associate Professor
Anesthesiology and Critical Care Medicine
Hadassah-Hebrew University Medical Center
Jerusalem, Isreal

JAE-WOO LEE, MD
Associate Professor
Department of Anesthesiology
University of California, San Francisco, School of Medicine
San Francisco, California

GUILLERMO LEMA, MD
Professor
Division of Anesthesiology
Pontifical Catholic University of Chile
Chief of Cardiovascular Anesthesia
Clinical Hospital
Santiago, Chile

BRIAN P. LEMKUIL, MD, FRCA, FCCM
Assistant Clinical Professor
Department of Anesthesia
University of California, San Diego
San Diego, California

CYNTHIA A. LIEN, MD
Professor of Anesthesiology
Department of Anesthesiology
Weill Cornell Medical College
New York, New York

LAWRENCE LITT, MD, PhD
Professor
Department of Anesthesia and Perioperative Care
Department of Radiology
University of California, San Francisco, School of Medicine
San Francisco, California

KATHLEEN LIU, MD, PhD, MAS
Associate Professor
Departments of Medicine and Anesthesia
University of California, San Francisco, School of Medicine
San Francisco, California

LINDA L. LIU, MD
Professor
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
San Francisco, California

ALAN J.R. MACFARLANE, BSc (Hons), MBChB (Hons), MRCP, FRCA
Honorary Clinical Senior Lecturer
University of Glasgow
Consultant Anaesthetist
Glasgow Royal Infirmary and Stobhill Ambulatory Hospital
Glasgow, United Kingdom

MICHAEL E. MAHLA, MD
Professor of Anesthesiology and Neurosurgery
Department of Anesthesiology
University of Florida College of Medicine
Gainesville, Florida

ANUJ MALHOTRA, MD
Assistant Professor
Department of Anesthesiology
Pain Management Division
Icahn School of Medicine at Mount Sinai
New York, New York

VINOD MALHOTRA, MD
Professor and Vice-Chair for Clinical Affairs
Department of Anesthesiology
Professor of Anesthesiology in Clinical Urology
Weill Cornell Medical College
Clinical Director of the Operating Rooms
New York-Presbyterian Hospital
New York Weill Cornell Center
New York, New York

JIANREN MAO, MD, PhD
Richard J. Kitz Professor of Anaesthesia Research
Harvard Medical School
Vice Chair for Research
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

JONATHAN B. MARK, MD
Professor and Vice Chairman
Department of Anesthesiology and Critical Care Medicine
Duke University Medical Center
Chief, Anesthesiology Service
Veterans Affairs Medical Center
Durham, North Carolina

†ELIZABETH A. MARTINEZ, MD, MHS
Anesthesiologist
Department of Anesthesiology, Critical Care, and Pain Medicine
Massachusetts General Hospital
Harvard School of Medicine
Boston, Massachusetts

†Deceased.

J.A. JEEVENDRA MARTYN, MD, FRCA, FCCM
Professor of Anaesthesia
Harvard Medical School
Director
Clinical and Biochemical Pharmacology Laboratory
Massachusetts General Hospital
Anesthesiologist-in-Chief
Shriners Hospital for Children
Boston, Massachusetts

LUCIANA MASCIA, MD, PhD
Department of Anesthesia and Intensive Care
University of Torino
S. Giovanni Battista-Molinette Hospital
Torino, Italy

GEORGE A. MASHOUR, MD, PhD
Bert N. La Du Professor and Associate Chair
Department of Anesthesiology
Faculty, Neuroscience Graduate Program
Faculty, Center for Sleep Science
University of Michigan Medical School
Ann Arbor, Michigan

MAUREEN McCUNN, MD, MIPP, FCCM
Associate Professor
Anesthesiology and Critical Care
R Adams Cowley Shock Trauma Center
University of Maryland School of Medicine
Baltimore, Maryland

BRIAN P. McGLINCH, MD
Assistant Professor
Department of Anesthesiology
Mayo Clinic
Rochester, Minnesota

DAVID McILROY, MB, BS, MClinEpi, FANZCA
Staff Anaesthetist
Adjunct Senior Lecturer
Department of Anaesthesia and Perioperative Medicine
Alfred Hospital and Monash University
Melbourne, Australia
Adjunct Assistant Professor
Department of Anesthesiology
Columbia University
New York, New York

CLAUDE MEISTELMAN, MD
Professor and Chair
Department of Anesthesiology and Intensive Care Medicine
Hopital Brabois
University of Lorraine
Nancy, France

JANNICKE MELLIN-OLSEN, MD, DPH
Consultant Anaesthesiologist
Department of Anesthesia, Intensive Care, and Emergency Medicine
Baerum Hospital
Vestre Viken Health Trust
Oslo, Norway

BEREND METS, MB, PhD, FRCA, FFA(SA)
Professor and Chair of Anesthesiology
Milton S. Hershey Medical Center
Penn State Hershey Anesthesia
Hershey, Pennsylvania

RONALD D. MILLER, MD, MS
Professor Emeritus of Anesthesia and Perioperative Care
Department of Anesthesia and Perioperative Care
University of California, San Francisco, School of Medicine
San Francisco, California

VICKI E. MODEST, MD
Assistant Professor
Harvard Medical School
Anesthetist
Department of Anesthesia, Critical Care, and Pain Medicine
Massachusetts General Hospital
Boston, Massachusetts

Preface

For more than 30 years *Miller's Anesthesia* has been recognized as the most complete and thorough resource on the global scope and practice of contemporary anesthesiology. It is used worldwide and has been translated into several languages. Since the publication of the seventh edition in 2010, the associate editors, the Elsevier publishing staff, and I have had many conversations regarding the eighth edition and how we could ensure that *Miller's Anesthesia* continued to rank as the most influential and comprehensive text on our specialty in the world. Together we gathered information from various sources and solicited comments from colleagues worldwide to evaluate the seventh edition's content. We carefully updated each chapter and introduced new chapters with topics that represent the changes and current information in anesthesiology as it evolved over the past 5 years. The results of these deliberations are presented in the pages that follow.

The eighth edition of *Miller's Anesthesia* has several new chapters that have been created in one of two ways—either by introducing topics that have grown in importance since the publication of the previous edition or by dividing a very large chapter into two smaller ones. Ten of the chapters cover topics new to this edition, such as "Perioperative and Anesthesia Neurotoxicity" (Chapter 15), "Gastrointenstinal Physiology and Pathophysiology" (Chapter 21), and "Palliative Medicine" (Chapter 65).

Historically, anesthesia has been dominated by intraoperative care. Over many years, the preoperative and postoperative periods of perioperative care have become more prominent. This development is evident in the names of our institutions as more and more anesthesia departments have changed their titles to better reflect both anesthesia and perioperative care. Accordingly, the chapters "Perioperative Management" (Chapter 3) and "Anesthesia Business Models" (Chapter 12) were included. Developments in pharmacology have necessitated a new chapter, "Nonopioid Pain Medications" (Chapter 32). Because transplantation of various organs continues to expand, "Anesthesia for Organ Procurement" (Chapter 75) has been added. The associate editors and I thought that we should look to the future by adding "Anesthesia for Fetal Surgery" (Chapter 78) and "Administration of Anesthesia by Robots" (Chapter 86). Lastly, the expansion of anesthesia administration into non–operating room settings has been occurring for many years; thus the chapter "Non–Operating Room Anesthesia" (Chapter 90) was needed.

The splitting of four large chapters has resulted in eight chapters that are of greater focus. This has allowed us to more thoroughly present material that reflects current knowledge in these subjects. The following shows how these new chapters were created:

Seventh Edition Chapter	*Eighth Edition Chapters*
11. Sleep, Memory, and Consciousness	13. Consciousness and Memory 14. Sleep Medicine
29. The Pharmacology of Muscle Relaxants and Their Antagonists	34. Pharmacology of Neuromuscular Blocking Drugs 35. Reversal (Antagonism of Neuromuscular Blockade)
37. Neuromuscular Disorders and Malignant Hyperthermia	42. Neuromuscular Disorders and Other Genetic Disorders 43. Malignant Hyperthermia and Muscle-Related Disorders
75. Anesthesia for Eye, Ear, Nose, and Throat Surgery	84. Anesthesia for Eye Surgery 85. Anesthesia for Ear, Nose, and Throat Surgery

The separation of these topics into two chapters has another noteworthy benefit; we have added to our list of experts new authors who are recognized authorities in their specialties. Also, three chapters devoted to transfusions and coagulation have been placed in the overall category of "Patient Blood Management" (Chapters 61, 62, and 63).

As we proceeded with this book, a unique opportunity was presented to us and resulted in Chapter 112, "Evaluation and Classification of Evidence for the ASA Clinical Practice Guidelines." For many years, the American Society of Anesthesiologists (ASA) has developed practice guidelines on a broad spectrum of clinical and anesthetic specialty activities. These guidelines have been developed based on a well-defined process that incorporates input from many sources, including extensive examination of the literature and clinical insights from anesthesia practitioners. We think that the ASA guidelines have had considerable positive influence on our clinical practices and that it is important to document and understand their history and the course by which these guidelines were developed. We are grateful to Richard T. Connis, David G. Nickinovich, Robert A. Caplan, and Jeffrey L. Apfelbaum for organizing these guidelines for the current edition of this book.

The revision of the table of contents and the selection of authors was a very intense process. Initially, the associate editors, the publishing staff, and I discussed the new table of contents and potential authors online. We then met as a group to carefully review and select subject matter experts. Often the authors who wrote a chapter for the seventh edition were asked to do so for the eighth edition. To ensure that submitted chapters were updated and met our quality standards, we initiated a very thorough review process that included the associate editors, editorial analyst Tula Gourdin, and myself. After our reviews were completed, the manuscript for each chapter was then sent to the publisher for further review and creation of the page proofs. From there, all chapters were sent through a final review cycle by the editorial staff and the authors. We tenaciously adhered to this rigorous and comprehensive editorial process so that we could present an international text like no other in our field. This edition is a collection of the knowledge and experience of some of the world's most renowned anesthesiologists. It thoroughly covers anesthesiology, its subspecialties, and related subjects, and its content is brought to our readers with our upmost attention to quality and veracity.

We are especially proud of Chapter 2, "International Scope, Practice, and Legal Aspects of Anesthesia." This chapter was introduced in the previous edition and continues in this edition with new and updated content. In this edition, we elicited individual contributions from leaders in anesthesiology all over the world. Each contributor describes the development and current status of anesthesiology in his or her region or country. The following have been added for this edition:

1. Discussions of anesthesiology in Brazil by Maria J.C. Carmona
2. New coauthors for Japan (Naoyuki Hirata), Europe (Jannicke Mellin-Olsen), and Russia (Yury S. Polushin)
3. A section on safety and medicolegal initiatives in various regions of the world

A significant number of the chapter authors are from countries other than the United States. All of our decisions regarding this edition were made with the strong motivation to make this text truly international. Fortunately, the increasing prominence of information technology has facilitated the transfer of clinical concepts globally; so with just a handful of exceptions, most countries are no longer intellectually isolated.

Miller's Anesthesia, eighth edition, includes access to the Expert Consult website, allowing users to view the complete text online from any computer and to download the electronic book to a smartphone or tablet. Fully searchable and containing references linked to PubMed abstracts and full-text articles, the website is a powerful tool that gives the reader access to interactive content and a seamless integration between devices. In addition, Expert Consult offers the reader regular content updates and an extensive video library that features video presentations of anesthesia procedures, including airway and ultrasound-guided regional anesthesia techniques.

In addition to our authors, the associate editors of *Miller's Anesthesia* are recognized internationally for their contributions to anesthesiology. One of our associate editors, William L. Young, MD, passed away at the beginning of the review process for this edition. The Remembrance section summarizes Bill's enormous contributions to anesthesiology and his passion for jazz music. During our concerted efforts with writing, editing, and developing the eighth edition, Dr. Young's influence and dedication to excellence were always present.

We wish to express our appreciation to the individual contributors of this 112-chapter book, including those authors from previous editions whose contributions laid the foundation for this edition. *Miller's Anesthesia* would not have been possible without their hard work and dedication. We also acknowledge the contribution of time and expertise by the associate editors, Neal H. Cohen, Lars I. Eriksson, Lee A. Fleisher, and Jeanine P. Wiener-Kronish, and William L. Young. We are grateful for the ongoing efforts of editorial analyst Tula Gourdin, who managed communication with the contributors and the publisher, facilitated the flow of manuscript and page proofs, and checked every detail to ensure that the chapters are as accurate and consistent as possible. We also wish to acknowledge our publisher, Elsevier, and the help and dedication of their staff, in particular executive content strategist, William R. Schmitt; senior content development specialist, Ann Ruzycka Anderson; and senior project manager, Doug Turner.

RONALD D. MILLER, MD, MS

Remembrance

William L. Young, MD
August 6, 1954–August 1, 2013

Director, Center for Cerebrovascular Research
University of California, San Francisco, School of Medicine
Associate Editor, *Miller's Anesthesia,* editions six through eight
(Courtesy Christine Jegan.)

William L. Young, MD, the James P. Livingston Endowed Chair in the Department of Anesthesia and Perioperative Care at the University of California, San Francisco (UCSF), was an accomplished anesthesiologist and prolific investigator. His work has had an impact on the scholarly development of neuroanesthesia and on our ability to understand the mechanisms, pathophysiology, and care of patients with neurovascular disease.

In 2009 he was awarded the American Society of Anesthesiologists (ASA) Excellence in Research Award, the highest honor that the ASA can bestow on an investigator, and it is hard to imagine a more deserving colleague. He was instrumental in establishing the multidisciplinary UCSF Center for Cerebrovascular Research, which has been the vehicle for extending the boundaries of our specialty's influence to include neurosurgery, radiology, neurology, and other various neuroscience fields. When interviewed for our department's fiftieth anniversary, Bill said, "Ultimately, the current status of our specialty should be an effect—not a cause—of the questions we ask, and our reach should exceed our grasp." It is this approach that distinguished his career and points the way for anesthesiology to continue to thrive.

Bill grew up in Munster, Indiana, and coincidentally we both attended medical school at Indiana University. In 1985, after clinical anesthesia training at New York University Medical Center, he joined the faculty at the Columbia University College of Physicians and Surgeons, where he had completed clinical and research fellowships. He quickly grew into a productive and successful National Institutes of Health (NIH)–funded investigator in the specialty of anesthesiology. In 2000 he relocated to UCSF where he became the James P. Livingston Professor and Vice Chair of Anesthesia and Perioperative Care. His unwavering dedication to excellence had an enormous impact on faculty members in our department and across the entire UCSF campus. His productivity in research and NIH grant funding was incredibly consistent. He had continuous NIH funding since 1990, two concurrent NIH grants since 1994, and at least three—and up to five—NIH grants concurrently since l999. He was one of the most prolific recipients of NIH grants in the history of anesthesiology.

He was the principal director of a program project grant, "Integrative Study of Brain Vascular Malformations," which was renewed in 2009 for a second 5 years. Bill's remarkable run began when he was an early recipient of the Foundation for Anesthesia Education and Research (FAER) award system; his success supported the direction that FAER and the ASA pursued in those days. Bill's focus and calm dedication to excellence were inspiring to me personally, and he served as a role model for the entire UCSF faculty.

The substance of his research was even more impressive. From his early studies on the cerebral effects of anesthetics, he gradually moved to more unexplored pathophysiologic areas in anesthesia, neurocritical care, and intraoperative neurosurgery. This led to the understanding of reperfusion hyperemia, or perfusion pressure breakthrough, which is associated with arteriovenous malformation treatment. This work also led to epidemiologic, clinical risk prediction, and imaging studies. When he arrived at UCSF from Columbia University, Bill

approached cerebrovascular biology of vascular remodeling and angiogenesis using molecular and genetic techniques. Studying patients with giant cerebral aneurysms, he used network models, including innovative collaborations with bioengineers and imaging scientists.

Bill was someone the NIH would turn to when it needed leaders. From 1997 until his death, he served on various NIH review committees. In 2005 he became a member of the Clinical Neuroscience and Disease Study Section. In 2008 he was selected to co-chair the first-ever National Institute of Neurological Disorders and Stroke (NINDS) workshop on vascular malformations of the brain. The workshop, which took place in Madrid, involved a gathering of some 50 international clinical and basic science experts. In addition, Bill was instrumental in expanding the number of anesthesiologists conducting high-level basic and clinical research—filling a critical need that was well recognized by ASA leadership and several Rovenstine Lecturers.

He had remarkable success in helping junior faculty obtain career development awards and served as primary mentor on seven NIH-funded K awards (K08, K23, and K25) and three American Heart Association development awards. He was one of the first to be recognized by the NIH for mentoring efforts by receipt of a K24 award in 1999. Several of his trainees are faculty in institutions that include Columbia, Cornell, and UCSF.

His editorial responsibilities were also extensive, having served on the editorial boards of the *Journal of the American Heart Association, Stroke,* and *Neurosurgical Anesthesia*, as well as on the associate editorial board of *Anesthesiology* earlier in his career. He was also the coeditor of a major text, *Cerebrovascular Disease*, and an associate editor for the sixth, seventh, and eighth editions of *Miller's Anesthesia*.

Perhaps the most intriguing evidence of Bill's multifaceted approach to his work and his world was that he was a passionate and professional-level jazz pianist. Being a pianist myself, I was stunned by the complexity and innovation of the many chord progressions he used in his jazz music. When he moved to San Francisco, he gravitated toward the jazz scene and easily worked his way into jam sessions with some of our city's superb professional jazz musicians. And for our department's fiftieth anniversary party with more than 300 attendees, he provided our after-dinner music. Why hire someone else when Bill could do the job as well as anyone?

By using the unique skillsets gained from his training in anesthesia, Bill Young made major contributions to understanding both the biology and the management of neurovascular disorders that many anesthesiologists must manage. He would say, "If anesthesiologists take care of vascular disease patients, then we should strive to understand the totality of the disease process and not accept any *a priori* limitations to the nature of the questions we ask nor investigations we pursue." Indeed, his search for answers began at the bedside, thus instigating the most innovative and productive physiologic approach to understanding these disorders to date, and he continued to conduct this search at the level of program director of an NIH program project grant at the time of his death. Reaching the limits of current physiologic technology, Bill recognized real progress would only occur through a thoughtful laboratory and bedside approach.

For all of these reasons and more, my colleagues and I remember Bill Young and the life he led, which was one of dedication to excellence in all he did.

Acknowledgment: The editors and the publisher recognize the contributions of Dr. William L. Young, who was a contributing author to this topic in prior editions of this work. It has served as the foundation for the current chapter.

Key Points

- Advances in anesthesia care and the scope of anesthesia practice have impressively facilitated the overall care of increasingly complex patient populations. This is especially important for the care of patients who are at the extremes of the age spectrum (i.e., younger and older). One indication of the expanded scope of anesthesiology is the increase in the number of chapters in this book, from 46 in the first edition (1981) to 112 in the eighth edition (2014).
- The scope of anesthesia services has expanded, in part due to the increase in the number of minimally invasive or noninvasive procedures being offered to patients. These changes in practice create both opportunities and challenges for anesthesiologists. The settings in which anesthesia is required continue to expand outside of the operating room and into ambulatory and other settings. These changes in practice require new providers with varying backgrounds and skills. These changes also provide the opportunity to identify new models of care, including telemedicine, to support the diverse patient and provider needs. A major challenge will be to continue the emphasis on safety as these new approaches to anesthesia care become less invasive but in non–operating room locations.
- Overall, national and international mandates for quality, competency, and uniform processes will change the manner in which anesthesia is delivered. More standardization and protocols will be used. These mandates will allow and require more evaluation of clinical practices and research to define the optimal approach to anesthesia and the clinical competence of the providers caring for each patient.
- The anesthesia workforce is changing as a result of subspecialization and expanded use of advanced practice nurses, anesthesia assistants, and other provider groups. The increase in nurses with advanced degrees will have added effects on the practice of anesthesiology. Team management will become more commonplace and, as a result, relationships between physicians and nurses will become a critical determinant of patient outcomes.
- Advances in anesthesia practice based on the underlying science and quality initiatives have been impressive. Although these advances have contributed greatly to the quality of patient care and to patient safety, current trends suggest that there is insufficient breadth and scope of research in anesthesiology to ensure its continued success. Anesthesiologists must be encouraged to engage in research to maintain and even enhance our academic foothold in medicine overall. There are increasing opportunities for multidisciplinary research; these approaches need to be embraced to increase the number of research-trained anesthesiologists. It is also necessary to identify alternative funding sources to support the specialty.

SCOPE OF ANESTHESIA AND PERIOPERATIVE CARE IN HEALTH CARE AND FORCES THAT WILL CHANGE PRACTICES (Fig. 1-1)

Since 1940, the specialty of anesthesiology has contributed greatly to major advances in health care. The contributions by anesthesiologists to the care of surgical patients have been well described in the literature. With the use of new approaches to general and regional anesthesia, new technologies to facilitate the handling of patients with complex physiologic and anatomic (e.g., airway) management and improved monitoring, anesthesiologists and surgeons have been able to provide care to an increasingly complex patient population safely and with few complications. At the same time, anesthesiologists have been instrumental in a number of other ways to improve patient care, including but not limited to new approaches to cardiopulmonary resuscitation, technical developments such as arterial blood gas machines, pulse oximetry for monitoring adequacy of gas exchange, the creation of critical care medicine as a subspecialty, and for advances in pain medicine and transfusion medicine. Each of these advances has benefited patients greatly, but they have also resulted in marked expansion of the scope of anesthesiology. Many of these advances are outlined in detail throughout the 112 chapters in this edition of the text. Each chapter also reflects the advances in the topics covered in these chapters. The book also reflects the commitment of anesthesiologists to addressing the medical needs of society in addition to providing outstanding care to individual patients. Anesthesiologists both in the operating room environment and throughout the health care system currently provide care to a considerable portion of the population in industrialized countries. Approximately 7% to 8% of the total worldwide population requires anesthetic management in association with surgical or diagnostic procedures annually. Perioperative care and anesthetic management have thus had a considerable effect on global public health and have a vital role in health care systems throughout the world. In addition, the specialty of anesthesia has extended beyond the boundaries of perioperative care to include critical care, pain management, sleep medicine, and palliative care.

Advances in diagnostic, pharmacologic, and technical resources have made it possible to provide anesthesia and perioperative care to patients at the extremes of age (i.e., both very young and very old) and to those with complex comorbidities. These systematic developments and enhancements in perioperative care have paralleled and

perhaps facilitated an equally rapid introduction of novel surgical techniques and resources for less invasive surgical approaches. Surgical outcomes have improved considerably, allowing anesthesiology to care for patients with more advanced and complex disorders. At the same time, anesthesiology is recognized as a cornerstone within the modern hospital, extending beyond the operating room.

While most patients understand how important anesthesiology has been to their care, the Institute of Medicine (IOM) of the National Academy of Sciences has publicly praised the commitment of anesthesiology to patient safety and the successful initiatives to ensure it in the book *To Err is Human*.[1] These improvements in the quality and safety of perioperative care are the result of the combined dedication of the entire profession, including both community practices and academic anesthesia departments and their training programs. The combined efforts to obtain a fundamental understanding of the mechanisms behind anesthesia and regulation of vital organ functions and the biologic processes that drive organ failure and complications in the perioperative setting have been crucial. Novel therapies and advanced monitoring equipment have improved patient safety and outcomes in the perioperative setting, pain management, and intensive care medicine.

Although the role of anesthesiology services within the health care system has expanded and the effect of anesthesia on overall quality and safety has been remarkable, health care continues to undergo radical changes that will affect the roles, responsibilities, and scope of anesthesia services in the future, within the United States and throughout the world. The involvement and role of anesthesia providers is gradually increasing within modern perioperative care processes. A more extended scope for preoperative and postoperative care includes more specialized preoperative evaluations and risk assessments with potential biomarkers of adverse outcomes. As the importance of extended and intensive postoperative care for at-risk patient populations increases, the role of anesthesiologists will expand and the practice of anesthesia and perioperative care will become more diversified. In addition, because an increasing percentage of the general population within industrialized countries is older, many with comorbidities will require diagnostic and surgical procedures, with the participation of anesthesiologists in their perioperative care becoming even more critical. In addition, as more of these patients receive complex clinical services, the financial burdens associated with care will escalate throughout the world. The increased cost will be counterbalanced with more scrutiny on the need for surgical care, the expectation that providers must document quality of care, and the requirement to use care pathways and protocols to standardize care. In a changing health care system, anesthesia and perioperative care need to have well designed quality assurance systems and outcome measures that document that the services provided are of the highest quality and safety. Relevant measures of patient outcomes, costs, and cost-benefit analysis will be required for payers, government agencies, and the general public.

Technology is also having a major effect on clinical care. In the surgical setting, technical advancement has led to less invasive and traumatic procedures with fewer negative side effects (e.g., tissue trauma, pain, risk of complications). These advancements can potentially shorten the duration of the perioperative period and subsequent need for in-hospital care. New devices are becoming available to allow remote monitoring of patients not only during and immediately after procedures, but also in the extended care and home environments. Alternative delivery systems for anesthesia will allow it to be provided in nontraditional settings beyond the operating room or procedure rooms, to the intensive care unit, other hospital units, and perhaps other clinical settings. Changes in the anesthesia workforce are also occurring, and additional will be created to facilitate the care of a larger group of patients by a collaborative group of providers working in physical proximity to the patient and, at the same time, with remote monitoring and medical direction from anesthesiologists. The involvement of advance practice nurses and other medical personnel in anesthetic practice has also allowed anesthesiologists to assume greater roles in perioperative management, rapid response teams, triage, and resuscitation outside of the operating room environment.

Electronic health records are being used worldwide, allowing for improved documentation of individual patient care and providing important data for millions of patients. Eventually, minimal to no human interaction will be required for complete data capture and integration for an automatic vigilant system. Complete integration of surgical equipment, anesthesia, and monitors of infusion pumps will enable an analysis of all patient data and clinical responses to facilitate patient care. Assessments regarding the quality of anesthesia can be made by analyzing information from large numbers of patients to evaluate outcomes of care and to facilitate the development of evidence-based clinical practices. One example is the comparative effectiveness and data-mining studies in orthopedic surgery patients; these studies have concluded that neuraxial techniques lead to superior outcomes.[2,3] Furthermore, data can be collected prospectively in consecutive patients from different environments and countries so that perioperative outcomes can be compared and best practices can be identified.[4] Of approximately 46,000 patients in this investigation, 4% died before hospital discharge and the majority of patients who died (73%) were not admitted to a critical care unit after surgery. Conclusions from this investigation suggested that planned critical care after surgery improved outcomes as compared with unplanned admissions to critical care, which were associated with poorer outcomes. Given the more frequent incidence of perioperative mortality than expected, future investigations are planned, including similar investigations in the United States. These investigations will lead to an understanding of the factors that are important behind perioperative mortality and investigations into the treatments that lead to better outcomes.

The IOM described and evaluated the effectiveness and cost of American health care systems (Report Brief, January 2013).[5] They have compared health care outcomes in the United States with those in the rest of the world. The United States spends more money per person than any

other country, yet ranks seventeenth in the world for life expectancy at birth. The IOM concluded that Americans fare worse in several health areas, including infant mortality, injuries, adolescent pregnancy, HIV, drug-related deaths, disability, and especially obesity and diabetes. They also noted that the United States has a larger uninsured population with lapses in the quality and safety of care outside the hospital and more frequent rates of drug abuse, violence, and use of weapons. Americans benefit less from safety net programs than in other countries. In another report (Report Brief, July 2013),[6] the IOM concludes that Medicare payment (i.e., a major source of funding for American medicine) needs to "reorient competition in the health care system around the value of services provided rather than the volume of services provided." These brief conclusions serve as the basis upon which major changes are occurring in health care delivery and financing, particularly regarding the need to demonstrate value. Anesthesia must understand all these changes and priorities in health care delivery and finance to define how to participate and benefit as a specialty and to retain its leadership role in quality and safety.

This summary emphasizes the implications for anesthesiology, but there are also ramifications for medicine overall, particularly in but not limited to the United States. Worldwide, the quality and expense of health care is a challenge. The changes occurring in health care obviously have implications for the role of anesthesiology in both the practice and delivery of medicine overall. Some of the guidelines developed by the American Society of Anesthesiologists (ASA) document the leadership role the specialty has assumed in addressing the needs of our patients (see Chapter 112.).

As mentioned previously, the availability of large clinical databases will also prove to be a valuable tool for refining and improving clinical care. These databases will enable data mining to evaluate the process of care and approaches to identify best practices. Anesthesiology, with its expanding roles in the health care delivery system must be an integral participant in these changes. Clearly, the outcomes after major surgery need far more attention globally with sufficiently large clinical studies focusing on patient-centered outcome measures related to survival and relevant quality-of-life end points. We can only speculate as to what the practice of anesthesia will be like in the future, but these forces will likely have a major effect on the overall scope of anesthesia and perioperative care, thus creating new opportunities that anesthesiology should embrace. Analysis of current national and global priorities can provide some basis for anticipating the future of anesthesiology.[7]

AGING OF SOCIETY

The aging of the world's population combined with improvements in anesthetic and surgical methods are resulting in older patients undergoing increasingly complex surgical procedures. This patient population commonly has decreased general health and organ function, and an increased incidence of chronic medical illness (see Chapter 80). In the United States, the national social insurance program, Medicare, covers more than 47 million Americans, with 39 million being older than 65 years and 8 million having disabilities (data from IOM). The use of surgical services by older patients is not unexpectedly more frequent than with younger patients. For example, in a report by the Centers for Disease Control and Prevention studying inpatient hospitalizations in the United States for 2005, there were 45 million procedures performed on inpatients with a similar number of outpatient procedures. From 1995 through 2004, the rate of hip replacements for patients 65 years and older increased 38%, and the rate of knee replacements increased 70%.

CHANGES IN LOCATION OF CARE

Because of the high costs associated with hospital care, the funding agencies (governmental and private insurance companies) are pressuring providers to perform more procedures in nontraditional settings, both within the hospital and in ambulatory and other less costly sites.[8] Technology and the shift to minimally invasive procedures associated with advances in anesthesia care are facilitating this transition. Providing anesthesia in ambulatory surgical settings and out-of-hospital offices has dramatically increased over the past several decades. With this transition, it is becoming critically important to determine when an anesthesiologist or other anesthesia provider is required to provide care, when alternative providers with or without supervision might be appropriate, and the role for the anesthesiologist in defining standards of care. There are many situations when an anesthesiologist may not be required, for example in administration of conscious sedation to an otherwise healthy patient, but an anesthesiologist is the most appropriate provider in many situations. Not only are there situations in which the risks associated with airway compromise are great (e.g., deep sedation), but there are many clinical situations in which care by an anesthesiologist has been demonstrated to improve clinical outcome and often reduce overall costs of care. Anesthesiologists need to participate actively in discussions within their respective institutions or health systems to define the standards of care, implement best practices, and document clinical value.

In many cases, in part because of costs and changing capabilities, extended postoperative care has shifted from the medical setting to the home. For some families, this transition has created significant clinical and social problems. As care is moved from inpatient settings to other nonhospital settings, anesthesiologists must be involved in determining the most appropriate setting for a procedure and how to manage the transitions of care. Advances in technology can facilitate some of these changes by allowing remote monitoring, and they can create opportunities for anesthesiologists to assume a role in managing patients in these new settings.[9]

COST OF MEDICAL CARE

As the cost of health care in the United States approaches 18% of the gross domestic product,[10] there has been an intensified interest in determining the factors that are

increasing the costs, attempting to find methods to decrease the cost, and obtaining more value for money spent. The primary cost driver in the United States appears to be technical progress, because to some extent the increases in health care costs are occurring throughout the world, regardless of the payment system.[11-13] The increases in the elderly population and patients with chronic disease within that sector are also adding to health care costs.[12]

The escalating costs have led to pressure to get more value for the money spent. There have been pay-for-performance programs—that is, rewarding medical care that is consistent with published evidence and not paying for care that is inconsistent with evidence.[15-17] For the most part, the performance measures, at least in the United States, are process measures rather than measures of outcome (e.g., for anesthesia services, administering antibiotics within 1 hour of incision rather than rates of infection). The concept of pay-for-performance and its implementation have also migrated to other countries, particularly the United Kingdom.[18]

In the nonsurgical arena, the concept of pay-for-performance has been studied for several years.[19,20] In addition to paying for performance, in the United States there is increasing emphasis on not paying for "never" events, such as decubitus ulcers or urinary tract infections, unless they are present on admission to the hospital. The translation of this approach is lack of payment for complications, especially if they could have been prevented with better care (i.e., never events). Because of anesthesia's role in the entire continuum of perioperative care, including postoperative intensive care and pain management, we have an opportunity to influence many of these practices, which can be associated with poor outcomes and increased cost, but which have traditionally not been considered under our domain of care. For example, appropriate and timely administration of antibiotics has a significant effect on surgical site infection, but prior to the initiation of the Surgical Care Improvement Project (SCIP), many anesthesiologists were arguing that control of antibiotics was not within their domain.[21] Anesthesiologists and intensivists can also have a significant effect on the rate of ventilator-associated pneumonia or outcomes that are dependent on strategies for intravenous fluid therapy in the critically ill patients.[22] However, some of these proposed measures, particularly the use of ventilator-associated pneumonia as a quality measure, have become controversial.[23] Pain is considered the fifth vital sign, and the management of postoperative pain is another area in which we can have a significant effect on cost and potential interactions with other members of the hospital team.

PROCESS ASSESSMENT AND QUALITY METRICS

Anesthesiology was among the first professions to focus on reducing the risk of complications partly by developing evidence-based guidelines and standards. The American Society of Anesthesiologists standards and practice parameters are prime examples of this important direction in medicine.[24] Anesthesiology should continue to be involved in these initiatives and should do so collaboratively with other disciplines, including but not limited to surgical specialties. Examples from the perspective of the United States are the involvement of anesthesiologists in the Society of Thoracic Surgeons database and the National Surgical Quality Improvement Project (NSQIP).[25,26] More recently, the Society of Cardiovascular Anesthesiologists has begun discussions with the Society of Thoracic Surgeons. On the other hand, anesthesiologists have been involved from an early stage in quality initiatives with the Institute for Healthcare Improvement and the Surgical Care Improvement Project.[27] Moreover, in many countries, anesthesiology has a key role in the development of quality assurance systems within prehospital care, multidisciplinary critical care, and pain medicine.

Another quality measure that will have global impact on anesthesiologists and all physicians is the new demand for documentation of competency for each clinical privilege assessed not just at the time of recredentialing, but also assessed on an ongoing basis. Defining competency will demand that medicine in general and anesthesiologists specifically adhere to more protocols; the concept of safe anesthesia includes standardization of clinical management overall, including the development and use of standardized protocols. Rather than stifling medical innovation, standardization should be viewed as a mechanism for evaluating process and outcomes; such comparisons cannot be made without standardization. Anesthesiologists will need to be leaders in creating quality and competency metrics. This opportunity can be used to formulate meaningful metrics for practicing anesthesiologists and training physicians. Such metrics will also be required for certified nurse anesthetists and other health care professionals as well. In some cases, documentation of competencies will require the use of simulation or other models to emulate the clinical environment, particularly for rarely performed procedures.

"Change process" has become a cottage industry in medical care, with courses being offered on how to change behaviors and processes in medical care. These mandates can be imposing and possibly frustrating, but they offer the opportunity for more research on identifying the processes that actually improve patient outcomes. These mandates also allow anesthesiologists to assume a leadership role in team management. To accomplish this mandate, new skills need to be taught, including leadership training, improved communication skills, and improved relationship training in the overall atmosphere of pursuing excellence in clinical care and education.

Anesthesiologists already have a long tradition with and training in system approaches to care. These approaches date back to the original checklists created over 50 years ago for the anesthesia machine. It is critical that this skill set be disseminated beyond the intraoperative setting to medicine overall. The understanding of these principles has created many leadership responsibilities for anesthesiologists in a variety of venues including surgical facilities, ambulatory surgery centers, and medical centers.

CHANGES IN PERSONNEL

Within the United States, there are approximately 250,000 active physicians, one third of whom are older than 55 years and are likely to retire by 2020.[28] Although the enrollment in U.S. medical schools in the 1960s doubled, there has been no such increase from 1980 to 2005. Thus, there has been zero growth in U.S. medical school graduates. Yet, the U.S. population has increased by more than 70 million, creating a discrepancy between the supply of medical school graduates and the demand for physician-associated care. Similar developments are seen elsewhere (for more detailed description of workforce changes in Europe, see Chapter 2).

From a global perspective, the number of women in medical schools has increased, so that approximately 50% of the medical students are now women.[29,30] Furthermore, independent of gender, physicians work hours have decreased over the past 40 years.[28,31] To decrease the incidence of fatigue and long durations of "being on call," the reduction in work hours is probably accounting for improved quality of care in addition to lifestyle, but it has consequences. The workforce requirements will have to increase in response to the reduced duty hours and to address the implications of the aging anesthesiologists.

A number of methods have been used within the United States to expand the work force. There has been a steady increase in the recruitment of international medical graduates; approximately 60,000 international medical graduates are residents and constitute 25% of all residents in training.[32] In the United States, the number of osteopathic schools and schools offering advanced degrees in nursing, including training of nurses to become nurse anesthetists, has increased.[28] Given the growing demand for medical care partly owing to the increase in the geriatric population, this need will most likely be met by a combination of physician and nonphysician personnel.

RESEARCH

In terms of creative new investigations, most benchmarks suggest that the specialty of anesthesiology fares poorly in funding when compared with other disciplines, especially clinical disciplines. Using data gleaned from publicly available National Institutes of Health (NIH) sources, Reves[33] compared the specialty with a number of other medical disciplines and produced a troubling figure showing that anesthesiology ranked second to last in funding. Disturbingly, this low ranking has existed for many years preceding Reves's publication in 2007 and has not improved in the years since. However, the fact that anesthesiology in the United States is in the lowest quartile of NIH funding continues to be a concern, particularly because the external forces on the practice components are generally applicable to all specialties. The NIH is not the only source of funding that might influence the specialty; in fact, it is not even the largest source of total research funding in the United States (Fig. 1-2).[34] For all sources, there has been a doubling over the past decade in research expenditures for health and biomedical science research, although compared with biologically based disciplines, health services research is considerably less well funded. In fact, much of the clinical and some basic research are funded from other sources other than the NIH or other federal programs. These sources include foundations (e.g., Foundation for Anesthesia Education and Research) and industry and local institutional sources. Some departments have traditionally supported research by devoting some of their clinically derived incomes for research, especially for young faculty members.

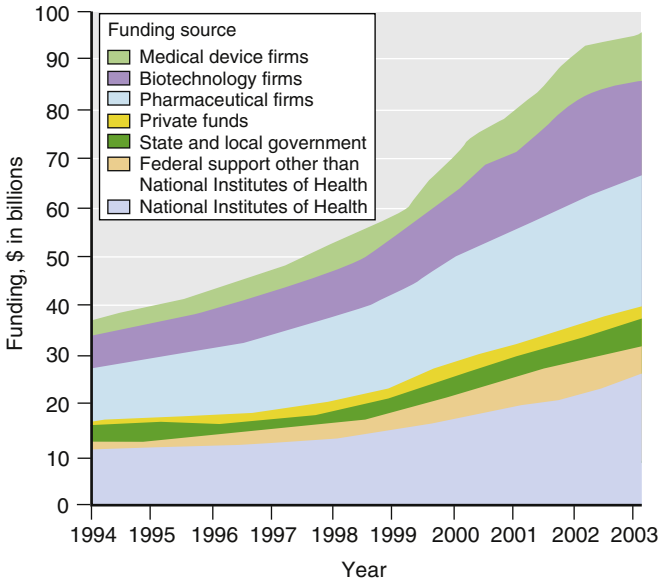

Figure 1-2. U.S. Research expenditures, 1994 to 2003, by funding source. *(From National Center for Health Statistics: Health, United States, 2007, with Chartbook on Trends in the Health of Americans. <http://www.ncbi.nlm.nih.gov/books/bv.fcgi?indexed=google&rid=healthus07.chapter.trend-tables>; National Center for Health Statistics: Health, United States, 2007 With Chartbook on Trends in the Health of Americans Hyattsville, MD: 2007. <http://www.cdc.gov/nchs/hus/previous.htm.>(Accessed 19.05.14.))*

The financial challenges of funding research and the increasing clinical demands of faculty in the United States are evident when reviewing the publications in peer-reviewed journals. In anesthesiology journals, the fraction of original peer-reviewed articles from non-U.S. authors has increased dramatically. The reasons for this change are probably multifactorial, but warrant evaluation. Some have suggested that European and Asian investigators are better funded than in the United States. Yet, adjusted per capita, research support in Europe is only 10% of that in the United States, even though the proportion of scientists in the population is similar.[35] Perhaps, U.S. Food and Drug Administration (FDA) policies bear some responsibility. In the 1980s and 1990s, much "new anesthetics and drug" research started in the United States. Now, most of the new drugs are initially approved in countries other than the United States. Historically, the clinical studies with new drugs are started in the countries of initial approval, which is often not the United States. Finally, many young anesthesiologists have started their research based on opportunities driven by industry-funded novel drugs, a situation that is not as readily available currently as in the past.

Participating in research projects that advance clinical care and translate basic science to the bedside requires the

involvement of a diverse group of investigators. Practically all new frontiers lie at the boundaries of established departmental or specialty divisions, which are largely a historical relic of nineteenth-century or early twentieth-century conceptualizations. A look at any large institution's roster of academic divisions yields a growing number of "centers," "programs," and "institutes," reflecting the ever-increasing interdependency of branches in biomedical knowledge.[36,37] In basic science departments, with conjugate names like Physiology and Cellular Biophysics, Anatomy and Cell Biology, Biochemistry and Biophysics, and Cellular and Molecular Pharmacology, it is becoming increasingly difficult to differentiate one faculty research program from another, solely on the basis of the topics and methods of study. Although this is clearly less complicated for those domains that do not involve patient care, the trend is evident. One might cite the example of endovascular surgery as but one example in the collision of technology and historical boundaries of medical specialties.[38] With this change in approach to advances in the specialty, anesthesiology must actively seek collaborative research environments or organizational structures that allow the development of anesthesiology research in close collaborations to relevant basic science groups and departments such as epidemiology and health policy.

Medical research is at one level original creative work that involves systemic investigation of medical phenomena with the direct or indirect consequence of improving health care. However, anesthesiology is in a position to address research questions in new and creative ways, and it has done so taking advantage of the large clinical databases to assess clinical practices, outcomes of care, and evaluate personalized medicine in defining the best way to manage an individual patient. The Anesthesia Quality Institute (sponsored by the ASA) has implemented a robust database of anesthesia care that will improve the current understanding of clinical practices and outcomes and provide valuable insights to guide future advances in care.

More than ever, anesthesiologists are involved in measuring perioperative outcomes and evaluating the comparative effectiveness of medications and techniques, as documented by an increase in the number of NIH training grants in anesthesia.

To have an influence and impact on the clinical and policy research domain, anesthesia must continue to be involved in all aspects of perioperative care. Building on these experiences, an area of potential focus for anesthesia research is in the perioperative outcomes associated with a variety of new or controversial clinical programs that involve a variety of specialties. It is reasonable to assume that in the future reimbursement for delivery of clinical care will be tied to documentation of quality outcomes that are based on demonstrated efficacy of a procedure, such as randomized clinical trials that involve anesthesiologists and surgeons who assess efficacy and define the right patient populations to undergo a procedure. One such example is the randomized clinical trial of lung reduction surgery for patients with bullous emphysema.[39] Similar approaches can be used to evaluate controversial or costly procedures in high-risk patients, as in the case of minimally symptomatic cerebrovascular diseases.[38,40] By participating in the multidisciplinary teams, anesthesiologists can continue to exert influence in other aspects of patient care besides anesthesia and remain key contributors to defining best surgical practices.

In addition to helping define best practices and advance perioperative care, it is critical for anesthesiology as a physician specialty to remain at the forefront of basic science and clinical research. Other disciplines are becoming more actively involved in health care and health policy research, offering advanced degrees, including doctorates in their own disciplines. While their contributions are important to the overall health care needs of patients, it is critical for physicians to pursue and take leadership roles in investigative research. The various governmental and institutional bodies that regulate health care delivery and patients demand that we do so and require that we document our commitment to high-quality, safe, and efficient care—the mainstay of our specialty for the past 50 years.

Conclusion

At an international anesthesia conference several years ago, the value of using modern electronic monitoring devices in the operating room was emphasized. Because appropriate monitoring (see Chapter 50) improves patient safety, the speaker hoped that hospitals worldwide would adopt and use these devices. During the question and answer session, however, a physician from another country—one whose hospital resources were limited—expressed his frustration and disagreement with this argument. In his country, he believed, there were other priorities and the sheer cost of monitoring equipment prohibited its widespread adoption. Another physician, also from a country whose hospitals had limited resources, disagreed; he argued that by understanding what monitoring devices were available, he would pick the most effective equipment in accordance with his hospital's limited resources. A spirited exchange ensued. Of course, there is no single correct way for hospitals to spend their limited resources. There was, however, enormous value in this exchange among physicians from different countries with distinct cultures, resources, and perspectives. With these types of discussions, the profession can create fully informed baseline standards that foster more successful levels of patient safety and improved outcomes worldwide.

Such discussions also inspired this chapter on the international or global scope and practice of anesthesia. Throughout the career of this book's editor, Ronald D. Miller, he has had the privilege and pleasure of speaking and working with leading anesthesiologists from all over the world. His work and discussions with international colleagues spurred a desire to recognize and honor the growth and practice of anesthesia outside North America. He wanted to describe the different ways that anesthesia began from place to place and to follow the regions through time so that we can better understand how the various regions influence each other today.

This chapter is the first step in realizing Dr. Miller's hope. Work on this chapter began in earnest when the editor invited a number of colleagues whom he had met over the years—prominent anesthesiologists in their parts of the world—to contribute a short summary describing the growth and practice of anesthesia in their country or region. When the contributions arrived, they proved to be a fascinating read: creative, informative, and inspirational. Yet for all their rich content, they also posed an editorial challenge in that the unique geographic features, cultures, politics, economics, and developments in various regions prompted the contributors to emphasize different ideas, discoveries, or time periods. These differences in emphasis and coverage reflect the freedom that the contributors were given to describe their country or region. In the future, we hope to expand on this topic by covering other areas of practice and including world regions not featured in this chapter.

It was in the face of this challenge that Dr. Schwartz was asked to integrate the short individual contributions into a single chapter without compromising their integrity in the seventh edition of *Miller's Anesthesia*. Dr. Miller and Dr. Schwartz chose to create a chronologic narrative that progresses through three distinct periods. Each period is discussed by region; each regional narrative draws directly from the work of the international contributors. Our intent was to always acknowledge and document the sources and wherever possible maintain each contributor's individual voice, and we hope that we have achieved that goal. Because this chapter was so successful, the associate editors and Dr. Miller decided to retain and update it.

Dr. Miller is deeply grateful to all the colleagues who contributed to this chapter, for their insightful writing and the time that they devoted to their tasks, with the only regret that more contributions of this kind could not be included in this edition because of time and space constraints. This chapter represents a preliminary endeavor and by no means a comprehensive look at the development of anesthesia around the world. Future editions will deepen and broaden the international focus.

The first section of this chapter is a sprint through a vast stretch of history, from ancient times through the early twentieth century. Over these 2000 or so years, with a few notable exceptions, the practice of anesthesia grew independently by region in response to the need for pain relief during medical procedures.

The second section covers the period from the 1920s through the early 1980s. Modern communications and international travel expanded dramatically during this period, leading to increased cross-pollination of anesthesia techniques. Physicians and researchers began to travel regularly to foreign countries, receive training and education abroad, and hear others speak at conferences. As the number of international journals increased, knowledge about emerging practices in anesthesia spread further.

The third section covers the time from the late 1980s through the present. This period has been exciting because today nearly all anesthesiologists, no matter where they practice in the world, can gain access to the information necessary to deliver safe anesthesia at the most basic level. Although there are still significant differences in resource levels, some of which undermine the practice of safe anesthesia, at least all anesthesiologists worldwide today know how to avoid the common complications of anesthesia that can endanger patients' lives. This section details the state of anesthesia in the regions covered—from education, accreditation, professional exchanges, and actual practice to available facilities and equipment. No matter how remote a clinician may be, access to a computer will enable the use of the most current principles of perioperative care. Knowledge should no longer be a limiting factor. Unfortunately, limited financial resources can constrain the availability of modern technology.

A fourth section has been added to cover safety and medicolegal aspects. To accommodate the contribution of one of our authors, a future considerations section has also been included.

The chapter concludes by raising questions about what is next in terms of the way various countries and regions practice anesthesia. How integrated should the practice of anesthesia become? What can be done to increase the quality of care worldwide? Certainly many international organizations have tried to enhance the quality of patient care worldwide, which this author recognizes. Leading authors from around the world have been asked to describe the evolution and status of anesthesia in their respective countries. Although there are no simple answers, learning from each other will enhance the transfer of information and knowledge worldwide.

EARLY HISTORY OF INTERNATIONAL ANESTHESIA

Before the early twentieth century, transfer of information internationally was obviously limited. This editor thought that a comparison of the evolution of anesthesia in different countries would not only be interesting, but also educationally instructional regarding the effects of societal pressures and clinical needs on its development. In response to patient needs, physicians from various regions came to different but often similar conclusions about pain relief and surgical anesthesia. In many places, herbs, opium, and alcohol were the mainstays of pain relief medication.

Regions were not completely isolated, however. As the narratives herein describe, the traditional ways of spreading culture and information, such as war, trade, and immigration, enabled at least some sharing of anesthesia techniques. In particular, the first published account of ether used as an anesthetic in 1846 seems to have been a watershed for the field of anesthesia.

BRAZIL (Maria Carmona)

The first ether anesthesia in Brazil was administered in the Military Hospital of Rio de Janeiro by Dr. Roberto Jorge Haddock Lobo on May 25, 1847. Ether was soon replaced by chloroform, which became widespread until other new anesthetic drugs were discovered and introduced into medical practice. Until the early twentieth century, anesthesia was delivered primarily by nurses and surgeons.

INDIA (Deepak K. Tempe)

The history of anesthesia in India dates back to the era of Susruta, the great surgeon of ancient India. During his time, around 600 BC, operations were performed with the use of opium, wine, and Indian hemp (an herb). Surgical science was called *salya-tantra* (*salya*: broken parts of an arrow and other sharp weapons; *tantra*: maneuver).[1]

Much later, in AD 980, Pandit Ballala mentioned in *Bhoj Prabandh* that Raja (King) Bhoj underwent a cranial operation under the anesthetic influence of a plant called *sammohini*. The same plant was applied as a healing balm to surgical wounds. A drug called *sanjivan* was administered to revive the Raja and help him regain consciousness.[2]

Nearly 900 years later, after the first widely publicized demonstration of ether anesthesia in the United States in 1846, India quickly followed suit by administering ether anesthesia on March 22, 1847, in Calcutta under the supervision of a surgeon named Dr. O'Shaughnessy.[3] Later, chloroform was also used but fell into disrepute because of the frequent morbidity associated with it. Despite this morbidity—and the fact that the world began to discard chloroform in preference for ether by 1890—India continued to use chloroform until 1928.

Among the several interesting case reports related to anesthetic practice is the emergency appendectomy performed on Mahatma Gandhi on January 12, 1925, at Sassoon Hospital, Pune (Fig. 2-1). During an electricity failure, the mahatma was administered open-drop chloroform anesthesia, with the surgery being completed by the light of a kerosene lamp and battery-operated torch.[4]

JAPAN (Naoyuki Hirata and Michiaki Yamakage)

In Japan, it is believed that Seishu Hanaoka (Fig. 2-2, *A*) probably first introduced general anesthesia for surgery on October 13, 1804, which was 42 years before W. Morton introduced ether anesthesia to the world.[5] Hanaoka achieved general anesthesia using an herbal concoction

Figure 2-1. Mahatma Gandhi after surgery with the surgeon Col. C. Maddock. *(Courtesy Professor Kalpana Kelkar, Head of Anesthesiology, Sasoon Hospital, Pune, India.)*

Figure 2-2. A, Seishu Hanaoka (1760-1835), the Japanese pioneer of anesthesia and surgery. **B,** Seishu's disciple recorded his first operation (mastectomy, *bottom*) using general anesthesia performed on Kan Aiya (*top*). *(With permission from Wakayama prefecture and Naito Museum of Pharmaceutical Science and Industry.)*

Figure 2-3. A, *Datura alba* was the primary ingredient of mafutsusan, which was the first general anesthetic produced by Seishu. **B,** *Datura alba* is now a symbol of the Japanese Society of Anesthesiologists (JSA).

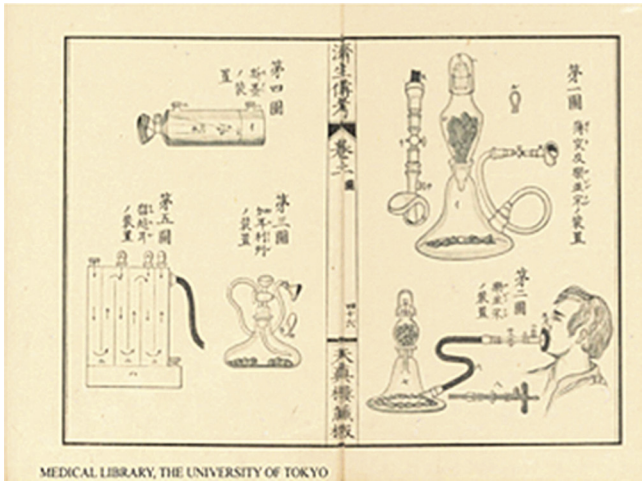

Figure 2-4. Seikei Sugita introduced materials and methods of ether anesthesia to Japan in 1850 by translating Dutch text. *(With permission from Medical Library of Tokyo University.)*

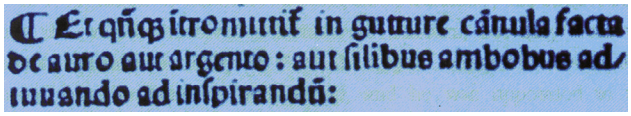

called *mafutsusan*, which mainly contained *Datura alba*, for Kan Aiya, a female patient with breast cancer (see Fig. 2-2, *B*). Hanaoka's colleagues recorded the anesthetic and surgical courses. According to these records, after mafutsusan was administered orally, the patient became drowsy and lost consciousness; Hanaoka then performed a mastectomy without any patient movement. After several hours, the patient recovered from anesthesia. However, the patient died 4.5 months after the surgery. After this first general anesthesia for performing a mastectomy, Hanaoka improved his surgical and anesthetic skills and performed over 200 surgeries using general anesthesia. He accepted many medical students to his school and instructed them privately. At that time, Japan closed its doors to most of the outside world. Therefore, Hanaoka's method had little effect on Western medicine. Nevertheless, Hanaoka's surgical and medical treatments spread widely throughout Japan and prepared the way for the rapid and smooth acceptance of modern Western surgery. *D. alba*, the main component of mafutsusan, is now a symbol of the Japanese Society of Anesthesiologists (JSA; Fig. 2-3).

Forty-six years after Hanaoka's first use of general anesthesia, Seikei Sugita introduced ether anesthesia to Japan in 1850. He translated the Dutch text by J. Sarluis that described the methods and materials of ether anesthesia (Fig. 2-4). The Dutch text was not original but was translated from the German text by J. Schlesinger in 1847.[5a] As mentioned previously, Japan limited its contact with the outside world in those days. Japan was conducting trade with only China and the Netherlands. Therefore, Japan obtained information and knowledge about Western medicine from the Netherlands in the 1800s.

THE MIDDLE EAST (Anis Baraka and Fouad Salim Haddad)

With the decline of the Greco-Roman Empire in the fifth century AD, the Middle East witnessed the rise of an Arab/Islamic civilization that within 100 years (AD 632-732) expanded over a 3000-mile stretch extending from the

A

B

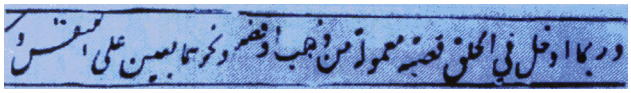

Figure 2-5. A, The Latin version of oral intubation: *Et quandoque intromittiture in gutture canula facta de auro aut argento: aut silibus ambobus, adjuvando ad inspirandu.* **B,** The Arabic version of oral intubation; it translates as, "When necessary, a cannula made of gold, silver, or another suitable material is advanced down the throat to support inspiration." *(From Haddad FS: Ibn Sina [Avicenna] advocated orotracheal intubation 1000 years ago: documentation of Arabic and Latin originals.* Middle East J Anesthesiol *17:155-162, 2000.)*

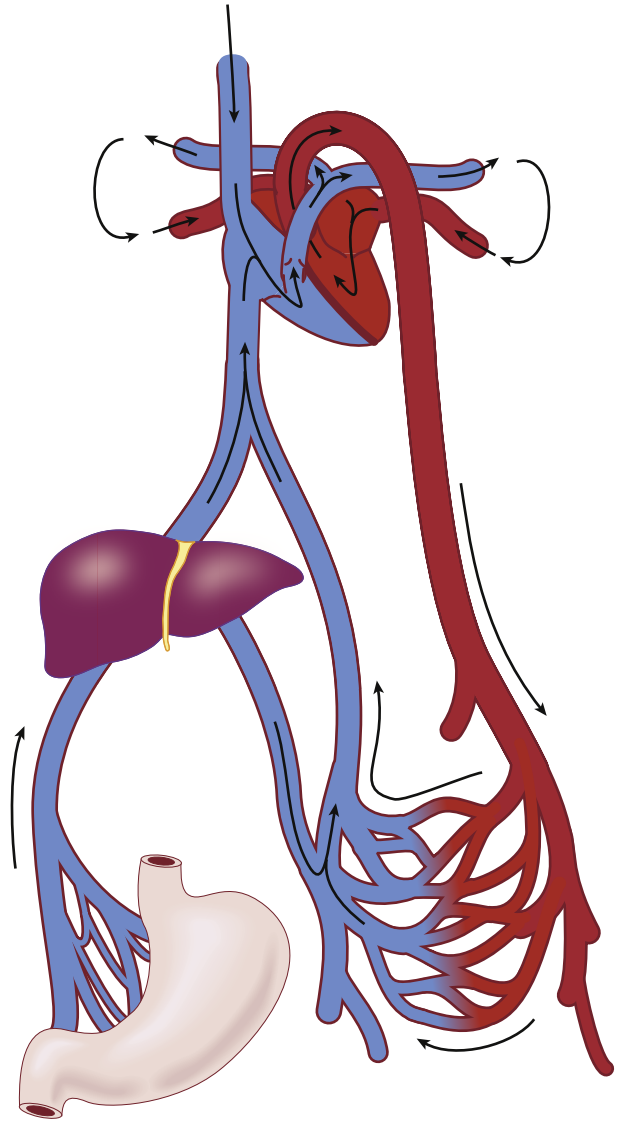

western borders of India, through northern Africa and Sicily, to Andalusia on the Atlantic coast of Spain. This civilization interacted with the ancient Egyptian, Hellenistic, Byzantine, Syrian, Persian, and Indian cultures. Many Arab/Islamic, Christian, and Jewish scholars translated, refined, and augmented the knowledge contained in these cultures. The new civilization that evolved lasted for approximately 1000 years, carried the torch of knowledge in the Middle Ages, and through its transmission via Spain and Sicily, contributed to the European Renaissance.

In this epoch, some prominent Arab/Islamic, Christian, and Jewish scholars made important contributions in the fields of medicine, philosophy, astronomy, mathematics, and chemistry. A wealth of knowledge was thus inherited by several succeeding ages. Of special interest, the following scholars made contributions to the field of anesthesia. First, Al-Rhazi (AD 865-925), born in Ray, Persia, described the pupillary reaction to light and the laryngeal branch of the recurrent laryngeal nerve.[6] Second, Avicenna (AD 980-1037), born near Bukhara, Persia, enumerated drugs that alleviate pain: opium, henbane, and mandrake; in his *Canon of Medicine*, he advocated oral endotracheal intubation: "When necessary, a cannula of gold, silver, or another suitable material is advanced down the throat to support inspiration" (Fig. 2-5).[7,8] Third, Ibn al-Nafis (AD 1208-1288), born in Quresh, near Damascus, Syria, criticized in his *Sharh Tashrih Al Qanou* Galen's theory of blood movement, which said that blood from the right ventricle passes into the left ventricle through small invisible pores in the septum (Fig. 2-6, *A*). Ibn al-Nafis asserted that there is no direct pathway between the chambers and the thick septum of the heart is not perforated, and he described the pulmonary circulation as we know it today (see Fig. 2-6, *B*).[9,10] And fourth, Al-Khawarizmi (died AD 840), born in Balkh, Persia, was a famed mathematician; the word *algorithm,* a mathematical tool, is attributed to him. Algorithm is defined as "a step-by-step problem-solving procedure."[11]

Use of Spongia Somnifera

In the Middle Ages, the concept of inhalation to induce sedation before surgery with use of the sleeping sponge, or *spongia somnifera*, is attributed to Arab origins.[12,13]

A

B

Figure 2-6. A, Galen's theory of blood movement. According to Galen, blood reached the periphery through the veins (most of it departing from the liver), as well as through the arteries (departing from the heart). Little blood went to the lungs from the right ventricle of the heart. He thought that most of the blood passed from the right to the left ventricle through pores in the intraventricular septum. **B,** Photographic reproduction of the original manuscript of Ibn al-Nafis, denying the presence of intraventricular pores and describing the pulmonary circulation.

With the Arab conquest of Sicily in the ninth century and the Latin translations of Arabic medical books that followed, Arabic medicine, including the soporific sponge, took hold in southern Italy (Salerno, Monte Cassino). From there it spread to other parts of Europe and was used in the Middle Ages.[13] A probability also exists that it was carried from the Andalus of Spain by Michael Scot, who in the thirteenth century transmitted scientific culture from Toledo to Bologna via the Court of Frederick II Hohenstaufen in Sicily.[14,15]

After the Middle Ages, major political events in the nineteenth century affected the development of medicine throughout the countries of the Middle East. First, with Napoleon's invasion of Egypt in 1798, the medical awakening of Middle Eastern countries to Western medicine can be said to have started. To win the cooperation of the Egyptian people, Napoleon brought with him men of all specialties.[16] After Napoleon's departure from Egypt and the assumption of power by Mohammad Ali in 1805, efforts to propagate knowledge and education continued. Mohammad Ali brought doctors from Europe and France to take care of the health of his army. Of those, the most remarkable was Dr. Antoine Berthelemy Clot (later Clot Bey) (1793-1868), who was brought to Egypt in 1825. In 1835, Bey established a medical school in Kasr Al Aini Hospital in Cairo, the only Arab medical school in the Middle East at the time.[16]

The developing renovation of Egypt then influenced other regions of the Middle East, either through students flocking to study medicine in Kasr Al Aini Hospital or through the influence of the Egyptian military campaign (Ibrahim Pasha, son of Mohammad Ali) against the then known Syria (1831-1840). Graduates from the medical school in Cairo practiced in all big cities of the Middle East: Beirut, Damascus, Allepo, Jerusalem, Safad, Nablus, Haifa, and Nazareth. It is assumed that the analgesia practiced in major cities of the Middle East was the same technique used in Cairo. Relief of surgical pain in Cairo then consisted of herbal medications and antispasmodics.[16] No kind of inhaled anesthesia was known.

After the invasion of Syria by Ibrahim Pasha from 1831 to 1840, the Egyptians, with the influence of Western missionaries, built two military hospitals—one in Allepo and one in Damascus—and established free medical clinics.[16,17] The presence of Clot Bey in the campaign was instrumental in sending the first five Lebanese students to study medicine at Kasr Al Aini Hospital.[16]

Finally, after massacres in 1860, Western powers (American, French, and British) intervened in Lebanon, and with the inflow of missionaries, more medical schools and hospitals were established. In 1866, the Americans founded the Syrian Protestant College, which in 1920 became the American University of Beirut. In 1883, the French founded their medical school (Faculté Française de Médecine).[16]

Introduction of Modern Anesthesia to the Middle East

In 1846, the first published account of the use of ether anesthesia for a surgical operation appeared, and the innovation spread rapidly,[18,19] including to London in December 1846 and Paris in January 1847. Twenty-seven years later, in 1873, anesthesia arrived in Beirut[16] with the help of an American surgeon, Dr. George Post (Fig. 2-7, *A*).

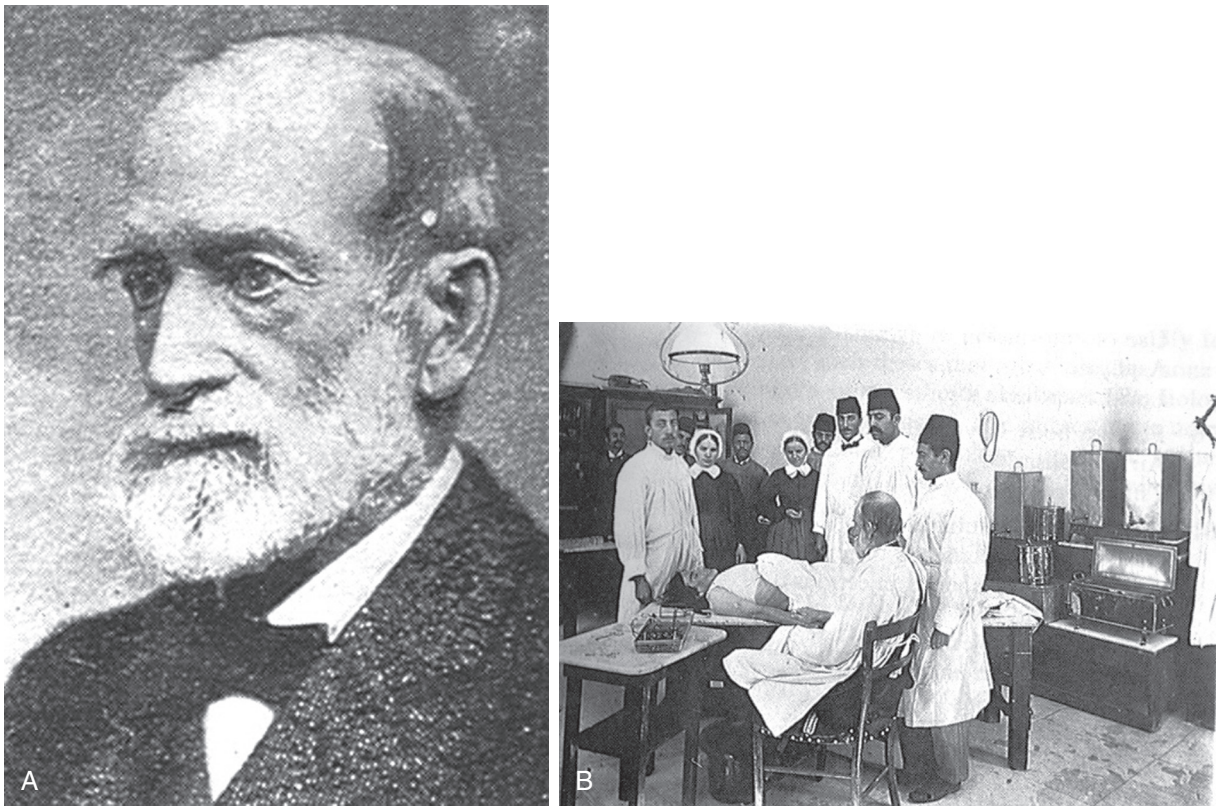

Figure 2-7. A, Dr. George Post (1838-1909). **B,** Dr. George Post in the operating room with a female patient on the operating table.

Dr. Post arrived in Lebanon in 1863 to assist with missionary work. In 1867, he and others established the medical school of the then Syrian Protestant College, and in 1873, Dr. Post wrote a book on surgery in the Arabic language, which included a chapter on general anesthesia, the first of its kind in the Middle East. This chapter described the administration of chloroform. This anesthetic facilitated the ability to reduce a dislocated shoulder of a patient, which was performed at the Syrian Protestant College's Johanniter Hospital in Beirut. To describe this action, Dr. Post coined the word *kulfera,* an Arabization of the word *chloroform*. Dr. Post rightly deserves the title of the First Pioneer of Modern Anesthesia in Lebanon and the Middle East (Fig. 2-7, *B*).[16]

Graduates of the Syrian Protestant College in Lebanon and other graduates of medical schools in the Middle East probably administered open-drop ether or chloroform along with local and spinal anesthesia through the rest of the nineteenth century and middle of the twentieth century. Physicians, students, nurses, nuns, and technicians were most likely also involved.

RUSSIA (Yury S. Polushin)

The history of Russian medicine has its roots in the history of medieval European medicine. Right through the eighteenth and nineteenth centuries, much of the information about anesthetic techniques—applying "snow" 15 minutes before surgical procedures and analgesics for the cardiovascular and respiratory systems and wound healing, as well as the use of bellows for lung ventilation—came from various leaders in European medicine. In addition, like their colleagues in the Middle East and India, Russian physicians heard of the first use of ether on October 16, 1846; that day is still a professional holiday for anesthesiologists in Russia. A brief 4 months later, Dr. F. I. Inozemtzev of Moscow became the first in Russia to use ether for anesthesia during surgery.

Around the same time, the art of local anesthesia was developing rapidly after the publication of an article by the Russian doctor Vassili von Anrep. He described the effects of cocaine as a topical and subcutaneous local anesthetic in 1879. Isolated by the German chemist Friedrich Gaedcke in 1855 and purified by University of Gottingen student Albert Niemann in 1859, cocaine was first given to a patient in 1884. It was the only local anesthetic until 1904, when procaine was synthesized.

Von Anrep's ideas of local anesthesia were highly popular. Famous physicians of Europe and Russia (Shleich, Lukashevich, Vishnevskiy, Bier) were developing the knowledge of local anesthesia, which gave rise to new methods of preventing pain: local field anesthesia, local infiltration anesthesia, nerve blocks, plexus anesthesia, intravenous anesthesia, and neuraxial anesthesia.

In general anesthesia, Nikolay Pirogov (1810-1881) was a prominent Russian physician and surgeon, well known in Europe. He was the first to describe the negative effects of general anesthesia and the possibility of severe complications. He postulated the necessity of acquiring detailed knowledge of the physiologic and clinical effects of anesthetics and requiring a separate course on anesthesia during medical education. He also described many of the modern methods of anesthesia, including inhaled endotracheal anesthesia, intravenous anesthetics, rectal use of anesthetics, and spinal anesthesia. In 1847, he was the first to use ether narcosis on wounded soldiers, and he performed approximately 100 operations on the battlefield during the war in the Caucasus. This had a major effect on the analgesia provided to wounded soldiers in terms of increasing surgical success and rates of survival. (R.D. Miller: Although wars cause an enormous harm to humanity, they have facilitated development of anesthetic techniques for patients undergoing trauma and other major surgical procedures, including Russia in the late 1800s.)

In 1904, the Russian physicians S.P. Feodorov and N.P. Kravkov described and demonstrated total intravascular anesthesia with the intravenous anesthetic gedonal. They were also the first to use combined narcosis through induction with gedonal and maintenance with inhaled chloroform.

Another area in which Russian physicians made advances was in the field of blood transfusions (see Chapter 61). In 1901, Karl Landsteiner reported his discovery of the possible existence of blood types. In 1909, he expanded his initial discovery by establishing the A, B, AB, and O blood types. He demonstrated that transfusions between individuals with the same blood group do not result in the destruction of new blood cells and that this catastrophe occurs only when a person is transfused with the blood of a person belonging to a different group. In 1930, Landsteiner received the Nobel Prize for his work. In 1907, Russian physician Yanskiy had also described four blood types and created the basics of blood transfusion. His work, however, went unnoticed.

Just a few short years later, World War I began, followed by the October Revolution in 1917, which destroyed the monarchy in Russia. Civil war, general poverty, and empowerment of the Communist Party in the early 1920s led to dramatic changes in Russia's political philosophy, economics, and technical and scientific progress, all of which affected the development of medicine. With Joseph Stalin coming to power in the 1920s, communication with other countries in Europe was terminated, exchange of information stopped, and Russian physicians had to continue treating their patients while developing the art of medicine separate from the knowledge and advances in the rest of the world. Likewise, Russian medical advances were not known to the rest of the world and were often reinvented elsewhere.

THE CROSS-POLLINATION PERIOD: 1920-1980

In the late 1970s, the editor (R.D. Miller) took a sabbatical in Holland, during which time he lectured at a local university hospital. Also in residence at the time was a young anesthesiologist from Ecuador. The two physicians became friends as they shared ideas about the practice of anesthesiology and its future. This rich exchange about their profession continues to this day. This was the beginning of this editor's understanding of the interesting

and varied approaches in different parts of the world to achieve the status of anesthesiology as it now stands.

This cross-cultural exchange, however, is no aberration. Over the approximately 60 years from the end of World War I through the early 1980s, anesthesiologists from around the world began to meet in a variety of forums facilitated by air travel and modern communications.

Physicians received training and education abroad. Lecturers from diverse nations spoke frequently outside their home country and brought in new ideas and techniques. Academic and research journals proliferated, as did international congresses and access to textbooks, thereby laying the groundwork for a common understanding of how to practice anesthesia.

BRAZIL (Maria Carmona)

The participation of some Brazilian physicians in World War II was an excellent opportunity to practice and learn more about this emerging specialty (another example of the advance of anesthesia in a military conflict). In 1948, the Brazilian Society of Anesthesiology (SBA) was founded, and since then the SBA and the Federal Council of Medicine have played important roles in defining anesthesia policy and guidelines in Brazil.

CHILE/SOUTH AMERICA (Guillermo Lema)

General Concepts

Geographic and economic diversity have characterized the development of South America. The continent is the site of the Andes (the longest continental mountain range in the world), five desert regions, and rain forests—all of which have given rise to countries with distinct features. This geographic diversity has isolated most of the countries and created huge natural frontiers.

The immigrant populations and the heritage of the native peoples have added their own characteristics. Development has been unique for most countries, resulting in enormous disparity. This disparity is present in numerous aspects of people's lives.

South America's economic growth has been influenced by foreign countries, their economic resources, and investment policies. Some have assumed that most countries would have developed at almost the same speed; however, this has not been the case.

Immigration has also played an important role. The European influence may have been one of the factors for better and faster development in some countries, possibly because of a higher standard of education, a strong will to overcome hard times in their own native countries, and good integration into the South American society. This has certainly been the case in medicine.

South American countries have had to overcome local structural and economic difficulties over the last 50 years, and this has had an obvious effect on daily life.

It is obvious that, because of an economic liberalism in several countries in South America, economic development and disparity throughout the countries has increased enormously, with a discernible effect on medicine, including anesthesia.

In general, economic growth leads to the availability of better and more expedient medical care; however, this is not the case in many South American countries. Although personal incomes have increased, access to medicine of good quality has not been achieved as expected, probably because of the increasing complexity and rising costs of medical care. Indeed, more patients claim that they are receiving good medical care, but according to government authorities at the National Health Services, most countries have not been able to reach the desired goals.

These general concepts should be borne in mind when consideration is given to anesthesia in this region.

Medicine

The main influences on the South American practice of medicine in general, and anesthesia and surgery in particular, come from Europe. For many years, and particularly during the first six decades of the twentieth century, many doctors were trained in different parts of Europe, including France, Germany, and Scandinavian countries. The European influence was as strong in medicine as it was in other aspects of daily life.

One example of Europe's influence was the widespread use of the Ombrédanne in South America (Fig. 2-8). This device, used to deliver ether anesthesia, was invented in France in 1908 by a surgeon named Dr. Louis Ombrédanne (1871-1956). It is believed that South America is likely the only continent where this equipment was clinically acceptable and used widely.

Of course, ether was not the only anesthetic used during this time. Cyclopropane was also used, although Chile had a dramatic experience with this gas that eventually caused it to be banned. In 1963 at the Manuel Arriarán Hospital in Santiago, a cyclopropane tank exploded in a pediatric operating room. Two small boys and four physicians—two of them anesthesiologists—died. This remains one of the worst anesthesia-related accidents

Figure 2-8. The Ombrédanne anesthesia delivery device.

ever to happen in the world. New standards, including the banning of cyclopropane, were imposed to avoid further accidents.

The European influence remained strong for many years. In the 1970s, the influence of North America started to grow and continues through today. The North American influence is evident in many countries such as Argentina, Brazil, Colombia, Chile, and Uruguay, which have advanced technology, monitoring devices, drugs, and associations with various institutions in North America. In other South American countries where cultural and economic growth are deficient, contact with more developed countries is still lacking.

Because Spanish is the predominant language on the continent, with the exception of Brazil, a language barrier affects the relationship between doctors and foreign institutions. English is considered a second language in only a few countries. As a result, doctors can communicate fluently in English in relatively few places, such as in their sharing of medical experiences, attendance of meetings, and access to medical and anesthesia journals.

English as a second language is essential to obtain access to full information and to stay updated. If one is not able to do this, then there is the likelihood of being left behind. Unfortunately, this is the current situation in many countries.

Even with the availability of medical information online, a foreign language such as English is needed and should be part of undergraduate or postgraduate medical education. There are many medical journals in Spanish, but anesthesiologists must understand that English is by far the most common language used in the medical field.

CHINA (Yuguang Huang)

In the early twentieth century, with the introduction of Western medicine into China, modern anesthesia began to be applied in clinics. At that time, anesthesia was implemented mainly by nurses or surgeons. Only a few Western professional anesthesiologists, such as Yueqing Ma from the Peking Union Medical College, could undertake clinical anesthesia in China.

After the foundation of the People's Republic of China in 1949, some early pioneers—such as Jue Wu and Xingfang Li from Shanghai and Rong Xie, Deyan Shang, and Huiying Tan from Beijing—returned from the United States and Europe to help modern anesthesia take shape in China.

In the 1950s, only simple anesthesia was available in China, such as the ether open-drop method, inhaled tracheal intubation anesthesia, and single procaine spinal anesthesia. Peripheral nerve block and continuous epidural anesthesia were introduced on a gradual basis. From the 1950s to the 1980s, intravenous procaine combined anesthesia and continuous epidural anesthesia were the most common methods in China. When anesthetic drugs and monitoring tools became scarce in the 1960s, Chinese anesthesiologists tried to develop acupuncture anesthesia based on the pain-relieving mechanisms of traditional Chinese acupuncture. In the 1970s, Chinese anesthesiologists investigated the anesthetic effect of Chinese herbal medicine. However, beginning in the late 1970s, because of the success of reform and the government's more open foreign policy, many new anesthetic drugs and instruments were introduced into China. At that time, acupuncture anesthesia and herbal anesthesia stepped down from the clinical stage because of their unsatisfying anesthetic efficacy and adverse effects.

Raising the Professional Profile of Anesthesia

Chinese anesthesiologists also began raising their profile as early as the 1950s, when they took part in the rescue of critically ill patients via cardiopulmonary resuscitation. For example, in 1959, Professor Yuanchang Wang from Tianjin Medical College shared his experience in the *Chinese Journal of Surgery* by reporting that a woman whose life was in danger during cesarean section was saved by chest compressions. Partly because of the influence of anesthesiologists, since the 1970s intensive care units (ICUs) and postanesthesia care units (PACUs) have gradually been established in many domestic hospitals.

China has also participated in numerous international conferences and professional groups (Fig. 2-9). The First National Conference on Anesthesia was held in Nanjing in 1964, during which the development and achievements of Chinese anesthesiology were systematically reviewed. In 1979, the Chinese Society of Anesthesiology (CSA) was founded during the Second National Conference on Anesthesiology held in Harbin. Professor Deyan Shang was elected as president of the first CSA committee. Since then, national CSA conferences have been held every 3 or 4 years.

During this period, there was also a foray into professional publications, most notably by Professor Jue Wu, the leader of Chinese anesthesia, who was the lead editor of *Clinical Anesthesiology* in 1954 and *Practical Anesthesiology* in 1976.

Western medicine introduced by the United States also helped to promote the development of modern medicine in China. A good example is Peking Union Medical College Hospital, which was founded by the Rockefeller Foundation in 1917. Even today, Peking Union Medical College Hospital is still regarded as an "ivory tower" of Chinese medicine. Some professors from Peking Union Medical College Hospital moved to Taiwan in 1949, and some of them changed their specialization from surgery to anesthesiology and became the early practitioners of anesthesiology there. They made important contributions to the foundation and development of modern anesthesiology in Taiwan.

INDIA (Deepak K. Tempe)

Until approximately 30 years ago, anesthetic equipment in Indian operating rooms often consisted solely of a simple anesthesia machine, a suction unit, and perhaps an electrocardiographic monitor. Even the oxygen supply was mainly via cylinders, with few hospitals having a centralized medical gas supply. The first medical pipeline system was installed in Vellore in 1954.

Today it is widely accepted that postoperative care is crucial for the success of surgery, but in previous days,

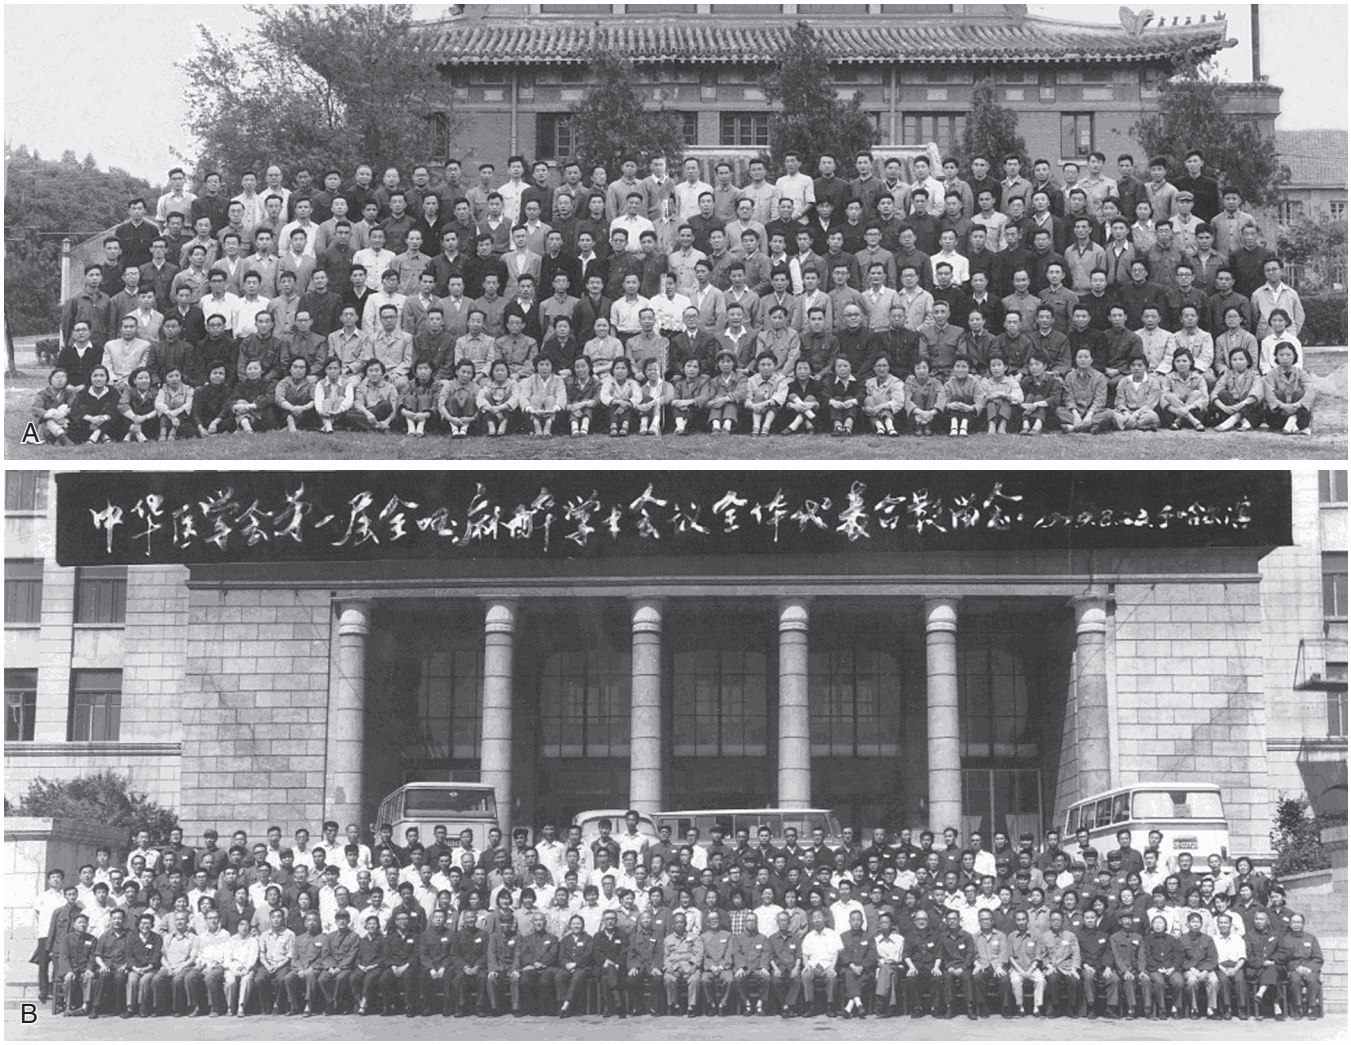

Figure 2-9. A, Participants of the First National Conference on Anesthesia, Nanjing, 1964. **B,** Participants of the Second National Conference on Anesthesia, Harbin, 1979, during which the Chinese Society of Anesthesiology was founded.

many patients were sent back to the ward directly after surgery and only a few would go to the recovery room. In recognition of the fact that surgical patients often need to be observed in a specialized area, India commissioned its first ICU in 1963 in an Army hospital in Delhi. Notably, that was the same year that an ICU was first established by an anesthesiologist at the University of California, San Francisco.

During this period of the twentieth century, Indian anesthesiologists also recognized the need for professional societies. The idea of the Indian Society of Anaesthesiologists (ISA) was conceived in 1946, and the group was formally established in 1947. The first ISA meeting was held in 1949 during a surgeons' conference in Mumbai, and the first independent ISA conference was held in Hyderabad in 1965. Professors Macintosh and Gray were the distinguished guests during the conference. The ISA published its first official journal in July 1953 and joined the World Federation of Societies of Anesthesiologists (WFSA) in 1956. The group has grown from 19 members when it began to nearly 18,500 members in 2012. The Diploma in Anesthesia (DA) was first started in 1946 in Mumbai University, and the postgraduate degree course (Master of Science in Anesthesia) was started in 1955 at Darbhanga Medical College, Bihar.

JAPAN (Naoyuki Hirata and Michiaki Yamakage)

In the early 1900s, the Japanese government began using primarily Western medicine rather than Eastern medicine, which had been used for a long time. The Japanese government invited many medical instructors from Germany (Prussia at that time) to teach in Japan, and medical students from Japan studied in Germany. In those days, German physicians promoted local anesthesia rather than general anesthesia. Therefore, surgeons in Japan focused on local anesthesia, whereas general anesthesia dramatically developed in the United States and the United Kingdom.

In 1950, Dr. Meyer Saklad came to Japan to participate in the Joint Meeting of American and Japanese Medical Educators. He presented novel information on anesthesiology, including general anesthesia, to Japanese surgeons. His lectures created shock waves among Japanese

surgery professors. Since his lecture, anesthesiology in Japan has become much more developed; a Department of Anesthesiology was established at Tokyo University in 1952, and the JSA was established in 1954.

THE MIDDLE EAST (Anis Baraka and Fouad Salim Haddad)

At the end of World War I, the Middle East was divided by Western powers into small countries that were placed under British and French mandate. The major pattern in the practice of anesthesia was complete dependence on foreign surgeons, who could administer anesthetics, and on local and foreign nurses or nonanesthesiologists and technicians, who administered ether or chloroform. This period also witnessed the foundation of faculties of medicine in some countries of the Middle East (Syria, Sudan, and Iraq).[17]

By the end of World War II, the beginning of oil production contributed to an improving economy, which meant more funds available for anesthesia machines, endotracheal tubes, and thiopental, all of which began to appear in many countries of the Middle East. An influx of newly trained surgeons increased the demand for qualified anesthesiologists, thus prompting anesthesia residencies. In addition, in response to a manpower shortage in many countries in the Middle East, nurse and technician training began as well, although this was gradually phased out as locally and internationally trained and certified anesthesiologists began arriving in many countries of the Middle East.

During the second half of the twentieth century, all countries of the Middle East were striving to attain state-of-the-art anesthesia. The World Health Organization (WHO) played a significant role in encouraging and sponsoring graduate physicians for training in anesthesia at the World Anesthesiology Training Center in Copenhagen.

Raising the Professional Profile of Anesthesia

As in many other places in the world, the status of anesthesia in the Middle East depends partly on the establishment of fully independent departments of anesthesia that have their own structure, staff, residency training, research, and certification by international academic institutions and that offer fellowships in cardiovascular, obstetric, and pediatric anesthesia, as well as pain management. To that end, certain landmark strides were taken during this period.

In 1966, the *Middle East Journal of Anesthesiology* was founded. Its main objectives are to act as a forum for education and exchange of opinions and to promote research and publication of Middle Eastern medicine and anesthesia. The journal is accepted for inclusion in the Index Medicus and MEDLARS system.

In addition, in the 1960s and 1970s, many Middle Eastern countries founded their own national societies of anesthesia, which promoted the practice and image of the specialty. In 1990, The Pan Arab Society of Anesthesia and Intensive Care was founded and became a member of the WFSA. Every 2 years, the Pan Arab Society holds The Pan Arab Congress of Anesthesia and Intensive Care in one of the member countries.

RUSSIA (Yury S. Polushin and Olga N. Afonin)

In the midst of the economic difficulties and political upheaval after the Russian civil war, medical services underwent dramatic reorganization and expansion, and some positive developments ensued, including campaigns against diseases and poor hygiene. Thousands of unpaid men and women underwent short courses in nursing. They then went all over the country to educate people and treat deadly diseases, often risking their own lives. This remarkable effort was rewarded in just a few years. Epidemics were stopped, and control of many diseases was established. This experience emphasized the importance of preventive measures, including vaccinations, and Soviet physicians began working on preventive medicine.

Meanwhile in Moscow, Dr. Vadim Yurevich was the first in the world to begin using citrate for blood conservation. His colleague Dr. Vladimir Shamov was the first to use cadaveric blood for transfusion in 1928, thus giving birth to a new field of medicine—transplantation.

The first Institute of Blood Transfusion, a scientific center for study and development of the science of blood and blood component use and storage, was formed in 1926 in Moscow by Professor A. A. Bogdanov. Physicians of the institute developed and published the first systematic approach to the treatment of shock, including traumatic, hypovolemic, and "burn related." Another dramatically important innovation by Russian physicians was the introduction of methods of diagnosis and treatment of electrolyte and acid-base imbalances with complex salt solutions, blood substitutes, and total parenteral nutrition solutions.

In 1924, S. S. Bryuchonenko and S. I. Chechulin constructed and used the first artificial heart machine in the world, the forerunner of what is now known as a cardiopulmonary bypass machine. Surgical procedures were becoming more complex and required more advanced methods of exposure of the abdominal and thoracic organs. The bellows of Dr. Henry Hickman was transformed into many different machines to provide artificial ventilation, including the famous iron lung at Harvard, used first in Boston in 1928.

In Moscow in 1936, the Laboratory of Resuscitation of the Academy of Medical Sciences of the U.S.S.R. began investigations on the dynamics of vital functions during the terminal period and methods for the resuscitation of the dying organism.[20] As the head of the laboratory, V.A. Negovsky was instrumental in the integration of resuscitation in practical health care.

In 1939, N.L. Gurvich and G.S. Yun'ev developed the physiologic basis and methods of indirect heart massage and electrical defibrillation. These methods were used successfully on patients requiring complicated cardiothoracic surgeries in Russia.

In the U.S.S.R., the first endotracheal anesthesia with muscle relaxants was given by M. Anichkov in 1947 at the Military Medical Academy in Leningrad. The book *Intratracheal Anesthesia in Thoracic Surgery,* by S. M. Grigoriev and M. N. Anichkov, chronicles this event. After its publication, doctors from different regions of the country started to apply this method clinically.

As all these developments grew into complex surgical procedures and as the use of neuromuscular blocking drugs spread, it became necessary in Russia to develop a new kind of subspecialty in medicine: anesthesiology. This would require extensive and detailed knowledge of many disciplines, including physiology, biochemistry, surgery, medicine, neurology, pharmacology, traditional anesthesia, and critical care.

The first Department of Anesthesiology in Russia was formed in 1958 at the Military Medical Academy in Leningrad. Within a year, a second Department of Anesthesiology was formed in the Department of Cardiothoracic Surgery in Moscow (now the Russian Medical Academy of Physicians Postgraduate Education); this is the same year that the current Department of Anesthesia was formed at the University of California–San Francisco. The first postgraduate courses for physicians to become anesthesiologists lasted 4 months. Later, more courses of anesthesiology were incorporated, requiring additional months of training and including the basics of intensive care.

The broad variety of topics covered and the complexity of the potential patient care issues meant that the new specialists needed more time to prepare properly for their careers. These careers were in demand as newly formed anesthesiology and intensive care departments required more anesthesiologists to teach and take care of patients.

In 1966, the Ministry of Health of the Soviet Union released the "Order of improvement of anesthesiologic and reanimatologic (intensive care) services in the country." This governmental act legalized anesthesiology and gave it the financial and administrative support required at that time for any significant changes to take place. Along with the legalization of anesthesiology came the definition of functions and organizational structure. Most hospitals deployed units of anesthesiology, whereas institutions and universities formed departments of anesthesiology. Since 1969, anesthesiology and intensive care have been merging into a single specialty called anesthesiology-reanimatology.

THE MODERN PERIOD: THE ESSENTIALS OF MODERN ANESTHESIA AROUND THE WORLD

The last 30 years has been an exciting period for anesthesia, largely because the ability to share clinical and research experience has made the practice safer and better than it ever has been.

Today, all anesthesiologists, no matter where they practice in the world, can gain access to the information necessary to deliver safe anesthesia. However, there are still places in the world that do not have access to the equipment or supplies needed to implement that knowledge. This section details the essentials: the roles and responsibilities, the facilities and equipment available, the education and accreditation, the professional societies, the research conducted by anesthesiologists around the world, and the safety and medicolegal initiatives that have developed in these countries.

ROLES AND RESPONSIBILITIES OF ANESTHESIA PROVIDERS

Brazil (Maria Carmona)

Currently, only physicians are allowed to administer anesthesia, and the care of simultaneous procedures is prohibited. In other words, anesthesia was given to only one patient at a time. The Resolution from the Federal Council of Medicine (CFM 1802/06) related to the use of anesthesia recommends routine preoperative evaluation, and it defines the minimal structures and required equipment to perform anesthesia safely and for adequate postoperative care.

An electrocardiogram, noninvasive blood pressure meter, and a pulse oximeter are the minimal monitors for any kind of anesthesia. End-tidal carbon dioxide ($ETCO_2$) monitoring should also be available for any patients undergoing assisted or mechanical ventilation.

Chile/South America (Guillermo Lema)

For the past 50 years, anesthesiologists have been involved in PACUs and more recently have been responsible for them, including determination of the standards of care for these areas. Pediatric and cardiovascular anesthesia is generally performed by physicians with subspecialty training in these areas. Pain management and critical care reflect important areas in which the influence of the anesthesiologist has been important. Anesthesia-trained personnel run most of these units.

Another area of interest is the choice that many physicians, including anesthesiologists, must make between public and private hospitals. Historically, anesthesiologists have worked in public hospitals. The development of private practices in small clinics and in other institutions attracted many practitioners, who then reduced their work in public hospitals to part-time in the mornings. Currently, anesthesiologists work solely in one hospital, either public or private, with strict professional duties and cost containment as a major responsibility.

Most of the private clinics are run by private economic groups that operate under stringent financial criteria. In these institutions, the activities of anesthesiologists and other specialists are restricted, and only a few colleagues dedicate their time to administrative duties.

Although the resources to public hospitals are increasing, the benefit of these resources is less than one might have expected, probably because of their centralized administration, which is not run by practitioners. Thus, economic restraints and inadequate conditions for anesthesiologists make positions in public practice unlikely to be filled completely, because private work is a more attractive option.

China (Yuguang Huang)

In the last decade, the overall professional level and social status of Chinese anesthesiologists have gained prominence, as has medical education in the field. Each year, large numbers of outstanding medical graduates enter the anesthesiology resident training program, adding greatly to the activities of existing teams. Accompanying the country's economic prosperity are developments in the medical field that put China on par with developed

countries in terms of routinely prescribed drugs and commonly used sophisticated monitoring equipment. The development of anesthesiology has also encouraged the continuing growth of other surgical departments.

The specialty of anesthesiology in China is mainly composed of clinical anesthesia, pain management, emergency resuscitation, and extracorporeal circulation. The scope and versatility of clinical anesthesia have greatly expanded. For example, Chinese anesthesiologists can now receive training for transesophageal echocardiography (TEE) examinations through continuing medical education lectures at large hospitals, with the more outstanding ones having obtained the senior certification for TEE from the United States and Hong Kong. These clinicians are capable of performing intraoperative ultrasound examinations independent of assistance from ultrasound physicians. Therefore, the nation's objective is to train Chinese anesthesiologists so that they have multidisciplinary talents within the near future. Aside from clinical practice in the operating theaters, anesthesiologists are also becoming involved in such clinical diagnostic and therapeutic procedures as endoscopy, fetus reduction at the fertility center, and provision of comfortable alternative solutions to patients undergoing mini-invasive procedures outside the operating theater. Anesthesiologists are earning more respect and recognition from physicians of other specialties and patients in China.

Anesthesiology has also evolved to be the perioperative medicine in multiple aspects. Patient blood management and perioperative blood conservation techniques are an internationally acknowledged issue. Over the years, the Chinese Ministry of Health (MOH), which in 2013 was integrated into a new agency called the National Health and Family Planning Commission, has invested tens of millions of dollars to support the study and improvement of clinical rational blood use, in which anesthesiologists have played a crucial role in education and team leadership. MOH is the leading unit and pilot center for this project, and the Anesthesiology Department of the Peking Union Medical College Hospital has made great contributions to the project through collaborations with other medical centers in Wuhan, Shanghai, Chengdu, and Zhejiang.

Currently, national guideline and blood management standards have been adopted in a majority of provinces, greatly alleviating the pressures exerted by limited blood supply and avoiding transfusion-related complications to a large extent. In addition, a number of hospitals have pain clinics providing good pain management for in-hospital patients. Anesthesiology has evolved as a crucial medical specialty that enjoys rising status in general hospitals, with department chiefs being involved in the leadership of hospital management.

In addition, anesthesiologists have become integral to multidisciplinary collaborations, reflecting the growing status and recognition of anesthesiologists by their peers. Primary trauma care, a program promoted globally by the WHO, focuses on increasing awareness, and enabling and promoting training of medical practitioners in trauma management. MOH has designated the project as a high priority and assigned the Chinese Association of Anesthesiologists and Chinese Association of Emergency Physicians to oversee its responsible implementation. In the past 2.5 years, 4847 doctors and nurses in 1927 hospitals from 15 provinces have been trained with primary trauma care throughout China, resulting in an improvement in the level of primary trauma care in China. This project has received great acclaim and recognition from physicians and local hospital leaders, reflecting the execution skills, unified collaboration, and leadership capabilities of Chinese anesthesiologists.

Europe (Lars I. Eriksson and Jannicke Mellin-Olsen)

The main activities in European anesthesia departments are to provide operating room anesthesia, postoperative care, critical care medicine, pain medicine, and critical emergency medicine.

The concept of anesthesiologists as perioperative physicians is a hallmark and well developed in many European countries. A considerable proportion of health care leaders are anesthesiologists who have a good overview of hospitals in general. In addition, in recent years anesthesiologists have taken more responsibility in leading patient safety initiatives.

In some countries, such as the Czech Republic, Germany, Italy, Moldova, Norway, and the United Kingdom, more than 30% of the activity of anesthesiologists is devoted to critical care medicine. Even in those countries where critical care is recognized as a separate primary specialty, as in Spain and Switzerland, anesthesiologists are involved in the care of the critically ill. Some physician groups want to introduce more specialties on a European level, such as in critical care medicine. Thus far, anesthesiologists have opposed such initiatives as counterproductive and assert that it is more desirable to define and develop competencies and particular qualifications to develop critical care medicine further. Emergency medicine is currently a separate specialty in Europe, but anesthesiologists regard critical emergency medicine a part of the professional domain. Anesthesiologists are involved, not least in the prehospital phase. In some countries, a large proportion of anesthesiologists are also active in acute and chronic pain medicine.[19]

In most of Europe, unlike in the United States, anesthesia can be delivered only by an anesthesiologist. In most European countries, nurses are involved, but with varying tasks and responsibilities. In general, there are two models of anesthesia nurses who participate in care. One model is the nurse anesthetist who is allowed to provide anesthesia without the presence of the in-charge physician in the room. Nurse anesthetists generally have a nursing degree with an additional 1 to 4 years of training, resulting in a diploma that entitles the nurse to administer anesthesia according to a plan defined by the anesthesiologist, including medication administration, tracheal intubation, and monitoring, depending on local protocol and terms and conditions of service. Countries where anesthesiologists work with nurse anesthetists are Scandinavia, the Netherlands, France, the Slovak Republic, and Bulgaria. The other model is the circulation nurse or anesthesia nurse, who can assist anesthesiologists during procedures but are not allowed to perform any direct patient-related roles beyond basic nursing tasks, such as preparing medication and administering intravenous fluid. In Ireland and Malta, even this model is not

allowed, in contrast to Finland, Germany, Italy, Romania, United Kingdom, and other countries.[21]

India (Deepak K. Tempe)

The current Indian government expenditure on health is 1% of gross domestic product (GDP). This amount will increase to 1.5% during the next 5-year plan (2012-2017).[22] This public spending on health as a proportion of GDP is far too small as compared with the expenditure in the United States and Europe (6% to 7%). In India, anesthesia can be administered by a qualified anesthesiologist or by a trainee anesthesiologist under the supervision of a qualified anesthesiologist. In some states, such as Delhi, a directive from the government has been issued that states, "Anesthesia must be administered by a qualified anesthesiologist, that is, an anesthesiologist with a postgraduate qualification and who has been actively working."

The duties and responsibilities of anesthesiologists have been evolving, but they have not yet been clearly defined by the ISA or Ministry of Health officials. Nevertheless, it is now well recognized that an anesthesiologist's work is not limited to the operating room. Typically, anesthesiologists in India are involved in the following types of care: (1) preoperative assessment and preparation of patients; (2) perioperative care of patients; (3) pain relief during the perioperative period; (4) management of critically ill patients; (5) management of acute, chronic, and cancer-related pain; (6) management and teaching of resuscitation skills; (7) provision of outpatient anesthesia services; (8) administrative involvement in establishing and managing health care organizations; (9) disaster management coordinator in the hospital; and (10) teaching and training of the medical and paramedical staff.

In addition to the duties just listed, both natural and manmade disasters have provided an extra challenge for anesthesiologists. By virtue of their ability to administer emergency life support measures, as well as their perioperative management skills, anesthesiologists were at the forefront during the 2001 Gujrat earthquake and tsunami disasters, and they actively participated in establishing operating theaters on site and providing care to victims. Likewise, during the 2011 Mumbai and Delhi bomb blasts, anesthesiologists played a leading role in performing emergency surgery and perioperative management.

Preoperative Evaluation. Preoperative evaluation and preparation of the patient are integral components of safe surgery; however, no dedicated preoperative anesthesia clinics (PACs) existed in India until the early 1980s, and currently almost all hospitals have a dedicated PAC that screens patients before surgery (including outpatient day surgery). In some government hospitals, the PAC is located in the main outpatient department block, signifying that it is an integral part of this department. PACs have become increasingly important because of the growing incidence of cardiovascular and other systemic diseases in patients undergoing surgery. In PACs, anesthesiologists review and optimize the treatment of other systemic diseases and detect new diseases and health concerns. PACs have improved patient outcomes, and they are credited with facilitating the patient-physician relationship and discussions on patient awareness of anesthesia. A few hospitals have started awareness programs wherein a lecture is delivered (with illustrations) on a monthly basis to patients and their relatives to familiarize them with the anesthetic techniques and procedures that they will undergo.

Operating Room. The operating room continues to be the mainstay of anesthetic practice, where the anesthesiologist fulfills his primary responsibility of providing safe anesthesia to patients undergoing surgery. Operating rooms are major consumers of hospital resources and major sources of income for private hospitals; therefore, it is imperative that they be managed in the most efficient manner. However, there is no consensus on an ideal system to ensure efficiency in this area. The anesthesiologist is actively involved in trying to improve efficiency, especially with triage and the scheduling of urgent and emergency cases. In addition, the anesthesiologist is responsible for designing and equipping the operating rooms.[23] Safety is another concern. The professional risks (especially those related to needlestick injuries) of anesthesiologists, as well as other operating room staff, are well recognized, and preventing such health care hazards has become an important consideration.

Recovery Room and Postoperative Intensive Care Units. Appropriate postoperative care is crucial for the success of surgery. Today in India, depending on the nature of the surgery and the patient's condition, the patient is transferred to a recovery room or an ICU. Some version of an ICU or recovery room exists in almost all major hospitals in India today. The nomenclature used to describe these areas is not uniform. As a result, terms such as *postoperative ward, recovery room, high-dependence unit, critical care unit,* and *PACU* are often used to describe the same facility. At some hospitals, especially those in which major and complex surgery requiring postoperative ICU management is not performed regularly, there is no demarcation between an ICU and the recovery room. A single area designated as a recovery room is used for both purposes.

Where there is a distinction, the decision about where a postsurgical patient belongs is governed by the degree of morbidity. If a patient is very sick and requires ventilation and careful hemodynamic monitoring, the patient is transferred to an ICU. If mechanical ventilation and continuous hemodynamic monitoring are not required, the patient is transferred to a recovery room, which is perhaps the equivalent of the PACU. Patients undergoing day surgery (if practiced in a given hospital) are also transferred to the recovery room before discharge.

Most recovery rooms are under the charge of an anesthesiologist; in the case of ICUs, sometimes the anesthesiologist is in charge. Practice varies by location, and it is generally governed more by the logistics involved in a particular hospital than by any definite norms.

Ambulatory Care and Other Areas. Although it is recognized and appreciated that ambulatory care is a distinct possibility in a substantial number of patients, it

is not practiced as much as it should be. It is difficult to provide exact figures in this matter, but in general, the private (corporate) hospitals provide ambulatory care. The number of government hospitals practicing ambulatory care is relatively small, mainly because of logistic reasons. However, that is likely to change with the increasing availability of short-duration anesthetic drugs and modern surgical facilities (tools for minimally invasive surgery). Saving costs to the patient and the hospital and increasing patient turnover have been the major factors influencing interest in ambulatory care. The safety issues related to ambulatory care are well recognized, but there are no guidelines or recommendations from the ISA or any other regulatory body on this matter.

Anesthesia services are also frequently required in several other areas within the hospital but outside the operating room. These areas tend to be less familiar to most anesthesiologists and provide less access to the facilities typically available in an operating room. Their proliferation, however, has increased the demands on the field of anesthesiology. Areas where anesthesia is playing an increasingly prominent role include radiology suites (computed tomography, magnetic resonance imaging [MRI], and interventional radiology), the cardiac catheterization laboratory, electrophysiologic laboratories, the endoscopy room, and the electroconvulsive therapy room. In most of these areas, patients require sedation, but with some lengthy procedures—such as MRI, electrophysiologic studies, and some interventional procedures—patients tend to get restless and may require general anesthesia. In addition, special considerations such as long breathing circuits or MRI-compatible equipment may be necessary. The anesthesiologist should be familiar with these requirements to maintain safety standards. There is a tendency to consider these procedures as minor (by our clinical counterparts), thus undermining the safety requirements. However, the anesthesiologist must ensure that adequate safety standards are maintained in all these areas.

Critical Care Medicine. In the beginning, the anesthesiologist's focus on critically ill patients was ventilatory care because anesthesiologists are well versed in cardiorespiratory physiology and ventilatory management. Furthermore, managing a critically ill patient was considered an extension of the job that anesthesiologists performed in the operating room. Therefore, the anesthesiologist managed patients receiving controlled ventilation via a ventilator and, ultimately, weaned patients from mechanical ventilation.

Subsequently, however, it became obvious that respiratory function was only one aspect (albeit a crucial one) of the care of the critically ill. Anesthesiologists then became well informed about cardiovascular support, nutrition, infection, and various other diagnostic procedures. However, the interest of anesthesiologists in critical care medicine has vacillated, and other specialists have entered this field. Currently, management of critical care units in India tends to be split: some are managed by physicians not trained in anesthesia, others by anesthesiologists.

There is widespread agreement that a critical care specialist who is devoted full-time to the care of critically ill patients should manage a critical care unit. The consensus includes three key items: (1) a dedicated expert irrespective of the specialty (if not holding a critical care qualification) should be in charge of the critical care unit; (2) each hospital can follow practices according to the availability of trained or experienced personnel with the primary aim of giving the best possible care; and (3) care of critically ill patients is always a team-based process, and the practice of taking the advice of different experts in managing a particular case is encouraged to achieve better outcomes.

Critical care training has long been part of the anesthesia residency program in India, but in 2001 the National Board of Examinations initiated a full-fledged 2-year training program in critical care medicine with six seats throughout India; the number has now increased to 40. Anesthesiologists, chest physicians, and general physicians are eligible to seek admission to this program. Clearly, the number of these specialized intensivists is not sufficient to cater to the critical care units that have mushroomed all over India. In an attempt to increase the number of critical care specialists in the country, the Indian Society of Critical Care Medicine has initiated a 1-year diploma course (335 total seats), and 1-year fellowship course after obtaining the diploma (66 total seats).[24] Although these courses are not recognized, they have helped to increase the number of critical care specialists in the country. Anesthesiologists account for approximately half of the training seats, followed by general physicians (30%) and chest physicians (20%). The fact that all the seats in this program are filled suggests the growing interest in this specialty area. The Medical Council of India has recognized critical care medicine as a separate subject vide by way of amendment notification dated December 8, 2010. Thus, it will not be long before medical colleges start postdoctoral courses (DM and others) in critical care medicine.

In summary, critical care medicine has emerged as a new specialty that is still evolving in India. Because the number of people with a qualification in the critical care area is not sufficient to fill current needs, anesthesiologists and physicians with an interest in the specialty continue to practice critical care medicine. Such an arrangement is likely to continue until a sufficient number of qualified critical care specialists are available in the country. Going by the current number of seats available in critical care training programs, this transition period is likely to be rather prolonged. The author believes that once the transition period is over, critical care units will be manned full time only by qualified critical care personnel so that the anesthesiologist–turned–critical care expert will not practice anesthesia and a physician–turned–critical care expert will not practice medicine. Anesthesiologists will be more focused on postoperative care, which will include pain relief and short-term ventilation.

One problem that has emerged in India is the indiscriminate use of antibiotics, leading to the emergence of resistant bacterial strains.[25] The emergence of New Delhi metallo-B-lactamase-1 (NDM-1) and its prevalence in India was highlighted recently.[26] There is thus

a potential for wider international spread of plasmids encoding NDM-1. A coordinated, concentrated, and collective effort from clinicians worldwide is needed to prevent the emergence of resistant strains and their spread.[27]

Pain Management. Over the last 30 years, there has been a growing interest in managing acute and chronic pain. Yet the specialty is in its infancy in India, the number of pain clinics is limited, and there is no formal training program. According to one estimate, only about 10% of medical colleges in the country have pain clinics, so aspiring pain management professionals will almost always have to train abroad.[28] Some private corporate hospitals have now incorporated this facility. The focus has largely been on the treatment of chronic pain, including cancer pain. Most anesthesiology departments perform nerve blocks, with a few even practicing acupuncture. There are, however, few departments that have the facilities to conduct procedures such as radiofrequency ablation, implantation of intrathecal pumps, or spinal cord stimulation. The thrust now is toward treating pain as a disease, especially in patients suffering from nervous disorders or in terminal cancer patients, for whom the only possible form of management is alleviation of pain.

There is also growing awareness of the management of acute pain, including the possibility of providing the patient with a totally pain-free surgical experience. After all, the WHO now recognizes pain as the fifth vital sign, and alleviation of pain is regarded as a basic human right. Various forms of medicine and equipment (patient-controlled analgesia pumps, intrathecal, epidural, and intrapleural techniques) can now offer the possibility of a relatively pain-free course of surgical treatment. Indeed, management of acute pain during the entire perioperative period is a leading concern of all anesthesia departments, and it is actively practiced in recovery rooms or PACUs. Still, much remains needs to be done regarding pain management in India.

The Indian Society for the Study of Pain was formed in 1984 and currently has more than 1300 members from almost 25 different specialties.[29] The society is working toward improving pain management, but it is facing tough challenges, mainly because of lack of awareness. Most medical professionals tell most patients to live with pain, and patients tend to believe that pain is simply an expected part of the suffering caused by their disease. In addition, many doctors believe that referring a patient to a pain management expert would essentially be a statement of their medical shortcomings—and if the pain is relieved, the patient may never come back.[28] This author looks forward to improving pain relief facilities in the country.

Japan (Naoyuki Hirata and Michiaki Yamakage)

Anesthesiologists in Japan work in operating rooms, emergency departments, ICUs, pain clinics, and palliative units. The JSA recommends that perioperative management be provided by experienced anesthesiologists or residents supervised by certified anesthesiologists. Based on a survey of the JSA membership in 2005, over 90% of surgical anesthesia was provided by anesthesiologists or supervised residents at university hospitals. On the other hand, about 10% of surgical anesthesia was still performed by surgeons at nonuniversity hospitals. In Japan, there is no educational program for nurse anesthetists. The JSA survey also showed that the ratio of daily time spent by anesthesiologists on perioperative management was 60% to 70%, with 10% in ICUs, 13% in emergency departments, 30% in education and research work at university hospitals, and 12% in education and research work at nonuniversity hospitals.

Middle East (Anis Baraka and Fouad Salim Haddad)

In the Middle East, anesthesia is routinely administered by a qualified anesthesiologist. Trainee anesthesiologist or anesthesia nurses can administer anesthesia under the supervision of a qualified anesthesiologist. In addition, the departments and societies of anesthesiology in the different countries of the Middle East are responsible for setting the guidelines for sedation and analgesia by doctors who are not anesthesiologists.

The responsibilities of the anesthesiologist have evolved to include preoperative assessment, premedication, and preparation of patients, as well as postoperative anesthesia care in the PACU, which functions for 24 hours, as well as in the ICU. A preoperative informed consent for anesthesia must be completed by the anesthesiologist and signed by the patient, the guardian, or his or her legal representative.

Anesthesia administration is not limited to the operating room, but includes other areas such as the radiology department, ambulatory anesthesia, and obstetric anesthesia in the delivery suite. In addition, pain management, whether acute postoperative pain management or chronic pain management, is becoming routinely practiced and is evolving as a subspecialty of anesthesia. Subspecialization by a fellowship program is expanding to cover many areas such as obstetric, cardiopulmonary, and pediatric anesthesia, as well as critical care and pain management.

Russia (Yury S. Polushin and Olga N. Afonin)

Until the 1980s, Russia's anesthesia educational system was unified and structured into courses for nurse anesthetists and postgraduate education for physicians that included either a 1-year anesthesiology internship or a 2-year "Orditatura" (analogue of residency). All the programs included intensive care (reanimatology) as an obligatory part of the education. Participants were working in operating rooms and ICUs under the supervision of attending physicians and had a required course of lectures. Self-education was encouraged as well. After completion of training, graduates had to pass an oral qualification examination and were granted a Diploma of a Physician Anesthesiologist-Reanimatologist.

The quality of the education and the amount of experience varied significantly from program to program, and there were no universally accepted standardized examinations. Many conscientious anesthesiologists took additional courses on "qualification improvements" from the

Academy of Physicians Postgraduate Education. However, there were also "specialists" whose education was finalized on completion of the courses.

By the end of the 1980s, it became clear that the quality of education had to be monitored; debate led to the acceptance of standardized examinations. Meanwhile, the Iron Curtain had become partially permeable to some of the information about accepted standards of education and care in the other countries. The future promised improvements, but not for long. The "era of stagnation" of the 1980s led to economic imbalance and a gradual decline in political structures. By the end of the 1980s, Communist leaders embarked on major reforms in an effort to revive the country's economics, which led to the collapse of the Soviet Union.

Consequently, government financial support for the entire medical structure was reduced and eventually disappeared. All financially unsound programs, such as research, education, and the development of new technologies or educational methods, were frozen. The government-funded health care system no longer existed. Many professionals had to quit their careers for their families to survive. The private sector was in the very beginning of its development, and the majority of the population could not afford private health care. It was not uncommon for patients to be asked to bring supplies for the medical care that they required, even for surgeries, and it was not uncommon for people to die because of the lack of proper medications or proper medical care. This continued until the mid-1990s, when things began to turn around. The damage, however, has not been completely overcome, even now.

Southeast Asia (Florian R. Nuevo)

The political, geographic Association of Southeast Asian Nations (also known as ASEAN) includes Brunei Darussalam, Cambodia, Indonesia, Laos, Malaysia, Myanmar, the Philippines, Singapore, Thailand, and Vietnam. During the past 5 years, the role of physician anesthesiologists in this region has changed remarkably. Physician anesthesiologists have gained recognition by peers and the populace, undeniably maintaining a strong respectable presence in the operating suites and ambulatory centers. Apart from this role, the physician anesthesiologists who have undergone subspecialization are now recognized as coequals by their colleagues in the realm of pain management and intensive care.

Tangible evidence of the fortified role of ASEAN physician anesthesiologists in pain management is the Association of Southeast Asian Pain Societies (ASEAPS), formed in 2004 with the goal of further advancing the study of pain in the region. As a result, there are more academic pain management fellowships in the region. This specialized body has inspired anesthesiologists and other pain specialists to work together and develop practical, cost-effective, and rational approaches in addressing the continuing concerns of acute surgical pain, cancer pain, and chronic nonmalignant pain problems, particularly in resource-challenged work environments. Their unified objectives paved the way for governments to join in the advocacy of adequate pain control, particularly among cancer patients. Hospice care and palliative medicine are also areas in which anesthesiologists are now team leaders.

Another recent development is the increased interest among newly qualified physician anesthesiologists to become intensivists with special focus in areas such as pediatric intensive care, cardiothoracic intensive care, neurosurgical intensive care, and surgical intensive care. This development has broadened leadership in ICUs to include anesthesiologists, which had been dominated by specialists such as cardiologists, pulmonologists, and surgeons.

Specific mention must also go to the increased presence of the Asian Society of Cardiothoracic Anesthesia (ASCA). The ASCA serves as the unifying body for Asian cardiac anesthesiologists and envisions itself as the focal organization to address the evolving responsibilities of cardiac anesthesiologists on the utility of intraoperative TEE monitoring. This is now at a critical phase that is challenging the ASEAN cardiac anesthesiologists who must, for the moment, continue to share the stage with cardiologists inside the operating rooms.

Through ASCA, efforts to develop proficiency on TEE as an essential monitoring tool have instigated collaborations and strengthened cooperation between cardiologists, surgeons, and cardiac anesthesiologists. The Japanese Society of Cardiovascular Anesthesiologists has pioneered the proficiency on TEE and its Japanese Board of Perioperative Transesophageal Echocardiography has gained recognition by accreditation commissions in the United States and Europe. In the last 5 years, ASCA has offered basic TEE workshops for noncardiac anesthesiologists in many anesthesia conferences. Today, ASCA plans to offer more intermediate TEE workshops and introduce master TEE workshops for cardiac anesthesiologists in the region. It is hoped that in the next 5 years, ASEAN cardiac anesthesiologists will be duly given an independent role, similar to the current situation of cardiac anesthesiologists in Japan, China, Korea, and Taiwan.

With the introduction of ultrasound machines into the region, the application of regional blocks in orthopedic surgery has soared because of the increased demand from surgeons. This evolvement has contributed to better pain management in orthopedic surgery patients.

Among ASEAN anesthesiologists, the overall mood is optimistic and forward thinking. As ASEAN anesthesiologists succeed in their new roles that are outside the traditional anesthetist role in delivery rooms and operating suites, they must remember their primary responsibilities as anesthesia care providers while also recognizing the need to continue to evolve in order to become truly competent perioperative physicians.

Nurse anesthesia practitioners in the region do not yet have full autonomy. They are part of the perioperative anesthesia care team and are supervised as appropriate by physician anesthesiologists (Table 2-1). Nurse anesthesia practitioners are legally allowed only in Thailand, Indonesia, and Taiwan. In these countries, physicians design and conduct their respective nurse anesthesia training programs. However, in the Philippines, Singapore, and Malaysia, these societies maintain that anesthesia is a practice of medicine by qualified medical doctors.

TABLE 2-1 **WORKFORCE, SCOPE, AND TYPE OF PRACTICE IN SOUTHEAST ASIAN COUNTRIES**

	Indonesia	Malaysia	Philippines	Singapore	Thailand
Workforce					
Physician anesthesiologists	Yes	Yes	Yes	Yes	Yes
Nurse anesthetists	Yes	No	No	No	Yes
Anesthesia Scope of Practice					
Anesthetizing locations	Yes	Yes	Yes	Yes	Yes
Pain management	Yes	Yes	Yes	Yes	Yes
Intensive care	Yes	Yes	Yes	Yes	Yes
Type of Practice					
Physician and nurse anesthetists	Nurse anesthetists trained and supervised by physician anesthetists		Group practice slowly gaining support		Nurse anesthetists trained and supervised by physician anesthetists

With professional pride, ASEAN anesthesiologists have emerged as capable leaders in their respective national medical organizations, and they are driven with passionate social advocacies to help society and to partner with their government agencies to improve the delivery of medical and surgical care. It is no longer unusual for physician anesthesiologists to be designated as quality management officers or as medical directors.

FACILITIES AND EQUIPMENT

Brazil (Maria Carmona)

Brazil is the fifth largest country in the world in terms of area and the fifth most populous with approximately 200 million inhabitants. Although the Brazilian constitution declares health care to be the right of every citizen and its provision to be a duty of the state, there is a substantial gap between the aspirations of Brazil's Unified System of Health and reality. Total expenditure on health in Brazil is only 8.4% of gross national product, which is half the amount invested by the United States. In addition, almost half of all health care costs in Brazil are met by private health care. Consequently, both the provision of anesthesia and the entire health care system itself present a great heterogeneity in quality and service throughout the country, and this is closely related to the economic development of different regions. Apart from the excellent anesthesia care available in some government and private hospitals in a few cities, the majority of the poor population in urban and rural areas do not receive good quality care, regardless of whether the financing is public or private. On the other hand, the dynamics between private and public health sectors is constantly changing with continuous pressure on both to expand delivery. However, the bureaucracy of the public system and the apparently superior performance of private health care sometimes involve the transfer of public funds to the private sector, followed by reductions in public sector service budgets and staff availability. These public–private partnerships and the increasing number of people buying into private services are moving the Brazilian health care system through a slow, passive privatization.

Brazil's aging population is increasing faster than ever before, and it has the sixth largest population of older adults in the world. Although longevity is a significant measure of social well-being, it is a challenge for public health care and increases the complexity of anesthesia care.

Considering obstetrics care, although the WHO guidelines state that the proportion of cesarean births should range between 5% and 15%, the incidence of cesarean sections in Brazil is approximately 50%—one of the highest worldwide. The higher rates of cesarean section are observed both in private and public hospitals, and spinal anesthesia is the most frequent technique for this surgery.

Regional anesthesia is popular in Brazil because of its many advantages, such as a smooth recovery, maintenance of the patient's own airway, low risk of aspiration of gastric contents, and less need for skilled nursing care than with general anesthesia. Brazilian anesthesiologists are highly skilled in different regional anesthesia techniques.

Most of the equipment and drugs used in anesthesia are produced in Brazil. The country has several equipment manufacturers who are trying to develop products that match the best in the world. They provide products to the domestic market and export to a number of Latin American and African countries. Moreover, the world's most important manufacturers of equipment and pharmaceutical companies also manufacture or market their products in Brazil. To improve the population's access to health care, incentives have been offered for marketing generic drugs at a lower cost than brand name products.

Chile/South America (Guillermo Lema)

The huge disparity in economic growth among countries in the region has produced an enormous difference in public resources allocated to health care and created different conditions for public health management. Governments view anesthesiology as a low priority because, in their view, it has not had a significant effect on the improvement of health care, and the technology involved is costly.

The current status of the practice of anesthesia is being replicated by all countries in South America with most

at different stages of the process. Some countries have standards of care comparable to American or European countries, whereas others are only beginning to have anesthesia as a mature specialty. Countries such as Argentina, Brazil, Colombia, Chile, and Uruguay are in the mature phase and have modern equipment, advanced monitoring technology, and access to a variety of anesthetics and ancillary drugs.

Anesthesia techniques vary, and many different types are being practiced. Anesthesia with halogenated drugs has been used widely, for many years, and in all countries. Total intravenous anesthesia is now common, especially with younger colleagues. The use of regional anesthesia has been widespread in all countries, and each country has its own training programs and congresses.

Although some countries have modern equipment, monitors, and drugs comparable to the United States or Europe, others have very basic systems to perform anesthesia appropriately; therefore, cost containment has been a critical aspect in clinical practice. Indeed, this situation is common globally. This disparity in medical resources among countries has been reduced because of trade with different countries, such as China, India, Brazil, and some European countries. Prices of products from these countries are much lower than from North American companies.

China (Yuguang Huang)

China's rapid economic growth has been accompanied by the acquisition of updated anesthetic equipment and apparatus. Except for a few distant rural areas and smaller provincial hospitals, the ratio of anesthetic machines, multifunction monitors, and expirium gas monitors in the operating theaters has reached a 1-to-1 capacity. National-level hospitals in more developed areas are equipped with international-class modern anesthetic machines and a variety of monitors, including neuromuscular monitors, anesthesia depth-monitoring devices, coagulation function test equipment, three-dimensional TEE or portable ultrasound equipment, neurostimulation devices, and pulse index continuous cardiac output hemodynamic monitors. Even MRI-compatible anesthesia machines are available in some large hospitals. By using current equipment and devices, medical practitioners and their facilities are providing better patient care and safety. Upgraded utensils on difficult airway carts and workshops on various airway techniques (e.g., visual digital laryngoscope, laryngeal mask) have helped China to realize great improvements in airway management.

However, an imbalance in economic development across massive mainland China has resulted in a corresponding imbalance in the sophistication and quantity of anesthesia devices. Currently, primary-level hospitals lack sufficient modern anesthesia equipment. Local investigations indicate that in second-level hospitals, the ratio of anesthetic machines to operating theaters is 0.7-0.8 to 1, whereas the ratio in national-level hospitals is 0.5 to 1. Thus, safety in clinical anesthesia faces major challenges. To resolve the existing problems, MOH approved the *Anaesthesiology Standard Regulatory Protocol* in 2012, which established national standards for all hospitals. These standards address facility and personnel qualifications and determine the minimum standards and facility requirements for clinical anesthesiology safety. The expectation is that the protocol will bring about changes to the current status in remote and rural areas.

Europe (Lars I. Eriksson and Jannicke Mellin-Olsen)

The WHO lists 53 countries in their Regional Section of Europe, reflecting diversity from Scandinavia and Germany to Georgia and Uzbekistan. The European Union (EU) has 28 member countries, and an additional nine have applied to become members, most of them from Eastern Europe.

Despite their political and economic partnership in the EU, the countries of Europe remain heterogeneous, which is reflected in the prevailing diversity of medical systems, research, and education, as well as in language and culture.

India (Deepak K. Tempe)

In India, the journey from open-drop chloroform and ether anesthesia to the present day high-tech operating rooms with anesthesia workstations and monitors, ICUs, PACUs, pain clinics, and preanesthetic checkup clinics is nearly complete. In fact, the operating rooms in India have undergone significant change during the last 20 to 30 years. The present-day operating room is modular in structure with high-tech anesthesia workstations, monitoring systems, and on-line networking. Such a change has been largely due to the arrival of private investment and management in the health care business. These corporate hospitals have built state-of-the-art operating rooms that match the best operating rooms in the rest of the world.

However, it is necessary to keep in mind that like many other things in India, diversity is also a hallmark of the health care system—that is, the assortment of medical facilities and level of available services vary considerably. Although corporate and other private hospitals have state-of-the-art operating rooms, government hospitals—other than those in cities such as Delhi and Mumbai—may not. In general, government hospitals cater to the general population, are overcrowded, and have long waiting lists. The situation in rural areas in particular is not up to the benchmark because these places typically have only primary health centers with basic facilities, and the operating rooms are equipped to deal with minor surgical procedures. However, it is possible to perform extraordinary procedures successfully in some of these rural hospitals. For example, on June 20, 2012, six doctors from the 1982 graduating class of Christian Medical College in Vellore, Tamil Nadu, and their former professors successfully operated on conjoined twins in a village in Betul district of Madhya Pradesh. This was the first successful separation of conjoined twins in a rural setting in India. The equipment necessary for this operation was borrowed from private industry. The case demonstrates that if the government and the doctors care enough, such complex surgeries can be performed even in remote settings. Thus, operating rooms of several

varieties can still be seen in India, and one hopes that this diversity gradually changes to uniformity in times to come.

Accreditation for Quality Health Services. In 2006, the Quality Council of India established the National Accreditation Board for Hospitals and Healthcare Providers (NABH) to address the needs of consumers and to set benchmarks for the progress of the health industry. The accreditation by the NABH ensures high-quality care and patient safety in a given hospital. More hospitals in India are striving to obtain NABH accreditation, and to do so they have to achieve standards set by the NABH. Thus, the establishment of NABH is a welcome step toward ensuring quality health care in the country. Two hundred nineteen hospitals have received NABH accreditation so far. Although, this includes mostly private hospitals, some public hospitals have also been accredited by the NABH.[30]

The evolutionary development of anesthesiology in India has been a challenging and turbulent journey from the days when Mahatma Gandhi was operated on with the open-drop chloroform technique to today. However, it is satisfying to see that developments in anesthesia have kept pace with time in India. Even the heads of government such as governors, cabinet ministers, and the prime minister no longer travel to foreign countries for their complex surgeries. Anesthesiologists have access to most modern medicines and equipment to provide the care of the highest order to these officials. The use of balanced general anesthesia with drugs such as fentanyl, midazolam, sevoflurane, and atracurium, full-fledged monitoring, and pain relief by patient-controlled analgesia pumps is now readily available in larger hospitals.

Indian College of Anaesthesiologists. The idea of forming an Indian College of Anaesthesiologists (ICA) was conceived in 2001. The objective was to form an academic wing of the ISA that could subserve the function of supervision and guidance of anesthesia education all over the country so that uniformity in medical education is maintained. Thus, it is expected to function as a leading advisory body to the Medical Council of India. In addition, it has undertaken a major challenge of formulating practice guidelines and protocols for anesthesiologists in the country. The existing Western guidelines are often difficult to apply in the Indian scenario. The college also awards fellowships in anesthesia. The ICA was officially registered November 2008 and currently has 450 members.[31]

Japan (Naoyuki Hirata and Michiaki Yamakage)

The following summary of the facilities and equipment of anesthesia in Japan was excerpted, with permission, from the *Journal of Anesthesia*.[32]

In the 1980s, general anesthesia was mainly conducted using halothane or enflurane with nitrous oxide. Fentanyl, an opioid analgesic, was also available, but was rarely used because it was believed to cause delay in awakening. Epidural anesthesia was used more frequently than it is now. For example, cervical epidural anesthesia was generally used in surgery on upper limbs or for breast cancer. The only intravenous anesthetics available at that time were thiamylal and ketamine, which was administered to asthma patients despite its known secretion-promoting effects. The depolarizing neuromuscular blocking drug (NMBA) succinylcholine was used for induction of anesthesia, and the nondepolarizing NMBA pancuronium was the only NMBA available for maintenance of anesthesia. During the 1980s, there was no awareness of the progression of acute renal failure during emergency surgery, and some patients did not awaken from anesthesia for a long time after surgery because of the prolonged effect of pancuronium.

Since the 1980s, various anesthetic drugs have become available in Japan. The availability of a wide range of anesthetics and the development of anesthetic monitors have made anesthesia a much safer and more comfortable procedure for patients. However, Japan (possibly because of its unique medical system) lags behind the United States and Europe in the use of anesthetic drugs other than sevoflurane. Remifentanil, rocuronium, and desflurane have finally been launched in Japan. In 2010, sugammadex was approved for clinical use in Japan, 2 years later than in Europe. As of this writing, it has been reported that sugammadex shares 70% of the relaxant antagonists [market] in Japan, which may be the highest share in the world.

General anesthesia with airway management using a laryngeal mask is increasing in Japan because of the promotion of this device and the widespread use of ProSeal (Laryngeal Mask, Jersey, UK) with high sealability, which makes it easy to eliminate leaks around the mask. The indication for this method of anesthesia depends on the anesthesiologist, although it is generally not used for laparotomy, thoracotomy, or prolonged general anesthesia. If the device has high sealability and can withstand positive-pressure ventilation, anesthetic management is sometimes performed using artificial ventilation with the use of NMBAs. The use of the laryngeal mask is expected to continue to increase.

Because of the high costs of hospitalization in the United States and Europe, day surgery has become popular. Day surgery in Japan, however, is rare because most patients have national and private medical insurance. However, the duration of hospitalization is expected to become shorter with the introduction of a comprehensive medical system, although it is impossible to predict whether this will have an effect on the methods of anesthesia used.

Methods used for postoperative analgesia differ greatly between countries and between institutions in Japan. In the United States and Europe, patient-controlled analgesia is popular, and intravenous opioids alone are used in approximately two thirds of patients. The combination of intravenous opioids with epidural analgesia appears to be used only for patients who have undergone upper abdominal surgery or thoracotomy. In Japan, epidural analgesia with or without intravenous opioids is used for postoperative pain control in approximately 50% of patients.

Finally, the number of surgical cases in specialized hospitals, including university hospitals, is expected to continue to rise in Japan. This increase is related to the

Figure 2-10. The operating room at the American University of Beirut Medical Center, which shows the updated anesthesia equipment and monitoring of a patient undergoing coronary artery bypass grafting.

growing population of older patients and the increase in incompatibility complication; the number of cases anesthetically managed by neural block or general anesthesia alone is also expanding.

The Middle East (Anis Baraka and Fouad Salim Haddad)

The anesthetic machinery, monitoring equipment, and anesthetics used match the international standards that are approved by international societies, such as the American Society of Anesthesiologists (ASA). Every patient undergoing surgery under general or regional anesthesia is routinely monitored with electrocardiography, pulse oximetry, noninvasive arterial blood pressure monitoring, and end-tidal capnography. In critical care patients or in patients undergoing cardiac surgery, monitoring includes pulmonary artery catheterization, mixed venous oximetry, cerebral oximetry, intraarterial blood pressure monitoring, and blood gas analysis. Figure 2-10 shows the operating room and illustrates monitoring of a patient undergoing coronary artery bypass grafting at the American University of Beirut Medical Center, which has updated anesthesia equipment.

Preoperative checking of anesthesia equipment and gases and the labeling of drug syringes are routine practices. In addition, the "time out" policy confirming the identity of the patient, the type, and site of surgery are practiced before surgery by the anesthesiologist, the surgeon, and the operating room nurses involved in the surgical procedure.

Russia (Yury S. Polushin and Olga N. Afonin)

By the end of the twentieth century, the country faced a severe political crisis resulting from former President Mikhail Gorbachev's program of economic, political, and social restructuring called *perestroika*. The Soviet Union collapsed into separate and independent states, causing the destruction of the national economy and leading to violations of the links between the regions that had evolved over the years. In the field of medicine, the manufacture of medical equipment almost ceased while the pharmaceutical companies either stopped production or moved outside the country. The results were drastic in the lives of the Russian people. There was a change of economic structure, which led to the need to reform the system of medical aid to the population. This was a difficult period in the history of Russian medicine, with the breakdown of existing health care mechanisms and a void in establishing new systems of medical care. In anesthesiology and intensive therapy, which rely on sound economic factors, the situation was particularly difficult. In many small hospitals, units of anesthesiology were closed because it was not possible to update equipment and medications. The salary of doctors and nurses was extremely low, and the prestige of the specialty declined, leading to a considerable shortage of personnel. The All-Union Scientific Society of Anesthesiologists and Intensive Care of the U.S.S.R. ceased to exist, and it was replaced with a variety of regional organizations that did not have legal status or proper authority with the institutional health managers.

Just over 20 years after the end of perestroika, the economy has revived and the state can distribute considerable resources for the development of medicine. A new health care system has been developed, multifunctional medical centers have been built in several regions of the country, and funds have been allocated for the modernization of hospitals, including the anesthesiology and intensive care units. In 2011 a new order of the Ministry of Health of the Russian Federation was activated that defines the procedure for the provision of anesthesia and intensive care in hospitals. As a result of these changes, the field of anesthesiology is again recruiting young and active professionals. In addition, the Federation of Anesthesiologists and Reanimatologists of Russia has strengthened its position and is uniting its ranks with members of affiliated organizations in the Russian Federation, and communications between Russian anesthesiologists with colleagues from other countries has improved.

Of course, the reform of medicine is still far from complete, and some institutions still have not made noticeable changes. Although modern, influential, and well-equipped hospitals exist, there remains a need for medical services, particularly in remote regions that lack facilities and access to medical care. There is a great shortage of personnel, which limits the needed radical reform of the medical education system, including anesthesiology, to meet international requirements. However, progress is evident and is continuing at a gradual pace and with the support of the Russian Federation.

Southeast Asia (Florian R. Nuevo)

The biggest change in the region in the last 2 years is the mandatory use of pulse oximetry as a basic monitoring standard on any patient who is given an anesthetic that leads to changes on sedation levels. The requirement for pulse oximetry monitoring is part of the WHO Surgical Safety Checklist, which has become part of the requirements prescribed by most accreditation organizations in the region. Credit must be given to the WFSA, which has

worked closely with the WHO to make pulse oximeter monitoring a part of the surgical safety checklist. The WFSA has also made pulse oximetry a mandatory requirement at all levels of care in the 2010 WFSA International Standards for Safe Anesthesia Practice.

Although there is no robust database available to measure the reduced incidence of intraoperative deaths in the last 5 years because of pulse oximeter monitoring, no ASEAN anesthesiologist would readily agree to administer a general anesthetic without this monitoring device. Nevertheless, surveys among anesthesia care providers confirm that the change is palpable. The audit reviews also report this observation.

The safety of remote anesthesia continues to be a great challenge. Safe delivery of anesthesia is frequently compromised because of the limited availability of proper equipment and manpower. A typical example is the lack of MRI-compatible devices and equipment. Quite often anesthesiologists have to rely on visual assessment of breathing patterns in sedated patients during MRI procedures because MRI-compatible oximeters are not available.

The use of capnography in the operating room is still infrequent and usually limited to laparoscopic procedures. This situation is typical in low-to-middle income countries in the region. There is still much work to be done to make capnography a part of the safety standards for every patient who undergoes mechanical ventilation, not only in the operating theaters but also in ICUs.

Another persistent challenge in the region is the inadequate availability of anesthesia machines that have passed the safety standards prescribed by the American Society for Testing Materials. Because of this, the practice of mixing anesthetic gases, such as oxygen-air or oxygen-nitrous oxide, and applications of closed-circuit or low-flow anesthesia techniques are limited. The administration of 100% inspired oxygen is often the norm in places without modern anesthesia machines. In developing countries, there is a need for oxygen concentrators in clinical practice, because their use can reduce costs and make oxygen more readily available in difficult and remote work environments.

The advent of laryngeal mask airway devices has greatly improved the management of difficult airways in the region. Until recently, fiberoptic bronchoscopy was rarely available for use by anesthesiologists. Use of the LMA has curtailed the loss of lives of those who succumbed to failed intubations or difficult mask ventilation scenarios. A related and integral contributor to improved airway management in the region has been the addition of difficult airway workshops that are conducted in collaboration with industry in almost all anesthesia meetings throughout Southeast Asia.

Uganda and Sub-Saharan Africa (Ronald D. Miller and D.G. Bogod)

A recent editorial stated that the United States spent an average of $8233 per person per year for health care.[33] In contrast, in countries with either "low" or "intermediate" budgets, this expenditure rarely reaches $30 per person per year.[34] From a quality-of-care point of view, in a 2007 survey of more than a quarter of Uganda's anesthetic practitioners, only 23% thought that their facilities met all the widely accepted minimal standards for the practice of safe, adult anesthesia. Categories surveyed included access to updated information, basic operating room equipment, and the most basic supply of anesthetic drugs. For safe pediatric anesthesia, only 13% thought that their facility met the basic requirements.[35]

For spinal anesthesia techniques, more than half of the anesthesiologists surveyed did not have regular access to the necessary local anesthetics, and others did not have a ready supply of spinal needles. Only 23% could guarantee being able to find a brush to clean their tracheal tube between procedures.[35]

For cesarean sections in women during childbirth, nearly all the respondents (94%) said that they did not have the facilities to perform this procedure safely. More than three fourths did not have reliable access to magnesium sulfate, and half of them said that they could never get it.[35]As D.G. Bogod, editor-in-chief of *Anaesthesia*, wrote in the editorial of the issue in which these numbers were published:

The figures revealed by this survey show that despite the best efforts of all involved, 27 million Ugandans essentially enter a lottery every time they undergo anesthesia—a lottery with poor odds of a happy outcome. What the authors cannot tell us is whether this problem is confined to Uganda alone . . . it would be foolish to try to extrapolate from one country to another, but it is unlikely that Uganda data differ wildly from most of Sub-Saharan Africa. . . . If the situation in Uganda is bad, it is likely to be far worse in Ethiopia, Somalia, Tanzania and many other neighbouring countries.[35]

The above description was published in the seventh edition of *Miller's Anesthesia*. Have conditions improved in the last 5 to 6 years? Current literature is available regarding the status of personnel in anesthesia (described later). The status of facilities and equipment is less clear. A direct quote[36] is not encouraging:

The most common technique is general anesthesia (with spontaneous or manually assisted ventilation). Nonmedical anesthetists with limited training and supervision and lacking the most common drugs and anesthetic equipment administer anesthesia usually for emergency surgery . . . the morbidity and mortality rate is high.

This description strongly suggests a lack of facilities and equipment.

EDUCATION, ACCREDITATION, AND AVAILABILITY OF PRACTITIONERS

Brazil (Maria Carmona)

Currently, more than 10,000 Brazilian anesthesiologists are affiliated with the SBA, the second largest anesthesiology society in the world. In addition, a significant number of physicians not affiliated with the SBA or without a specialization also work as anesthesiologists, primarily in smaller towns and poor areas of the country. Yet, over the last decade, it has become evident that

there is a lack of anesthesia providers in most Brazilian cities because of the increasing elderly population, the diversity of surgical and diagnostic procedures, and the extension from 2 to 3 years for specialization in anesthesiology. Partly because of this shortage, clinical anesthesia is the main activity of Brazilian anesthesiologists with only a minority involved with intensive care, pain care, and research. This deficiency has led to an expansion in the number of training centers and positions for specialization in anesthesiology in most residency programs in the country.

In Brazil, residency in anesthesiology is regulated by both the Ministry of Education and the SBA, and approximately 650 physicians are admitted annually to a 3-year specialization program. Although the best residency programs are related to university hospitals, the majority of the 93 training centers are isolated programs in medium-sized hospitals. The residents have intensive training in the different areas that qualify them to administer anesthesia safely. All the centers are accredited, and they should offer good training in preoperative evaluation, the main anesthesia specialties, intensive care, and pain treatment. A practical and theoretical program is followed, and the residents are evaluated annually with a test conducted by the SBA, which publishes a ranking of the training centers based on specific criteria. The majority of candidates in residency programs are Brazilian, but a few candidates from other Latin American and African Portuguese-speaking countries have also participated. The official instructors on these residency programs are certified by the SBA, and few of these have PhDs. For PhD certification, which is the top title in anesthesiology, specialists undergo a multiple-choice test followed by an oral examination administered by a board assigned by the SBA.

The high quality of teaching and clinical care contrasts with the poor focus on research, which is the greatest weakness in the field of anesthesia in Brazil. There are few universities with well-structured anesthesia departments, and the effect of the few publications in existence is limited. Although the rules for the training centers also recommend that residents be involved in research projects, few universities are able to offer such opportunities. This situation is changing, and many training centers are realizing the importance of research as a way to improve education and assistance. Each year, a greater number of anesthesiologists are enrolled in the few postgraduate programs available in Brazil, and some PhD students are enrolled in postdoctoral programs in Brazil or abroad. The large number of attended cases is a robust base for observational and randomized clinical trials, and these are gradually increasing. The peer-reviewed *Brazilian Journal of Anesthesiology* is the official journal of the SBA, and it publishes most of the country's anesthesia research, together with other high-impact international journals in anesthesia or related areas.

Chile/South America (Guillermo Lema)

The training of anesthesiologists is a contentious issue in South America. There is a large discrepancy between the views of governments and those of anesthesia societies, and this relates to the number of anesthesiologists needed and the quality and duration of training required. All countries on the continent have anesthesia training programs of varying quality. The governments run a few, but universities conduct most of the programs.

There is agreement among all about the basic length of time needed for training; regardless of whether the government or the anesthesia society runs the program, 3 years is required to complete training. Some countries have added a fourth year with emphasis on research or a specific specialty; however, there is lack of financial support from governments, and this has stymied acceptance of this additional year. In addition, some countries have specific scientific organizations run by universities and scientific societies to certify the various places where anesthesia is taught. However, some facilities without proper certification contine to teach residents. Gradually, these places are being restricted from teaching.

Governments and scientific societies also view the requirements for anesthesiologists differently. Governments are pushing for more practitioners, whereas universities prefer better training. Despite such difficulties, anesthesiologists and their scientific societies have campaigned for greater influence in the process of accreditation.

Although advances in medical training by the universities, anesthesia societies, or both, continue, there remains the issue of an inadequate number of practitioners. Public hospitals do not have enough anesthesiologists, and universities are teaching at full capacity. In an effort to create more practitioners, governments are driving the universities to enroll more students, while the universities are concurrently striving to accommodate the growing number of students and provide quality education. Both institutions are diligently working to meet their respective needs. The results will be seen in the near future.

Anesthesia meetings achieve the goal of educating residents and older generations of anesthesiologists. Anesthesia journals are in existence, and although none are comparable to the Institute for Scientific Information, efforts are being made to become part of international medical databases.

China (Yuguang Huang)

Currently in China, medical students are educated for 5 to 8 years in medical colleges (5 years for undergraduate education and an additional 3 to 5 years for a master's or doctoral degree), followed by a resident training program of 5 years.

Differences in education quality still exist among medical colleges across the country because of imbalances in local economies. Despite the improved overall standard of anesthesiologists in the country, it is obvious that in primary-level hospitals, both the clinical performance of the resident and the level of resident training are still relatively low. As a result, anesthesia providers in larger medical centers usually excel beyond their counterparts at primary-level hospitals by a large magnitude.

To address the imbalanced human resource distribution in different areas, the government has been promoting standardized resident training nationwide since 2000. The act was first implemented in pilot centers in Sichuan, Beijing, Shanghai, and other large cities and

has extended to all the other cities throughout China. Medical graduates are required to start their training at an accredited institution upon graduation, and only those who have passed national examinations receive their license. The *Anesthesiology Standard Regulatory Protocol* released in 2012 clearly states the requirements for anesthesiologists in different hospitals; these requirements will help to improve the basic knowledge and clinical practice of young anesthesiologists in primary-level institutions. Meanwhile, the Chinese Medical Association and Chinese Society of Anesthesiologists have also been providing various continuing medical education programs to local hospitals. The overall professional level of Chinese anesthesiologists is expected to be elevated through such efforts.

In summary, the Chinese anesthesiologist team is continuing to evolve. As anesthesiologists have gained prominence in China, more medical graduates are selecting anesthesia as their career after graduation. Graduates with higher education levels are primary contributors to the medical team. In some well-known medical centers, personnel with master's and doctoral degrees hold over 75% of the positions in the department. However, there is a significant gap between the country's urgent clinical needs and the number of competent anesthesiologists. This situation requires additional recruitment efforts.

Europe (Lars I. Eriksson and Jannicke Mellin-Olsen)

Shortly after the European Economic Community (EEC) was established in 1958, representatives from professional organizations representing the Inner Six founding member countries (Belgium, France, West Germany, Italy, Luxembourg, and the Netherlands) created the European Union of Medical Specialists (UEMS). The UEMS soon established contacts with the EEC to define basic principles for medical specialist training in Europe. The aim was to define a high level of training with common general criteria for future European medical specialists, which would lead to harmonized and coordinated specialist training throughout Europe. It would also facilitate the free movement of European specialists from one member country to another. As a tool to achieve this objective, the UEMS created Specialist Sections for the main specialties in 1962. One of these sections is the European Section and Board of Anaesthesiology (EBA), which includes reanimation and intensive care medicine. The role of the EBA is political, working as the anesthesiology branch of UEMS and the EU. EBA is also the interface with other medical specialties including multidisciplinary fields such as critical care and pain medicine, education, and patient safety.

Migration and Work Force Shifts. The EU has defined the duration of training needed to become a specialist in anesthetics to be 3 years; however, in most EU countries, it currently takes 4 to 7 years to fulfill the requirements of a certified anesthesiologist. The content of the training programs varies largely by country with the specialist certificate awarded by each individual country. Yet, being on the specialist register in one EU country entitles the person to be accepted as a specialist in any other EU country, in line with the principle of free movement of specialists within Europe. Although in accordance with the EU spirit, this can create problems. Sometimes, the hired anesthesiologist is not qualified to work in the local setting of another EU country because of insufficient or inappropriate training and lack of language skills.

As in other parts of the world, the quality of care in hospitals and the opportunities for professional and economic development are in general better in the cities. Similarly, the less affluent EU member states that invest in the training of anesthesiologists often do so only to see their practitioners move to other countries within the EU, typically from Eastern to Western Europe. Of course, the main driving forces behind this migration are better economic and professional development opportunities. Recently, financial issues have led to new routes of work migration with practitioners moving from southern European countries to the north.

The supply and demand of anesthesiologists varies considerably between parts of Europe for many reasons. All countries are experiencing an increased aging population who require more health interventions, thereby increasing the demand for workers. Another contributing factor is the European Working Time Directive, a mandatory regulation that limits the number of hours any person is allowed to work per week. In addition, there is an increasing tendency by younger anesthesiologists of both genders who want to spend more time with their families and less time in the hospital. All these issues underlie the current labor shortage that exists in a majority of EU member states.

The shortage of specialists is not made easier when governments fail to foresee the consequences of shortsighted planning and then have to seek ad hoc solutions when avoidable problems arise. This seems true for all countries, but it manifests in various ways depending on a country's historical and cultural factors. When financial restrictions are added to these factors, even traditionally rich countries have to face the probability of compromising their standards by reducing training requirements and recruiting less educated anesthesia providers.

However, statistics on workforce availability and migration in Europe are ambiguous and often associated with error. Unfortunately, the data do not reflect whether individuals are working full time or whether an anesthesiologist is registered in more than one country. Some medical students go abroad to study and return to their home countries but are then counted as a migrated doctor. These issues all add to the complexity of workforce planning. Despite the statistical shortcomings, there is no doubt that the average number of anesthesiologists in Europe has increased over the last few decades.[19,37] The increase is larger in older EU member countries than in the newer ones because of demand, training, availability, migration, and other factors. The average number of anesthesiologists is unscientifically estimated as 14.5 per 100,000 population in Western Europe, but in the East it is only 6.1 per 100,000 population.[19]

In most European countries, health care is funded by the government, although there are local exceptions. Whereas more than 50% of anesthesiologists in some Western European countries (Luxembourg, the

Netherlands) are involved in private practice, anesthesiologists within Scandinavia and the United Kingdom rarely (less than 5%) work in private practice, although the number is increasing.

European Society of Anaesthesiology. The European Society of Anaesthesiology (ESA) is Europe's counterpart to the ASA; however, there are differences. Whereas the ASA is the national society of one country, the ESA Council consists of representatives from 30 nations (data from 2013). European countries with 25 individual members or more (or more than 10% of practicing anesthesiologists in smaller countries) are entitled to council representation. The council members serve to facilitate and harmonize the activities of national and international societies of anesthesiologists in European countries. In addition, all national societies in Europe have formed a separate body within the ESA, known as the National Anaesthesia Societies Committee.

The objectives of the ESA are to promote the exchange of information among European countries; to disseminate information on anesthesiology; to raise the standards of the specialty by fostering and encouraging education, research, scientific progress, and the exchange of information; to promote and protect the interest of its members; and to promote improvements in safety and quality of care of patients undergoing anesthesia by facilitating and harmonizing the activities of national and international societies of anesthesiologists in European countries.

The Euroanaesthesia Annual Congress is the main scientific event of the ESA, but other scientific meetings are arranged, such as the autumn meeting. Education, research, and providing specialty resources are also major activities of the ESA.

European Postgraduate Training Program in Anesthesiology, Pain, and Intensive Care Medicine. In 2011, the EBA published a completely revised postgraduate training program in the specialty[38] based on consultations with national societies, the ESA, and other stakeholders. The new program is considered a paradigm shift from structure- and process-based to competence-based training.

Some years ago, an EU directive mandated a 3-year training program to become a specialist in anesthesia; however, that decision was made at a time when the complexity of anesthesia was much less. This directive is still valid, but the current duration in most EU countries varies from 4 to 7 years, and it is described as a traditional process-based education model. Several governments have recently tried to reduce the duration of training in an effort to train more anesthesiologists in less time and more inexpensively, but this has been fiercely opposed by the EBA.

Since 2001, the EBA has stated that the minimum duration of training should be 5 years, of which at least 6 months should be spent in critical care, 3 months in emergency medicine, and 3 months in pain therapy. Simulation-based training, logbooks, and portfolios were recommended. These guidelines were streamlined and developed further in 2008. The resulting 2011 program requires training of at least 5 years, but with at least 1 year specifically directed to intensive care medicine training. The guideline now states the minimum estimated time required to achieve the defined competences to fill the roles of an anesthesiologist, rather than just a description of length of time.

The training program builds on the competency initiative—the Canadian Medical Education Directives for Specialists definition of the seven roles of a medical specialist. In turn, a list of 10 domains of general core competencies (e.g., disease management, patient assessment and preparation, anesthesia nontechnical skills, and quality-safety-management-health economics) and seven domains of specific core competencies (e.g., obstetric anesthesiology, multidisciplinary pain management) were described. For all competencies in each domain, learning objectives are defined in the form of knowledge, technical skills, clinical and case-management skills, drills, and specific attitudes. This has resulted in a completely new syllabus.

The new curriculum requires new assessment tools, in addition to the old summative examinations.[39] Examples are self-assessment, evaluation of clinical performance, and patient management problems. New online assessment systems are being launched in all-in-one formats. The new curriculum has been introduced in Moldova and Romania, and several other European countries are changing their education systems.

European Diploma in Anesthesiology and Intensive Care. Introduced in 1984, the European Diploma in Anesthesiology and Intensive Care (EDAIC) remains the recommended theoretical examination tool. It is a multilingual, end-of-training, two-part examination covering the relevant basic sciences and clinical subjects for a specialist anesthesiologist. It provides an international European standard that allows harmonization of training and assessment of knowledge across Europe. The EDAIC has been adopted as the national examination in Austria, Switzerland, Hungary, Poland, Malta, Romania Slovenia, Turkey, the Czech Republic, Moldova, Finland, and in 2014, the Netherlands. In 2007, non-Europeans were also allowed to sit for the EDAIC, as stated by the Glasgow Declaration by the Council of European Specialist Medical Assessments. Although the EDAIC does not represent a ticket to work in Europe, the examination has become increasingly popular worldwide.

EDAIC Part 1 consists of multilingual, multiple-choice questions, one part on basic physiology, pharmacology, physics, clinical measurement, and statistics, and a second part on clinical practice associated with anesthesia and its subspecialty areas. It is to be taken after approximately 2 years of anesthesiology training. Part 2 consists of four oral examinations, each with two examiners moderating each other. Candidates may choose the language in which they wish to be examined within the constraints available at the examination center. Part 2 is an end-of-training examination, and successful completion qualifies the candidate to receive the EDAIC. Because the EDAIC is an assessment of theoretical anesthesia knowledge, it must be supplemented by the local assessment of skills and professional attitudes or behavior that takes place in each country according to local systems and is

a requirement before an individual can be placed on the specialist register in that country.

The Committee for European Education in Anaesthesiology (CEEA) was formed as a foundation, Foundation for European Education in Anaesthesiology (FEEA) in 1986. The program consists of a cycle of six courses, covering all the fields of anesthesia, intensive care, emergency medicine, and acute pain management. The program is to be completed in sequences of 3 years and is conducted in the national language of each country. The initial aim was to provide continuing medical education in anesthesiology within the European Community. With the expansion of the EU, the FEEA was introduced to the new member countries and to other European countries. Since 1995, new centers have been established in cooperation with the WFSA in other parts of the world, such as Latin America, Africa, and in Asia. In 2009, the FEEA activities were transferred to the ESA, and the CEEA was created as a joint committee of the ESA and WFSA. Currently, there are more than 100 regional CEEA centers.

ESA/EBA Joint Hospital Visiting and Training Accreditation Program. The ESA/EBA Joint Hospital Visiting and Training Accreditation Program (HVTAP) has been in place since January 1996 as a joint permanent committee of the ESA and the EBA. The goal is to encourage and enhance training standards across Europe and to ensure that an academic institution meets the prerequisites of training in anesthesiology specified in the EBA training guidelines. Together with the EDAIC, the HVTAP serves to improve the overall quality of the specialty of anesthesiology and to harmonize its activities throughout Europe. The visit consists of a detailed presentation of the staffing and organization of the hospital, the department (or the institute), and the structure of training. This forms the basis for discussion and evaluation of all aspects of the teaching and training process with the staff members involved for the purpose of complementing and building on strengths and encouraging development and change to address areas of weakness. A subsequent comprehensive report of the visit, together with recommendations for improvement or accreditation (or both), is presented by the program committee.

India (Deepak K. Tempe)

In India, there are mainly two types of postgraduate qualifications that can be obtained in the field of anesthesiology. The first, provided by medical colleges (MD in anesthesiology, a 3-year degree program), is governed by the Medical Council of India, which oversees the syllabus and other teaching and training standards. The second one is provided by the National Board of Examinations, which awards a Diplomate of National Board (DNB). In addition, the Medical Council of India regulates the diploma in anesthesiology (DA), which is a 2-year training program that is available at medical colleges.

In 1992, it was determined that no new medical college or postgraduate course could be started without the prior approval of the Medical Council of India, and its recommendation became mandatory for all medical colleges. Thus, it was only after the addition of this section, known as *10a,* that teaching and training in the medical field in India were standardized and minimum standards were enforced. In 1998, a Supreme Court judgment reinforced the statutory body's position in establishing and maintaining high standards of medical education and recognition of medical qualifications in India. The recognition awarded by the Medical Council of India for all courses must be reviewed every 5 years by a Medical Council of India inspection team. Thus, teaching and training in anesthesiology in India are standardized through the setting of minimum standards throughout the country in terms of the facilities (space, equipment, manpower, and infrastructure) and the syllabus.

Growth of the Specialty. The interest of Indian medical students in the specialty of anesthesiology has shown a dramatic increase during the last decade. Previously, candidates for a postgraduate course in anesthesiology were admitted based on scores obtained on the MBBS examination. The practice now is to conduct a common entrance examination, with admission into a given subject area based on the rank attained by the student. In a few states such as Delhi, this has been the practice for approximately 25 years.

Table 2-2 shows the top and bottom ranks that were admitted into an MD anesthesiology program between 2002 and 2007 in the states of Maharashtra and Delhi. The table indicates that interest among students to learn and practice anesthesia is increasing. Over the years, the situation has remained more or less similar, except that the total number of MD seats has more than doubled. Reasons for the growing interest in anesthesia among students could be related to the increasing scope of anesthesia (as discussed earlier) and better job prospects. In addition, other fields such as general surgery and general medicine require further subspecialty training, and this could be motivating students to pursue anesthesia. In Delhi, anesthesiology is among the top six specialties preferred by medical students, along with radiology, dermatology, pediatrics, orthopedics, and gynecology. This development is in sharp contrast to the situation 15 to

TABLE 2-2 **OVERALL RANKINGS OF POSTGRADUATE STUDENTS ENROLLED IN ANESTHESIOLOGY PROGRAMS IN MAHARASHTRA AND DELHI (2002-2007)**

	Maharashtra		Delhi	
Year	Top Rank	Bottom Rank	Top Rank	Bottom Rank
2002	228	854	65	98
2004	No exam		53	96
2005	405	642	32	96
2006	160	606	33	99
2007	106	504	61	85

The total number of postgraduate seats in all subjects is 140 in Delhi and 450 in Maharashtra. The students often sit for entrance examinations in several states, which probably explains why the last rank exceeds the number of seats in Maharashtra.

20 years ago, when anesthesiology was among the bottom five choices.

There are a total of 381 medical colleges in India with 50,078 seats.[40] Of these, there are 1386 seats in MD anesthesia and 644 in DA anesthesia. In addition, the Ministry of Health and Family Welfare of India recognizes the DNB as a qualification in the given field and equates it with the postgraduate degrees awarded by other Indian universities. There are approximately 200 DNB seats in anesthesiology.

Assigning seats is especially challenging because it remains unclear just how many anesthesiologists India needs. According to one estimate, there are approximately 35,000 to 40,000 anesthetists in India for a population of 1.27 billion (personal communication, Dr. Anjan Dutta, President of ISA). The majority of these anesthesiologists are in cities. This number is far too few as compared with the United Kingdom, which has 12,000 anesthetists for a population of 64 million.[41] This fact has been recognized by health officials and, as a result, the number of postgraduate seats in anesthesia has more than doubled during the last 5 years. Major factors that limit any additional increase in the quantity of seats are the inadequate supply of recognized medical teachers and the limited number of medical colleges. Consequently, although the situation has improved, the shortage of anesthetists continues. It is generally believed that in the interest of safety, short-term courses in anesthesia should be discouraged to fill this deficiency.[42] The ISA has also suggested that during the teaching course of MD, the final-year student can have a rural posting for 3 to 6 months with one qualified anesthetist.[43] However, the government is actively considering a short-term training course in obstetrics anesthesia (3 to 6 months) for MBBS doctors to provide much needed anesthesia services to improve maternal health. Some states, such as Andhra Pradesh, already have this in place while other states are considering it. The Delhi High Court has proclaimed that training for life-saving anesthesia skills and emergency obstetric care will continue until the requirement of anesthesiologists is fulfilled[32]; however, these doctors will be allowed to administer anesthesia only in government rural health centers.

Japan (Naoyuki Hirata and Michiaki Yamakage)

In Japan, the specialty of an anesthesiologist is certified differently by the government and by the JSA. To be certified by the government, a trainee anesthesiologist must perform general anesthesia in more than 300 cases over a 2-year period under the supervision of certified anesthesiologists. On the other hand, the JSA certifies anesthetic specialists by clinical training over a 5-year period in various types of anesthesia that include academic activities and success in oral, written, and skill examinations. The present examination pass rate is approximately 60%. To update the certification of the JSA (the government does not require updates), anesthetic specialists must report on their anesthetic case experience, teaching career, and academic activities every fifth year. When the first renewal is accepted by the JSA, the anesthetic specialist is also qualified as a supervisory anesthesiologist. Thus, 10 years of substantial experience in the field of anesthesiology is required to be certified as a supervisory anesthesiologist in Japan.

The Middle East (Anis Baraka and Fouad Salim Haddad)

The departments of anesthesia in the different countries of the Middle East are staffed by highly qualified academic faculty certified either by the Arab Board or by foreign academic bodies, such as the American Board of Anesthesiology of the United States and the Faculty of the Royal College of Anaesthetists of the United Kingdom.

Anesthesiology training following MD graduation consists of 4 years of residency in a recognized medical center. This may be followed by 1 to 2 years of a subspecialization fellowship in areas such as pain management, critical care, obstetric anesthesia, cardiopulmonary anesthesia and more. Anesthesia specialization and Board certification by the training hospitals must be recognized by the anesthesia societies within the respective countries, which also track medical training, as well as continued medical education.

In addition to the annual regional anesthesia society conferences such as Egyptian Anesthesia (Fig. 2-11, *A*), and the Pan Arab Congress of Anaesthesia (see Fig. 2-11, *B*), the Anesthesiologists of the Middle East participate actively in the activities of other national society meetings such as the Pan African meetings, and the annual meetings of the ESA and the ASA. In addition, they actively participate in the administrative and academic activities of the World Congress of Anaesthesiologists (WCA) and the WFSA.

Russia (Yury S. Polushin and Olga N. Afonin)

As of today, anesthesiology education in Russia still requires revision and improvements. There is need for structured residency programs that teach the standards accepted around the world, which are based on decades of experience in the safe practice of anesthesiology. The Academy of Postgraduate Education recently introduced new standardized tests, comparable to internationally accepted graduation examinations that permit objective measurement of the knowledge of newly graduated anesthesiologists.

Southeast Asia (Forian R. Nuevo)

The required number of years of training in anesthesiology varies among the member countries of the ASEAN region between 2 to 3 years (Table 2-3). Some countries follow the European model, and some adopt the American model (see Chapter 9), whereas others develop a hybrid model that is a combination of training programs from across the world. Of course, selection of an appropriate model is heavily influenced by the country's prevailing education system, which has been in place from the time it was colonized through the time it gained sovereignty. Currently, the lack of anesthesia care providers continues to be a persistent problem, and most countries are reviewing their respective curricula to address their particular needs.

An education abroad, such as in the United States or Europe, can be cost prohibitive for many young physicians,

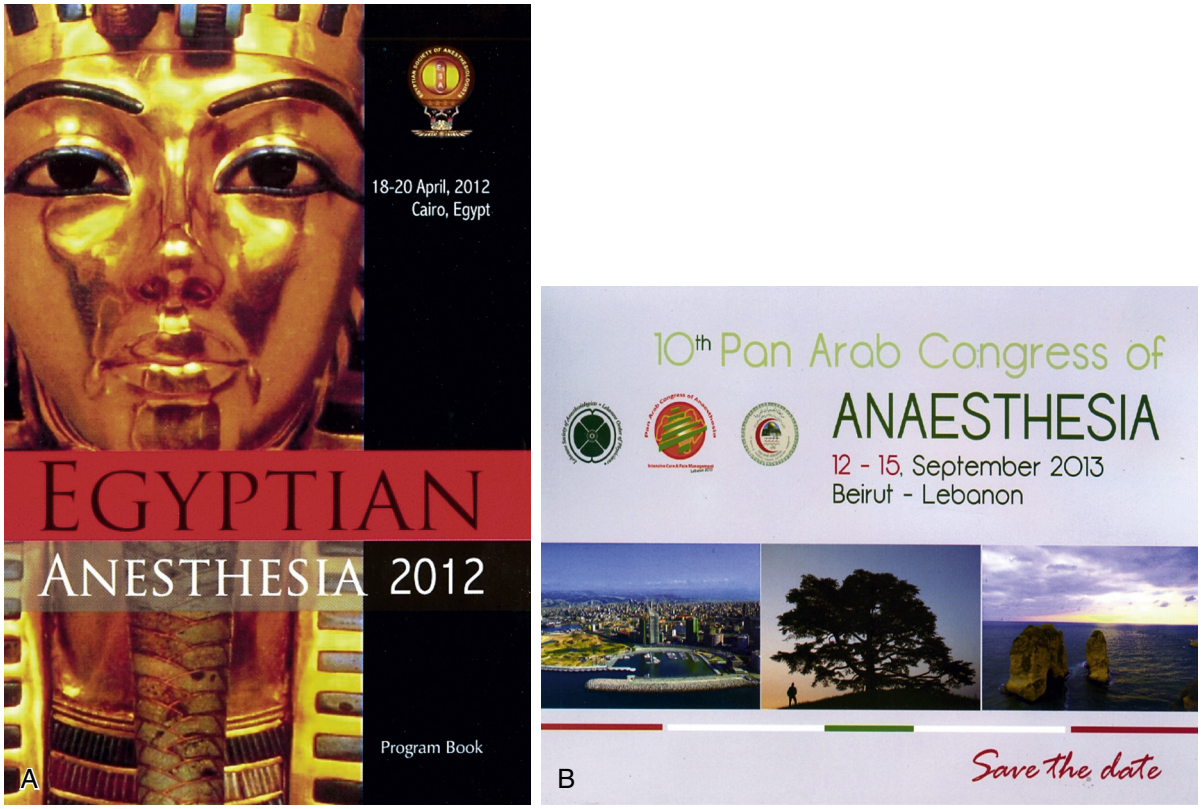

Figure 2-11. A, The Annual Conference of the Egyptian Society of Anesthesiologists, 2012. **B,** The Pan Arab Congress of Anaesthesia, 2013.

TABLE 2-3 **ORGANIZATIONS, CERTIFICATION REQUIREMENTS, AND RECOGNITION OF ANESTHESIOLOGISTS IN SOUTHEAST ASIAN COUNTRIES**

	Indonesia	Malaysia	Philippines	Singapore	Thailand
Influence on medical education	Britain	Britain	United States	Combination Britain + United States	Britain
Anesthesia					
Residency	3.5 years		3 years		3 years
Subspecialty fellowship	Variable number of training years, depending on subspecialty				
Pain			Yes	Yes	Yes
Obstetrics			Yes	Yes	
Cardiovascular/ thoracic	Yes	Yes	Yes	Yes	Yes
Pediatric			Yes	Yes	
Intensive care		Yes		Yes	Yes
Neuroanesthesia	Yes	Yes		Yes	Yes
Certifying body	Collegium of Indonesian Anesthesiologist	Malaysian Society of Anesthesiologists	Philippine Board of Anesthesiology	Singapore Society of Anesthesiologists	Royal College of Anesthesiologists in Thailand

particularly those coming from low- to middle-income countries. Thus, many young anesthesiologists select Singapore, Malaysia, or Thailand for anesthesia subspecialty fellowships because of the country's proximity and affordability. Furthermore, these training destinations are equally excellent centers of learning. However, in Indonesia, there are only 10 accredited training institutions, and being admitted into a program on the anesthesia fundamentals can be nearly impossible for many Christian Indonesians. As a result, many come to the Philippines for their 3-year anesthesia residency training, which is facilitated by institutional memorandum of agreements. The Philippines has accepted anesthesia trainees from many countries, including Nepal.

Anesthesiology Center for the Western Pacific. In January 1970, the Philippines established the Anesthesiology Center for the Western Pacific (ACWP) in Manila. It had an 11-month course on the basic fundamentals of anesthesia. This was a joint activity of

the WHO Regional Office for the Western Pacific, the University of the Philippines, the China Medical Board, and the WFSA.

The rationale for the creation of the ACWP was to help alleviate the shortage of reliable anesthesiologists in the region and to underscore the importance of administering safe anesthesia. The center did not seek to provide a complete training program; rather its purpose was to emphasize the basic sciences in anesthesiology. It created a foundation for students to build on so that they could eventually qualify, through further training, as specialist anesthesiologists.

Students at ACWP were from the Pacific Islands, Southeast Asia, southern Asia, Hong Kong, Taiwan, Korea, Japan, Iraq, Russia, and Sudan. The program served the region for 16 consecutive years, and many of its graduates have become respected leaders in anesthesia and have contributed to the development of anesthesia programs and safe anesthesia care in their respective countries. Unfortunately, in 1986, the ACWP ceased its operations.

Bangkok Anesthesia Regional Training Center. After the closure of the ACWP, a very timely project arose in Thailand. The Bangkok Anesthesia Regional Training Center (BART) was created with modest financial assistance from the WFSA Education Committee. The impetus behind the formation of the BART was the need to train anesthesiologists from the neighboring countries of Laos, Cambodia, Vietnam, and Mongolia. This program is still operational and is a source of pride, because BART graduates have all gone back to their countries of origin and helped to advance the field of anesthesia in their respective workplaces.

Uganda and Sub-Saharan Africa (Ronald D. Miller and D.G. Bogod)

In a survey by Hodges and colleagues,[44] there was only one medical anesthesiologist among the 91 anesthesia practitioners who participated in the survey, which means that, as is often the case, many trained physicians in Uganda probably traveled to the West to obtain a better life for their families. In addition, based on the survey, access to up-to-date textbooks seems iffy at best—fewer than half of those surveyed have access to such texts.[35]

The preceding paragraph, published in the seventh edition of this text, pointed to an inadequacy of trained anesthesia personnel and equipment that is being increasingly recognized. As stated in 2007, "the absolute numbers of anesthesiologists decreased during the nineties. Most anesthesia was delivered by nurse-anesthetists, either certified or trained on the job."[34] Because of age, a shortage will occur in 15 years. Experienced anesthesiologists are now so few that, in most countries, the critical mass of knowledgeable specialists no longer exists to train new anesthesia providers.

These conditions and inadequacies have been recognized by international anesthesia groups and organizations for years. Many improvements have been made (e.g., increased use of pulse oximetry). A few years ago, a "parallel anesthesia and surgical provider training program was started in Sub-Africa in a rural hospital." Basically, this program was designed to provide integrated care to a certain geographic area. Although the specific outcome of this organizational approach was not described, there is evidence of creativity in trying to solve basic inadequacies in health care delivery.

Encouragingly, communications in *The Lancet* are appearing regarding anesthesia-related mortality in Sub-Saharan Africa. With the advancing sophistication of information technology, comparison of outcome data among countries and/or areas of the world are possible. Bainbridge and associates[45] compared anesthesia related mortality between developing and developed countries. The anesthesia-related mortality rate was at least twofold to threefold more frequent than in developed countries. Cesarean section was the most common procedure with a mortality rate of near 1%.[46] Further, in several low-income countries, anesthesia is administered almost exclusively by nonphysicians, regardless of the patient's physical status and often without supervision.

The attention that developing and poor countries are receiving regarding anesthesia care will likely improve that care. The evolution of information technology will probably become more important and direct our attention to where it is most needed. While emphasis has appropriately been on mortality rates, more sophisticated and detailed outcome data are required so that resources can be directed in a productive direction.

SUBSPECIALIZATION

Brazil (Maria Carmona)

As part of its focus on improving the progress of anesthesiology in Brazil and stimulating educational and regulatory activities, the SBA has created specific member committees, such as those for ambulatory anesthesia, cardiovascular and thoracic anesthesia, obstetric anesthesia, pediatric anesthesia, regional anesthesia, venous anesthesia, perioperative medicine, palliative care, organ transplants, sleeping disturbances, malignant hyperthermia, resuscitation, trauma care, difficult airway, and more recently, committees related to occupational health and quality and safety. The resuscitation and the difficult airway committees develop specific workshops related to continuous education and training on these topics. The SBA also offers both a physical and virtual library that deliver scientific publications on demand, as well as video lessons previously delivered in society meetings or specifically prepared for attendees of the residency program.

Chile/South America (Guillermo Lema)

In South America, only Colombia and Chile have specialty laws. In all other countries, physicians can perform professional actions without a law to certify the proficiency and quality of care and protect patients. In fact, physicians with a low level of training have practiced anesthesia for many years; in most of these countries, paramedical personnel have performed anesthesia because of the lack of sufficient medical personnel or interest in the specialty. In some countries, surgeons conduct both anesthesia and surgery with the help of technical personnel. This practice

has been abandoned in most countries, but in countries such as Bolivia, Ecuador, Paraguay, Peru, and Venezuela, this situation persists and with government authorization.

Currently, the law in most countries specifies that only physicians can provide anesthesia; however, the shortage of trained physicians has left some countries with inadequately trained ones. Nevertheless, the process of certification of specialties, including anesthesia, is present in several countries. Most countries have medical organizations and anesthesia societies demanding proper certification methods. In Chile, Colombia, and other countries, the government has definitively reached agreement on minimum standards for certification in all medical specialties. It includes the recognition that only certain universities with full accreditation can teach medical specialties. So, as of the end the end of 2013, only colleagues who complete their studies in accredited institutions will be considered anesthesiologists, and only they will be allowed to work in public hospitals and private clinics.

India (Deepak K. Tempe)

For more than two decades, anesthesiologists have recognized the need for dedicated practice in the field of cardiac anesthesia and neuroanesthesia. There are anesthesiologists who are working exclusively in these specialties, but very few separate departments of cardiac anesthesia and neuroanesthesia exist. The All India Institute of Medical Sciences (AIIMS), a group of autonomous public medical colleges of higher education, is an exception in this respect because it created two such departments in 1986. Postdoctoral courses in these specialties have been started in the country. AIIMS has conducted the courses in both specialties since 2002, whereas the Sri Chitra Tirunal Institute of Medical Sciences, Thiruvananthpuram, has offered a course in cardiac anesthesia since 2003. The number of seats, however, is grossly inadequate, with four seats in cardiac anesthesia and two in neuroanesthesia. The National Board of Examinations started a DNB fellowship program (2 years) in cardiac anesthesia in 2002; it began with 4 seats, and the number has increased to 18. The Medical Council of India has now recognized the separate subjects of cardiac anesthesia (based on a Gazette of India notification dated July 24, 2009) and neuroanesthesia (based on an amendment notification dated December 8, 2010). This recognition allows all medical colleges to start the postdoctoral courses in these specialties, and the number is likely to increase.

Japan (Naoyuki Hirata and Michiaki Yamakage)

Although most anesthesiologists in Japan have performed various methods of surgical anesthesia, it has been well recognized that cardiovascular anesthetic management requires specialized experience. Recently, TEE has been recognized as essential for diagnosis and intervention during cardiovascular anesthesia. The Japanese Society of Cardiovascular Anesthesiologists has established a qualification system that certifies specialists of cardiovascular anesthesia. To be a specialist, significant clinical experience with cardiovascular anesthesia and passing of the TEE examination, created in 2004 by the Japanese Board of Perioperative Transesophageal Echocardiography, are required. These specialized anesthesiologists may further improve cardiovascular anesthetic management.

PROFESSIONAL AND RESEARCH ACTIVITY

Brazil (Maria Carmona)

The SBA is a highly structured association that is also in charge of the monitoring and engagement with federal and state legislative and regulatory activities affecting the practice of medicine by anesthesiologists. The SBA website (http://www.sba.com.br) also has a specific area for communication with the lay public. The SBA promotes an annual congress of anesthesiology, and the state and regional societies promote their own congresses. Besides presenting scientific and educational topics, the congresses provide a venue for meetings of the educational and political committees. Every 4 years, the Brazilian Congress of Anesthesiology occurs in conjunction with the Portuguese Society of Anesthesiologists. The SBA's association with other South American societies of anesthesiology, all of them Spanish speaking, is less expressive, but the Latin American Society of Regional Anesthesia is in charge of the development of this area of anesthesia in South America and promotes its own annual congress and other activities.

In conclusion, the well-established teaching programs, along with the emerging economic situation in Brazil, are major contributors to the growth of good anesthesia care throughout the country.

Chile/South America (Guillermo Lema)

Time, funding, and expertise are the basic requirements for research of sufficient quality to support publications or communications internationally. These requirements are not found widely in South America. Only a few university anesthesia departments have the capability of producing clinical research of sufficient quality to be published in esteemed journals such as the Institute for Scientific Information, notably in Chile, Brazil, and Argentina. The government and some colleagues have argued that research is not important in a continent that has more pressing priorities. This author does not agree.

Research is a tool for learning, and it should be encouraged, at least at university-based anesthesia residencies. Unfortunately, research does not generate income, and most of the clinical groups are not willing to dedicate time or money to this particular activity. Funding is lacking, and although some countries have national research grants to support clinical research, most do not. Basic research in anesthesia virtually does not exist in South America.

Financial support from pharmaceutical companies is weak, usually depending on the effects of their drugs in a clinical setting. Because of economic constraints, a large number of generic drugs are used; therefore, major pharmaceutical companies are not willing to support activities of this nature.

Conflict of interest has become a major issue; yet its regulation is weak. Many anesthesia departments in

private and public hospitals face financial limitations, and in this author's opinion, it is obvious that the tendency is to ask for support from companies in the medical industry. Although anesthesia is not a large recipient of medical industry funds, other specialties (e.g., cardiology, ophthalmology) are supported by the industry without restraint.

China (Yuguang Huang)

There are now two large anesthesia academic organizations in China: the CSA and the Chinese Association of Anesthesiologists. The CSA seeks to improve the national academic level in anesthesiology and to offer patients higher standards of clinical service. The Chinese Association of Anesthesiologists was established in 2005 and is focused on team construction and humanistic concern for anesthesiologists. Annual meetings are held in September for the CSA and in April for the Chinese Association of Anesthesiologists, with attendance in the thousands for each. As general anesthesiology has advanced, its subspecialties have also flourished with the start of several subspecialty academic groups. More than 30 clinical guides and expert consensus materials have also been published.

In 1986, the Beijing International Conference on Anesthesia was held successfully. Many experts from abroad, including Professor Ronald D. Miller (this textbook's editor), were invited to join as keynote speakers. From that point on, Chinese anesthesiologists began to communicate more with international professionals. At the first Sino-Japanese Clinic Anesthesia Symposium held in 1986, the CSA and Japan Society for clinical Anesthesia agreed to hold a symposium every 2 years.

The rapid development of the discipline has led to increasing opportunities for Chinese anesthesiologists to communicate and exchange information with their international colleagues. Some of them have obtained recognition from international organizations. Several renowned Chinese anesthesiologists have been admitted into well-known international anesthesiology societies. Professors Rong Xie, Ailun Luo, and Xinmin Wu were named Honorary Academician by the Royal British College of Anaethetists. Professor Yuguang Huang was nominated President Elect for the International Society for Anaesthetic Pharmacology in 2012 and Board Member of the worldwide Primary Trauma Care Foundation. Professor Lize Xiong was elected as a standing committee member of the WFSA in 2012. Professor Yunxia Zuo was elected as President for the Asian Society of Paediatric Anaesthesiologists in 2012.

Anesthesiology publications in China include *Chinese Journal of Anaesthesiology, Journal of Clinical Anaesthesiology, Journal of Pain Medicine,* and the Chinese edition of *Anaesthesia and Analgesia*. More than 100 research programs in anesthesiology are supported by the National Natural Science Foundation of China each year, and large scientific grants have been invested in anesthesiology research in the past years. Authors from mainland China publish more than 500 Science Citation Index manuscripts per year on average, and more presentations and publications have been released at international meetings year by year.

Europe (Lars I. Eriksson and Jannicke Mellin-Olsen)

European Academy of Anaesthesiology. Before the formation of the European Academy of Anaesthesiology (EAA) in 1978, there was no formal representative structure except the EBA for the specialty within Europe. The five statutory aims of the EAA were (1) to raise the scientific level of the discipline; (2) to improve the training of anesthetists, their clinical and theoretical education, and their competence at the completion of the training period by holding examinations; (3) to hold scientific meetings, conferences, and seminars; (4) to facilitate research in anesthesia and its associated disciplines; and (5) to promote exchange among anesthetists and discussion of all matters concerning their profession.

The EAA had a limited number of members and academicians and, as European anesthesiology grew, was perceived by many to be an exclusive and elitist organization. In 1992, the ESA was formed and was open to everyone. Its chief aims were to conduct an annual Euroanaesthesia meeting to replace the European Congress, which had formerly run on a 4-year cycle alternating with the World Congress, and to support educational and research activities by awarding grants and fellowships. Whereas the ESA was concerned with the practice of clinical anesthesia and supporting its membership, the EAA had developed formal initiatives such as the EDAIC, the *European Journal of Anaesthesiology (EJA)*, and a system of hospital visiting and accreditation training in conjunction with the EBA.

The fourth organization that existed at that time was the Confederation of European National Societies of Anaesthesiology (CENSA), which was effectively the European section of the WFSA.

For some years, the roles of all the various organizations made it increasingly necessary for an individual anesthesiologist to be a member of more than one body to participate in and benefit from all the variety of activities. As a result, in 1998 a decision was made to amalgamate the former ESA, EAA, and CENSA into one organization. A temporary organization, the European Federation of Anaesthesiologists, was established in 2001, under which amalgamation was successfully achieved. Subsequently, the new European Society of Anaesthesiology, which now represents every anesthesiologist in Europe, was launched in January 2005 in its interim form before becoming fully established in January 2006. Moreover, because the formal, declared responsibilities of the parent organizations were essentially different with little overlap between them, a strong and comprehensive organization was established right from the start. Under this new organizational structure, CENSA became the ESA National Anaesthesiology Societies Committee, now ESA National. Each country has a number of delegates to ESA National, depending on the number of members in its national society. This body constitutes the European Regional Section of the WFSA.

The ESA National provides a comprehensive range of activities to support European anesthesiology, primarily aimed at sustaining and enhancing the safety, efficacy, and quality of care of patients through publication of the EJA and the Euroanaesthesia organization and other

meetings; it supports the interests of its members and facilitates the exchange and dissemination of information related to anesthesiology, critical care, pain, and emergency medicine. It encourages research and scientific progress by conducting academic meetings and clinical studies, by awarding grants and fellowships, and by raising and harmonizing the standards of anesthesiology. This is achieved by delivering education, training, continuous medical education, developing guidelines and accreditation of anesthesiologists through educational programs, the EDAIC, and in-service training examinations, as well as through the HVTAP run jointly with EBA. The whole structure of the new ESA is currently undergoing a major revision, including changes in the by-laws.

European Journal of Anesthesiology. The EJA is the official journal of the ESA and is distributed to all ESA members. It is published monthly and is owned by the ESA. It is also the official journal of EBA. A group of editors is responsible for the content of the journal. The EJA publishes original work of high scientific quality. Preference is given to experimental work or clinical observation in humans and to laboratory work of clinical relevance. The journal also publishes commissioned reviews by an authority in a field of interest to those working in anesthesiology, pain, or critical care. Editorials, commentaries, book reviews, news, and notices are also included. In addition, the ESA publishes a newsletter four times per year, separately from the EJA. This newsletter contains items of interest to ESA members as well as information and formal announcements.

India (Deepak K. Tempe)

Since its inception in 1947, the ISA has grown from 19 to nearly 21,000 members in 2014. The South Asian Confederation of Anaesthesiologists with member countries India, Bangladesh, Sri Lanka, Pakistan, Nepal, and Maldives was formed in November 1991. Currently, there are also separate Indian associations of cardiothoracic anesthesia and neuroanesthesia. The Indian Association of Cardiovascular and Thoracic Anesthesiologists (IACTA) is 16 years old and holds an annual meeting. The IACTA awards fellowships in cardiac anesthesia after holding an exit examination of eligible candidates. Furthermore, a fellowship program in TEE has been initiated in collaboration with the Indian Academy of Echocardiography. Since 2007, a national workshop on perioperative TEE has been organized for cardiac anesthetists to learn this technique, which is now readily available in most cardiac centers. The IACTA also publishes the journal *Annals of Cardiac Anaesthesia,* which is now in its fifteenth year of publication. It has the distinction of being included in MEDLINE and being the first Indian journal in anesthesia to be indexed in the National Library of Medicine and has been followed by the *Indian Journal of Anaesthesia* and the *Journal of Anaesthesiology and Clinical Pharmacology*. In addition, a number of societies have been formed, including ones for the study of pain (founded in 1984), for critical care medicine (founded in 1992), and for obstetrics anesthesia (founded in 2005). Asian societies in cardiac anesthesia, neuroanesthesia, and pediatric anesthesia have also been formed.

Professional and research activities in India have increased with the formation of subspecialty groups in the country. Among them, cardiac anesthesia has made a particular mark. An article published in the *Journal of Cardiothoracic and Vascular Anesthesia* has highlighted that India is second to the United States and leads the rest of the world in number of related publications during the last decade. Although there were fewer original articles published in India, the authors concluded that the research activities from India cannot be ignored.[47]

Japan (Naoyuki Hirata and Michiaki Yamakage)

As mentioned before, the JSA was established in 1954, and it has held annual meetings every year since then. Subcommittees on anesthesiology, focusing on cardiovascular anesthesia, pediatrics, obstetrics, geriatrics, monitoring and equipment, nerve blocks, research, and education have been established. As of 2012, the JSA has 5450 certified anesthesiologists and 3341 supervisors. Most Japanese anesthesiologists regularly interact with colleagues internationally and in Japan to maintain their own expertise, and more than 250 Japanese anesthesiologists attend the annual meeting of the ASA every year.

In addition, the JSA has published the *Journal of Anesthesia* since 1987, and it has been indexed in the National Library of Medicine, including the MEDLINE database. Numerous manuscripts have been submitted from many countries. The number of articles published annually has increased to nearly 180.

The Middle East (Anis Baraka and Fouad Salim Haddad)

Most anesthesiologists in the Middle East keep in close contact with developments in anesthesia throughout the world by attending national and international congresses, subscribing to various international anesthesia journals, and maintaining worldwide friendships. Some anesthesiologists in the Middle East, including those who have emigrated abroad, have become leaders in the specialty and have made original contributions in the fields of muscle relaxants,[48-50] semi-open systems, obstetrics,[51] pediatric anesthesia,[52,53] and the pathophysiology of open heart surgery.[54] In addition, the Middle East actively contributes to publications. The *Middle East Journal of Anesthesiology,* which is published by the Department of Anesthesiology at the American University of Beirut, is widely distributed all over the world and is recognized by Index Medicus (Fig. 2-12).

Russia (Yury S. Polushin and Olga N. Afonin)

With the exception of a few medical centers, most anesthesiologists have to practice their art of extremely invasive and possibly dangerous science without sufficient monitoring. Pulse oximeters, gas analyzers, and capnographs are still a luxury in many medical centers. Medical science is again government financed, but it is often still dependent on the good will of the physicians who carve out time for research from their private lives. Russian anesthesiologists, as well as medics in other specialties, have been raising their concerns to the government. The Ministry of Health has accepted a new national program

Figure 2-12. Cover of the *Middle East Journal of Anesthesiology*.

for improvement in medical services, but it will take dramatic measures and significant investments in the health of Russian citizens for the country to achieve the goal of a safe and effective health care system in compliance with international standards. Statistics and the experience of multiple countries prove that the huge initial investments are returned as improvements in population health as medical and illness-related costs decrease. It would be gratifying to see Russia, the country that contributed so much to the growth and development of medicine and anesthesiology, return to the international scene as a partner in health promotion in all forms of medical science and art.

Southeast Asia (Florian R. Nuevo)

Two pioneering anesthesiologists, Professor Quintin J. Gomez of the Philippines and Dr. Saywan Lim of Malaysia, conceived the Confederation of ASEAN Societies of Anesthesiologists (CASA) in Kuala Lumpur in September 1974 during a meeting after the Fourth Asian Australasian Congress of Anaesthesiologists, a regional congress of the WFSA. The first ASEAN Congress of Anaesthesiologists was held in December 1979 in Manila, Philippines, under the leadership of Professor Gomez, who was then the incumbent president of the WFSA (1976-1980).

The main objective of CASA is to enhance and promote the specialty of anesthesiology in the region by hosting biennial congresses of anesthesia called the ASEAN Congress of Anaesthesiologists. These congresses serve as a venue for ASEAN anesthesiologists to meet experts from the United States and Europe, as well as other international anesthesia leaders, and to learn current practices in anesthesia from them. The congresses also inspire trainees and younger anesthesiologists in Southeast Asia to present their clinical trials and modest research activity and to participate in scientific activities as resource speakers or workshop facilitators.

Currently, CASA member societies conduct clinical research activities in anesthesia, but there is much room for improvement. Most research studies involve clinical drug trials funded by pharmaceutical companies. There is a paucity of published papers in peer-reviewed anesthesiology. What is also lacking is translating the research activities into well-written research papers. The *ASEAN Journal of Anesthesiology* serves as a venue to publish all of these research endeavors in the region.

Over time, the objectives of CASA have grown. The group has strived to promote closer ties among member societies, to enhance the image of the specialty in the region, and to upgrade the specialty through the exchange of information between local and international experts in anesthesia. CASA also supports interacting with other anesthesia regional sections such as the South Asian Association for Regional Cooperation, which represents Afghanistan, Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, and Sri Lanka.

Many anesthesia subspecialty organizations have been created. To date, these include the Obstetric Anesthesia Society for Asian and Oceania (OASAO), Asian Society for Pediatric Anesthesiologists, ASCA, Asian Oceanic Society for Regional Anesthesia (AOSRA), Asian Society for Neuroanesthesia and Critical Care (ASNACC), and ASEAPS. Indeed, through CASA and these subspecialty groups, a wealth of information is paving the way to upgrade and develop the practice of anesthesia and the anesthesiologists themselves.

Despite threats of terrorism and the risks of epidemics such as avian flu and severe acute respiratory syndrome (SARS), the ASEAN confederation has persisted in hosting its biennial congress. Their leaders have been inspired to step up these academic activities, and CASA members take turns, with much enthusiasm and camaraderie, in hosting these meetings. Attendance has grown from 400 to almost 1000 anesthesiologists coming from ASEAN and non-ASEAN countries, such as Japan, Korea, China, Saudi Arabia, Mongolia, Canada, and the Middle East. The faculty of speakers includes local ASEAN and international anesthesia experts from the United States, Europe, Canada, Australia, and New Zealand, some of whom were supported by the WFSA, by industry, by respective anesthesia societies, and by the faculty themselves.

SAFETY AND MEDICOLEGAL INITIATIVES IN THE REGION

Chile/South America (Guillermo Lema)

Medicolegal issues and increased concern from patients have been behind the adoption of accreditation requirements. It is encouraging that most anesthesiologists are willing to obtain certification; clinics and hospitals are

also requiring certification for physicians to work in these institutions.

Furthermore, the medical community recognizes and has adopted certification of specialties, accreditation of both national and international public and private hospitals, the need for full and proper communication with patients and relatives, the creation of rules for different procedures, and the requirement for written consent. Disclosure of morbidity and mortality has also helped patients to be aware of the medical care to be received.

China (Yuguang Huang)

Anesthesia is undoubtedly a high-risk profession. The uneven development across the country in the economy and in clinical medicine in different areas has resulted in even larger differences in anesthesia safety. Therefore, well-established quality assurance systems and a culture that cultivates safety are keys to achieving higher safety coefficients. The National Anaesthesiology Quality Assurance Centre, which was established by the MOH in 2011, performed a series of measures for safety control, including designing standardized sheets for the intraoperative anesthesia record, encouraging surgical time out procedures, and constructing an incident report system. The National Anaesthesiology Quality Assurance and Assessment Standards were also established by the MOH in June 2012. Branches of the Quality Assurance Centre have also been established in each province throughout China, composing a nationwide network for quality and safety.

Europe (Lars I. Eriksson and Jannicke Mellin-Olsen)

Helsinki Declaration on Patient Safety in Anaesthesiology. Anesthesiologists are in a unique position to safeguard patients' best interests whenever they are at their most vulnerable, be it in the operating room, the critical care unit, in need of critical emergency care, or when suffering great pain. It is estimated that 200,000 patients in Europe die every year from complications due to surgical procedures. The EBA worked closely with the ESA and other bodies to develop the Helsinki Declaration on Patient Safety in Anaesthesiology (Declaration), which was launched in 2010.[55] The text emphasizes the roles of anesthesiologists, patients, clinical partners, funders of health care, and partners in drug and technical industries. It highlights the role of education, training, and human factors. The principal requirements to obtain the goals are listed, and anyone involved in health care was invited to sign. Representatives from the EBA, ESA, health politicians, patients' organizations, the WHO, WFSA, UEMS, and others participated in the launch. The declaration was immediately signed by most European anesthesiology societies. It has since been translated to several languages and is used actively to promote patient safety in a majority of European countries. EBA and ESA have installed a Patient Safety Task Force that is working on the follow-up and the implementation of the declaration.

An unexpected consequence of the declaration was the attention it has received across the world. It has been signed by the countries in CASA and the by those in Latin America. The South Asian Societies signed a similar Bangalore Declaration in 2011, and the Australian, New Zealand, and Canadian Societies also support the intention of the declaration. This support implies movement toward a global effort to improve patient safety.

Another program that is linked to patient safety is the Lifebox project, initiated by the WFSA, the Association of Anaesthetists of Great Britain and Ireland, and the Harvard School of Public Health to provide pulse oximeters to every operating room in the world, including education, training, and peer support. The goal is to close the pulse oximetry gap. The ESA and other European anesthesiology bodies endorse the program.

India (Deepak K. Tempe)

Medicolegal Aspects of Anesthesia Practice in India. As in most other countries, it is unlawful to practice medicine in India without proper registration with the State Medical Council or Medical Council of India.[56] The medical profession is regarded as noble in India, and at one time doctors were considered as having an integrity beyond doubt (next to God). This situation existed before 1980 when patients and the public accepted without question the outcome of their illness. However, this perspective has gradually changed as a result of the increased awareness brought about by consumer and social organizations and the media.[57] The gross commercialization of the medical profession coupled with the abject failure to self-regulate has also been responsible.

The Consumer Protection Act (CPA) of 1986 addresses the consumer grievances arising from the service providers. Section 2(1)(0) of the CPA defines the word *service,* and Section 2(1)(d) defines *consumer* (i.e., persons availing such services). Initially, it was controversial whether the medical practitioner could be regarded as rendering a service.[58,59] However in 1995, the Supreme Court judgment in the Indian Medical Association (IMA) *v* V. Shantha case clarified that service rendered to a patient by a medical practitioner (except where the doctor renders service free of charge to every patient or under a contract of personal service), by way of consultation, diagnosis and treatment, both medicinal and surgical, would fall within the ambit of "service" as defined in section 2(1)(0) of the act. Furthermore, any hospital, whether government or private, that collects charges from all or some of its patients is covered by the CPA. In these hospitals, even patients treated free of charge are entitled to go to the consumer courts for compensation for deficiency of service.[60] Likewise, anesthesiologists, even if not hired by the patient directly (i.e., hired by surgeon, private clinic, or hospital), are liable to pay compensation under CPA.[61]

Consequently, most of the cases relating to medical negligence go to the consumer courts, because these courts are inexpensive and provide a speedy disposal of cases. Depending on the value of services and compensation claimed, complaints can be filed with the district, state, or national commission.

The CPA created significant discomfort within the medical fraternity in India with initial protests from medical professionals and the IMA, as well as several heated and emotional debates among the senior doctors. Eventually, they came to the realization that the act covers the medical profession and is here to stay.[57]

As in many other countries, insurance companies in India consider anesthesiology a high-risk specialty. In addition, the public is still relatively unfamiliar and unaware about anesthetic risks. As a result, anesthetic complications are not as readily acceptable as surgical complications are. Many times the complaint is lodged against the treating doctor (generally the surgeon) or the hospital, and the anesthesiologist is subsequently made the party. Indian society is more aware of patient's rights as seen from the recent spurt in litigations concerning medical professionals or establishment liability, claiming redress for the suffering caused by medical negligence, vitiated consent, or breach of confidentiality arising out of doctor-patient relationships.[62] Slowly, people are also realizing that it is not easy to obtain compensation through the court unless there is strong evidence of negligence.[63]

Establishing medical negligence and successful litigation requires that four criteria be satisfied. First, the claimant must be owed a duty of care. Second, a breach of that duty of care by failure to provide reasonable standard of care should be established. Third, the claimant should have suffered damages resulting from the actions of the anesthesiologist. Fourth, a reasonably close causal relationship must exist between the anesthesiologist's actions and the resultant injury.[64] These criteria are similar to the ones followed in the Western world.[65] Therefore, it can be considered that following the Bolam principle can be the defense for the anesthesiologist. According to the Bolam principle, the doctor is not liable for his diagnosis, treatment, or refusal to give information to the patient, if he follows a responsible body of medical opinion.[66] This principle poses a significant problem in India, because the guidelines in most of the anesthetic areas are nonexistent. Barring the minimal monitoring standards, the health authorities or the ISA have no recommendations or practice guidelines for dealing with different clinical problems. In this respect, the ICA is expected to play a big role. It has the responsibility of formulating guidelines for the various anesthetic practice issues. However, this task is challenging and daunting because of the broad variations in the facilities and services that exist in this country.

Currently, most anesthesiologists in the country tend to follow the British or American guidelines. Unfortunately, these guidelines may not be applicable in a large number of clinical circumstances in India, and following them as a benchmark of standard of care is not without problems. First, it is important to ensure that clinicians are not following outdated ideas or principles. Second, acceptable clinical practice continues to evolve rapidly, necessitating frequent updates. Furthermore, the professional standards given in the guidelines might be insufficiently comprehensive or too vague, allowing for subjective interpretation of management strategies in a given clinical scenario. Because of the absence of guidelines as well as the equivocation of the guidelines (even if they were present), the processing of a negligence claim is predominantly opinion-based in India. Opinion on negligence claims is generally sought from the regional medical councils, which have a panel of experts to investigate a particular case. This is not to say that the ICA should not strive to prepare the guidelines; on the contrary, the need for guidelines is clear, at least in cases of common clinical scenarios, such as cesarean section, laparoscopic surgery, or cardiac patient undergoing noncardiac surgery.

The state medical councils have taken a lead in such matters. They have the responsibility of ensuring that no unqualified person practices modern medicine and of providing the expert opinion in complaints of negligence against doctors. For example, the 1997 Delhi Medical Council (DMC) act empowers this body to initiate disciplinary action or award compensation and to take action against frivolous complaints.[67] Currently, it has become a custom for the police and the criminal courts to send all complaints to the DMC for an expert opinion in the matter. The consumer courts, on the other hand, may or may not send all the matters for expert opinion; however, barring obvious cases in which the principle of *res ipsa loquitur,* meaning "the thing itself speaks," applies (e.g., artery forceps left in the abdomen during an operation), the expert opinion is generally sought. The matter may be referred to DMC or any other medical college for this purpose. In addition, the DMC receives complaints directly.

The DMC has an executive committee (consisting of executive members of the DMC and one or two experts in the field) that acts as a screening committee, and in case it finds any prima facie evidence, the matter is referred to the disciplinary committee. The disciplinary committee includes a member of the legislative assembly (nominated by the speaker), a legal expert, an eminent public person nominated by the government, an eminent medical specialist in the relevant specialty to which the complaint pertains, and a member nominated by the Delhi Medical Association with a minimum 10 years' standing.[67] The disciplinary committee is empowered to pass an order that can initiate disciplinary action. However, all decisions of the executive committee and the disciplinary committee need approval from the council, which consists of 20 council members. Table 2-4 shows the number of cases against doctors and anesthesiologists during the last 5 years in the state of Delhi.[68] It was observed that most of the complaints were related to relatively trivial matters against the hospital, such as overcharging, performing unnecessary investigations, practitioners practicing without valid registration, a laboratory submitting a wrong report, issuing of false medical certificates, and negligence in medical care leading to nonfatal harm to patients. A few cases were brought directly against

TABLE 2-4 NUMBER OF LITIGATIONS AGAINST HOSPITALS AND DOCTORS IN DELHI, 2007-2011

Year	Total complaints	Against anesthesiologists	Against hospital or treating doctor where anesthesiologist was made party subsequently
2007	105	0	7
2008	79	1	7
2009	98	0	8
2010	199	1	6
2011	107	0	10

anesthesiologists, but usually, anesthesiologists are made a party to a complaint against the hospital or the treating doctor (generally surgeons).

One unusual situation in which the anesthesiologist may be held liable is the use of local anesthetics by the surgeon for some minor surgical procedure, such as debridement or suturing. Often local anesthetics are used by surgeons and other practitioners for this purpose in the absence of an anesthesiologist. At times, a reaction to the local anesthetic can lead to serious consequences and because the anesthetist is often called for resuscitation and further management, he or she is also made a party if a complaint is filed by the patient's relatives. Thus, the anesthesiologist can be named in a legal suit even if he or she did not administer the local anesthetic. Likewise, use of ketamine and sometimes propofol is practiced by some practitioners in the absence of an anesthesiologist. Although such a practice is endorsed by some,[69] it is believed that the presence of an anesthetist is mandatory.[70] This may be hard to implement in India because of a shortage of anesthetists. This is just one of the many challenging issues the ICA has to address and resolve.

In India, it is accepted that there can be more than one way of dealing with a problem, and an anesthesiologist has the discretion of choosing the treatment, with broader discretion in emergency cases. The National Commission and the Supreme Court have held that the doctor should have a reasonable degree of skill and knowledge and exercise a reasonable degree of care. However, the doctor is not liable for negligence simply because someone else of better skill or knowledge would have prescribed a different treatment.[71] Thus, mere allegation of negligence is not enough; it is for the complainant to prove the negligence or deficiency in service by adducing expert evidence or opinion, and this fact is to be proved beyond all reasonable doubt.[72,73]

Frivolous complaints against doctors have increased in India, especially after the CPA was enacted. The courts recognize this.[74,75] The court has no sympathy for doctors who are negligent, but to avoid unnecessary harassment of doctors, the court has directed that whenever a complaint is received against a doctor or hospital by the consumer forum (district, state, or national) or by the criminal court, before issuing notice to the doctor or hospital against whom the complaint was made, the consumer forum or criminal court should first refer the matter to a competent doctor or committee of doctors specialized in the field to which the medical negligence is attributed. Only after that doctor or the committee reports that there is a prima facie case of medical negligence should a notice be issued to the concerned doctor or hospital, or both. The court has further directed that police cannot routinely arrest a doctor simply because a charge has been brought against him or her. Instead, the investigating officer should, before proceeding against the accused doctor, obtain an independent and competent medical opinion. Such an approach by the judiciary has come as a significant relief for doctors.

The effect of the CPA is evident on anesthesia practice in India. It is imperative that anesthesiologists have informed consent, be vigilant, keep up to date on the guidelines and their knowledge in the discipline, and maintain proper record keeping. Accurate and adequate record keeping can be their defense in cases of litigation. Under Indian law, a case can be filed with the consumer courts up to 2 years after the occurrence of an incident. Thus, there may be a considerable time lapse between the occurrence of an incident and the hearing of a court case. Therefore, the anesthetic record should be as accurate, complete, and neat as possible. In addition, developing good patient relationships is considered another important factor to avoid litigation.

It is imperative that ISA and ICA issue guidelines, recommendations, and protocols be followed in different clinical situations to help the judiciary apply the Bolam's principle to the facts collected in the investigation of a particular case.

Southeast Asia (Florian R. Nuevo)

As in the United States, medical malpractice lawsuits are increasing in the ASEAN region. The threat of malpractice has pressed the need for high standards of monitoring as a mandatory requirement, because some hospitals in low- to middle-income countries cannot afford to procure the necessary equipment and complete array of anesthetics and related medications.

The region's maldistribution of anesthesiologists, the poverty of some societies, the unavailability of essential drugs, and the lack of the necessary infrastructure or resources further aggravate the problem of patient safety.

Although remarkable improvements have occurred in anesthesia education and the development of life-saving skills, perioperative anesthesia-related morbidities still occur. There is growing awareness of the influence human factors and anesthesia nontechnical skills have on patient outcomes. All these factors should be subjects of discussion in anesthesia training programs and postgraduate medical education. Cultural sensitivities must also be underscored to find effective solutions to our problems.

Fortunately, the tides of change are continual, and almost all national anesthesia societies have adopted guidelines or standards for safe anesthesia practice. Credit must be given to Malaysia for its pioneering efforts establishing a national medical audit system. This model is currently used in Singapore and Thailand, as well. Thailand has developed its own national anesthesia incident reporting program and, through ASEAN anesthesia leadership, other ASEAN anesthesia societies are encouraged to duplicate this program.

The WHO Safe Surgery Saves Lives initiatives have helped to arouse interest in the promotion of patient safety. Anesthesia patient safety is now recognized as a public health concern because of the morbidities and mortalities related to surgery and anesthesia.

The Helsinki Declaration on Patient Safety in Anesthesiology further awakened the region with more practical guidelines. These have gained the full support of members of CASA. Many safety initiatives are now underway.

Thus, the current challenge is the earnest and sincere implementation and sustainability of all these safety initiatives. Steadfast leadership is necessary to sustain these patient safety programs. Collaboration among all

stakeholders is essential to bridge the existing gaps in patient safety.

CONCLUSION

As demonstrated in this chapter, anesthesiology as a discipline and a profession has grown dramatically around the world. Differences in the rate of growth and scope of practice exist for a variety of reasons, largely because of disparities in resources and socioeconomic and political factors. Nevertheless, regardless of country of residence, patients receiving anesthesia can feel much safer today than even 20 or 30 years ago in most countries (exception exist, as indicated in this chapter). Providing safe anesthesia requires knowledge, resources, and adequate numbers of trained anesthesia personnel. Over the previous decades, adequate resources for health care including anesthesia are increasingly available. However, some areas of the world still do not have adequate training or resources; Sub-Saharan Africa is an example. Fortunately, international organizations are attempting to address these deficiencies.

On the positive side, some of the most powerful advances are the spread of knowledge, professional integrity, curiosity, and the utmost desire to practice anesthesiology at the highest possible level. Especially with the widespread expansion of information technology anesthesiologists can quickly learn of the advances of their colleagues worldwide and better understand and respond to the needs of their patients.

So where do we go from here? Some authorities suggest taking advantage of the latest advances to further the interconnectedness of the profession, such as conducting more in-depth comparisons of the effectiveness of various techniques from country to country and engaging in more joint research. Others believe that such comparisons would serve no useful purpose, given the evident disparities in resources and different approaches to care. The editor has dreamed of the day that anesthesiologists worldwide would form global think tanks to ask and answer the most important questions to advance our intellectual foundations and benefit society. As noted in the opening paragraph, the purpose of this chapter is not to invite comparisons or highlight differences in the practice of anesthesiology around the world, but rather to encourage and invite anesthesiologists globally to keep talking to each other. The editor was thrilled and honored that his invitation to contribute to this chapter has resulted in so many interesting contributions from leaders of anesthesia worldwide. When viewed together, the journey of anesthesiology has been an amazing story worldwide.

Chapter 3

Perioperative Management

NEAL H. COHEN

Key Points

- The practice of anesthesia has expanded beyond the traditional operating room environment to other sites throughout the hospital and ambulatory facilities. Concurrently, anesthesia has evolved to include acute and chronic pain management, critical care medicine, palliative care, and sleep medicine.
- The expanded scope of anesthesiology creates opportunities for anesthesiologists to take on a broader role in perioperative care, providing management of patients through the continuum of the perioperative period and transition to outpatient care.
- Unfortunately, the costs of hospital care and perioperative care continue to escalate. In response to the increasing costs and emphasis on quality and patient safety, payers are modifying payment methodologies to better align goals of care. Both government (e.g., Medicare) and private payers (e.g., insurance companies) are implementing bundled payment and other payment methods designed to transfer the risk associated with management of complications and preventable harm to providers (e.g., hospitals and physicians).
- To provide optimal perioperative care under these circumstances requires more collaborative interactions among providers and new models of care. Many delivery models have been implemented with varying outcomes. Clarifying roles and responsibilities of the surgeon, anesthesiologist, and other providers is critical to delivering high-quality cost-effective care. Although nonanesthesiologists, including hospitalists, can be very helpful in addressing some clinical needs for the surgical patients, anesthesiologists are well positioned to take a more prominent role in overall perioperative management, benefiting patients, optimizing quality and outcomes of care, and improving efficiency during and after surgical procedures.
- Accomplishing these goals requires reevaluation of overall perioperative management strategies, including preoperative evaluation, intraoperative care, and postoperative management. These goals also depend on accessibility to clinical and financial data and personnel with the skills to analyze the information for delivery of optimal care while improving efficiencies.
- Many models of perioperative management have been implemented with varying success. The perioperative surgical home (PSH) is an example of a new model that might have great benefit for selected patient populations, aligning patient's, provider's, hospital's, and payer's goals, and significantly improving perioperative care.

Fifty years ago, anesthesia care was dominated by intraoperative management, and most clinical income came from services related to surgical care. Gradually, the scope of anesthesia broadened beyond the intraoperative period to include preoperative evaluation, intraoperative management, and postoperative assessment to determine whether the patient suffered any consequences of anesthesia care. Although this model of care—and the associated payment methodology—was an appropriate model of anesthesia care in the past, today the changing needs of the patient, complexity of care, and the role of the various health care providers mandate that we define alternative models for perioperative management to optimize clinical outcomes.

This chapter reviews the changing and expanding focus of the anesthesia practice. Management of clinical care throughout the perioperative period includes preoperative assessment and management to optimize outcomes after procedures, intraoperative care, and postoperative strategies. Thus, the anesthesiologist has an expanded scope of practice and participates more broadly in all aspects of care, with the overall result of improving outcomes and reducing costs.

The impetus for expansion of the scope of anesthesia practice comes from multiple perspectives. First and foremost is the commitment to provide patients with high-quality and safe care that fulfills their goals. To do so requires a broader focus on the overall perioperative course rather than a scope of care that is limited to the intraoperative and immediate postoperative care periods.

A second and equally important goal toward which the anesthesiologist plays an integral role is the increasing emphasis on evidence-based practice, limiting unnecessary or redundant services, and providing more efficient care, particularly in the immediate perioperative period. There is no question that the high costs of inpatient services, particularly for patients with underlying comorbidities who undergo complex surgical procedures, contribute to escalating overall health care expenditures.[1] Although many of these services are important to ensure that the patient is adequately prepared for anesthesia and surgery, some aspects of care may be based on tradition rather than demonstrated benefit. At the same time, the evolution and expansion of anesthesia practice have created many new opportunities for anesthesiologists to participate in perioperative care beyond the immediate postoperative period—and to define standards of care for selected patient populations. Some anesthesiologists are integral members of teams of providers who care for selected surgical patient populations, and they collaborate with surgeons to develop clinical pathways and identify ways to improve preoperative care as well as intraoperative and postoperative management strategies that enhance outcomes. For example, transplant anesthesiologists (also see Chapter 74) are often involved in discussions about patient selection, preoperative management, and transitions of care from the operating room to postoperative period. As a result of these efforts, many transplant patients who previously required postoperative care in the intensive care unit (ICU) can now bypass the ICU and have reduced hospital lengths of stay.[2] Similar outcomes have been documented for patients who have anesthesiologists participate in their perioperative management for cardiac surgery (also see Chapter 67), pediatric surgery (also see Chapter 93), neurosurgery (also see Chapter 70), and other subspecialties. In each of these examples, collaboration among the surgeons, anesthesiologists, and the overall team of providers both within and beyond the operating room environment is critical to realizing improved outcomes and reduced costs of care.

The role of the anesthesiologist in perioperative management also includes the subspecialties of pain medicine and critical care. Pain management strategies have significant positive impact on the care of patients with both acute and chronic pain (also see Chapters 64, 96, and 98). More rational approaches to perioperative pain management, particularly for patients with longstanding chronic pain, have had positive impact on perioperative outcomes and, in many cases, reduced lengths of stay in hospitals and improved patient satisfaction.[3-5] Similarly, critical care anesthesiologists play a large role in improving perioperative management of patients requiring ICU care. The critical care physician's value in improving ICU utilization, reducing complications of mechanical ventilation, providing early diagnosis and treatment of sepsis, and improving management strategies for patients with renal dysfunction is well documented[6-9] (see Chapters 96, 101-103, and 105). Although not frequently addressed by anesthesiologists, postdischarge care needs are often related to perioperative management; anesthesiologists can have a meaningful role in addressing some of these significant costs of care and the related issues that lead to dissatisfied patients and providers.

A third area of concern that has taken on greater importance over the past decade is the rising cost of health care in general and perioperative care in particular. Advances in technology for both anesthesiologists and surgeons have made it possible for patients who previously were denied surgery because of underlying chronic medical conditions, anesthesia risk, or limited surgical options to undergo often complex and costly procedures that may require prolonged postoperative and rehabilitative care. In addition to surgery costs, additional costs (often significant) are associated with complications of care, postdischarge care, and readmissions.[10] The acknowledgment of these frequently underestimated costs is having a major impact on models of perioperative care delivery and payment methodologies. For example, in the United States, both government and private payers have raised concerns about the costs associated with managing complications of care, some of which are relevant to anesthetic management. These payers have been reducing payment for costs associated with complications and denying payment for costs associated with readmissions.[11,12] Anesthetic management has implications for the occurrence of some of these complications, as well as for the need for prolonged ICU stays and other clinical outcomes. For example, central line infections, ventilator-associated pneumonia, decubitus ulcers, and renal failure may be either directly or indirectly related to perioperative (anesthetic) management. Implementing strategies to reduce these complications has been very successful; a more coordinated approach to perioperative management by the anesthesiologists can have significant positive impact on both clinical care and costs.

Another change that is having considerable impact on surgeon, anesthesiologist, and other provider relationships is the transition from fee-for-service (FFS) payment for clinical care to alternative bundled payment methodologies, such as providing a single payment for hospital care, physician services, and in some cases rehabilitation that is related to an episode of care or specific surgical procedure.[10] In the United States, FFS is still the most common payment methodology. Under this payment methodology, each provider receives compensation for the specific services provided to the patient. Payment is encounter based and does not encourage collaboration or coordination of care. Although the implications of FFS

payment on quality of care and resource utilization are widely debated, it is a methodology that has been demonstrated to result in overuse of some services and poor coordination of care.[13] In response to the perceived and documented problems with FFS payment, a number of alternative payment methodologies have been implemented with variable outcomes. Many of these payment methodologies have significant impact on anesthesiologists and the roles they play in perioperative management. For example, to the extent that anesthesiologists can help reduce costs during the course of care for a surgical patient, they can benefit financially under bundled payment methodologies, shared savings plans, and accountable care organizations (ACOs). Although issues related to payment methodologies differ greatly from one country to another and are beyond the scope of this chapter, the goals and implications of these newer payment methodologies have major effects on the practice of anesthesia. Also, these various models provide potential opportunities for expanding the role of the anesthesiologist or other providers in perioperative management.

Finally, although the expanded roles of anesthesiologists in perioperative management have had a positive impact and, in some cases, resulted in more cost-effective and efficient care, the subspecialization of anesthesia care has, in some ways, fragmented care and detracted from a coordinated approach to perioperative management. Under current models of care delivery, perioperative care is rarely provided by a single anesthesia provider. More often, the care is provided by multiple providers, each with a specific role and responsibility. Preoperative care is now often provided in a dedicated preoperative evaluation clinic, which is physically separate from the operating room or other clinical sites. The evaluation is performed at some time before the surgical procedure; communication about the patient's status and clinical plans is most often done electronically with no face-to-face communication with the anesthesiologist who will deliver care during the procedure. Operating room care is provided by an anesthesiologist either individually or as part of the anesthesia care team model. Postoperative management—including care in the postanesthesia care unit (PACU), pain management, and ICU care—is often provided by another set of caregivers. Although each of these providers is critical to the overall care of the patient, the coordination of care among the anesthesiologists as a group becomes a critical element in optimizing care, understanding and fulfilling the patient's goals for care, and improving efficiencies. New models of care that more effectively integrate the diverse roles of anesthesiologists are required to effectively fulfill the goals outlined here.

PERIOPERATIVE MANAGEMENT

Throughout this text, the role of the anesthesiologist in various aspects of perioperative management is discussed. For example, Chapter 38 emphasizes the changing role of the anesthesiologist in preoperative assessment and management. Formal preoperative assessment of an otherwise healthy patient may not be needed in all cases[14,15]; however, advances in surgery and anesthesia have made it possible to identify patients who require more comprehensive evaluation that includes extensive testing and management of underlying conditions in order to prepare them for surgery and the postoperative course.[16] Some patients require assessment and management by other specialists, such as cardiologists, nephrologists, or pulmonary medicine physicians. However, in many cases, the management strategies required to optimize the patient before surgery are best determined by the anesthesiologist, who is most knowledgeable about the impact of chronic conditions on perioperative care needs and the implications of anesthesia on underlying physiology. The anesthesiologist is the provider who can most appropriately coordinate the preoperative assessment and management of the patient to confirm that the evaluation and interventions are necessary to optimize the patient for surgery and anesthesia and to minimize unnecessary assessment and care that will not affect the perioperative course. Similarly, the anesthesiologist, whether individually or as part of the care team model, provides intraoperative care (although in some cases nurse anesthetists have obtained independent practice). In situations in which the anesthesiologist is personally providing or medically directing care, the anesthesiologist can and should ensure a coordinated approach to the transitions from preoperative to intraoperative care, as well as the collaboration required for optimal postoperative management. As important, the anesthesiologist—in conjunction with the surgeon, operating room nurses, and other staff—must communicate effectively to ensure that the correct procedure is being performed on the correct patient, to ensure that all supplies and equipment are available, to facilitate the timely turnover of operating rooms, and to optimize coordination of care from the preoperative to the postoperative period.

A number of initiatives have been implemented in hospitals throughout the world to improve intraoperative management, minimize complications, and reduce costs. The implementation of checklists has been demonstrated to improve patient safety in the operating room[17-19] (also see Chapters 4 and 6). Similarly, the routine briefing (i.e., time out) before beginning a surgical procedure reduces the incidence of wrong-site surgery, facilitates communication among providers, and permits optimal patient care.[20] Some hospitals and surgical services also conduct debriefings at the end of each surgical procedure to define what procedure has been completed, clarify the postoperative expectations for the patient, and ensure that all supplies and materials have been appropriately retrieved from the surgical field.[21] These initiatives have not only been very successful in reducing complications during surgery but, in some cases, reduced costs of care and waste in the operating room. For example, the British National Health Service instituted The Productive Operating Theatre (TPOT) to improve productivity and patient outcomes during surgical procedures.[22,23] The program includes both briefings and debriefings to identify critical issues during and after a surgical procedure. This process has reduced errors and facilitated the transition from the operating room after a surgical procedure. Efficient operating room utilization has increased, turnaround times have shortened, and waste has been reduced. Significant

financial savings have also resulted from this effort. The National Health Service is implementing similar initiatives in other hospital settings, such as "The Productive Ward" to build on the success achieved in the operating room environment.[24] Similar initiatives are required to ensure an integrated approach to management during the entire continuum of perioperative care in order to demonstrate a significant and sustained impact on outcomes.

Traditionally, anesthesiologists have focused on the intraoperative care setting to improve patient care. The transition out of the operating room represents another important opportunity for anesthesiologists to build on the quality and safety advances achieved in the operating room and to improve perioperative patient outcomes. Advances in anesthesia safety have been acknowledged by the Institute of Medicine of the National Academy of Sciences and other groups[25] as a result of better anesthetic drugs, new anesthetic techniques, and improved monitoring techniques (also see Chapter 44), such as pulse oximetry, capnography, and echocardiography. However, the implications of anesthetic management on postoperative outcomes—beyond the immediate postoperative period—have received increasing attention and importance for both patients who remain hospitalized and those who experience unintended and often unrecognized sequelae of anesthesia and surgery after discharge. For example, after a surgical procedure requiring tracheal intubation, a significant number of patients experience postextubation stridor or dysphagia that may last for days, thus compromising the ability to protect the airway, particularly during sleep.[26] Does the dysphagia contribute to postoperative pneumonia that may not become clinically apparent until after discharge? Similarly, the most common health care–associated infections are pneumonia and surgical site infection, which confirms that intraoperative management is an important determinant of postoperative outcome.[27] Many other intraoperative strategies also affect long-term outcomes beyond the immediate postoperative period. Three examples support this conclusion. First is the influence of intraoperative fluid and vasopressor management on postoperative metabolic status and renal function.[28,29] Second, intraoperative glucose control can have a major impact on wound healing.[30] Finally, and more recently, anesthetic management can influence postoperative cognitive dysfunction for both adults and children.[31-33] As a result of these findings, anesthesiologists have a responsibility and an opportunity to understand the causes for these and other complications. We need to understand how anesthetic management can be used more effectively to reduce these adverse outcomes and, if necessary, to manage them effectively in the postoperative period.

PERIOPERATIVE MANAGEMENT STRATEGIES

With this background, perioperative management strategies must be defined more broadly than in the past. Many patients require a limited preoperative assessment or postoperative follow-up, and some require significantly more perioperative support, particularly preoperative management and postoperative care. In addition, many surgical procedures and perioperative management strategies are neither efficient nor cost-effective—for patients or providers. Anesthesiologists, with their particular background, understanding of the environment, and clinical expertise, are equipped to address these issues and to ensure optimal perioperative care. To achieve these goals, anesthesiologists will need to reevaluate current models of care. In most clinical situations, it is no longer possible, or appropriate, for a single anesthesia provider to participate in all aspects of the perioperative course. Care—perioperative, intraoperative, and postoperative—is often provided by different anesthesiologists, in some cases including those who administer pain medicine and critical care needs. Optimizing perioperative management under this model requires improved communication and collaboration among the anesthesia providers, as well as others who participate in a patient's care. The electronic health record is a valuable source of clinical information, but it cannot substitute for more direct communication among providers, particularly in the management of complex clinical problems (also see Chapters 4 and 6).

This collaborative approach to care may not seem necessary for healthy patients undergoing straightforward procedures. However, the value and opportunities for anesthesiologists to play a larger role in perioperative care is clearly evident for most patients. For example, patients undergoing "simple" procedures often have postoperative clinical issues that are underrecognized and require assessment and management. Anesthesiologists, surgeons, and nurses provide patients with instructions and information to help them manage their postoperative course, often at a time when they are not able to understand or process the information. As a result, even in these simple cases, the anesthesiologist can be instrumental in addressing postoperative problems and coordinating the transition of the patient's care back to the primary care provider. The surgeon can provide information about the surgical procedure by forwarding the operative note to the primary care provider, but it rarely addresses any issues related to anesthetic management, concerns about the airway or potential for airway obstruction, or response to anesthetic drugs, narcotics, and muscle relaxants. A postoperative evaluation after discharge can be very helpful in determining whether complications of anesthetic care occurred and in addressing any questions or concerns the patient or family might have about postoperative needs. In many cases, a phone consultation or teleconference is sufficient to address clinical needs. In other cases, a formal postoperative office visit may be required. Some anesthesia departments provide these postoperative options to patients, most often using the preoperative evaluation site. Expansion of the postoperative assessment and management can be very helpful to patients, surgeons, and primary care physicians in providing a level of support to the patients that is often unavailable. The adoption of information technology resources and continued evolution of medical informatics (also see Chapter 5) can enhance communication between patients and physicians during the entire perioperative period.

Besides the desire for a more coordinated approach to the entire perioperative course for every patient, a more formal and robust perioperative management strategy

must be available for those patients with underlying medical conditions, those undergoing complex surgical procedures, and those needing prolonged hospitalization. In addition, for patients who require skilled nursing or rehabilitation services after discharge and for those needing home health services, the transitions of care create challenges for ensuring that postoperative management strategies are maintained, responses are assessed, and therapy is modified as needed. By its very nature, perioperative care for these patients is collaborative, requiring input and expertise from a number of different disciplines, including, but not limited to, anesthesia subspecialty expertise, surgeons, and medical subspecialists. Diverse perspectives and clinical expertise are essential, particularly for the more complex procedures in patients with multiple comorbidities. At the same time, the coordination of care must be assumed by a provider who is able to integrate the diverse perspectives into a comprehensive plan of care consistent with each patient's needs and goals. In the distant past, this coordination was provided by the patient's primary care provider, who maintained a role throughout the perioperative period. With the increasing complexity of perioperative care, changing demographics, and the need to provide more efficient and coordinated care to reduce overall costs, the anesthesiologist has the opportunity to assume a more involved role in the management of some of these patients. To do so will require the commitment of the anesthesia practice to this new model of care and, in many cases, the acquisition of new clinical and management skills to deliver optimized care that it is efficient and consistent with patient expectations.

Often, the most challenging barriers for a department that seeks more involvement in perioperative care come from its own members. It is imperative that there be consensus among all members of the discipline that this strategy is important and consistent with their expectations. To achieve department support, it is critical to clarify that perioperative management is a comprehensive approach to care that involves a diverse group of providers. Every member of the group must participate in the overall commitment to perioperative care. The care will be provided by a number of different anesthesiologists, each with different clinical expertise. One example of this coordinated approach to perioperative care is the management of a patient with a history of chronic severe pain who undergoes a complex surgical procedure. The patient will undergo extensive evaluation and optimization of care in the preoperative evaluation programs. Intraoperative care will be provided by another anesthesiologist, one who has communicated with the patient and understands all of the clinical issues identified and addressed preoperatively. When the patient is transferred to the ICU for postoperative care, which includes ventilator support, intensive respiratory care, hemodynamic monitoring, and fluid management, the transition from the anesthesiologist who provided intraoperative care to the critical care anesthesiologist is seamless. Pain management is provided by the pain service in collaboration with the critical care anesthesiologist (also see Chapters 64 and 98). The remainder of the patient's course of care will be managed by a member of the anesthesia department to facilitate transition to another care facility or home and to ensure effective communication with the primary care provider or other caregivers. Although this model is foreign to many practices, it represents one of many approaches to optimizing perioperative management and takes advantage of the expertise of anesthesiologists in the overall care of the patients they anesthetize.

Although clinical expertise is essential to provide optimal perioperative care for the individual patient, new approaches to perioperative management require that each practice have the necessary clinical and financial data, as well as the analytical capability to interpret it. Larger regional and national organizations tend to have the broad expertise available to analyze the practice and determine where improvements in processes can benefit patients and enhance the efficiency of the practice. For smaller practices, it can be a challenge to have this broad level of expertise and access to information. As a consequence, in the United States considerable consolidation of anesthesia practices has been adopted, with large regional and national organizations acquiring anesthesia practices.[34] In doing so, the larger group is able to ensure that the practice has the resources needed to optimize perioperative management and document the value of the anesthesia services from both a clinical and financial perspective. Some groups have recruited hospitalists or other providers that supplement the clinical skills of the anesthesiologists to ensure that the department has the diverse clinical expertise needed to optimize perioperative care. This multidisciplinary approach to perioperative care enables the group to expand its scope of practice and to develop clinical and administrative databases that allow them to document the value of their services to both patients and the institution. From an administrative perspective, this strategy allows the practice to negotiate from a position of strength with representatives from the hospital or health system, particularly when advocating for the share of bundled payments. Because the administrative and analytical capabilities are essential to optimize delivery of perioperative care, each practice will need to identify the most effective ways to develop this needed expertise and acquire the data needed to successfully address the many challenges facing anesthesia practices.

MODELS OF PERIOPERATIVE CARE

Most health systems and providers are challenged to identify ways to become more efficient and reduce costs while maintaining or improving the quality of care. Accomplishing these diverse goals is difficult. No single model of care works for every patient population or health care setting. As a result, many approaches to delivery of perioperative care have been implemented, some of these successful and some for which the outcome remains unknown. Although models of perioperative management include the anesthesiologist, other providers have participated in the preoperative and postoperative management of complex patient populations, each with variable success. Based on these experiences, the key aspects for any model for perioperative management include (1) an understanding of the specific patient population included in the model (e.g., specific surgical procedure), (2) sufficient clinical and financial information

to allow evaluation of the management strategies, and (3) coordination and collaboration among all providers participating in the model.[35] As models for perioperative management have evolved, they have taken advantage of the experiences from the hospitalist model for inpatient care and the medical home model for chronic disease management.

Patient-Centered Medical Home

The medical home model, also referred to as the patient-centered medical home (PCMH), is a model of care in which a primary care physician provides comprehensive care to improve health outcomes for a population of patients.[36] The critical element of the PCMH is the coordination of care to reduce emergency department visits and hospitalizations. In managing the patient population, a number of strategies have been used to reduce costs and improve outcomes. These models often utilize additional providers, including advance practice nurses, respiratory therapists, physical therapists, and patient advocates, to manage chronic diseases such as asthma, chronic obstructive pulmonary disease (COPD), heart failure, and diabetes mellitus. Payment for the PCMH includes FFS payments for episodes of care and payment to coordinate care. This model has been successful in improving care, particularly for some chronic diseases, although the financial success has not been as consistent.[36-38] In some cases, the PCMH actually resulted in increased hospital admissions.[36] Despite the variable success of the PCMH, some lessons can be learned in defining how to manage the perioperative period most effectively. First, preoperative assessment must be comprehensive enough to identify underlying clinical problems and effectively manage them, both preoperatively and postoperatively (also see Chapter 38). For the anesthesiologist managing the perioperative period, chronic conditions must be addressed; they cannot be deferred to other providers. Second, the underlying medical conditions must be addressed as part of the overall postoperative management in coordination with the issues specific to anesthesia and surgery. For example, a patient with peripheral neuropathy associated with diabetes mellitus may be unable to participate in traditional approaches to rehabilitation; care must be tailored to the specific needs of each patient. Third, many aspects of perioperative care can be managed by other providers, including other physicians and advance practice nurses. The keys to successful perioperative management, however, are the identification of a single physician to coordinate care among the team of providers, consistent and ongoing communication about patient care needs, and availability of data that can be used to analyze clinical and business practices, costs of care, and outcome measures.

Surgical Hospitalist

Another model that has been implemented in many hospitals in the United States and other parts of the world is the surgical hospitalist model, which builds on the hospitalist model of care for inpatient medical patients. Many studies have documented the clinical value and other advantages associated with implementation of a robust hospitalist program[39,40]; yet most hospitalist programs emphasize the care of patients with acute (and perhaps underlying chronic) medical problems. However, the increasing percentage of surgical patients in many hospitals, the changing role of surgeons in overall clinical management, and the complexity of inpatient care have brought attention to expanding hospitalist programs to support the care of surgical patients.[41,42] Many institutions have recruited surgical hospitalists to work collaboratively with specific surgical services (or individual surgeons) to manage overall care and transitions of care into and out of the hospital environment. The models for surgical hospitalist programs vary—in some cases incorporating hospitalists with primary training in internal medicine or pediatrics, in other cases having a surgeon with interest in perioperative care take on the hospitalist role. In each model, the clinical management issues are similar.

Many of these surgical hospitalist models have been successful, particularly in improving the management of underlying chronic diseases. Although the ability to document the effect on hospital lengths of stay and readmission rates has been limited, the models have been effective at improving timeliness of interventions and patient and staff satisfaction.[41] At the same time, medical care can be fragmented, with the hospitalist effectively managing the underlying chronic diseases (such as diabetes mellitus or hypertension) without having a significant role in the management of other aspects of perioperative care. For this model to be most effective, the surgical hospitalist must be educated in the idiosyncrasies of perioperative management of patients undergoing complex surgical procedures. The effectiveness of surgical hospitalist models is most evident when the care of underlying medical conditions is carefully coordinated with the other perioperative needs of the patient. For example, the neurosurgical hospitalist must understand concepts such as cerebral autoregulation and the impact of clinical interventions on cerebral hemodynamics. Similar considerations must be addressed for hospitalists working collaboratively with other surgical services.

The surgical hospitalist model has expanded considerably, allowing surgeons to concentrate their efforts in the operating room. However, the optimal relationship between the surgical hospitalist (either a surgeon who has assumed this nonoperative responsibility or a medical hospitalist) and anesthesiologist has not been defined. In some cases, perioperative care is transferred from the anesthesiologist to the hospitalist in the immediate postoperative period; in other cases, care may be transferred from the anesthesiologist to an intensivist (either a critical care anesthesiologist or another intensive care physician) while the hospitalist maintains responsibility for managing some of the underlying clinical conditions. In the latter case, the roles and responsibilities of the anesthesiologist, critical care provider, and hospitalist need to be clearly defined to ensure appropriate coordination and transitions. Either model can be effective when coordination of responsibilities is clearly delineated. Equally important, the transition from inpatient to outpatient care must be coordinated among the inpatient providers to ensure that the outpatient physician understands the intraoperative course and its implications, including any

issues that arise as part of the anesthetic management, and can facilitate management in the ambulatory setting.

Enhanced Recovery After Surgery

Enhanced recovery after surgery (ERAS) is another example of a creative approach to the perioperative management of patients who undergo major surgical procedures.[43,44] ERAS is designed to enhance recovery by managing the entire course of care by using evidence-based practices to optimize outcomes. ERAS emphasizes a multidisciplinary approach to perioperative care with particular emphasis on preoperative education, pain management, and early rehabilitation, particularly for patients who undergo laparoscopic surgery and colorectal procedures. This approach has been successful, with documented reductions in hospital length of stay and postoperative complications of 30% and 50%, respectively.[45-47]

The key features of the ERAS program, as with other pathways designed to improve perioperative care, are its multidisciplinary nature and the emphasis on collaboration of care and seamless coordination among the preoperative, intraoperative, and postoperative periods. The ERAS protocols emphasize the value of the anesthesiologist in providing optimal perioperative care, which facilitates early ambulation, returns bowel function to normal, and initiates nutritional support. Although the program has concentrated on optimizing care during and after elective and minimally invasive gastrointestinal surgical procedures, the same approaches should also be successful for other types of surgical procedures.

Perioperative Surgical Home

Although ERAS has identified strategies to provide an optimal continuum of care for patients undergoing minimally invasive procedures, most of the models of care described earlier in this chapter address individual components of care for the surgical patient. Some address improved preoperative screening and evaluation, others minimize complications and costs within the operating room environment, and a number of initiatives improve postoperative care. Many of these models have a positive impact on care, quality, and costs; however, in many cases, the overall costs of care have not been affected. More important, the coordination and transitions of care from the immediate perioperative period have generally not been optimal.

The expanding role of anesthesiologists, both within and outside the operating room, presents an opportunity for them to serve as perioperative physicians.[48-50] The increasing complexity of patient care related to surgical services has also created a demand for improved coordination of care from preoperative management through outpatient follow-up. Recently, the American Society of Anesthesiologists (ASA) proposed development of the perioperative surgical home (PSH), built in part on the PCMH model of care.[51-53] The PSH emphasizes clinical management of the patient through the perioperative period, with coordination of care specifically designed to optimize outcomes after surgery and facilitate the transition of the patient back to the primary care provider. Within the PSH, care is coordinated by the anesthesiologist, who works collaboratively with a team of providers to identify evidence-based clinical pathways, improve outcomes, and reduce overall costs of care across the continuum, including postoperative costs such as home care and skilled nursing facilities. As is true for the PCMH, the PSH is designed to be patient focused. This approach requires a reassessment of the entire perioperative experience to ensure that the patient's needs are an integral part of each element of the perioperative course. Although the PSH concept is currently being implemented for selected patient populations and the outcomes are still being defined, other initiatives that address some of the components of the PSH suggest that this more integrated approach to care (at least for some patient populations) should improve outcomes and patient (and provider) satisfaction while reducing costs.[53,54]

As envisioned by the ASA, the PSH has five major goals:

1. Identifying the patient and proposed plans and facilitating communication among the surgeons, anesthesiologists, and others as needed to coordinate care
2. Providing optimal preoperative assessment and plans, including management of underlying chronic diseases
3. Developing and implementing evidence-based protocols for clinical care throughout the perioperative period
4. Managing clinical care across the continuum
5. Measuring and publicly reporting outcomes and performance

The implementation of the PSH model could be a very effective way to optimize perioperative care for selected patient populations. The model may also define some generic strategies that can be implemented for all patients undergoing surgical procedures and new approaches to clinical care and assessment that will benefit patients, providers, and payers.

CONCLUSION

The changing demographics of hospitalized patients have created significant challenges for hospitals, health systems, and providers. For many hospitals, the percentage of surgical patients continues to grow. Many surgical procedures are performed on patients with underlying comorbidities that not only complicate surgical management and anesthesia care but also require coordinated care of primary care providers, surgeons, anesthesiologists, and other medical specialists. This chapter has defined some of the challenges of coordinating and optimizing perioperative management. Although no single strategy is appropriate for all clinical settings and patient needs, the one critical element in perioperative care is the need to implement a model of care that ensures coordination and transition across the continuum from preoperative assessment and management to postoperative rehabilitation. A number of alternative approaches can be used, and multiple strategies may be required to address the idiosyncrasies of each patient population, surgical procedure, and institutional capabilities. The expanded role for the anesthesiologist in many of these models requires the

commitment and skills to acquire and analyze data on outcomes and costs, while also defining ways to optimize clinical care. The PSH is an example of a new creative model that might have significant benefit for selected patient populations, thus aligning patient's, provider's, hospital's and payer's goals and significantly improving perioperative care by building on the experience and successes of other approaches, including ERAS, the surgical hospitalist model, and the PCMH.

Chapter 4

Operating Room Management

JAMES D. KINDSCHER

Acknowledgment: The editors and the publisher would like to thank Dr. Melissa Rockford, who was a contributing author to this topic in the prior edition of this work. It has served as the foundation for the current chapter.

Key Points

- Organizing the governance structure of the operating rooms (ORs) to consolidate control and authority into one position, such as the OR medical director, has many advantages in making the OR function at an optimal level.
- Improvement in the OR scheduling process may lead to the biggest gains in OR efficiency. Block time scheduling allows better predictability and satisfaction for OR personnel.
- On-time OR starts, surgical case performance benchmarks, and room turnover are all critical elements in making an OR run efficiently.
- Traditional OR use assessments may not reflect how well an OR is working. Newer methods that focus on OR productivity are increasingly being used to determine allocation of OR resources.
- Managing the daily surgical schedule requires careful planning, as well as frequent reevaluation, to deal with the variability in case times, add-ons, and cancellations.
- The OR director must create a professional environment in the OR and not allow disruptive behavior patterns to exist.
- OR management is often coupled with increasing numbers of non–operating room anesthesia settings (see Chapter 90).
- A detailed OR information system is essential in tracking OR activity and creating reports for assessment and improvement projects. OR cost accounting is essential to the OR director in guiding decisions for resource application.

The operating room (OR) is a major source of both revenues and expenses for hospitals.[1] Hospital chief executive officers must now focus on the profitability of the OR service, and this emphasis has led to the rapid growth and development of OR management. The goal of OR management is to replace the previously ill-defined structures for OR decision-making and administration with more formal and efficient structures. In the past 10 years, there has been an explosion of research and publications concerning OR management (see reference list).

HISTORY

The roles of the OR and non–operating room anesthesia within the hospital have evolved. The organized structure and daily management of the OR are markedly different than they were 20 to 30 years ago.[2] In the past, ORs generated large profits; their priorities were to maximize convenience for surgeons and attract a greater market share for the hospital, with little emphasis on controlling costs. Because most surgical patients required inpatient hospital beds, the surgery schedule was primarily limited by the number of beds allocated to each surgical service. Hospital administrators assumed that any new investment in the OR would lead to increased revenue. This mentality thrived in a period when revenues were plentiful, which allowed hospitals to provide new equipment or OR expansions upon request. Surgeons could schedule procedures as they desired, usually on a first-come, first-served basis. The authority for OR management was dispersed between hospital administrators, with little direct OR experience, and the OR nurse managers, who oversaw all of the complex activities in the OR. Because the hospital administrators had responsibilities for several areas of the hospital, they left daily control to the OR head nurse, who became the de facto leader of the unit. Many of the supporting services (housekeeping, admitting, materials management, and laundry) had separate administrative reporting structures. The low procedure complexity of ORs allowed for these simplified support services. Physicians often had a limited role in directing OR function.

As surgical procedures became more complex and competition for OR time increased, surgeons and anesthesiologists often became dissatisfied with the control structure of OR management. Physicians formed OR committees to voice their thoughts to hospital leadership. The hospital and OR committees created rules and policies governing OR function. Dedicated rooms for complex procedures and increased scheduling demands led to

the development of guaranteed reserved OR times called *blocks*. These blocks allowed better predictability for surgeons to schedule and perform their procedures and allowed the hospital to provide the necessary support for these cases, but the authority for daily OR management still resided primarily with nursing leaders.

As diagnosis-related group (DRG) reimbursement and capitated payment for care became more common, OR revenue declined. Hospital administrators noted that ORs were very expensive to furnish and staff with skilled nursing personnel. The overall hospital operating margin (profit) declined from 6.3% in 1997 to 2.7% in 1999.[3] By 1999, 43% of not-for-profit hospitals actually lost money. Such losses forced hospital leaders to rethink how ORs should be run. If the ORs consumed 9% to 10% of the institution's annual budget, the hospital needed to analyze and control these costs. With the advent of general medical restructuring and primary care "gatekeepers," it was predicted there would be reduced demand for specialists and surgical services. Therefore, hospitals reduced inpatient beds and limited OR growth. The net effect of these changes was increased frustration with OR function and management.

Predictions of reduced surgical caseload volume proved untrue. Surgical demand began to increase faster than the number of ORs that were available and staffed. Shortages of hospital beds, intensive care unit (ICU) beds, and personnel led to increased pressure to manage ORs with maximum efficiency while controlling costs. The hospitals expected all of these OR changes to occur simultaneously while maintaining high surgeon and patient satisfaction. Hospital administrators realized that they needed more direct physician leadership in handling complex OR matters. As a result, they appointed medical directors to give more voice and authority to physicians in OR leadership roles. This physician leadership structure began in academic departments but has now expanded to many public and private organizations throughout the world.

As more cost-efficient care became the focus of health care, a tremendous expansion of outpatient facilities took place. Ambulatory surgery centers and office suites began to overtake the traditional hospital as sites for the majority of surgical procedures in the United States (also see Chapter 89). Even in large community hospitals and academic centers, fewer than one third of patients came from inpatient wards to the OR. Challenges in running efficient outpatient surgical practices and large tertiary care facilities made the need for expert and dedicated OR management even more essential. The focus on leadership structure and management techniques to improve OR function has led to the organized approach to OR management described in this chapter.

STRUCTURE FOR OPERATING ROOM MANAGEMENT

Operating rooms are complex and expensive facilities that require a structure for management that allows rapid adaptability and integration of many different groups. As medical needs and regulatory requirements evolve, an OR governance structure must rapidly adapt to accommodate these changes. Traditionally, ORs followed a "top-down" management style. Hospital administrators were distant and unfamiliar with the daily workflow of the OR. They would often appoint the OR nursing director to serve as the unit manager, but this nursing director may have been unfamiliar with the specific needs of surgeons and anesthesiologists, leading to frustration in how the OR was managed. This created roadblocks to rapidly addressing the evolving needs of the OR. In response to this problem, the OR director position was created. Initially this concept involved creating an "OR czar," someone imbued with complete authority and decision-making power; but this approach was flawed because it implied an authoritarian ruling style that disenfranchised other physicians. This type of management style is rarely successful in actual practice.

Proper OR governance must include participation of the key stakeholders and offer transparent management practices to achieve improved performance of this unit. Surgeons, anesthesiologists, OR nursing staff members, and hospital leaders all need to participate together in the governance of this complex unit. The purview of the governance group includes creation of an OR Charter, setting performance metrics, development of policies, and participation in future planning decisions.

The position of OR director arose in response to the competing priorities of the diverse groups working within the OR (surgeons, anesthesiologists, nurses, and hospital administrators). For the OR to function effectively, the OR director must balance the priorities of each group while working cooperatively to achieve success for the overall unit. Surgeons want maximum convenience and service, easy OR access, and state-of-the-art equipment. Nurses want predictable hours and standardization of cases. Anesthesiologists want high demand during peak scheduled hours and adequate support for starting procedures and turnovers. Hospital administrators want high utilization and low cost for personnel and equipment. These competing priorities can create conflict and inhibit productivity. The purpose of the OR director is to align the forces working in the OR to work in an efficient and productive manner. The most important advantage to this structure is that providing control and authority to one knowledgeable individual allows the OR to adapt to changes and make critical improvements. Creating an organizational structure with an OR director improves OR performance; increases physician, nursing, and patient satisfaction; permits rapid adaptability to changing market forces; improves communications throughout the system; and strengthens accountability and enforcement of OR rules and regulations. Figure 4-1 shows an organizational structure that describes how the OR director may fit into the hierarchy of OR governance.

Anesthesiologists are good candidates for the position of OR director for several reasons. They often have a global view of the OR and understand each component of the OR process. They share with the hospital administrators a desire for a smooth-running and cost-effective OR. Because anesthesiologists are familiar with preoperative, intraoperative, and postanesthesia care unit (PACU) processes, they appreciate how to make the OR flow as a unit. They are also familiar with the different surgical specialties and can balance the needs of these different groups. Anesthesiologists

BOX 4-1 ***Characteristics of the Medical Director of an Operating Room***

- Experienced individuals, usually in the middle of their careers
- Respected for clinical skills
- Strong interpersonal skills
- Integrity and trust by all groups
- Perceived neutrality and balanced views on issues
- Leadership style by consensus development
- Strong analytical and problem-solving skills
- Detailed data management traits
- Ability to commit significant time and focus to operating room
- Appreciation of hospital's goals
- Good long-range planning development
- Ability to address regulatory and oversight controls

are present in the OR daily and can intervene in urgent situations. Box 4-1 identifies personal characteristics that are beneficial for an OR director to possess.

Another position that may complement the role of OR director is that of the hospital director of perioperative services. Responsibilities of this individual include managing the workflow of the hospital personnel in the preanesthesia testing clinic, ORs, and PACU (also see Chapter 96). This person works closely with the OR director managing preoperative and postoperative problems that have a direct impact on the flow of the OR. Bottleneck stoppages in throughput, which occur before or after the surgical procedure, will neutralize efficiencies developed within the OR.

OR directors face many challenges. The position requires time away from clinical practice to attend meetings, plan projects, and coordinate OR activities. The OR director must have buy-in from his or her group or department to accommodate these scheduling demands and accomplish the OR's mission. The hospital should view the OR directorship as an investment and provide the appropriate financial support. Likewise, the chairs of surgery and anesthesiology must cede some of their departmental control and authority involving OR matters. Time and energy demands may limit OR directors from advancing within their departments, organizations, or academic institutions. The OR director must make difficult decisions and be able to withstand criticism and challenges to his or her role. In addition, OR directors may require additional business training or data processing support.

Dealing with OR conflicts is another difficult aspect of management for OR directors, perhaps one of the least desirable roles of the position. With increased awareness of "culture" in the OR, it is imperative to maintain a professional environment in which staff members exhibit mutual respect for all parties.[4,5] The OR should develop performance policies including scheduling rules, surgeon presence in the OR, charting requirements, and behavioral expectations. The OR is one of the most common sites for disruptive physician behavior owing to the high intensity and stress of the environment. The OR director should have a leading role in developing clear policies for addressing disruptive behavior. Box 4-2 lists steps for dealing with disruptive behavior.[6] Disruptive individuals or those who attempt to circumvent the established OR policies and rules create a dysfunctional system and dissatisfaction among the OR staff.[6] The OR director should set the tone for teamwork in the OR.

In 2002, the Association of Anesthesia Clinical Directors (AACD) conducted a survey of its membership (Box 4-3).[7] The survey noted that the concept of a medical director, which began in academic organizations, has now spread to university-affiliated and private practice hospitals. Seventy-nine percent of OR directors served in hospitals with more than 200 beds. The survey disclosed that financial support varies, but most OR directors receive salary supplementation of less than $10,000 per year. Appendix 4-1 provides the AACD guidelines for the role of medical director. Information is also available on the AACD website (www.AACDhq.org).

BOX 4-2 *Dealing With Disruptive Behavior*

- Educate the OR staff on hospital policies and definitions of disruptive behavior.
- Set a low threshold for identification and reporting.
- Respond immediately to an incident.
- Make the behavior the issue, not the individual.
- Focus on the acute behavior and not past frustrations.
- Do not accept excuses or explanations of justification.
- Set clear target goals for behavior modification and then follow up directly with the individual.
- Be sympathetic to the perspective of public humiliation of the individual. Deal with the individual in a quiet, private setting with one or two witnesses.
- Seek out other issues in the physician's practice that may be the source of stress. Often, factors outside the OR lead to the disruptive behavior that is manifested in the OR.
- Be prepared to enforce your Disruptive Behavior Policy completely. If the physician does not reform or persists in the disruptive behavior, removal from the hospital staff may be the best solution.
- Enforce your policy evenly. Do not allow exceptions for behavior of high-profile individuals. Frequently, action against one physician will demonstrate the seriousness of your commitment to physician behavior standards and serve to deter others from acting out.

OR, Operating room.

BOX 4-3 *American Association of Clinical Directors 2002 Survey of Operating Room Medical Directors*

Hospital Type	
University teaching	44%
Community hospital	33%
University affiliated	33%
No. Hospital Beds	**Size**
<50	5%
50-100	4%
100-200	13%
200-500	54%
>500	25%
Hospital Compensation for Medical Director (per Year)	
None	40%
0-$10,000	25%
$10,000-$25,000	18%
$25,000-$50,000	13%
>$50,000	4%

If an organization adopts the position for an OR director, the responsibilities, expectations, and support should be clear. As stated earlier, the motivation for creating an OR director is often a result of frustration and low satisfaction among OR staff. Newly appointed OR directors can gain early success and acceptance by initially identifying issues that they can easily remedy. Coordination with the OR head nurse and OR business manager will unite the resources necessary for change. Regular communication with hospital superiors and OR staff will help define progress and identify future plans. OR directors need to involve other physicians in setting goals and priorities. Success will require hospital administration and physicians to bring about change through compromise. The OR committee, with hospital administration, should create reasonable rules and standards with equitable enforcement. Although individual contributions should be rewarded, a team approach is essential. Alan Marco's "game theory" is a useful analogy for various situations a director may encounter in running an OR.[8]

Operating room management may be improved by subdividing groups into functioning committees with discrete tasks and areas of control. Often a separate group that addresses OR use and awarding of surgical time or blocks is necessary. Resource or capital equipment needs may be best addressed by a committee with this solitary focus. Facility planning, regulatory compliance, and quality committees may also be used to support OR governance. These committees should report to the OR governance committee and OR director.

OPERATING ROOM FUNCTION GOALS

The OR is a complex environment that relies on distinct and separate working groups to pull together to achieve results. Some have equated the OR to a three-legged stool, with surgeons, anesthesiologists, and nursing personnel representing each leg. If any one leg does not perform to its best ability, the whole "stool" becomes dysfunctional and tips over. One of the goals for OR management is to integrate these different groups into a coordinated unit. The function of the OR depends on several important aspects. Scheduling, preanesthesia testing clinic, first case on-time starts, predictability of to-follow cases, turnovers, management of add-on cases and cancellations, measuring OR use, and employment of the necessary staff to run the ORs are all essential for maximizing OR function.

SCHEDULING

Accurate scheduling in the OR is crucial to running an efficient surgical service. Poor and inaccurate scheduling results in delays and confusion on the day of surgery. It also engenders dissatisfaction for patients, surgeons, and anesthesiologists. The scheduling process involves estimating, organizing, and assembling the necessary personnel, equipment, space, and time to perform a procedure.

Most ORs use a computerized scheduling system, with data integrity being of paramount importance. Errors or omissions in documentation, including the patient's name, age, disposition (inpatient versus outpatient), procedure description, or surgical case duration, can have a major impact on how efficiently the OR will function. The personnel who input these data should take precautions to reduce errors. Many computerized systems track posted cases to verify that available equipment matches resource needs. This prevents overbooking items with high demand, including C-arm radiography machines, microscopes, or robotic devices.

Accurate prediction of surgical case times is also essential to scheduling.[9] Errors in estimated times will affect

the predicted start of every subsequent case.[10,11] Gathering surgeon-specific data is important because operating times may differ significantly among surgeons and hospitals.[12] Strum et al. described how this uncertainty for case durations affects the schedule.[13,14] More recently, Dexter et al. identified the value of historical case durations and Bayesian methods to more effectively predict case durations.[15,16] Because there are wide differences among surgeons, as well as multiple variations of a particular procedure, the potential surgical times for a case may be difficult to predict. If the hospital has computerized historical data, it can base the surgical case time on a set number of similar performed cases. The scheduling system may give the expected time for the procedure at the time it is posted. The surgeon may then increase or subtract time from this estimate based on his or her knowledge of the patient or predicted difficulty of the case.[17] In our institution, based on this system, 50% of all cases were completed within 30 minutes of the scheduled time. Fifteen per cent of cases ran 30 minutes longer than the scheduled time, whereas 35% of cases finished more than 30 minutes ahead of schedule.

In reality, predicting a point value for case duration is not logical. As described by Dexter and Macario,[11,16] surgical cases are a probability estimate for time, with upper and lower bounds for duration. For example, a surgeon posts time for a Whipple procedure on a patient with a pancreatic mass, and the historical times for all cases posted by this surgeon average at 4 hours. Sixty percent of the time, it is determined the tumor is not resectable, and the case time is then 3 hours. The other 40% of the time, the Whipple procedure is performed with a case duration of 6 hours. Although the average duration used for scheduling is slightly more than 4 hours, in practice none of these cases uses exactly 4 hours. The case times are also not distributed as a Bell curve but are frequently right-shifted. Dexter has suggested that Bayesian analysis be used to predict case duration probabilities.[9] Other challenges to case duration scheduling is that more than one third of specific posted procedures by a single surgeon do not have enough historical data to make accurate predictions. Using a combination of historical data, specific patient predictors, and then allowing the surgeons to revise the duration up or down by 10%, may yield the best estimate for case duration.

Historically, ORs were scheduled under an "open block" system. Surgeons scheduled cases in available rooms on a first-come, first-served basis. This system worked if there was little demand for OR time and each room was suited for all types of procedures. However, open block scheduling has many undesirable consequences. Surgeons with a short lead time in deciding to operate are unable to predict the availability of rooms. Personnel have to move complex equipment from room to room to accommodate demand from multiple types of surgeries. There is also marked variability between busy and light days, resulting in poor overall OR efficiency and difficulty anticipating demand and allocating resources.

Because of the limitations of the open block system, ORs moved toward a system of "block" scheduling. Block scheduling guarantees a certain degree of OR availability to a specific service or surgeon. Under this system, the institution assigns a specific room on a specific day to a surgeon or surgical group. The surgeon or group may then schedule its cases for that room on that day. This arrangement permitted the development of specialized ORs (i.e., rooms with heart-lung machines for cardiothoracic surgery, rooms with ophthalmologic fixed ceiling–mounted microscopes, and rooms with dedicated laparoscopic equipment).

TABLE 4-1 SUGGESTED BLOCK RELEASE TIMES

Service	Release Time
Cardiothoracic	1 day
Vascular surgery	2 days
Orthopedics	3 days
Neurosurgery	4 days
Pediatric surgery	1 week
General surgery	1 week
Gynecology	1 week
Ophthalmology	1 week
Otolaryngology	1 week
Plastic surgery	2 weeks

The use of block scheduling follows several best practice standards. For example, block time may work most effectively when it is granted to a surgical service (e.g., orthopedics or gynecology) rather than to an individual surgeon. In addition, full-day blocks (8 hours of OR availability) work better than half-day blocks because patient flow and case start times are more predictable. The reduced movement of personnel and equipment improves room setup and shortens turnover times.

For block scheduling to succeed, the institution should develop rules governing its use. For example, ORs may use measures of surgical demand, such as historical surgical hours per week, to grant blocks to a surgical group. Key topics the rules should address include advance scheduling, turnover time,[18,19] and hold time or release time.[19,20] The release time, which varies among surgical specialties and institutions,[21] is the time when the block is no longer reserved for a particular service. Surgical procedures that are somewhat urgent or have a short lead time, such as heart or vascular surgery, have shorter times from release to the surgery date than services with a more elective practice, such as cosmetic plastic surgery or orthopedic joint replacement. Services with a high referral practice (cancer procedures or trauma) will also need shorter release periods for their blocks (Table 4-1). Once a release time is reached, the remaining time (unused block time) is available to any surgeon on a first-come, first-served basis.

An institution should closely monitor block time use and adjust it as surgical practice changes within the hospital. For example, if a surgical service is filling more than 90% of its block time, it becomes difficult to perform additional cases or manage variability in the surgical referral base. On the other hand, if block use is low (60% to 70%), predictable OR time is not available to other surgeons who may need several days of advance planning to schedule cases. Each institution should set a threshold for block use to determine how services will gain or lose OR blocks.[22,23] A block committee with representatives from hospital administration, surgery, anesthesiology, and nursing should develop these thresholds.

The institution should ensure it applies them equitably to avoid potential games to change OR availability.[8] The group should then monitor and enforce compliance with the rules.

Today, hospitals often schedule most of their ORs under a block system, reserving some ORs in open blocks to accommodate surgeons with small numbers of patients and urgent add-on operations. The number and availability of open rooms will depend on the volume of urgent, emergency, and add-on cases. If the hospital has a significant number of elective cases, it may be appropriate to block schedule up to 80% of the ORs and leave the remaining 20% as open rooms. If a hospital is large with a number of surgeons who do not have block time, then 25% to 30% of OR time should be open and not blocked. Several authors have described strategies to maximize surgical blocks and reduce variability to improve OR use.[24,25]

Decisions to expand OR capacity and provide more block time are complex. Because ORs are expensive, costing up to $1 million per room to build, the hospital should carefully plan growth in surgical services. Wachtel described the important factors that should be considered in adding OR capacity, including giving OR blocks to subspecialties with the greatest contribution margin per hour, those that have the greatest potential for growth, and those that have a limited need for additional system resources such as ICU beds.

A review by Sulecki et al. studying the influence of moving cases within a large health system with 12 separate operating facilities showed that it was not possible to shift cases between facilities to improve efficiency.[26] Surgeons' total case hours, travel between facilities, and proximity to clinic and other office support limited the utility of moving cases from busy sites to sites with more unused OR time.

A final important aspect of scheduling is how to manage non-OR anesthesia cases such as endoscopy, radiology, computed tomography, and magnetic resonance imaging. These patients often require perioperative resources, although they do not actually enter the OR. They often require a dedicated anesthesia team, spend recovery time in the PACU, and are processed through the preoperative unit. Institutions should include these patients and procedures in the OR scheduling system to assist the perioperative units and anesthesia schedule runner, assign appropriate resources, and track progress of the daily schedule.

PREOPERATIVE CLINIC

With 75% to 80% of surgical patients coming into the surgery suite from home, the ability to optimize their medical conditions is challenging. This has led to the development of the preoperative clinic, where an evaluation and testing algorithm are used to ensure best outcomes. This subject is covered in Chapter 38, but its value to OR management cannot be overlooked. Attending to patients who need additional time for evaluation or laboratory analysis may lead to delays in the surgical schedule. A well-organized preoperative clinic can also help reduce the number of cancellations and prevent delays for surgical procedures. The clinic also aids the hospital by reducing the risk for complications, which will result in added costs and application of resources to the surgical population. Patients who have been seen in the preoperative clinic in our institution have a lower incidence of cancellations and a higher rate of on-time starts than patients who have not been seen in this clinic.

On-Time Starts and Tardiness

Perhaps some of the most frequently discussed issues by OR committees are on-time starts and turnovers. Delays in getting the surgical list started and prolonged time between cases lead to inefficiency and frustration by everyone working in this environment. From an atmosphere standpoint, it is crucial to start the first procedure of the day on time. An on-time start provides tangible (scheduling) and intangible (mood and tone) benefits. If there is a delay in starting the first case, it can negatively affect the satisfaction of patients and surgeons, possibly leading to complaints relayed to the hospital's administration. One reason on-time start success is measured so commonly is that it is an easy data point to track and is less affected by issues like delays in a previous case. Often, institutions with a high on-time start success rate will also have brief turnover times. Therefore, on-time starts are one way to benchmark an OR facility's performance. It is important for everyone to agree on the definition of start time. Surgeons often define start time as when the first incision is made. Anesthesiologists define start time based on when they complete induction. Nurses associate start time with the completion of room preparation. Disagreements in what constitutes start time will result in misunderstandings and dissatisfaction with OR start times.

In 1997, a group in the AACD published a "procedure times" glossary that created standards for OR events and time periods.[25] This glossary is accepted by the American Society of Anesthesiologists, Association of Operating Room Nurses, and the American College of Surgeons and serves as the standard for descriptive terms in the OR. Appendix 4-2 contains an excerpt of the glossary; it describes *start time* as the time at which the patient enters the OR. This time has not proved to be useful in identifying cause for delay on a case-by-case basis. Furthermore, surgeons indicate that the time the patient enters the room has little bearing on when the patient will be ready for the surgical incision. The newer concepts of "anesthesia ready" (AR) or "anesthesia release time" (ART)[27] may be more helpful in determining surgical preparation and incision times. The AACD glossary describes *anesthesia ready* as the time at which the patient has a sufficient level of anesthesia established to begin their surgical preparation, and remaining anesthetic procedures do not preclude positioning and prepping the patient. At our institution, we reviewed times from the patient entering the OR to completion of preparation. In uncomplicated cases (patient supine with no invasive monitoring lines), staff completed preparation in 15 minutes in 78% of cases. If the case was complicated (position other than supine, invasive monitors), the duration from start time to completion of preparation averaged 30 minutes. These data are useful for surgeons to anticipate the time from room start (patient in room) until completion of preparation.

On-time starts depend on the completion of many factors. Patients must arrive on time and complete preoperative preparations including compliance with all preoperative instructions ("nothing by mouth," medications, laboratory tests). Preoperative testing clinics and assessment protocols have helped reduce delays on the day of surgery, as well as reduce costs.[28,29] The preoperative/admitting process should have sufficient personnel, organization, and space to process patients and make them available to surgeons and anesthesiologists. Operating room nurses must prepare the OR and equipment. Anesthesia personnel must check the equipment in the room, prepare drugs, complete paperwork, place intravenous lines, and address special patient or surgical needs. Surgeons must be available to complete the patient's consent, history, and physical examination and to address any patient questions or needs.

A common misconception is that anesthesia factors result in the majority of room start delays. Many anecdotal reports by OR clinical directors do not support this concept. We recently studied reasons for all delayed room starts and grouped those delays into factors controlled by patients, surgeons, anesthesiologists, and nursing/hospital. The results (Box 4-4) demonstrate that surgeons controlled the largest number of delays in first starts. Box 4-5 lists some of the most common reasons for delays.

Starting first cases on time is a complex and challenging process. When defining an on-time start as having the patient in the room by the start time, delays occur in 40% to 90% of first starts.[30,31] When defining an on-time start as having the patient in the room within 10 minutes of the scheduled start time, delays still occur in 5% to 50% of cases. Identifying causes of delays; removing barriers to smooth patient flow; improving communications among preoperative personnel, patients, surgeons, nurses, and anesthesiologists; and creating an atmosphere (culture) of shared ownership in starting on time will improve on-time starts. Box 4-6 lists other key factors for increasing the percentage of on-time starts.

The direct economic benefit for reducing first-case delays depends on the size and volume of cases performed in an institution.[32,33] In a study by Dexter and Epstein, only 1.1 minute was saved at the end of the day for each 1-minute reduction of delays.[34] If the OR suite has a small number of rooms and the cases finish within the scheduled time, then no economic benefit was achieved by reducing delays. As an example, if an eight-room surgical suite has an average of two rooms that start 10 minutes late, but all of the cases in the 8-hour nursing shift are completed, then no savings will occur if the cases start on time. However, in a facility with a large number of ORs and with some rooms running for more than 8 hours, reducing these delays may result in less overused time and expense.

The term *tardiness* may be used to describe the difference between scheduled start time and actual start time for all cases on the surgical schedule. This measures both first-case starts as well as the to-follow cases. Wachtel and Dexter have identified several factors that relate to tardiness of the surgery schedule.[35,36] As might be expected, the first case of the day had fewer instances of tardiness than cases later in the day. Because case duration is unpredictable, if the first case runs long, then the second case will be tardy in starting at the scheduled time. Although surgeons believed the most common time for tardiness was late in the afternoon during nursing shift change, the peak time for tardiness was between 11:00 AM and 1:00 PM, when most rooms were still running and multiple turnovers were occurring. Later in the day, tardiness decreased, likely balanced by some cases finishing earlier than predicted or when cases were moved to an available unoccupied OR. The best strategy to reduce tardiness was to recalculate the OR schedule and account for potential late-starting cases or case durations that may be longer than planned; then cases could be moved or adjusted to improve starting times.

BOX 4-4 *Delays in Start of First Case of the Day*

Surgeon controlled: 60%
Patient controlled: 20%
Anesthesia controlled: 6 %

BOX 4-5 *Reasons for Surgeon-Controlled Delays*

- No history and physical examination in chart
- No consent obtained
- Ordered new laboratory test; results not available
- Changed schedule order or procedure
- Surgeon not available

BOX 4-6 *Key Factors to Increasing On-Time Starts and Decreasing Turnover Times*

Keys to Increasing On-Time Starts

- Do not require the surgeon to be present before the patient enters the OR.
- Use guaranteed block time to allow for predictable OR times and locations for surgeons.
- Have specialty teams dedicated to complex cases.
- Standardize preoperative orders and testing.
- Review the patient's chart the day before surgery to identify potential delays in getting the patient ready.
- Call patients the day before surgery to clarify instructions and answer questions.
- Triage personnel in the preoperative area to effectively manage patient needs before start of the procedure.

Keys to Decreasing Turnover Times

- Organize a turnover team to clean and prepare the room.
- Have the same surgeon follow in the same room with all of their cases.
- Use specialty-specific nurses and anesthesiologists.
- Maintain an accurate surgery schedule and reduce changes in the surgical list (i.e., order changes, cancellations, add-ons).
- Streamline the preoperative process.
- Ensure that the communication process informs all personnel involved with case turnover in a timely manner.

OR, Operating room.

Turnovers

The definition of *turnover* varies among OR personnel, often leading to confusion.[37,38] A surgeon may view surgical "down time" (the time between closing the incision on one patient and beginning the incision on the next patient) as turnover. Academic surgeons consider turnover to be the period between leaving the OR (before the incision is closed by a junior resident or medical student) and returning for the beginning of the next case. Thus surgeons frequently complain that slow turnovers between cases cause significant delays in completing the surgery schedule. The OR nurse may treat turnover as the time from removing the used equipment from the first case until the equipment is in place for the next patient. Anesthesia personnel believe that turnover is the time between leaving the previous patient in the PACU and bringing the next patient into the room. With varying definitions of turnover, it can be difficult to measure and create improvements in this area of OR function.[39] The AACD glossary (see Appendix 4-2) defines *turnover* as the time from when one patient exits the OR until the succeeding patient enters. This turnover time applies only when the second case is scheduled to immediately follow the first case.

The period between patients occupying the OR is busy. The nurses must return used instruments for decontamination processing. A housekeeping service must clean the floors and sterilize all surfaces, including the OR table. Nurses must assemble and organize equipment for the next case. They must also check on the next patient and verify that the paperwork is complete and the procedure is listed correctly. Anesthesiologists must transport the previous patient to the PACU, assess vital signs, give a report to the PACU nurse, and submit the required paperwork. They must return unused drugs and prepare new drugs for the next case. They must also ensure that anesthesia equipment is replaced and prepared for the next patient. Finally, they must see the next patient, complete their preoperative paperwork, obtain consent forms, discuss anesthesia plans with the patient, and answer any questions.

Multiple system factors can affect turnover time, and several units must function efficiently together to be successful. Attention should be given to the preoperative process (see Chapter 38) to efficiently prepare patients for surgery and readily locate the required paperwork and preoperative test results. Hospital transportation services should allow patients to be reliably available when called for the OR.[40] The drug management system must permit access to medications and manage controlled substances. A turnover team must organize, clean, and prepare the OR for the next case. The PACU must function well to allow efficient OR throughput.[41,42] Limited hospital floor bed and ICU bed availability may result in delays in patients being discharged from the PACU, limiting PACU space for OR patients. Chapter 96 further discusses ways to improve PACU function. Each of these individual factors contributes to the overall ability of the team to facilitate turnover.

There is no national standard for acceptable turnover time. In most facilities, turnover represents only 10% to 20% of the total case time. When performing turnover between simple procedures, such as cataract extractions, it is reasonable to expect a turnover time of 10 minutes or less. However, when changing between heart bypass procedures or complex orthopedic cases, the turnover may require 45 minutes or longer. The complexity of room set-up and the need for specialized patient preparation contribute to the length of turnover. Box 4-7 illustrates average turnover times reported for various types of surgical procedures.[43] Some benchmarking data are available on turnover for specific procedures.[43,44] A review at four academic institutions indicated that turnover times ranged from 34 to 66 minutes.[45]An institution should consider this information when it looks at its specific turnover data to determine realistic goals for OR improvement.

BOX 4-7 *Average Turnover Times*

Total-hip replacement	44 minutes
Total-knee replacement	46 minutes
Knee arthroscopy	38 minutes
Coronary artery bypass	52 minutes
Laparoscopic cholecystectomy	30 minutes
Cataract extraction	21 minutes

Although reductions in turnover times may save 5 to 10 minutes per case, these time savings do not usually translate into large time reductions in a single OR's schedule. Reducing turnover time does improve efficiency and focus, which may translate to improvement in surgical preparation and case completion times. The intangible benefits of reducing turnover may be the most important. Reducing turnover can build teamwork and encourage the institution's focus on achieving maximum OR efficiency. However, excessive focus on turnover time is counterproductive. Staff risk losing more time strategizing than can realistically be gained from the resulting changes.[44] Turnover time is also a favorite topic of consultants because it tends to strike an emotional chord with surgeons and hospital administrators. In reality, most efforts to reduce turnover times result in modest reductions in completion of the surgical schedule.[45] As an example, if a single OR performs four cases in a day and can reduce turnovers by 10 minutes, the total time that can be saved is 30 minutes (3 turnovers × 10 minutes × 30 minutes). This small time savings may result in reduced overtime expenses if more than 8 hours of surgery are regularly performed, and improved satisfaction measures, but it will not provide sufficient time to perform additional cases.

Operating Room Utilization

Operating room utilization is an important concept that guides the direction of OR management.[46] It is also a significant part of the OR director's job. To understand the concept of OR utilization, it is important to understand several definitions from the AACD glossary (see also Appendix 4-2):

- *Case time* is the time from the start of room setup to the end of room clean-up. It accounts for the entire

TABLE 4-2 UTILIZATION COMFORT ZONES

Utilization	Hospital Administration	Anesthesiology	OR Nursing	Surgeons
>100%	++	--	---	----
85%-100%	++++	++	-	--
70%-85%	+++	++++	+	±
55%-70%	+	+++	+++	++
<55%	--	-	++	++++

Ranges of greater negativity (-,--,---,----) and ranges of greater positivity (± ,+, ++, ++++, ++++). As an example, + is a mildly positive aspect, but +++++ is strongly positive. Likewise, - is a mildly negative aspect, but ---- is strongly negative.

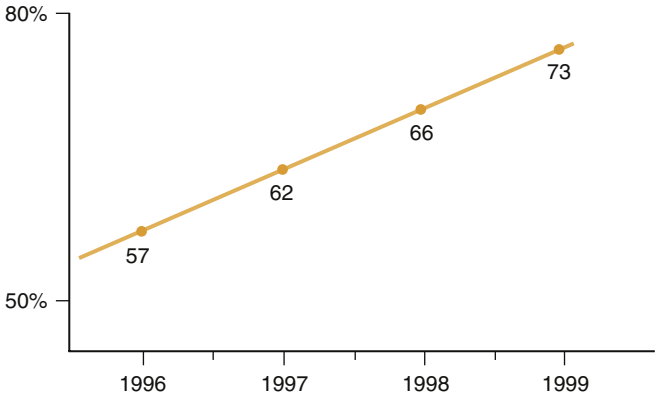

Figure 4-2. Raw utilization for operating rooms.

time that the OR is dedicated to the performance of a procedure and cannot be used for any other purpose.

- *Resource hours* are the total number of hours that a room is staffed and available for the performance of procedures. Many ORs are staffed for 8 hours of regular resource hours (e.g., 7:00 AM to 3:00 PM). Resource hours do not include overtime or periods when on-call personnel are staffing the OR. Resource hours serve as the denominator in calculating use of the available blocked or open scheduled elective OR times.
- *Raw utilization* is the ratio of the time that patients are in the OR to the available resource hours. It does not include time spent preparing the OR or turnover time; therefore, it understates the actual time that the OR is committed to a case.
- *Adjusted percent utilization* is similar to raw utilization, but it includes case setup time and turnover time. This figure more accurately reflects the time that the OR is used for case performance and is unavailable for any other activity.

Utilization is most commonly determined for a service or group of surgeons based on their set amount of block time. For example, if a group of orthopedic surgeons has block time in two rooms on Monday through Friday, their resource hours per week are 80 (2 rooms × 5 days per week × 8 hours per day). If their total case time (in-room time plus turnover) is 72 hours per week, the adjusted percent utilization is 90% (72 hours per week □ 80 hours per week).

Regularly tracking utilization is important. To achieve an efficient balance of available times for surgical divisions, hospitals should reassess block times based on utilization on a 3- to 6-month basis. For hospitals using utilization to track surgery performance and allocate block time, it is better to assign block time to a group of surgeons or a surgical division. Granting block time to individual surgeons produces more variability in use and may result in lower utilization.

There is no defined target for optimal utilization. Opinions of optimal utilization vary among entities involved in the OR (Table 4-2). As utilization increases to above 80%, surgeons may have difficulty scheduling patients, and the increased wait time may create patient dissatisfaction. Studies have shown that for elective procedures in the United States, most patients are willing to wait 1 week.[24] Waiting longer than this because of unavailable block time will lead to patient and surgeon dissatisfaction and possibly loss of the case to another institution. Utilization percentages that are very low represent lost opportunities to generate revenue. Anesthesiologists prefer to be busy during regular resource hours yet have some flexibility for covering urgent and emergent cases.

The exact break-even point for utilization is dependent on the OR's fixed versus variable costs and reimbursement mix. Consultants often quote 80% to 85% utilization as a target. This figure was used as a benchmark in the 1970s because hospitals were required to demonstrate a certificate of need before expansion of OR facilities. Most ORs seek a utilization of 70% to 85% to maximize benefits and reduce stress on the system. Trends have shown that, with increasing surgical volume and reduction in OR availability, the overall raw utilization has been steadily increasing in hospitals (Fig. 4-2). Data from 1999 revealed that hospital-based ORs have higher utilization than ambulatory ORs (73% versus 55%).[47] Tracking overall OR utilization may be beneficial in demonstrating the need to expand OR capacity.

There are costs associated with both underutilization and overutilization. There are fixed costs for ORs regardless of utilization. Underutilization results in lower revenue generation to offset the fixed costs. Overutilization (cases running late) may require overtime pay for nurses or hiring temporary nurse services, which results in higher costs per minute of OR use. In addition, personnel who frequently must stay late may become dissatisfied and quit, increasing the costs associated with recruitment. Many recent studies have identified ways to maximize utilization or to assist with scheduling to improve percent utilization.[47,48] Because many ORs have frequent last-minute changes, cancellations, add-ons, and emergency cases, the ability to apply these simulations to actual OR practice may be limited.

Utilization should not be used to assess how efficiently an OR is working. Utilization is only a measure of resource consumption. For example, if surgeon A takes 2.5 hours to perform a laparoscopic cholecystectomy and conducts three procedures in an eight-hour block, this results in a raw utilization of 94% (2.5 hours per case × 3 cases = 7.5 hours; 7.5 hours per 8-hour block = 94%). However, surgeon B, who completes laparoscopic cholecystectomies in 1 hour and is able to do 6 procedures during an 8-hour block, has

a raw utilization of 75% (1.0 hour per case × 6 = 6 hours; 6 hours per 8-hour block = 75%). Even though surgeon A has a more frequent utilization, surgeon B's financial margin is better. Table 4-3 illustrates these calculations.

Hospitals are becoming more refined at analyzing OR production. By looking at revenue generation and associated costs for each surgeon, they can determine the profit margin for each individual. Although studies have shown that nearly all surgeons contribute a positive profit margin for their OR cases, the range of profit margin is wide.[49] Table 4-4 shows an example of a report generated with this approach. OR managers and hospitals are increasingly using this type of information to make decisions concerning OR resources. Box 4-8 contains a list of key issues to improve OR utilization, throughput, and efficiency.

Another important way to approach OR function is to consider the OR workload (demand) and the fixed nursing shifts (typically 8 hours) that are scheduled. Some useful definitions in considering performance of each OR are:

OR Workload: The total hours of OR case time plus turnover on that day.
Allocated Time: Time reserved for a surgeon or service on a particular day (block time)
Underutilized Time: Allocated Time – OR Workload (if this value is <1 then default to 0)
Overutilized Time: OR Workload – Allocated Time (if this value is <1 then default to 0)
OR Labor Costs: 1.0 × Allocated Time + 1.5 × Overutilized Time
Inefficiency Measure of OR Time: Underutilized Time + 1.5 × Overutilized Time

As described in these definitions, nursing shifts are paid for their 8-hour shift, even if only 7 hours of OR workload occur. The underutilized time may be insufficient to perform another case, so no additional revenue can be generated in this OR, but neither can costs be reduced by finishing early. If an OR has 10 hours of OR workload, then there are 2 hours of overutilized time, which must be paid at overtime rates (1.5 times normal pay). Overutilized time may be even more expensive if this leads to staff dissatisfaction and added costs for retention and recruitment of nurses. Therefore, overutilized time is much more important to control than underutilized time. Wachtel and Dexter described this concept in a review article on OR management.[50,51] A goal for the OR directors might be to limit overutilized time so that it occurs in fewer than one third of the ORs and accept two thirds of the ORs being underutilized, finishing before the end of the nursing shift. This would limit expense and yet allow for higher economic performance.

DAILY SCHEDULE MANAGEMENT

The "running" of the daily schedule is a complex job.[52] An accurate and realistic schedule is one of the most important factors in completing the surgical list. Frequently, an anesthesiologist partners with an OR nursing leader to run the daily surgery schedule. This team must be able to make fair decisions regarding moving cases, managing add-on and cancelled cases, and using the nursing and anesthesia workforce to complete the surgical list efficiently. The OR nursing director's willingness to accept risk in running the schedule may create significantly less unused OR capacity and also improve the anesthesia group's productivity.[53] It is interesting that a recent paper by Masursky et al. showed that OR nursing directors may

BOX 4-8 *Keys to Increasing Operating Room Throughput*

- Schedule full-day blocks rather than half-day blocks.
- Surgeons should follow themselves in the same operating room.
- Verify schedule accuracy to decrease delays in case completion.
- Streamline preoperative processes and standardize testing.
- Use specialty teams of nurses and anesthesiologists.
- Organize supply and equipment needs for easy room setup.
- Focus attention on room starts and turnover to create a culture of timeliness and efficiency.
- If you have a significant number of add-on cases, plan for an open room or be able to move cases to available time slots.
- Ensure that the communication pattern throughout the perioperative area informs all necessary individuals of case progression.

TABLE 4-3 **RAW UTILIZATION CALCULATIONS**

	Case Time (hr)	No. Cases Performed	Total In-Room Time (hr)
Surgeon A	2.5	3	7.5
Surgeon B	1.0	6	6.0
Surgeon A	7.5 hr in room time 8.0-hr block available = 94% raw utilization		
Surgeon B	6.0 hr in room time 8.0-hr block available = 75% raw utilization		

TABLE 4-4 **OPERATING ROOM ASSESSMENT REPORT**

Surgeon	Cases	Collection	Avg Collection/Case	OR Minutes	Avg Minutes/Case	Collection/OR Minute
Green	53	$43,116	$813	1150	22	$37.49
Jones	17	$16,802	$988	989	58	$16.99
Smith	10	$17,179	$1718	588	59	$29.22
Rogers	19	$11,947	$629	800	42	$14.93
Wilson	12	$13,341	$1112	1052	88	$12.69
Lynch	13	$7,398	$569	883	68	$8.38

OR, Operating room.

have priorities that run counter to increased productivity.[54] The OR nursing director may prioritize nursing relations and budgets that lead to more underutilized time and therefore lower productivity. For these reasons, it is essential that the physician and nursing OR directors develop a management style that benefits the function of this unit.

Making the cases flow smoothly takes several steps (Box 4-9). The initial step is to review the schedule of cases the evening before and again the morning of surgery. These reviews should focus on identifying potential obstacles to patient flow such as delayed starts, surgeon preferences, and opportunities to deal with add-ons or changes. During the course of the day, the scheduler should frequently walk the "floor" in the OR to check on the status of room starts, case progression, and turnovers. Because surgical procedures have a high degree of variability, plans on how cases should proceed change frequently, and adaptation is paramount. The OR should create a tracking system to monitor the day's progress and should be available for people working in the OR so they can see schedule adjustments including starts, completed cases, cancellations, and add-ons.

Every OR has add-ons and case cancellations. As the number of add-ons and cancellations increases, so does the complexity of scheduling.[55-57] There are no national benchmarks for schedule changes, but planning measures to keep add-on rates less than 12% and cancellation rates less than 4% will help to effectively and efficiently manage the schedule. Cancellation rates vary, based on patient population and surgical procedures, but are generally in the range of 6% to 9%.[28] If an OR has a higher cancellation rate, staff should assess why this is taking place. One strategy to reduce cancellations is to evaluate patients in an organized and efficient preoperative clinic with standardized algorithms for further testing and evaluation. These clinics reduce delays and cancellations on the day of surgery.[28] Box 4-10 shows some of the common issues in case cancellations.

Cancelled cases can significantly affect OR productivity and access to elective scheduling for cases. Recent reviews by Dexter et al. and Tung et al. have identified issues related to cancelled cases.[58,59] Because the surgical schedule has so many changes with add-ons and cancellations, it is unproductive to actively manage the surgical list before 2 days leading up to the day of surgery. Beginning 2 days before surgery, the OR director should begin to look for opportunities to move cases and adjust the schedule to maximize filling rooms and decrease overutilized time. One predictor of the net added hours of surgery within the 2 days leading up to the day of surgery is the availability of open or underutilized time. The day before surgery the OR director should "sculpt" the schedule to balance overutilized and underutilized rooms. If flexible staffing is an option for nursing staff, decisions on the number of nurses needed to limit overutilized time can be made. Some patient predictors for cancellations are number of missed clinic appointments, insurance status, and patients not seen in the preoperative anesthesia clinic. Other factors identified that increase cancellations are surgical service (general surgery > gynecologic surgery) and size of the hospital (large or academic facility > medium or small hospitals). In a German study, the most common causes for cancellations were organization/resource based (overutilized time, emergency cases lack of ICU beds) followed by new medical issues discovered in patients.[60]

There should be a well-defined system for triage to improve the efficiency of performing add-on cases. Generally, the scheduled elective cases take precedence over add-on cases, but there are exceptions. Situations will arise in which an urgent or emergent case will delay or "bump" a planned elective case from the schedule. As a result, managing and scheduling urgent or emergent cases must also follow a well-understood system. Table 4-5 shows one algorithm used to handle emergency cases.

BOX 4-9 ***Ten Steps to Completing the Daily Schedule***

1. Recheck the schedule the afternoon before surgery to look for potential difficulties and to identify opportunities.
2. Review the schedule early in the morning on the day of surgery and note cancellations and add-ons.
3. Ensure that rooms have accurate start times by walking through the OR suites.
4. Set expectations for surgical case progress by using benchmark case times if available.
5. Organize the turnover process to manage peak room changes from midmorning until early afternoon.
6. Develop a well-understood policy for working add-on cases into the schedule.
7. Look for open room time to move cases from late-running rooms or to move add-on cases into them.
8. Identify cancellations early and redeploy the room and personnel resources to complete other cases.
9. Set realistic staffing patterns to meet the surgical caseload demand. Use nonstandard shifts so that rooms do not have to be closed in the early afternoon.
10. Use a case-tracking system so that others can see where resources are needed to complete the caseload.

BOX 4-10 ***Common Case Cancellation Issues***

PATIENT

Self-cancellation or no-show
Desired second opinion
Patient not NPO
Preferred transfer to another institution

SURGEON

Not available; busy with an emergency or another case
Decided surgery was not indicated
Patient needed further workup

ANESTHESIOLOGIST

Patient needed further workup

HOSPITAL

Nursing staff not available
Lack required equipment or implants for case
Scheduling error; wrong date for surgery
Lack beds; ICU at capacity

ICU, intensive care unit; *NPO*, nothing by mouth.

Surgeons often help control add-on placement by scheduling OR availability during specific days. If a group or division of surgeons is busy, they may have set OR days when they are available for surgical procedures and other days when they are committed to clinic visits and are unavailable. Often, the surgeons' add-on cases are self-channeled into days on which they are already using the OR. In this situation, the add-ons should be scheduled into that surgeon's preexisting room. If a hospital system has a large number of add-ons that surgeons must perform at the end of the elective schedule late in the day, the OR should be scheduled to properly staff and support these times. Nursing shifts using the traditional 8-hour (7:00 AM to 3:00 PM) shift may need to be modified to cover late rooms by creating either 12-hour shifts (7:00 AM to 7:00 PM) or staggered shifts (10:00 AM to 6:00 PM). Anesthesiology departments must also address coverage of this off-peak OR time. If a hospital had a large number of add-ons that are urgent, such as is frequently seen with trauma centers, consideration for keeping one or more rooms unblocked but staffed for urgent add-ons may be successful.

Despite the best planning, the daily schedule is often challenging because cases are unpredictable. A good rapport among schedulers and surgeons is helpful in diffusing potential scheduling conflicts. Macario's[11] article on game theory creates an interesting analogy of these interactions as they apply to the OR. This perspective can be helpful in scheduling efficiently and seeking support for organizational success. Routine reviews of utilization reports and the daily schedule are important to identify opportunities for improvement, including decreasing underutilized OR time (Figs. 4-3 and 4-4). Regardless of the desire to run the schedule efficiently, the quality of a patient's care should always remain the top priority.

TABLE 4-5 ADD-ON CASE MANAGEMENT

Emergency	Urgent	Elective
Come to the OR within 30 min *Example:* gunshot to the abdomen	Come to the OR within 2 hr *Example:* appendectomy or ectopic pregnancy	No time constraints *Example:* revision dialysis shunt
Place in any open room	Place in available staffed open block room or in room with cancellations.	Follow elective cases in first available room.
If no room is open, bump any room that is turned over and ready	If no room is open, bump the posting surgeon's elective cases.	
	If posting surgeon has no room available, bump same surgical division.	
	If no cases within same surgical division, bump room with the shortest surgical list.	

OR, Operating room.

ANESTHESIA SERVICE

It is important for OR directors to include anesthesia service management in their scope of OR management. If an OR director succeeds in streamlining and maximizing the efficiency of the OR, productivity within the anesthesia service will also increase. Better OR scheduling, on-time starts, efficient turnovers, and proper management

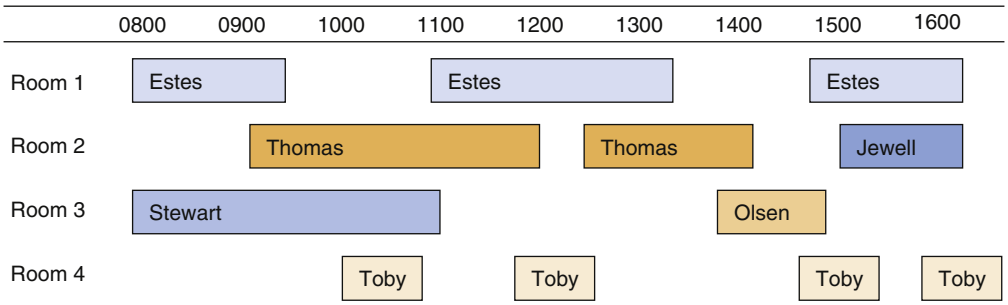

Figure 4-3. An example of schedule utilization.

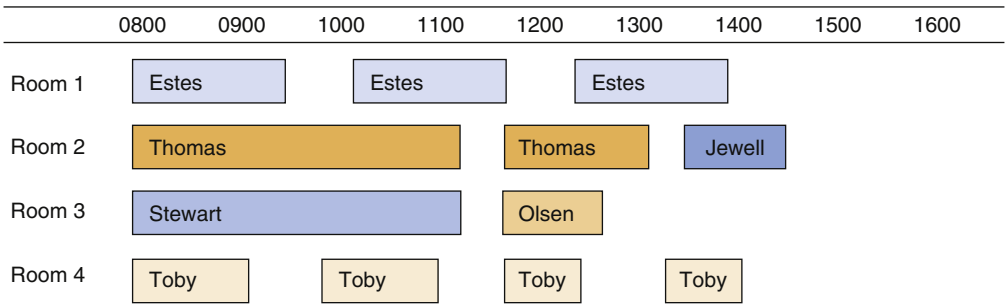

Figure 4-4. Improved schedule utilization.

of add-ons and cancellations will result in concomitant improvement in anesthesia service utilization.

The two main components of anesthesia service management involve personnel issues and pharmaceutical costs. Anesthesia-related costs represent 3% to 5% of the total health care expenditures in the United States.[61] Although most of these costs involve personnel,[62] anesthesia-related drugs comprise the majority of the 20 most costly drugs used in the hospital.

Optimal staffing patterns for providing anesthesia coverage for the surgical schedule[63] are a frequent point of discussion. Staffing coverage depends on provider availability and local conditions. The benefits of physician-only versus concurrent supervision of multiple providers are not clear cut.[64] ORs must also consider the requirements for specialty teams to cover areas such as cardiac, organ transplant, obstetric, trauma, and pediatric cases, which may limit the ability to maximize staff utilization. Supervision ratios may affect first-case starts and quality.[65] Today, more anesthesia groups are negotiating financial support from hospitals for added call coverage for these specialty teams. There are several models for calculating this support, with the intent of benefitting both the anesthesia group and the hospital. Within the anesthesia group, there are also models described that focus on mission-based compensation that can lead to increased productivity.[66,67]

As a result of growing pressure to quantify anesthesia output, ORs have refined the measurement of anesthesia productivity.[68,69] Methods to track anesthesia output have evolved from simple availability to more sophisticated measurements of production and call coverage.[70,71] Clear differences exist between academic and private settings. Abouleish et al.[69] and colleagues showed that an anesthesiologist in an academic setting needed to work 30% longer than one in private practice to generate the same level of billable services (7.8 hours versus 6.0 hours). Development of incentive plans can be useful to improve productivity and retain physicians.[72,73] Anesthesia drugs are expensive and are a frequent focus for reducing hospital expenses.[74] Overall, pharmaceutical costs approximate 5.6% of a hospital's total operating costs. Anesthesia drugs represent 22% of the total pharmacy costs.[75] Newly developed anesthesia drugs often have significantly higher costs (muscle relaxants, narcotics, antiemetics). Although these drugs may appear to be cost effective by improving patient throughput (decrease OR or PACU times) or increasing patient satisfaction (faster discharge, less postoperative nausea and vomiting), studies have been inconsistent in demonstrating those benefits.[76] Because there are many variables that contribute to change in resource utilization and drug cost, true assessment of the resulting changes from drug choices is difficult. It is also difficult to assess the fixed versus variable costs of those changes. If anesthesia-controlled costs represent 6% of the total cost for a surgical patient, it is likely that half of these costs are fixed. ORs can modify the remaining 3% of costs (drugs and supplies); however, experience has shown that intensive restructuring of anesthesia drug use only results in small reductions in overall pharmacy costs. In many cases, the savings are difficult to sustain and ORs return to previous drug choices.[75]

OPERATING ROOM QUALITY AND PATIENT SAFETY (Also See Chapters 6 and 7)

QUALITY MEASURES

Hospital care is particularly expensive in the United States, but the increased expense does not lead to uniform or improved outcomes. Federal and private groups have suggested ways to improve quality with standardized care and reporting of measure outcomes. The Surgical Care Improvement Project (SCIP) identifies several measures designed to reduce surgical site infections. Tracking these measures and achieving their benchmarks is increasingly being tied to payment, as well as being used to gain market share. Government programs such as Pay-for-Performance are also used to drive standardized care, with the goal of leading to improved outcomes at lower costs. The Affordable Care Act that overhauled the approach to health care in the United States has numerous provisions that deal with reporting and following best practices. Because many of these regulations involve surgical patients and activities in the OR, the OR director must ensure that compliance and strategies lead to success in meeting these expectations. The Centers for Medicare and Medicaid Services (CMS) and The Joint Commission use these regulations in evaluating a hospital for accreditation purposes. The OR director must be familiar with these regulations and facilitate data collection and compliance. Because the OR director is knowledgeable of OR function and policies, they occupy a lead role in site visits by these outside agencies.

Operating room activities are complex and critical to the delivery of health care. A large number of agencies and regulations oversee how an OR functions. The OR director must be familiar with these various agencies and regulations to ensure compliance within the OR. Box 4-11 lists these entities.

The OR director must focus on meeting the regulatory requirements for hospital accreditation. Patient and employee safety (infective agents, fire safety, laser safety, electrical safety) and proper use and tracking of drugs and medical devices are also important areas of focus. State and local regulations, as well as hospital policies, have

BOX 4-11 ***Operating Room Agencies and Regulators***

- The Joint Commission
- Accreditation Association for Ambulatory Healthcare (AAAH)
- Drug Enforcement Administration (DEA)

- National Fire Protection Association (NFPA)
- National Committee for Quality Assurance (NCQA)
- National Academy of Sciences/Institute of Medicine
- Safe Medical Devices Act
- Health Insurance Portability and Accountability Act (HIPAA)

specific requirements for the OR. Privileging and monitoring the quality of outcomes for physicians in the OR are paramount. Internal data collection and quality measures should be designed to demonstrate the performance of individual physicians and the OR.

CHECKLISTS

The focus on improving quality in the OR has led to the concept of using checklists to ensure best practices are followed.[77] Atul Gawande popularized this in the book *The Checklist Manifesto*. The use of checklists has been proven to improve safety in the airline and space industries. The World Health Organization has also adopted the plan to increase the use of checklists to reduce errors. Because the OR involves interactions among nursing, surgery, and anesthesia personnel working in a complex environment under production pressures, errors occur too frequently. Checklists are used to prevent things such as wrong-site surgery or identification of drug allergies. The OR director should balance the number of items on checklists with maintaining efficiency and quality in this unit.

ELECTRONIC MEDICAL RECORDS

With new federal regulations concerning medical information, the use of electronic record keeping has accelerated. Requirements that all patient information be readily available have caused hospitals to spend considerable amounts of their budgets for this support. The OR generates a large amount of data that presents challenges to electronic systems to organize and capture.[78] These anesthesia information management systems (AIMS) can be an effective way to increase compliance, demonstrate quality, and improve outcomes.[79,80] They can be designed to provide prompts when important points of care arise, such as antibiotic administration. The accuracy of these systems to capture data and potential errors in recording care have led to concerns about how these new systems will benefit anesthesia groups. But as AIMS become more refined and automated, they offer the OR director a tremendous source of data to track compliance and outcomes.

COST ACCOUNTING IN THE OPERATING ROOM

Financially managing the OR is a difficult task. Most physicians have not had a formal business education and are unfamiliar with OR financial management concepts. Health care in the United States is a complicated financial industry, with 17.6% of the gross domestic product devoted to it.

The concept of management control in nonprofit organizations is becoming more sophisticated.[81] Financial management of the OR is analogous to running a business.[82,83] A hospital can classify an OR as an expense center or a profit center. If it is an expense center, attempts to improve the financial position of the hospital would focus on minimizing costs. If, however, the OR is a profit center, the OR director must pay attention to the margin between costs and revenues and attempt to maximize profit. It is essential for hospitals to focus on the financial performance of the OR. The OR averages 40% of the total costs of a hospital, but it is responsible for as much as 70% of the revenue.[1] As ambulatory health care activity has moved out of the hospital, many hospitals have become primarily tertiary care surgical facilities. Managing costs and increasing revenue in the OR will result in a hospital with strong profitability and the ability to expand its health care delivery services.

The OR director needs a basic understanding of cost accounting to ensure effective OR decision making. Cost accounting focuses on understanding the costs of running the OR to determine an optimal price for services. Hospital management should use the information that cost accounting provides to plan and control activities, to make strategic decisions, and to improve the quality and efficiency of services in the OR. Box 4-12 contains a list of accounting terms.

It is important to recognize the difference between costs and charges. Costs include all of the fixed and variable expenses associated with a specific procedure. Charges are the sum of all the costs plus the amount of profit over the costs that the hospital bills to insurers. In the 1970s and 1980s, most hospitals used the theory of cost-plus billing. In cost-plus billing, the hospital added an amount of money (profit) to the costs for a procedure. It submitted the resulting charge to insurers. However, as reimbursements declined, insurers began to contract services for a specific price, regardless of the hospital's costs for that service. The ratio of costs to charges varied widely for different services throughout the hospital.[1] For example, the cost-to-charge ratios at Stanford Hospital were 0.29 for anesthesia, 0.50 for laboratory, and 0.92 for the surgery admission unit.[1]

Because of the arbitrary nature of assigning charges to a service, as well as the variable reimbursement, decisions concerning OR management should use costs and not charges. Costs are either fixed or variable. Fixed costs (overhead) are costs that do not change in the short term regardless of the number of completed procedures. In the OR, these costs include rent or depreciation of the surgical suite, capital equipment in the OR, salaried employees, and administrative overhead (OR directors, medical records, admitting personnel). Fixed costs may change over longer periods if the hospital changes the number

BOX 4-12 ***Operating Room Accounting Terminology***

Charges: The fee listed for an item or procedure based on assumptions of resource consumption
Costs: The actual expenses incurred in delivery of a service
Fixed costs: Overhead; costs that do not change up or down over a finite period, regardless of the volume of activity
Variable costs: Costs that change directly up or down with changes in volume of activity
Profit: Revenue–costs (both fixed and variable)
Contribution margin: Revenue–variable costs
Capacity: Maximum amount of activity that a facility can deliver without increasing fixed costs

of OR suites or the budgeted number of OR staff. Variable costs will increase or decrease directly with the level of surgical activity. In the OR, variable costs include disposable supplies, sutures, linens, implants, and contracted labor. Fifty-six percent to 84% of OR costs are fixed.[84] Short- and intermediate-term cost reductions will apply only to the variable portion of OR costs, representing a smaller part of the total OR costs as fixed costs remain unchanged.

The two methods to account for costs in the OR are either top-down or bottom-up. Top-down accounting uses cost-to-charge ratios to average and estimate the costs for a particular procedure. This is an easy and simplified calculation but has critical disadvantages. Top-down accounting is imprecise, and the ratio will vary because of changes in either costs or charges. This makes period-to-period comparisons difficult because it is difficult to isolate whether the cost-to-charge ratio trend is a result of changes in costs, charges, or a combination of both. Bottom-up accounting (microcosting) is more precise, requiring a detailed measurement of all the expenses for a procedure. Bottom-up accounting also requires classifying costs as fixed or variable, which makes decision-making easier in OR planning.

Profit for the OR is equal to the total revenues minus the total costs. The OR must produce profit to pay for other areas within the hospital (e.g., emergency department) that operate at a loss. However, in assessing changes in surgical activity, the "contribution margin" is more important. Contribution margin is equal to the total revenues minus the variable costs. A larger contribution margin indicates that more money is available to pay the overall fixed costs of the institution.

A specific example of OR cost analysis is provided in the 1999 review of costs by Macario.[84] In the review, he found that the majority of costs for care of a patient undergoing laparoscopic cholecystectomy occurred in the OR.[84] The OR (37%), anesthesia (7%), PACU (6%), and OR-related laboratory and pharmacy costs accounted for more than 50% of the total hospital costs. For any OR procedure, most of the costs occur in the first hour of the case. These costs include room preparation, opening basic supplies, linens, and use of instruments or implants for the procedure. Subsequent time in the OR is less expensive and consists primarily of labor costs. Using a detailed analysis, Macario[84] established that the basic costs of an OR, exclusive of procedure-specific needs (e.g., trocars or implants), was $13.54 per minute. Of this amount, 62% of the costs were fixed and 38% were variable. Cost-savings measures (i.e., changing physician practice) will affect only the variable costs of this expense. OR costs vary by institution, depending on labor and overhead costs.[85,86] Ambulatory surgical facilities, with reduced overhead, may have overall OR costs that are 20% less than traditional hospital facilities.

The potential benefit of cost analysis is illustrated by considering the amount of costs that can be reasonably reduced. For example, anesthesia costs, such as machine depreciation, supplies, and drugs, average 6% of the total hospital costs for a procedure.[1] Of these costs, approximately 50% are fixed and 50% are variable. To reduce overall anesthesia costs in the OR, a hospital can only modify the variable part of the anesthesia costs. Therefore, it is only possible to manage 3% of the total hospital costs when reviewing the anesthesia practice for cost savings. The PACU is also an area with high fixed costs—up to 67% of the total PACU costs.[1] For this reason, opportunities for large cost reductions in the PACU by changing practice are difficult.

The largest variable costs associated with health care and the OR are personnel costs.[87] The unpredictable nature of the surgical volume, as well as late-running cases, may lead to increased labor costs. The Fair Labor Standards Act requires overtime wages of 150% of regular wages for hours worked over 40 per week. As a result, personnel costs increase significantly with poorly planned labor use in the OR. Strategies to minimize overtime including using 12-hour shifts, staggering nurse work times, and creating greater scheduling control will help reduce these labor costs. Careful analysis of nursing requirements and the creation of optimal staffing patterns can have a significant impact on OR costs.[88,89]

Studies on the contribution margin of individual surgeons to the hospital have shown that nearly all surgeons have a positive contribution margin.[49,90] However, the difference in the contribution margin between surgeons varies greatly, in some cases by as much as 1000%.[91] To improve profitability for the OR, efforts to increase the volume of highly profitable surgeons will have the greatest impact. However, before assigning more OR time to these surgeons, several questions must be addressed. Will the surgeon's utilization decrease if volume or OR time is increased? Do the surgeon's cases require hospital resources (ICU beds, specialty nursing) that have limited capacity? Does the system have enough overall capacity (OR rooms, nurses, anesthesia coverage) to increase volumes of services and hold fixed costs neutral? If an additional volume of cases requires building more infrastructure (new rooms or more OR nurses), the fixed costs will increase and negate profit. Clear, accurate information is necessary for the OR director to track costs and make rational decisions to improve OR performance.

SUMMARY

Operating rooms are complex environments that are vital to the success of hospitals. Hospitals have reevaluated OR management structures to improve efficiency while emphasizing quality and cost. Redesigning OR governance has been essential in addressing the changes required to make ORs run more effectively. Such redesign has resulted in an increasing trend to place overall responsibility in the hands of a single person, the OR director.

The OR director must understand OR economics and use sound strategies for cost control and revenue enhancement. A comprehensive OR information system that can capture and organize OR data is essential for the OR director. Hospitals set targets for performance, and regulatory organizations set quality measures for the OR. Information systems help monitor whether the OR is meeting these targets and standards. Detailed data are required for instituting a successful business plan for the OR and implementing changes in how the OR functions.

The OR director's position has evolved into a broad and encompassing role as a manager of the perioperative process. The director must focus efforts on ensuring smooth, efficient throughput of patients in the perioperative area. Accurate scheduling, on-time OR starts, efficient turnover, and proper surgical case management are critical to the success of running the surgical schedule. OR directors must develop strategies to manage surgical schedule variability as a result of add-ons, emergency cases, and cancellations. They must also construct systems to control surgical and anesthesia costs. Although the challenges in making an OR function optimally are great, the benefits of an efficient and successful OR are critical to the hospital, to anesthesiologists, and to surgeons who work in this environment.

APPENDIX 4-1 *Guidelines for the Role of the Clinical Director of Anesthesiology and Director of the Operating Rooms*

I. Responsibilities to the Department of Anesthesiology
  A. Personnel management
    1. Long-term faculty scheduling
    2. Daily faculty/resident/certified registered nurse anesthetist assignments; assurance of comprehensive resident case exposure/coordination with program director
    3. Staffing calculations and planning; recommendations to chairman
    4. Creation of management team representing all clinical aspects of the department
  B. Subspecialty coverage
    1. Develop appropriate faculty daily and on-call coverage
    2. Participate in resident subspecialty rotation development
  C. Daily operations
    1. Early morning review of schedule
    2. Morning clinical/staffing conference
    3. Assignment changes during the day
    4. Chief arbiter of clinical and interstaff disputes
  D. Participative roles (with significant institutional variations)
    1. Preoperative evaluation clinic/preadmission testing procedure
    2. Anesthesia equipment/monitoring
    3. Quality assurance/quality management process
    4. Disaster planning
  E. Evaluation and promotion of the clinical director
    1. Clinical management–oriented job may require special criteria
    2. Clinical tract appointment most appropriate
    3. Teaching time may be limited
    4. Research areas may exist in management and statistical and clinical studies

II. Responsibilities to the OR/Hospital/Medical Staff
  A. Scheduling and data collection
    1. Daily review/final arbiter of OR scheduling
    2. Supervisor of scheduling/data processing personnel
    3. Enforce scheduling policy
    4. Management of OR utilization data and submission of reports to appropriate governing body
  B. Communications center (OR desk)
    1. Establish practices that provide expeditious service
    2. Supervise OR desk personnel
  C. Clinical director's role with OR nurses, PACU nurses, and support staff (with significant institutional variation)
    1. Leadership and supervisory role for OR personnel
    2. Strong working relationship with nursing hierarchy and hospital administration
    3. May function as OR manager with budgetary, materials management, and quality assurance functions
  D. Chief liaison to:
    1. Hospital administration (formal position)
    2. Nursing administration
    3. OR committee (may serve as chairman of the committee); authority must be delegated from surgical and anesthesiology departments and hospital administration
  E. Basic support from hospital administration
    1. Office, secretary, scheduler, and other personnel as necessary
    2. Financial subsidy may be appropriate
    3. Administrative authority

III. General Qualifications
  A. Seniority, appropriate academic rank—associate or professor level may facilitate the role
  B. Clinical proficiency/commitment—being respected for clinical abilities is a significant attribute
  C. Educational qualifications—formal training or experience in negotiation and interpersonal relationships and business administration may be desirable

OR, Operating room; *PACU,* postanesthesia care unit.

APPENDIX 4-2 *Selected Items From the Procedural Times Glossary of the American Association of Clinical Directors*

Room ready: Time when the room is cleaned and supplies and equipment necessary for beginning of next case are present.

Start time: Patient in room time.

Preparation completed: Time at which prepping and draping have been completed and patient is ready for the procedure or surgery to start.

Case time: Time from room setup start to room cleanup finished. This definition includes all the time for which a given procedure requires an OR. It allows for the different duration of room setup and room cleanup times that occur because of the varying supply and equipment needs for a particular procedure.

Turnover time: Time from prior patient out of room to succeeding patient in room for sequentially scheduled cases.

Resource hours: Total number of hours scheduled to be available for performance of procedures (i.e., the sum of all available block time and open time).

Block time: Hours of OR time reserved for a given service or surgeon. Within a defined cutoff period (e.g., 72 hours before day of surgery), this is time into which only the given service may schedule.

Open time: Hours of OR time not reserved for any particular service, into which any service or surgeon may schedule according to the rules established by the given institution.

Raw utilization: For the system as a whole, this is the percent of time that patients are in the room during resource hours. For an individual service, this is the percent of its block time during which it has a patient in the OR.

Adjusted percentage: (In-own block hours + Outside-own block hours × 100 per block time)

Service utilization: This measures the percentage of time a service uses its block time during resource hours. It is adjusted compared with raw utilization, in that it gives a service "credit" for the time necessary to set up and clean up a room, during which time a patient cannot be in the room. It may exceed 100% because of the inclusion of cases performed during resource hours that are outside-own block hours.

OR, Operating room.

Chapter 5

Medical Informatics

C. WILLIAM HANSON

Key Points

- A computer's hardware serves many of the same functions as those of the human nervous system, with a processor acting as the brain and buses acting as conducting pathways, as well as memory and communication devices. Clinical information systems and most medical devices have computers as a core component of the instrumentation.
- The computer's operating system serves as the interface or translator between its hardware and the software programs that run on it, such as the browser, word processor, and e-mail programs. The software used to support medical informatics allows the computers to manage information for clinical uses, including manipulating the data to optimize patient care and communication among providers.
- The hospital information system includes a network of interfaced subsystems, both hardware and software, that are integrated to serve the multiple computing requirements of a hospital or health system, including business services (scheduling, admissions, discharge, and financial transactions) and clinical services (electronic health record [EHR], order entry systems, laboratory and radiology studies, and other clinical information).
- An EHR is a computerized record of patient care that gives a comprehensive overview of all clinical problems and their management and medical reconciliation, and it replaces the traditional paper record.
- Computerized provider order entry (CPOE) systems are designed to minimize errors in ordering, increase patient care efficiency, and provide decision support at the point of entry. CPOE systems ensure that the care provided to the patient is safe and takes into account underlying medical conditions, minimizes the likelihood of duplicate ordering, addresses incompatibilities of medications, and reduces redundancies.
- Decision support systems (DSSs) can give health care providers descriptions of current clinical practices, disseminate best-practice protocols, and provide up-to-date information on diseases and their management. DSSs also can be used to act or to automatically intervene in patient care when appropriate and assist patients in managing their clinical problems.
- The *Health Insurance Portability and Accountability Act* is a comprehensive piece of legislation designed in part to enhance the privacy and security of computerized patient information. The *Health Information Technology for Economic and Clinical Health Act* enacted as part of the *American Recovery and Reinvestment Act* of 2009 is designed to promote the adoption and meaningful use of health information technology. It also addresses the privacy and security concerns associated with the electronic transmission of health information. Because this legislation addresses important issues in the management of clinical information, all clinicians must understand it to minimize risks associated with electronic communication between health care providers and patients.
- Using electronic health records and telecommunication technologies, health care providers are increasingly able to communicate with and care for patients remotely via the Internet. Telehealth strategies are being implemented to improve access to specialty care and optimize clinical care to underserved populations. Advances in technology, improved patient access, and new payment methodologies will be required to take full advantage of telehealth capabilities, and telemedicine will continue to grow as technology improves, reimbursement becomes available, and legislation evolves.

COMPUTER HARDWARE

CENTRAL PROCESSING UNIT

The central processing unit (CPU) represents the "brain" of a modern computer. It sits on the motherboard, which is the computer's skeleton and nervous system, and communicates with the rest of the computer and the surrounding world through a variety of "peripherals." Information travels through the computer on "buses," which are the computer's information highways or "nerves," in the form of "bits." Bits are aggregated into meaningful information in exactly the same way that dots and dashes are used in Morse code. Bits are the building blocks for both the instructions, or programs, and the data, or files, with which the computer works.

Today's CPU is a remarkable piece of engineering, totally comparable in scope and scale to our great bridges and buildings but so ubiquitous and hidden that most of us are unaware of its miniature magnificence. Chip designers essentially create what can be thought of as a city, complete with transportation, utilities, housing, and a government, every time they create a new CPU. With each new generation of chips, the "cities" grow substantially, yet their size remains miniaturized.

For the purposes of this text, the CPU can be treated as a black box into which flow two highways: one for data and the other for instructions. Inside that black box, the CPU (Fig. 5-1) uses the instructions to determine what to do with data—for example, how to create this sentence from interaction with the computer's keyboard. The CPU's internal clock is like a metronome, pacing the speed with which the instructions are executed.

The speed with which a computer processes information is critically important, particularly when used in the clinical setting. Clinicians expect an "immediate" response to every interaction with the computer, keyboard, or instrumentation. Most people think that the clock speed of the CPU, which is measured in megahertz (MHz) and gigahertz (GHz), or millions and billions of instructions per second, determines the performance speed of the unit. In reality, the performance of a CPU is a function of several factors that should be familiar to the anesthesia provider when an operating room analogy is used. Let us first compare the clock speed of the computer to surgical speed, with a fast clock comparable to a fast surgeon and vice versa. Second, similar to operating rooms, CPUs have what are called caches, which are holding areas for data and instructions, quite comparable to preoperative holding areas. Information is moved around in the CPU on buses, which can be likened to the number of operating rooms. In other words, it is possible to have a CPU that is limited because it has a slow or small cache, in the same way that operating room turnover is limited by the lack of preoperative preparation beds or too few operating rooms for the desired caseload.

The speed of a processor is a function of the width of its internal buses, clock speed, the size and speed of internal caches, and the effectiveness with which it anticipates the future. Although this last concept may seem obscure, an operating room analogy would be an algorithm that predicts a procedure's length based on previous operations of the same type by the same surgeon. Without going into detail, modern processors use techniques termed *speculation, prediction,* and *explicit parallelism* to maximize efficiency of the CPU.

True general-purpose computers are distinct from their predecessor calculating machines in that, regardless of whether they are relatively slow and small, as in dedicated devices such as smart phones, or highly streamlined and fast, as in supercomputers, they can perform the same tasks given enough sufficient time. This definition was actually formalized by Alan Turing, who is one of the fathers of computing.

Each type of CPU has its own instruction set, which is essentially its language. Families of CPUs, such as Intel's processors, tend to use one common language, albeit with several dialects, depending on the specific chip. Other CPU families use a very different language. A complex instruction–set computer has a much more lush vocabulary than a reduced instruction–set computer, but the latter may have certain efficiencies relative to the former. It is the fact that both types of computer architecture can run exactly the same program (i.e., any windowed operating system) that makes them general-purpose computers.

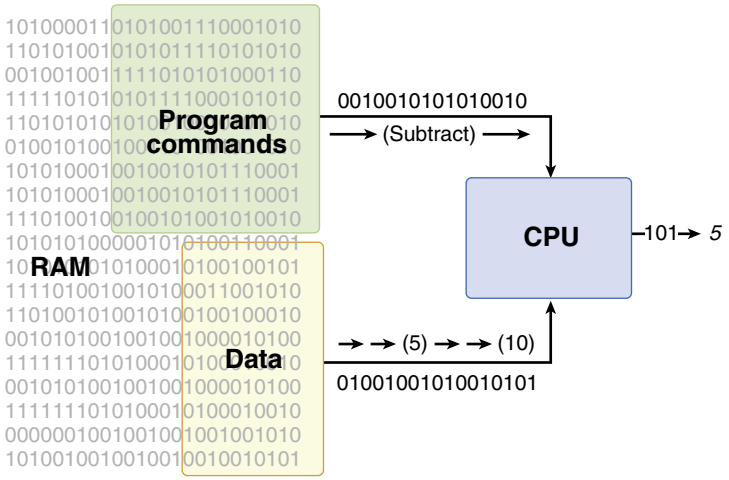

Figure 5-1. Programs and data are stored side by side in memory in the form of single data bits. The program tells the central processing unit (*CPU*) what to do with the data. *RAM,* Random-access memory.

MEMORY

Memory is the method by which the computer stores information and allows the user to retrieve the data needed to perform a task or complete an interaction. Computers have a variety of different kinds of memory, ranging from very small, very fast memory in the CPU to much slower, typically much larger memory storage sites that may be fixed (hard disk) or removable (compact disk, flash drive).

For clinical purposes, we would like to have an infinite amount of extremely fast memory immediately available to the CPU, just as we would like to have all of the operating room patients for a given day waiting in the holding area ready to roll into the operating room as soon as the previous case is completed. Unfortunately, this would be infinitely too costly and probably would never completely achieve the desired goals. The issue of ready data availability is particularly important now—as opposed to a decade ago—because improvements in central processing speed have outpaced gains in memory speed such that the CPU can sit idle for extended periods while it waits for a desired chunk of data from memory.

Computer designers have come up with an approach that ensures a high likelihood that the desired data can be easily retrieved. This necessitates the storage of redundant copies of the same data in multiple locations at the same time. For example, the sentence I am currently editing in a document might be stored in very fast memory next to the CPU, whereas a version of the complete document, including an older copy of the same sentence, could be stored in slower, larger capacity memory (Fig. 5-2). At the conclusion of an editing session, the two versions are reconciled and the newer sentence is inserted into the document.

The very fast memory adjacent to the CPU is referred to as cache memory, and it comes in different sizes and speeds. Cache memory is analogous to the preoperative and postoperative holding areas in an operating suite in that both represent rapidly accessible buffer space. Modern computer architectures have primary and secondary caches that can either be built into the CPU chip or be situated adjacent to it on the motherboard. Cache memory is typically implemented in static random-access memory (SRAM), whereas the larger and slower "main memory" consists of dynamic random-access memory (DRAM) modules. RAM has several characteristics, including the fact that it can be read or written (in contrast with read-only memory), it disappears when the electricity is turned off, and it is much faster than the memory on a disk drive.

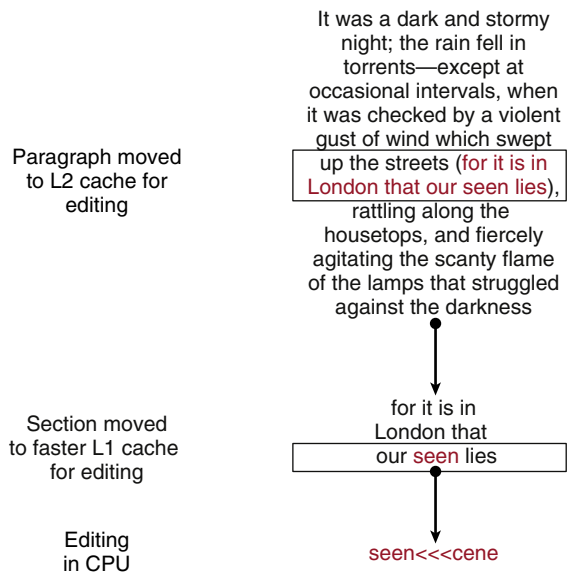

Figure 5-2. Processing of text editing using several "memory" caches in which duplicate copies of the same text may be kept nearby for ready access. *CPU,* Central processing unit.

To understand the impact of the mismatch in memory access times and CPU speed, consider the following. Today's fastest hard disks have access times measuring about 10 msec (to get a random chunk of information). If a 200-mHz CPU had to wait for 10 msec between each action requiring new data from a hard disk, it would sit idle for 2 *million* clock cycles between each clock cycle used for actual work. Furthermore, it takes 10 times longer for the computer to get data from a compact disk or digital video disk than it does for data from a hard disk.

COMMUNICATIONS

The many functionally independent parts of a computer need to communicate seamlessly and rapidly. The keyboard and mouse have to be able to signal their actions, the monitor must be refreshed continuously, and the memory stores have to be read and written correctly. The CPU orchestrates all of this by using various system *buses* as communication and data pathways. Some of the buses are dedicated to specific tasks on newer computers, such as communication with the video processor over a dedicated video bus, and others are general-purpose buses.

Buses are analogous to highways traveling between locations in the computer (Fig. 5-3). In most computers, the buses vary in width, with the main bus typically being the widest and other buses narrower and therefore of lower capacity. Data (bits) travel along a bus in parallel, like a rank of soldiers, and at regular intervals determined by the clock speed of the computer. Older computers had main buses 4 or 8 bits wide, whereas newer Pentium-class computers use buses as wide as 64 or 128 bits. Many current-generation computers actually have multicore processors, in which multiple CPUs collaborate, operating on complex problems in parallel.

Input-output buses link peripheral devices such as the mouse, keyboard, removable disk drives, and game controllers to the rest of the computer. These buses have become faster and increasingly standardized. The universal serial bus (USB) is a widely accepted standard, as is Apple's proprietary FireWire bus. These buses allow "on-the-fly" attachment and removal of peripherals by a standardized plug, and a user can expect that a device plugged into one of these ports will identify itself to the operating system and function without the need for specific configuration. This is a distinct improvement over the previous paradigm, in which a user typically needed to open the housing of the computer to attach a new peripheral and then configure a specific software driver to permit communication between the device and the computer.

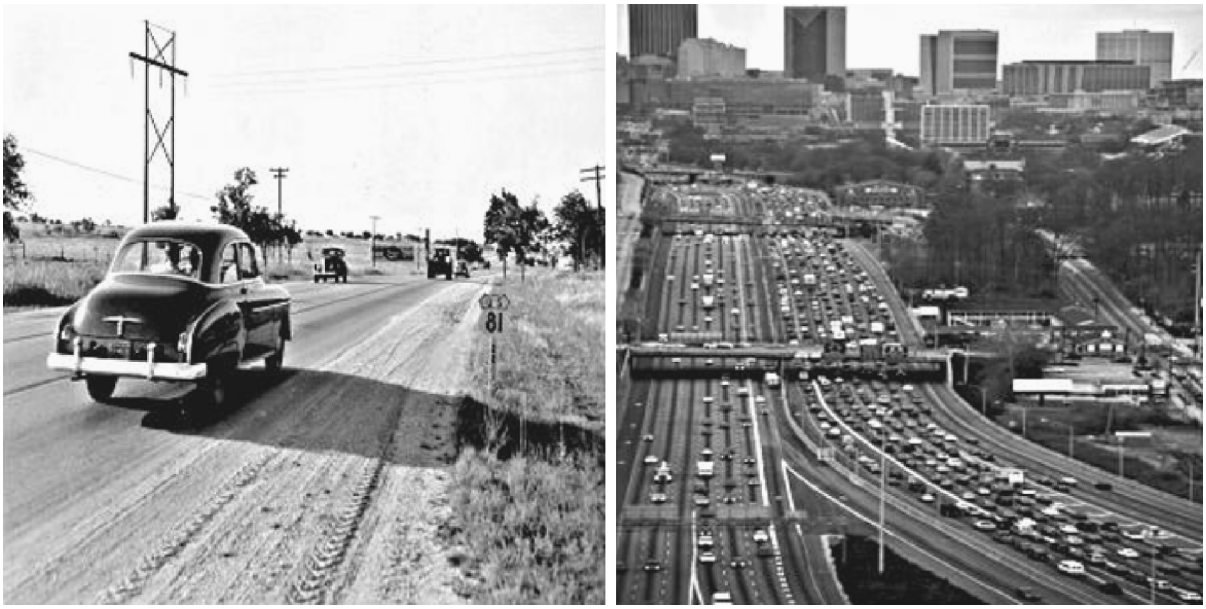

Figure 5-3. Buses are like highways, where the number of available "lanes" relates to bus capacity.

In addition to their local computing function, modern personal computers have become our conduits to networks and must therefore act as terminal points on the Internet. As with houses or phones, each computer must have an individual identifier (address, phone number) to receive communications uniquely intended for it. Examples of these kinds of specific addresses are the Internet protocol (IP) address and the media access control (MAC) address. The IP address is temporarily or permanently assigned to a device on the Internet (typically a computer) to uniquely identify it among all of the other devices on the Internet. The MAC address is used to specifically identify the network interface card for the computers that assign IP addresses.

The computer must also have the right kind of hardware to receive and interpret Internet-based communications. Wired and wireless network interface cards are built into all new computers and have largely replaced modems as the hardware typically used for network communications. Whereas a modem communicates over existing phone lines also used for voice communication, network cards communicate over channels specifically intended for computer-to-computer communications and are almost invariably faster than modems.

Although we commonly think of the Internet as being one big network, it is instructive to understand a little bit about the history of computer networking. In the beginning there were two independent types of networks: the office networks and the progenitor Internet. The first office network was designed at the Palo Alto Research Center, which is the Xerox research laboratory where some of the major computer innovations were developed. That office network was called Ethernet and was designed as part of the "office of the future," where word-processing devices and printers were cabled together. Separately, the ARPAnet was the Defense Advanced Research Project Agency's creation and linked mainframe computers at major universities. Over time, the two networks grew toward one another almost organically, and today we have what seems to be a seamless network that links computers all over—and above—the world.

Networking technology has evolved almost as rapidly as computer technology. As with buses in a computer, the networks that serve the world can be likened to highways. Backbone networks (Fig. 5-4) are strung across the world and have tremendous capacity, like interstate highways. Lower-capacity systems feed into the backbones, and traffic is directed by router computers. Before transmission, to facilitate traffic management, messages are cut into discrete packets, which travel autonomously to their destination and are there reassembled. Internet packets may travel over hard-wired, optical, or wireless networks en route to their destination.

COMPUTER SOFTWARE

OPERATING SYSTEM AND PROGRAMMING

The operating system (OS) is the "government" of the computer. As with a municipal government, the OS is responsible for coordinating the actions of disparate components of a computer, including its hardware and various software programs, to ensure the computer runs smoothly. Specifically, it controls the CPU, memory, interface devices, and all the programs running on the machine at any given time. The OS also needs to provide a consistent set of rules and regulations that new programs must adhere to if they are to participate.

Although most of us think of Apple and Windows synonymously with OSs, other OSs deserve mention. Linux is an open-source, meaning nonproprietary, OS for personal computers that is distributed by several vendors and is continuously maintained by a huge community of passionate programmer devotees who contribute updates and new programs. In addition, every cell phone, tablet, and smart device has its own OS that performs exactly the same role as a personal computer OS.

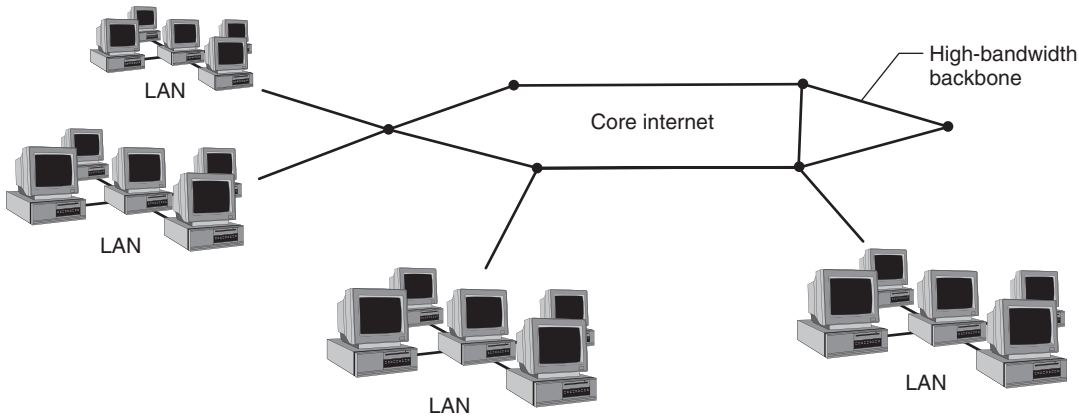

Figure 5-4. Lower-speed networks are attached to high-speed "core" networks that span the globe. *LAN,* Local area network.

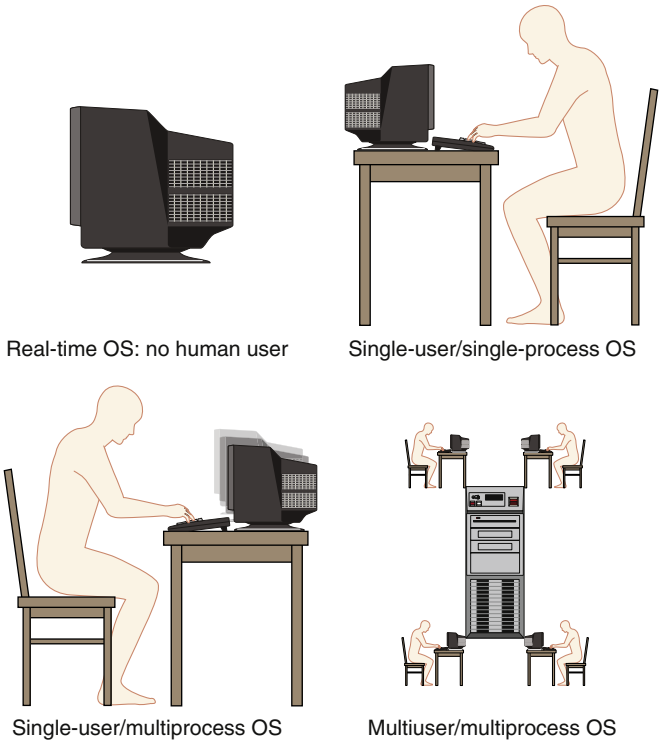

Figure 5-5. Several operating system (*OS*) configurations.

OSs can be categorized into four broad categories (Fig. 5-5). A real-time OS is typically used to run a specific piece of machinery, such as a scientific instrument, and is dedicated solely to that task. A single-user, single-task OS is like that found on a cell phone, where a single user does one job at a time, such as dialing, browsing, or e-mail. Most of today's laptop, desktop, and tablet computers are equipped with single-user, multitasking OSs, whereby a single user can run several "jobs" simultaneously, such as word processing, e-mail, and a browser. Finally, multiuser, multitasking OSs are usually found on mainframe computers and run many jobs for many users concurrently.

All OSs have a similar core set of job tasks—CPU management, memory management, storage management, device management, application interfacing, and user interfacing. Without getting into detail beyond the scope of this chapter, the OS breaks a given software job down into manageable chunks and orders them for sequential assignment to the CPU. The OS also coordinates the flow of data among the various internal memory stores, determines where that data will be stored for the long term, and keeps track of it from session to session. The OS provides a consistent interface for applications so that the third-party program purchased at a store will work properly on a given OS.

Finally, and of most importance for many of us, the OS manages its interface to you, the user. Typically, today that takes the form of a graphic user interface (GUI).

E-MAIL

E-mail communication over the Internet antedated the browser-based World Wide Web by decades. In fact, the earliest e-mail was designed for communication among multiple users in a "time-sharing," multiuser environment on a mainframe computer. E-mail was used for informal and academic communications among the largely university-based user community. Without going into great detail, an e-mail communication protocol was designed so that each message included information about the sender, the addressee, and the body of the message. The protocol is called the Simple Mail Transfer Protocol (SMTP), and the process of message transmission proceeds as follows. The sender composes a message using a software-based messaging program (such as Outlook, Gmail). The sender then applies the recipient's address and dispatches the message. The message travels through a series of mailboxes, much as a regular letter does, and eventually arrives at the addressee's mailbox, where it sits awaiting "pickup."

Although e-mail has had dramatic and largely positive implications for the connectedness of organizations and people, it also has created previously unimagined problems, including spam, privacy issues, and the need for new forms of etiquette.

The term *spam* is said to have come from a Monty Python skit. Spam is such a ubiquitous problem that most e-mail crossing the Internet is spam at this point. Spam is essentially bulk e-mail and was never envisioned by the creators of SMTP. Spam is a generic problem with e-mail communications, but the issues of privacy and etiquette are of much greater relevance for medically oriented e-mail.

The American Medical Informatics Association has taken a lead role in defining the issues associated with e-mail in the medical setting. The organization defined patient–provider e-mail as "computer based communication between clinicians and patients within a contractual relationship in which the health care provider has taken on an explicit measure of responsibility for the client's care."[1] A parallel set of issues relates to medically oriented communications between providers.[2-5] Another category of medically oriented communications is that in which a provider offers medical advice in the absence of a "contractual relationship." An egregious example of the latter is the prescription of erectile dysfunction remedies by physicians who review a web-based form submitted by the "patient" and then prescribe a treatment for a fee.

In theory, e-mail is a perfect way to communicate with patients.[6-9] Because of its asynchronous nature, it allows two parties who may not be available at the same time to communicate efficiently (Fig. 5-6), and it represents the middle road between two other types of asynchronous communication: voice mail and traditional mail. E-mail also can be tailored to brief exchanges, more structured communications, and information broadcasts (such as announcements). Thus, a patient could send interval updates (blood pressure, blood sugar) to the physician. Alternatively, the physician could follow up on an office visit by providing educational material about a newly diagnosed condition or planned procedure.

Even though e-mail has many advantages in medicine, a variety of risks are associated with its use.[10] Some of the problems are generic to any e-mail exchange. Specifically, it is a more informal and often unfiltered form of communication than a letter and often has the immediacy of a conversation but lacks its visual and verbal cues. Emoticons (such as the use of ":)" to indicate that a comment was sent with a "smile") evolved as a remedy for this problem.

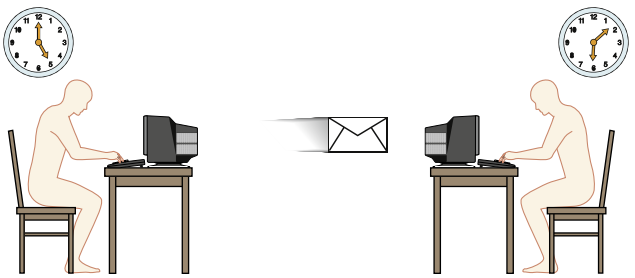

Figure 5-6. E-mail is an effective form of communication between a patient and a physician because it does not require both parties to be present at the same time.

E-mail is also permanent in the sense that copies of it remain in mailbox backups even after deletion from local files (Fig. 5-7). Every e-mail should therefore be thought of as discoverable from both a liability and recoverability standpoint. Before dispatching, e-mail should be scrutinized for information or content that might be regretted at a later date.

Perhaps of greatest significance for communication between patients and health care providers is the lack of security of personal health information. E-mail is vulnerable to inadvertent or malicious breaches in privacy or disclosure through improper handling of data at any point along the "chain of custody" between the sender and the recipient. Alternatively, a hacker could potentially acquire sensitive medical information from unsecured e-mail or possibly even alter medical advice and test results in an e-mail from physician to patient.

The HIPAA legislation mandates secure electronic communication in correspondence regarding patient care. Three prerequisites for secure communication include authentication (that the message sender and recipient are who they say they are), encryption (that the message arrived unread and has not been tampered with), and time-date stamping (that the message was sent at a verifiable time and date), although these techniques are not yet widely deployed in the medical community.

It is beyond the scope of this chapter to go into great detail about the methods used to authenticate, encrypt, and time-date stamp e-mail. However, these elements can be ensured by using mathematically linked pairs of numbers (keys), in which an individual's public key is published and freely available through a central registry (like a phone book) whereas a linked private key is kept secret (Fig. 5-8). Public key encryption combined with traditional encryption is used to transmit messages securely across public networks, ensure that messages can be read only by a specific individual, and digitally sign the message.

Although the use of e-mail for medical patient–provider and provider–provider communications is growing, it is not yet universally adopted for several reasons, including physician distrust of the medium, unfamiliarity with software, lack of standards, and lack of clear methods for reimbursement for time spent in e-mail communications. Nevertheless, several professional societies have published

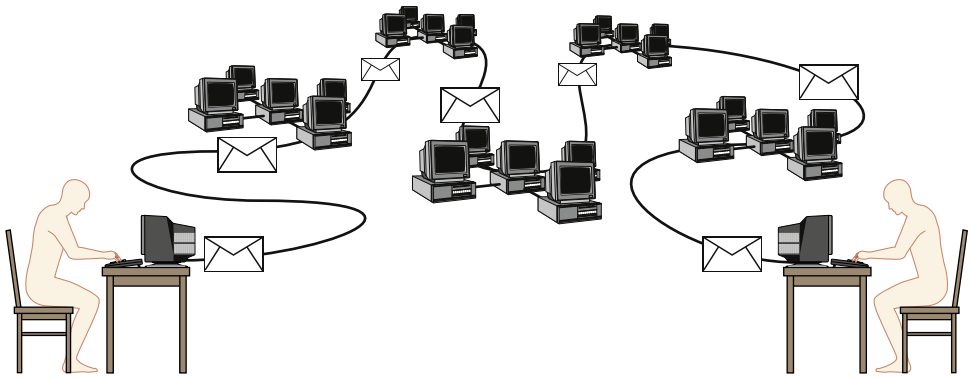

Figure 5-7. E-mail leaves copies of itself as it travels across the Internet.

consensus recommendations about the management of e-mail in medical practice. Common consensus-based elements are enumerated in Box 5-1. Even when these security measures are adopted, e-mail is probably not the best way to communicate with patients. Most importantly, if e-mail is used, the e-mail system must be encrypted to minimize the risk for inappropriate access by others. It is difficult for an individual provider to be sure a patient's e-mail is encrypted. In addition, although the information in e-mail accounts is "saved," it does not become a part of the permanent medical record. As a result, communication through e-mail creates risks related to documentation of the communication, assurance that information has been received, and, to the extent needed, confirmation that appropriate follow-up actions have been taken. Most electronic health records (EHRs) now allow the option of communicating directly through the EHR—providing documentation of the communication, allowing access to laboratory and other test results, and fostering follow-up communication between patients and their providers. This type of secure communication can be very effective in facilitating patient care and follow-up, although electronic communication may not always adequately address high-risk patient needs.[11]

BROWSER

Many people think of the Internet and the World Wide Web as one and the same. The Internet is the worldwide network, whereas the Web is one of its applications characterized by the browsers with which its users interact. The browser was invented in 1990 by Tim Berners-Lee at the European Organization for Nuclear Research, commonly known as CERN. Marc Andreessen wrote the Mosaic browser and subsequently the Netscape browser, which, like all subsequent browsers, has a GUI and uses a specific "language" called hypertext markup language (HTML). Microsoft eventually developed its own version of the browser, Internet Explorer, after recognizing the critical value of the Web.

The browser is a computer program, just like a word-processing or e-mail program, with a GUI. It can be thought of as a radio or television insofar as it serves as an interface to media that do not originate within it. The address of a webpage is analogous to the channel or frequency of a television or radio, and the browser "tunes in" to that address. In actuality, the local browser on your computer communicates with a server somewhere on the Internet (at the address specified in the address line) and uses the communication protocol HTML as its language. The webpage displayed on your local browser was first constructed on the server and then sent to you.

The original HTML was extremely spare and had significant limitations, such as the construction of only very simple webpages. A variety of new "languages" and protocols have subsequently come into existence, such as Java, JavaScript, ActiveX, Flash, and others, that allow enhancements to HTML. New browsers support interactivity, security, display of audio and video content, and other functions. Even though the scope of topics that could be covered in discussing browser communications far exceeds that of this chapter, certain issues deserve mention.

Cookies is the term used for short lines of text that an Internet server (such as Google or Yahoo) can store on a user's hard disk. Cookies allow a website to store information about the client computers with which it interacts. Cookies allow the server to keep track, for example, of the items that you have put in your virtual shopping cart as you shop (Fig. 5-9). Although cookies are not inherently risky, other risks exist to the use of a browser.

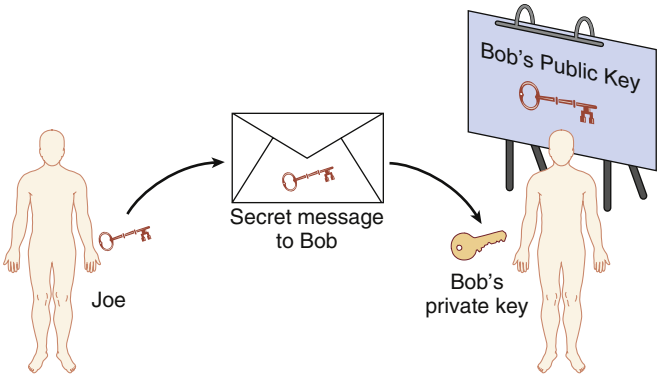

Figure 5-8. Public and private key encryption in which Joe sends a message intended only for Bob by using Bob's public key—the message remains encrypted until Bob decrypts it with his private key.

BOX 5-1 ***Suggested Rules for E-mail Correspondence in a Medical Setting***

All patient–provider e-mail should be encrypted.
Correspondents should be authenticated (guarantee you are who you say you are).
Patient confidentiality should be protected.
Unauthorized access to e-mail (electronic or paper) should be prevented.
The patient should provide informed consent regarding the scope and nature of electronic communications.
Electronic communications should (ideally) occur in the context of a preexisting physician–patient relationship.
Online communications are to be considered a part of the patient's medical record and should be included with the same.

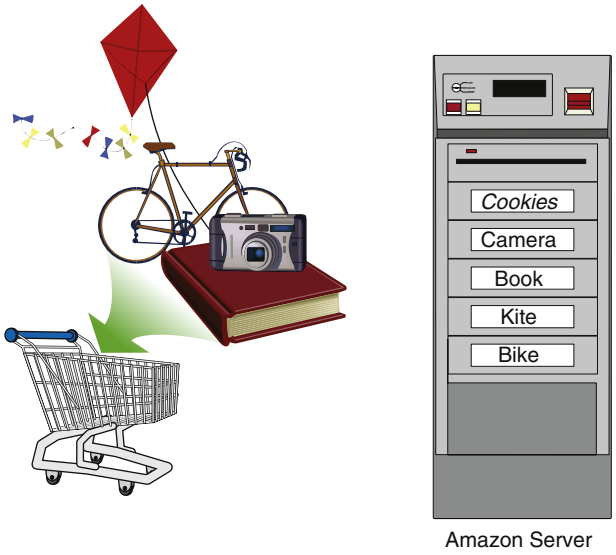

Figure 5-9. Cookies are used by a website, for example, to keep track of the items that a user has put in the "shopping cart."

Like a television, the browser acts like a window on the Internet, and for a long time it was safe to think of that window as being made of one-way glass. Unfortunately, many of the new innovations that allow us to function interactively with websites also have built-in flaws that permit malicious programmers to gain access to your computer or to track movements from website to website. Companies such as Google and Facebook can now develop highly detailed profiles of individuals and populations from their interactions with the network. The best way to protect a computer involves timely application of all updates and patches issued by software manufacturers and the use of antivirus software with up-to-date definitions. The best way to preserve privacy is to minimize the amount of personal information stored on the Internet and use independent passwords for each site that are not easy to hack.

COMPUTERS AND COMPUTING IN MEDICINE

HOSPITAL INFORMATION SYSTEMS

Modern hospital information systems invariably fall somewhere on the spectrum between a monolithic single comprehensive system design, in which a single vendor provides all of the components of the system, and a "best-in-breed" model consisting of multiple vendor-specific systems interacting through interfaces or, more typically, an interface "engine."[12-15] The monolithic system has the advantage of smooth interoperability, but some of the component elements may be substantially inferior to those offered by best-in-breed vendors.

Component elements of a hospital information system include administrative, clinical, documentation, billing, and business systems.[16-18] Medical information technology is increasingly subject to governmental regulation, security concerns, and standards. Standards are essential for interoperability among systems and to ensure that systems use uniform terminology.[19]

Health Level 7 (HL7) is an accepted set of rules and protocols for communication among medical devices. Clinical Context Management Specification (also known as CCOW) is a method to enable end users to seamlessly view results from disparate "back-end" clinical systems as though they were integrated. Some of the common medical terminologies or vocabularies include the Systematized Nomenclature of Medicine (SNOMED) and the International Classification of Diseases (the ICD family of classifications).[20] Modern complicated medical information systems often weave a host of disparate systems at geographically dispersed locations into an extended "intranet." A core hospital, for example, may share an intranet with a geographically remote outpatient practice, or several hospitals in the same health system may coexist within the same intranet. Some of the elements may be physically connected (Fig. 5-10) along a network "backbone," whereas others may use virtual private network (VPN) connections that allow the user to appear to be part of the network while at a remote location.[17]

ELECTRONIC HEALTH RECORD

The electronic record (see also Chapter 4) has been described variously as a computerized medical record, computerized patient record, electronic medical record, and EHR.[21-24] Various settings clearly require radically different EHRs, and EHRs need to interface seamlessly.[25,26]

Historically, patient records have been controlled or "owned" by hospitals and doctor's practices, and their electronic manifestation in the form of the EHR creates a series of issues pertaining to privacy, security, and economic interests of the involved parties. For example, patients have an interest in the privacy and security of the information contained in their records and claim some ownership and control over what is recorded in the medical record. In contrast, doctors have traditionally "owned" their patients' records and transferred patient records to another provider in the course of the sale of a medical practice (albeit with appropriate notice to the involved patients). Most importantly, hospitals and health systems

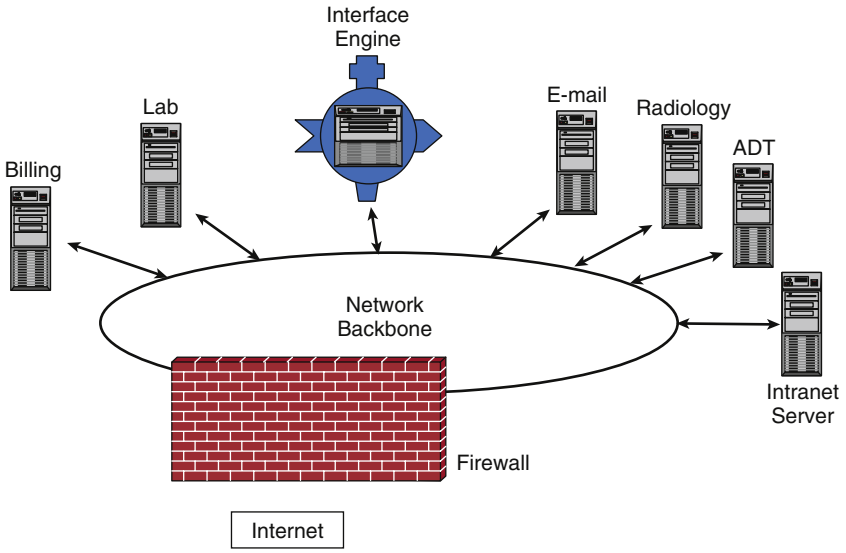

Figure 5-10. Modern health care information systems consist of elements attached to a backbone. *ADT,* Admission, discharge, and transfer; *Lab,* laboratory.

have historically exercised significant controls over the records and access rights to medical records. The transition to the electronic record, interoperability between health systems and physician practices, and improved communication with patients has significantly changed the concept of medical record ownership. The Centers for Medicare & Medicaid Services (CMS) meaningful use regulations have also focused attention on the issue of ownership of health information and are designed to enhance the patient's access to discharge summaries. The patient has the right to challenge information in the medical record, and the health care provider is obligated to respond to the request, either by modifying incomplete or inaccurate information or by including the patient's statement of disagreement in the record. After each visit the provider is required to give each patient access to the discharge summary, including information about the evaluation, care provided, and reconciliation of all medications. This increased access puts greater responsibility on the patient to "manage" their health information, ensure its accuracy, and exert control on accessibility by others.

The current evolution of software-based EHRs is recapitulating the evolution of hospital information systems as it occurred over the 1980s and 1990s—in both cases, specialized individual systems have contended with integrated packages of modules. Best-in-breed commercial systems or "home-grown" site-specific systems are evolving, such as automated anesthesia EHRs[27,28] and intensive care unit (ICU) EHRs (Fig. 5-11). At the same time, large vendors have developed generic inpatient and outpatient EHRs. Health systems face the same choices about whether to go with monolithic or best-in-breed EHR software that they have with clinical systems.

The Institute of Medicine issued a report characterizing key aspects of an EHR, including an integrated, longitudinal view of patient data; concurrent access to the body of knowledge pertaining both to the patient's condition and to the rules and regulations associated with reimbursement in this age of managed care; order and data entry; and decision support tools that provide current knowledge about diseases, treatments, drug interactions, and risk profiles.

Ideally, the electronic record provides tools for communication among providers. The EHR also should provide immediate access to population-level information for administrative and research applications.

The U.S. Veterans Health Administration is an example of a very successful EHR implementation; however, in most hospitals, orders, notes, and reports are still maintained on paper. Additionally, very few small-practice environments have undergone any degree of computerization, because the barriers to computerization are formidable.

Technical obstacles to computerization of the medical record are relatively obvious, but organizational, financial, and policy obstacles also exist.[29-31] Adoption of an EHR implies a fundamental reorganization of the way medicine is practiced in a clinical environment.[32,33] For example, many older physicians have had little occasion to use a computer and are likely to be slowed in their performance of formerly routine tasks, which is a major barrier at a time when demands for efficiency are increasing substantially (Fig. 5-12).

Despite the barriers, governmental and private stakeholders are developing incentives, bonuses, and low-cost capital to encourage use of the EHR. Providers may eventually mandate EHR systems as a condition of participation in certain U.S. insurance plans, such as Medicare. *American Recovery and Reinvestment Act* of 2009 provided 19 billion dollars for health information technology (HIT), and specifically supported a plan of incentives for the adoption of certified EHRs by hospitals and providers. Specifically, to receive an EHR incentive payment, the hospital or provider must show that they are "meaningfully using" EHRs by meeting thresholds for discrete objectives as defined by the CMS. The meaningful use EHR incentive program has been designed with progressively more rigorous stages. Stage 1 concluded in 2012 with 50% of providers and 82% of hospitals adopting EHRs—a substantial improvement over the preceding era. Stages 2 and 3 are scheduled for 2014 and 2016, respectively. These stages put increasing emphasis on the use of the information included in the integrated health record to improve patient quality and safety.

The EHR was originally designed to digitize the information in the medical record and improve access to it. In addition the EHR was meant to improve patient care by reducing redundancies and errors in management that resulted from a lack of coordination of care. Although these values are significant, the transition to a comprehensive health record that includes documentation of ambulatory and inpatient care provides other important enhancements to both individual patient care and the care of patient populations. The shift to electronic records has led to follow-on opportunities, such as enhanced patient care delivery, improved efficiency,

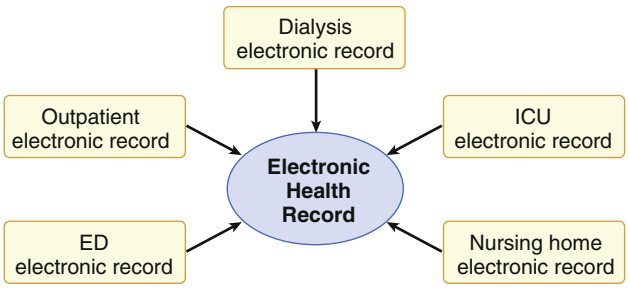

Figure 5-11. Vendors have developed specialty electronic health records. *ED,* Emergency department; *ICU,* intensive care unit.

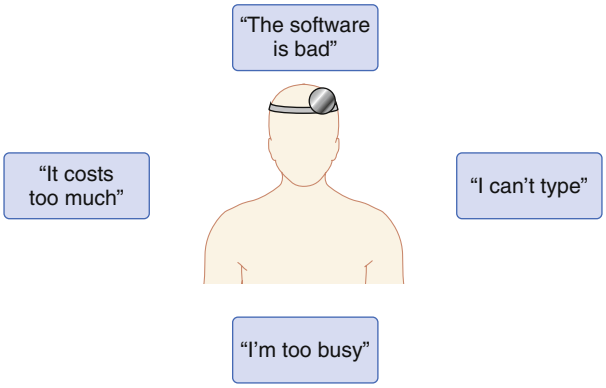

Figure 5-12. Various barriers to adoption of electronic health records.

reduced redundancy in the processing of ancillary support services (e.g., laboratory, radiology, housekeeping, transport), and automation of many administrative functions (e.g., billing and reimbursement). The EHR also has been used as a vehicle to improve communication among providers and patients and foster education, provider regulation, clinical and translational research, public health, and health policy support (Fig. 5-13).

The core functions of EHRs fall into eight general categories: (1) Management of patient health information and data; (2) presentation of results acquired from patient testing; (3) computerized order entry (CPOE); (4) decision support, whereby automatically generated reminders and prompts are used to guide clinicians and support evidence-based practice; (5) communication tools for provider to provider or provider to patient messaging that automatically generate patient support materials such as pamphlets that describe a disease or give discharge directions; (6) integrated administrative processes, including scheduling systems, billing management, and insurance validation; and (7) and (8) internal and external reporting requirements are simplified by using the systems built into the EHRs.

Although stand-alone anesthesia information management systems (AIMS) have been in existence for well over a decade, these products have historically functioned in isolation—that is, unintegrated with electronic inpatient or outpatient records. However, with the increased adoption of both inpatient and outpatient EHRs, spurred by federal incentives, desire is growing in the anesthesia community to deploy AIMS that can interface with or be integrated with clinical and billing software (e.g., KLAS report).

The selection of an AIMS involves trade-offs between a best-of-breed versus an enterprise model and the accompanying differences in functionality and integration, also taking into consideration the needs of the anesthesia department versus those of the hospital. Some of the factors that must be considered include the ease of access to preoperative information, which is often entered electronically into another system or module, the ease of intraoperative use, and the integration with devices in the operating room and with other systems such as the laboratory, and the facility with which information can be transferred to the receiving team at the conclusion of the procedure. As electronic records have matured, the needs of the hospital and the anesthesia community relative to interoperability (KLAS) and quality of care are increasingly convergent.[33a] Hospitals and practitioners are increasingly at risk financially and in the eyes of the public and must have access to published quality data for measures such as those targeted by the Surgical Care Improvement Project (SCIP), a national consortium of quality organizations. Anesthesiologists play a critical role in compliance with these measures, and AIMS are a tool by which compliance can be recorded and tracked.

AIMS are increasingly embedded into the more general hospital EHR, permitting information transparency as patients move through an operative encounter. As with the ICU, which is a similarly high-tech, data-rich environment, automated data capture from physiologic monitors and devices such as infusion pumps is highly desirable—freeing the hands and time of providers from transcription, but data entering the record requires validation to prevent the inclusion of inaccurate information in the chart. Inaccurate information may be recorded or transmitted during the course of normal care, such as artifactually elevated blood pressure during the process of flushing a transducer or moving a patient from one position to another. Most ICU systems mandate validation of vital signs, for instance, before they become official entries, whereas most AIMS allow the clinician to edit (albeit with an audit trail) individual data elements but do not require validation.

The concept of a universal medical record also deserves specific attention. It has always been desirable for providers in one location to have access to data from a medical record generated at another location. Although many potential models exist of a universal medical record, such as a record owned and kept by the patient on a piece of hardware such as a flash drive, this approach has a variety of problems; patients may not be able to or wish to maintain such a record, it is unclear how information would be securely ported from a provider to the patient's medical repository, and hardware devices such as a USB are susceptible to loss. Google and Microsoft both attempted in recent years to provide a personal health record controlled by the patient, but neither initiative has met with widespread public adoption. A more practical approach is currently being deployed by large vendors, which now offer patient medical "vaults" that are maintained online and over which the patient has read and write and access control.

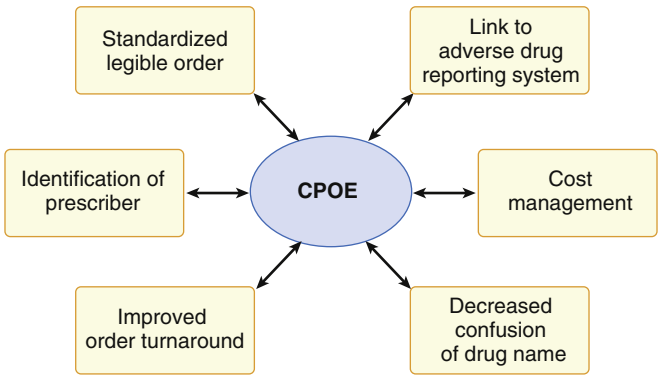

Figure 5-13. Various benefits of a computerized order entry (CPOE).

COMPUTERIZED ORDER ENTRY

CPOE systems have gained prevalence in the provision of care at many hospitals, spurred in part by the meaningful use incentive program of the CMS, yet 50% of American hospitals still lack one. Prescribing errors are the most common source of adverse drug events, and CPOEs—with or without decision support tools—are widely viewed as being integral to a reduction in errors and improved formulary control. CPOEs came into the spotlight after the Institute of Medicine's 1999 report "To Err Is Human: Building a Safer Health System," in which 44,000 to 98,000 deaths per year were attributable to medical errors; however, although CPOE has great

potential, poorly designed or deployed systems will either not be adopted or potentially cause errors.

Broadly, the term CPOE is used to refer to computer-based ordering systems designed to automate the ordering process, be it for drugs or for requesting pathologic or radiologic tests. Benefits include the output of standardized, complete, legible orders consistent with the hospital's formulary and automatically sent to the pharmacy (see Fig. 5-13). CPOE is also almost invariably associated with a decision support system (DSS), which will be discussed in more detail in the next section.

Successful deployment of CPOE will occur only when the system is deployed as part of a fundamental redesign in the delivery of patient care. The organizational aspects of CPOE deployment have been described by a recent consensus panel from the American Medical Informatics Association in which the following nine elements of successful systems were highlighted:

1. Development of a clear understanding of the institution-specific drivers for implementation of a CPOE system, be they regulatory, regional competition for patients, or internal
2. Sustained internal leadership-level support during implementation of the CPOE system
3. A CPOE system adequately funded in all respects, including training of personnel
4. Prospective understanding of the way in which CPOE will affect workflow at all sites in the organization (Fig. 5-14)
5. A positive cost-to-benefit ratio for each of the providers who use the system, ensured by the creation of time-savers such as order sets
6. Selection of an appropriate deployment strategy, whether it be an all-at-once or a staged approach
7. Attention paid to the technical details of CPOE implementation, such as the replacement of legacy systems
8. Comprehensive training and support
9. A plan designed for continuous quality improvement after implementation of the system

Medication safety is critical to safe patient care because medication errors are a key cause of adverse events; according to the Institute of Medicine, medication errors injure 1.5 million people and cost $3.5 billion each year. Computerized medication management systems have been designed to cover the entire medication process from prescription to administration, including the following discrete elements:

- Computerized provider order entry (CPOE)
- Electronic medication administration record (eMAR)
- Electronic prescription (ePrescribing)
- Integrated pharmacy administration systems (which may include pharmacy-based robotic medication dispensing and labeling)
- Electronic medication reconciliation at each point of patient transition from one environment or provider to another
- Bar code medication administration matching the right medication to the right patient at the right time

As with many of today's electronically based medical functions, a variety of vendors operate in the medication management space and providers are inevitably faced with issues relating to integration among systems, varying and changing formularies, and drug lexicons. Some vendors market end-to-end integration, whereas others specialize in one step of the process.

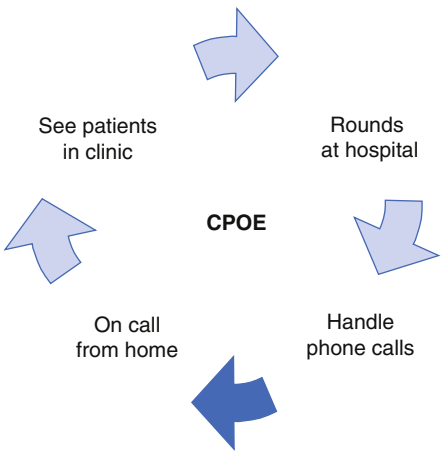

Figure 5-14. Integration of computerized order entry (CPOE) into the workflow of an organization.

DATA REGISTRIES

Electronic records, order entry systems, and automated device interfaces are several mechanisms by which the data associated with anesthesia care can be captured and subsequently used to populate data repositories. These data may then be stored in a local, vendor-specific data store (i.e., in an AIMS-specific database), ported to a hospital or system data "store" and integrated with other data sources, or extracted to a multiinstitutional registry such as the Multicenter Perioperative Outcomes Group (MPOG)* hosted at the University of Michigan. MPOG is an academic consortium "aggregating large volumes of observational inpatient electronic health record data, patient reported outcomes and long term administrative outcomes." Data repositories may be used to analyze and track individual patients, groups of patients, or pathologic conditions. Much as the availability of large, comprehensive data sets has transformed other industries by enabling, for example, sophisticated pattern recognition algorithms that can detect fraud, analyzing purchasing patterns, or projecting election outcomes, perioperative data registries have been used to evaluate perioperative practices.[34]

The Anesthesia Quality Institute created a nationwide system to collect data about adverse events relating to anesthesia, pain management, and perioperative care in 2011. The system is called the Anesthesia Incident Reporting System (AIRS) and represents a data registry designed to collect information about anaphylactic reactions, device malfunctions, medication side effects, unusual vascular or neurologic injuries, and complications relating to the use of EHRs in anesthesia settings. Data are submitted anonymously or confidentially over a secure, encrypted Internet link and used for educational purposes or for monitoring emerging trends in anesthesia patient safety

*Multicenter Perioperative Outcomes Group: <http://mpog.med.umich.edu/>

relating to new medications and techniques, data records, or patient risk factors.

DECISION SUPPORT SYSTEMS AND ARTIFICIAL INTELLIGENCE

Decision support tools integrated into the EHR and CPOE can provide immediate access to current medical knowledge, institutional best practices, billing compliance information, and administrative functions and can facilitate cost control. Although a wide range of architectures are used, DSSs fall somewhere on the spectrum between expert systems, in which rules developed by domain experts are used to drive decision support, and autonomous systems that have the ability to "learn" and make observations about large data sets. An example of the latter might be a system that automatically culls through a physician's orders to develop a profile of prescribing patterns.

A DSS can "act" in one of three ways. It may be a passive system that responds with information when asked. Alternatively, it may be semiactive and provide alerts or alarms only when certain conditions are met. Finally, a system may be active and autonomous and generate an order set or manage a medical process automatically, such as automated weaning of mechanical ventilation according to built-in rules.

Clinicians want certain functions from a DSS, such as access to national consensus guidelines when available, concurrent presentation of relevant patient information when ordering, intelligent alerts, reminders to engage in patient-specific activities (such as immunizations), and the ability to measure their performance versus that of peers in a way that results in continuous improvement in performance.

THE HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT AND DATA SECURITY

Enacted in 1996, the *Health Insurance Portability and Accountability Act* (HIPAA) was initially designed to protect workers from losing their health insurance (portability) during job transition and to protect the integrity, confidentiality, and availability of their medical information (accountability). HIPAA covers three critical aspects of automated health care information: privacy, universal coding formats, and security.[35-40]

The target of the privacy element is what is known as protected health information, and the bill ensures a patient's right to control the use of that information as it relates to health care, the business of health care, and research. HIPAA mandates the creation of universal code sets that cover, for example, the classification of diseases and describes both a national provider and national patient identification number. The many concerns about the latter have prevented its adoption to date. The security aspect of the legislation relates to the physical and electronic aspects of ensuring the protection of patient health information (Fig. 5-15).

The *Health Information Technology for Economic and Clinical Health Act* (HITECH) was enacted as part of the *American Recovery and Reinvestment Act* of 2009, and its final regulations represent "the most sweeping changes to the HIPAA Privacy and Security Rules since they were first implemented"[†] and went into effect in September of 2013. The rules extended the responsibility of physicians and other health care providers regarding patients' protected health information (PHI), expanded those responsibilities to cover parties that do business with providers (business associates) and thereby gain access to PHI, and enhance penalties for violations of these obligations.

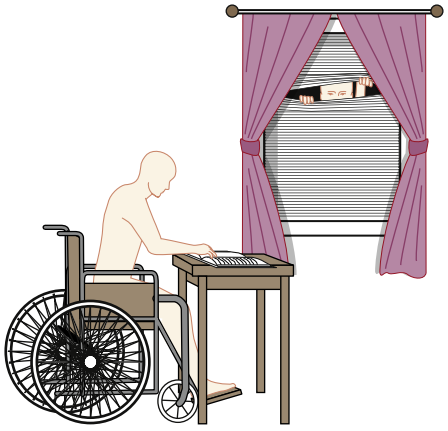

Figure 5-15. Security aspects of the Health Insurance Portability and Accountability Act legislation relate to the physical aspects protecting unauthorized access to protected health information.

TELEMEDICINE

Telemedicine and telehealth are the application of health care services across space, time, and social and cultural barriers. Telemedicine has been demonstrated in a variety of disciplines, including surgery, emergency medicine, cardiology, dermatology, ophthalmology, neurology, gastroenterology, rehabilitation, and critical care medicine.[27,41-52] However, although telemedicine has already had an enormous impact on the ability of patients to access medical information, a variety of barriers exist to widespread implementation of clinical care at a distance, including licensure, credentialing, malpractice, and reimbursement. Although advances in the use of telehealth are progressing at a rapid pace and the technologic improvements will create new applications, these issues, including credentialing of providers across state lines and determining how to compensate providers for telehealth, must be overcome.

Telemedicine holds great promise as a means of making medical care available to underserved areas, providing access to specialists at remote locations, and allowing patients to receive medical attention in their home when physical contact is not a critical element of an encounter. In addition, new technologies are currently under development, including teleimmersion and telepresence. Teleimmersion permits geographically dispersed people to collaborate in a shared virtual space, and telepresence refers to a system in which the human practitioner may

[†]See The Health Insurance Portability and Accountability Act (HIPAA) Omnibus Final Rule Summary <http://www.ama-assn.org/resources/doc/washington/hipaa-omnibus-final-rule-summary.pdf>

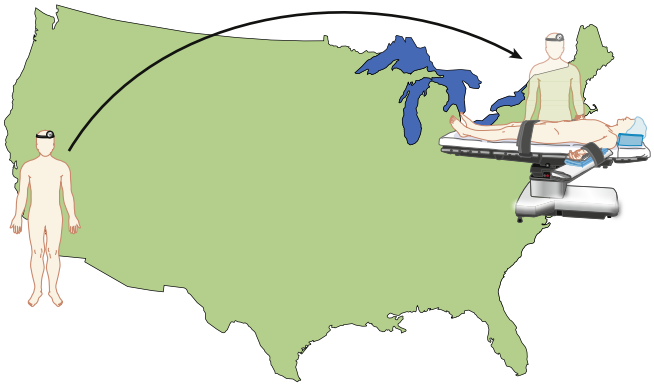

Figure 5-16. Telepresence relates to the ability to be virtually present at a patient's bedside.

have visual and mechanical actuators and sensors permitting them to "see," "feel," and "move" objects in a remote environment (Fig. 5-16).

Telesurgery demonstration projects have been done, for example, with both laparoscopic and robotic instruments to operate at a distance. Other demonstration projects are under way in various fields of medicine, and reimbursement agencies are beginning to develop methods of reimbursement for telemedicine-based activities. In addition, a few commercially available models for delivery of telemedicine exist, including remote radiographic interpretation, in some cases from appropriately credentialed radiologist interpretation from international locations, and critical care coverage from remote, virtual ICUs.

Telemedicine has specific application in the provision of anesthesia care as well. Anesthesiologists may participate in preoperative evaluation, anesthesia monitoring, and perioperative consultation via telemedical links, as well as in simulation and training. In sparsely populated areas, for example, anesthesiologists can evaluate remotely located patients to optimize preoperative preparation and limit the possibility of day-of-procedure cancellation when a patient has travelled a great distance to the hospital or surgery center. Many products have been developed to permit remote monitoring of physiologic data and audio and video links by which an anesthesia provider can remotely support a health care provider in the field, such as during a military or mass-casualty situation. Similarly, the same equipment and linkages can be used for remote consultation during a complicated procedure. Although remote preoperative evaluation is common, a variety of licensing, credentialing, professional liability, and billing barriers must be hurdled before remote provision of care becomes commonplace. Finally, sophisticated simulation suites have been developed that permit training students remotely.

Telemedicine will eventually change the way that medicine is practiced in many fundamental ways. It is equally certain that the speed of technologic change will outstrip that of regulatory, reimbursement, and legislative change.[53]

MOBILE

Another area in which health information technology is evolving rapidly has to do with the deployment of medical software on mobile devices such as cell phones and tablets or on small form-factor, Wi-Fi–enabled devices such as notebooks or netbooks.

Although the deployment of mobile technology is a critical enhancement to the workflow of providers, associated risks are the transmission of HIPAA-protected information over wireless networks and the security of such information once it arrives on the device. Although an extensive discussion of these issues is beyond the scope of this chapter, the benefits of mobile health care information technology clearly outweigh the risks, and ways to mitigate risks include encryption, password protection, and the use of techniques that allow interaction with protected data without storing it on a device.

New devices allowing remote monitoring of patients are in use or under evaluation. For example, remote telemetric transmission of pulse oximeter, blood pressure, glucose, and other data are now being used to manage patients after surgery or to help guide management of patients with chronic illnesses. Other devices are capable of determining that patients are taking medications as prescribed or following other clinical recommendations. The implications of advances in mobile technologies can be significant for any patient and for the anesthesia practitioner. The use of these technologies for managing patients in the perioperative period has not been extensively evaluated and remain largely untested. Smartphone applications such as Airstrip permit remote monitoring, event review, trend assessment, and alert delivery. These capabilities are not suited to primary provision of anesthesia care, but they can be used to support an anesthesia provider supervising care in multiple rooms or locations, by providing vital sign and event alerts. Continued advances in the use of these devices could have significant impact on perioperative care and the role of the anesthesiologist in managing patients before and after surgical procedures.

Chapter 6

Quality Improvement and Patient Safety

†ELIZABETH A. MARTINEZ • ANNA M. VARUGHESE • DAVID W. BUCK • EUGENIE S. HEITMILLER

Acknowledgment: The editors and the publisher would like to thank Dr. Peter J. Pronovost for his contribution to prior editions of this chapter. It has served as the foundation for the current chapter.

Key Points

- Quality is an integral characteristic of the system in which care is delivered, and ideally, every system is perfectly designed to realize the results that it achieves. Improving the quality of care probably requires reorganization of the way we work. A challenge to the anesthesia provider is to combine efficiency in perioperative care (especially the operating room) with safety and the best quality possible (see Chapters 3, 4, and 7).
- The growing demand from patients, providers, insurers, regulators, accreditors, and purchasers for improved quality and safety in health care requires that anesthesiologists and other anesthesia providers persistently evaluate the quality of care they provide.
- Improving quality of care requires measuring performance. Clinicians have an enhanced ability to obtain feedback regarding performance in their daily work, in part because of the increasing use of information systems. Unfortunately, consensus has not been reached on how to measure quality of care.
- The goal of measurement is to learn and improve. The measurement system must fit into an improvement system; caregivers must have the will to work cooperatively to improve, and they must have ideas or hypotheses about changes to the current system of care. Also, the clinical team must have a model for testing changes and implementing those that result in improvements.
- Outcome measures, including in-hospital mortality rates, have been the basis for evaluating performance and quality. However, hospital mortality alone provides an incomplete picture of quality and does not include all domains of quality. A balanced set of structures (how care is organized), processes (what we do), and outcome measures (results we achieve) is needed to evaluate the quality of care overall.
- Future efforts to improve quality of care require development of valid, reliable, and practical measures of quality. Identification of clinical care that truly achieves excellence would be helpful not only to anesthesia, but also to health care overall. Examples of excellence in clinical care could serve as models to other anesthesia providers.
- Developing a quality measure requires several steps: prioritizing the clinical area to evaluate; selecting the type of measure; writing definitions and designing specifications; developing data collection tools; pilot-testing data collection tools and evaluating the validity, reliability, and feasibility of measures; developing scoring and analytic specifications; and collecting baseline data.
- The best opportunities to improve quality of care and patient outcomes will most likely come not only from discovering new therapies, but also from discovering how to better deliver therapies that are already known to be effective.

†Dr. Elizabeth Martinez, a wonderful friend, a delightful and energetic colleague, a role model physician who loved taking care of patients, and a passionate and productive researcher in quality improvement, died on September 19, 2013. She will be remembered with much love by all who knew her.

Key Points—cont'd

- A system that has been used by the airline industry, reducing complexity and creating redundancies, can ensure that critical processes occur. The practice of anesthesia may also benefit by reducing complexity and redundancies.
- Health care providers can organize their patient safety and quality improvement (QI) efforts around three key areas: (1) translating evidence into practice, (2) identifying and mitigating hazards, and (3) improving culture and communication. Although each of these areas requires different tools, they all help health care organizations evaluate progress in patient safety and quality.

The need for improving the quality and reducing the cost of health care has been highlighted repeatedly in the scientific literature and lay press. Improving care, minimizing variation, and reducing costs have increasingly become national priorities in many countries. Quality improvement (QI) programs that address these issues not only improve delivery of care but also have a positive effect on practitioner job satisfaction and organizational commitment.[1]

The goal of this chapter is to present a practical framework for developing and implementing QI programs in anesthesiology and critical care medicine that are both scientifically sound and feasible. To accomplish this goal, we review the science of QI, present measures that help evaluate whether QI programs have resulted in improvements, and describe examples of successful QI efforts.

WHAT IS QUALITY?

DEFINITION OF QUALITY

W. Edwards Deming, scholar, professor, author, lecturer, and consultant to business leaders, corporations, and governments defined quality as "a predictable degree of uniformity and dependability with a quality standard suited to the customer."[2] This early definition of quality, in the context of QI, stems from its application to industrial production. However, when the term *quality* is applied to health care, the subtleties and implications of treating a human being are of prime importance, as opposed to the concerns involved in producing consumer goods. Use of the term *quality* in the context of health care can sometimes lead to defensive attitudes, economic concerns, and even ethical debates.

In the health care sector, quality can have various meanings to different people. For example, a daughter may evaluate quality by the level of dignity and respect with which her elderly mother is treated by a nurse. A cardiac surgeon may see quality as a percentage of improvement in the function of a heart on which he or she has just operated. A business may judge quality by the timeliness and cost effectiveness of the care delivered to its employees and its effect on the bottom line. Finally, society may evaluate quality by the ability to deliver care to those who need it, regardless of their cultural or socioeconomic backgrounds.

Despite the numerous definitions of quality in both business and medicine, a unified definition of quality in the context of QI should exist in health care. This definition of quality may have implications for both its measurement and its improvement. In order to help standardize the definition of quality in health care, the Institute of Medicine (IOM) published its own definition in a 1990 report titled *Medicare: A Strategy for Quality Assurance*. The IOM defined *quality* as "the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge."[3] Inherent in this definition are the elements of measurement, goal orientation, process and outcomes, individual and society preferences, and a dynamic state of professional knowledge. This IOM definition of quality in health care has gained the most widespread acceptance.

SIX AIMS OF QUALITY IN HEALTH CARE

The IOM subsequently outlined six dimensions or aims of quality in its 2001 report, *Crossing the Quality Chasm*.[4] These dimensions include and go beyond the issues of patient safety described in their earlier report *To Err Is Human*.[5] The aims have been adopted by many organizations, including the Institute for Healthcare Improvement (IHI), as a basis on which quality is evaluated and improved. The six aims of the IOM are safety, effectiveness, patient-centeredness, timeliness, efficiency, and equity.

1. Safety. No patient or health care worker should be harmed by the health care system at any time, including during transitions of care and "off hours," such as nights or weekends. Errors may be categorized as either failure of an action to occur as planned, such as the administration of a wrong medication to a patient, or having the wrong plan altogether, such as misdiagnosing and subsequently mistreating a patient.[4] As much as possible, patients should be informed about the risks and benefits of medical care in advance. If a complication does occur, medical staff should make full disclosure, provide assistance to the patient and family, and exercise due diligence in preventing any recurrences of the error.
2. Effectiveness. Effective medicine necessitates evidence-based decisions about treatment for individual patients, when such evidence exists. The best available evidence should be combined with clinical expertise and patient values in forming a treatment plan. With effective care, medical practitioners avoid underuse by

providing a treatment to all who will benefit and avoid overuse by refraining from giving treatment to those unlikely to benefit.

3. Patient-centeredness. Patient-centered care is respectful of individual patient preferences, needs, and values and uses these factors to guide clinical decisions.[4] More specifically, according to Gerteis and colleagues,[6] patient-centered care encompasses respect for patients' values; coordination and integration of care; information, communication, and education; physical comfort; emotional support that relieves fear and anxiety; and involvement of family and friends. The dramatic increase in access to health information on the Internet has resulted in more patients who are well informed and proactive in their care. Patient-centered care embraces this trend and shifts more of the power and control to patients and their families. Examples of patient-centered care include shared decision making, patient and family participation in rounds, patient ownership of medical records, schedules that minimize patient inconvenience, and unrestricted visitation hours.[7]
4. Timeliness. Reduced wait time is important to both patients and health care practitioners. Long waits signal a lack of respect for a patient's time. Furthermore, delays may not only affect patient satisfaction, but may impair timely diagnosis and treatment. For health care workers, delays in availability of equipment or information may decrease job satisfaction and the ability to perform their jobs adequately.
5. Efficiency. Rising costs have increased scrutiny of waste in health care; this includes waste in labor, capital, equipment, supplies, ideas, and energy.[8] Improved efficiency reduces waste and results in an increased output for a given cost. Examples of efficiency measures include mean length of hospital stay, readmission rate, and mean cost of treatment for a diagnosis. In many circumstances, efficiency can be improved by eliminating waste, which often results in better quality of care for patients.
6. Equity. Equitable care does not vary in quality based on personal characteristics such as gender, ethnicity, geographic location, and socioeconomic status. The IOM defines equitable care at two levels. At the population level, equitable care means reducing or eliminating disparities between subgroups. At the individual level, it means absence of discrimination based on factors such as gender, race, age, ethnicity, education, sexual orientation, disability, or geographic location.[4]

METHODS OF QUALITY ASSESSMENT

QUALITY ASSURANCE VERSUS CONTINUOUS QUALITY IMPROVEMENT

Although the terms *continuous quality improvement (CQI)* and *quality assurance (QA)* are often used interchangeably, substantial differences exist between the two. Most medical CQI systems have been built on the foundation of a traditional QA system that uses *standards* to define quality.[9] Standards can be defined as an "acceptable" level of performance. For example, a standard for overall mortality after cardiac surgery is less than 3%; however, is 3% (versus 4% or 2%) mortality after cardiac surgery acceptable? Similarly, a standard for head injury evaluation is a computerized tomography (CT) brain scan within 4 hours of admission, but in certain circumstances, patients with head injury may warrant a CT scan sooner than that.

Most standards are inherently arbitrary and often lack consensus among medical professionals.[9] Additionally, QA systems typically react only when a standard is not met. Examples of traditional standard-based QA systems are peer review systems and morbidity and mortality reviews. These systems often exist to flag certain cases or practitioners for intense review. Practitioners may regard this intense review as a punishment because only "failures" or "bad apples" are identified, and process failures are not connected with the outcome on every case. Thus, QA systems are inherently judgmental and, if not carefully administered, can hold practitioners responsible for random causes over which they have no control. CQI systems, on the other hand, are gaining popularity because they recognize that errors occur and require different responses. Often excellence in health care is not identified by analysis of QA systems. Excellence is sometimes defined by the lack of failure. Is there a difference between good (acceptable) and excellent health care?

Systems within health care are a series of interlinked processes, each of which results in one or more outputs. CQI systems, as opposed to QA systems, include an explicit approach to process and the use of specifications to improve a process or outcome. A specification is an explicit, measurable statement regarding an important attribute of a process or the outcome it produces.[9] Specifications identify variables that need to be measured but typically do not set acceptable limits or standards. Once specifications have been defined in a CQI system, all outputs or cases, not just failures, are evaluated against these specifications. The system then attempts to correct errors by fixing the process rather than the people. Thus, CQI aims to change the process and prevent quality failures before they happen by building improvements into the process. To quote Philip Crosby, "The system for causing quality is prevention, not appraisal."[10]

FRAMEWORKS FOR IMPROVEMENT

Model for Improvement

The journey toward improvement can be made more efficient and more effective with a systematic approach. The Model for Improvement, developed by the training and management consulting company Associates in Process Improvement, is one such approach adopted by organizations across varied disciplines and is currently the approach used by IHI. It is a structured, dynamic model that applies the scientific method to testing and implementing a change.[11] In 1939, Walter A. Shewhart, a physicist, engineer, and statistician, introduced the science of modern QI.[12] He introduced a three-step scientific process of specification, production, and inspection, stating that "these three steps must go in a circle instead of in a straight line."[13] In the 1940s, his protégé, W. Edwards

TABLE 6-1 STEPS OF A PLAN, DO, STUDY, ACT (PDSA) CYCLE

Step	Description
Plan	Make a plan for the test of change. Include predictions of results and how data will be collected.
Do	Test change on a small scale. Document data, observations, and problems that occur.
Study	Use data gathered from previous stages to build new knowledge and make predictions. Knowledge is gained from both successful and unsuccessful changes.
Act	Adopt the change, or use knowledge gained to plan or modify the next test of action.

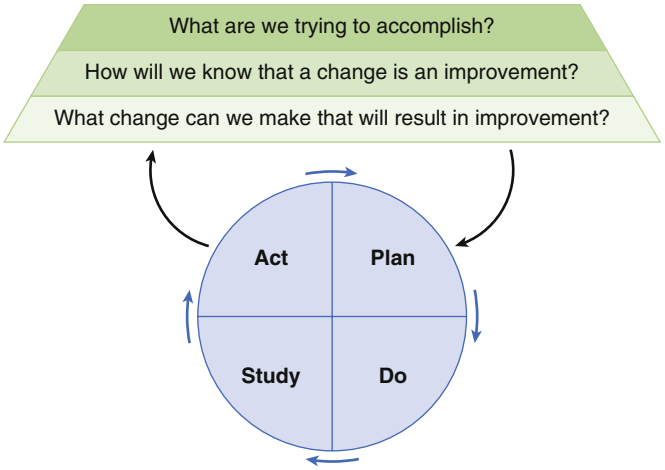

Figure 6-1. Diagram of Model for Improvement. *(From Langley GJ, Moen RD, Nolan KM, et al.* The improvement guide: a practical approach to enhancing organizational performance. *San Francisco, 2009, Jossey-Bass. With permission from John Wiley & Sons.)*

Deming, applied these concepts to government and industry and developed the Plan, Do, Study, Act (PDSA) cycle (Table 6-1).[14] A modification of the PDSA by the addition of three fundamental questions resulted in the Model for Improvement (Fig. 6-1).[13]

Beginning an improvement project with the three fundamental questions for improvement helps set a clear direction for the project, define what success will look like, and hypothesize successful interventions. The three fundamental questions for improvement are:

1. What are we trying to accomplish? (Aim) The aim (or objective) for improvement should be specific, measurable, actionable, relevant, and time-specific (also referred to as a SMART aim). Ideas for improvements may come from interviewing those involved or affected by the process, such as staff or patients. Ideas may also come from examining previous data on operational, clinical, or financial processes.
2. How will we know if change is an improvement? (Measures) Ideally, measures should be linked directly to the aim or goal of the project and should ensure that the interests of the stakeholders of the process are represented.[11] Quantitative measures should be used when possible to measure change over time. These measures provide the feedback that enables one to know whether or not the change is an improvement. However, not all projects have an easily quantifiable outcome and the outcome may be more qualitative. It is worth the time and effort to identify opportunities to translate goals into quantifiable outcomes if possible. These can be easier to use to communicate success.
3. What changes can we make that will result in improvement? (Changes) Ideas for changes that result in improvement often start with observations, modeling the success of others, and brainstorming. The more intimate the understanding of a process and its key drivers, the higher the likelihood of generating successful changes.

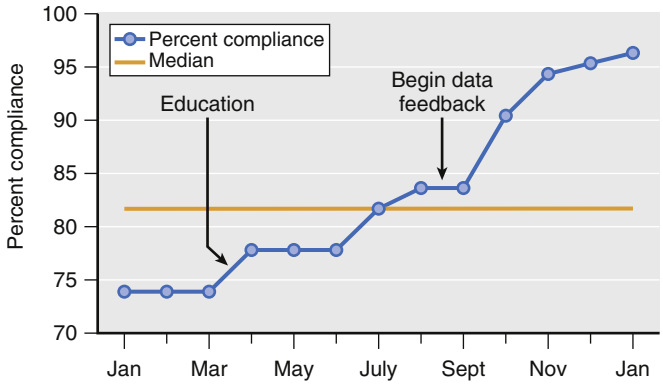

Figure 6-2. Example of a run chart. This chart shows the plot of a performance measure over time. The horizontal (*x*) axis represents time in months, and the vertical (*y*) axis represents the performance measure—the percentage of compliance with the timing of preoperative antibiotics.

The three fundamental questions are followed by a PDSA cycle, which is the framework for testing and implementing previously generated ideas for change. Improvement may require multiple cycles of preferably small tests of change over time. By testing changes on a small scale before implementation, risk is mitigated. Small tests of change may also help overcome individuals' resistance to change. Through repeated cycles, increased knowledge is acquired, and actions are continuously modified or changed. Measures defined in the first part of the model help determine whether or not a change is a success. These measures are often plotted over time on run charts or control charts (Figs. 6-2 and 6-3). Knowledge can be gained from both successful and unsuccessful tests! Finally, PDSA cycles both test a change and implement a successful change on a larger scale or in diverse clinical areas.

Lean Methodology and Six Sigma

In addition to the Model for Improvement, CQI initiatives have many other frameworks. Two of these frameworks, Lean Production and Six Sigma, are briefly discussed here. These frameworks are sometimes combined, such as in Lean-Six Sigma. Regardless of which framework is employed, benefits are gained by retaining a structured and consistent approach to CQI.

Lean methodology has its roots in Japanese manufacturing, particularly in the Toyota Production System.[15] More recently, Lean has found success in the health

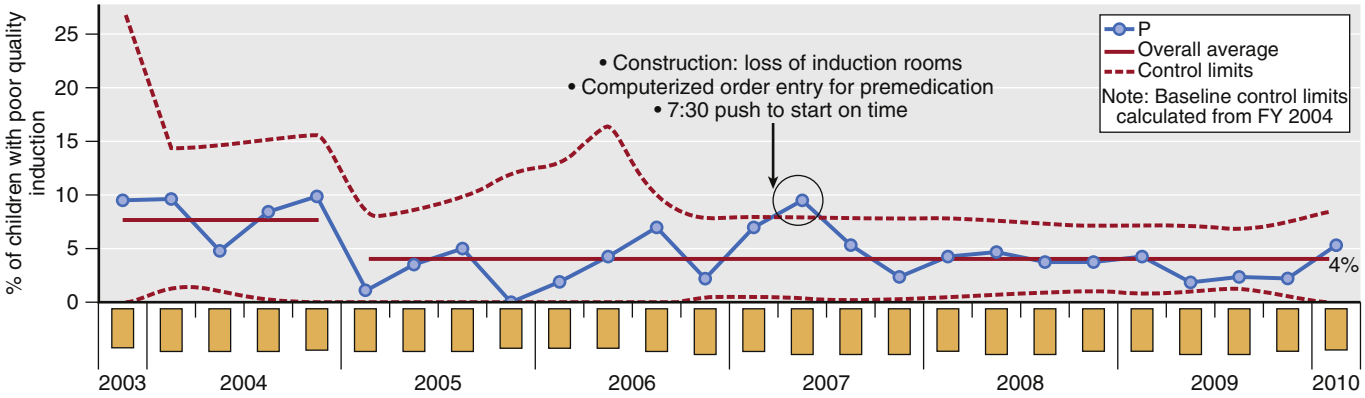

Figure 6-3. Example of a control chart that monitors the quality of the anesthesia induction process, as measured by an induction compliance checklist. The *solid red line* marks the mean, and the *dashed lines* indicate the upper control limit (UCL) and lower control limit (LCL), which are ±3 standard deviations from the mean. The *circled point* represents a single special cause variation in quality of induction. *ICC,* Induction Compliance Checklist score. *(From Varughese AM: Quality in pediatric anesthesia,* Paediatr Anaesth *20:684-696, 2010.)*

care industry. Two notable examples of its use are Virginia Mason Medical Center and ThedaCare, Inc., both of which have transformed their organizations through the application of Lean principles. In fact, ThedaCare reported $3.3 million in savings in 2004 with reduced accounts receivable, redeployed staff, reduced phone triage times, reduced time spent on paperwork, and decreased medication distribution time.[15]

Lean methodology is focused on creating more value for the customer (i.e., the patient) with fewer resources. Every step in a process is evaluated to differentiate those steps that add value from those that do not. The ultimate goal is to eliminate all waste so that every step adds value to a process. Other key components of Lean include reducing unevenness of workflow—for instance, what we might find in intensive care unit (ICU) admissions or emergency cases—and eliminating the overburdening of people and equipment. Five principles govern Lean improvement:[11]

1. Define the value that the customer is seeking.
   Virginia Mason Medical Center has a "Patient First" focus for all its processes.[15]
2. Identify and map the value stream.
   If evaluating preoperative assessment (also see Chapter 38), map the physical flow of a patient from the scheduling of a procedure through the day of surgery (history and physical, preoperative counseling, lab tests, imaging, consultations, etc.). In this process, all of the steps are accounted for, including the back-and-forth flow of the patient to the front desk, to the laboratory, and so on. Time spent during each step of the process should be documented.
3. Smooth the flow between value-added steps.
   Eliminate steps that do not add value to the overall process and are likely a poor use of time or effort on the part of the caregivers or the patient. An example of this process might be eliminating unnecessary tests or consultations in a patient's preoperative evaluation and reducing excess wait times that are the result of correctable inefficiencies.
4. Create pull between steps.
   Customer demand should trigger the start of a downstream process. Examples include opening operating rooms or increasing staffing based on surgical demand, as opposed to having a fixed amount of time for each surgeon or surgical division.
5. Pursue perfection by continuing the process until you have achieved ultimate value with no waste.

The transformation of Motorola in the 1980s from a struggling company to a high-quality, high-profit organization helped give rise to the Six Sigma methodology. Two key fundamental objectives of Six Sigma are a virtually error-free process and a large focus on reducing variation.[16] In fact, a Six Sigma process, or a process six deviations from the mean, corresponds to just 3.4 errors per million.

Health care often falls far short of this standard. In a 1998 report, Chassin[17] reported that hospitalized patients harmed by negligence were at a four sigma level (10,000 per million), patients inadequately treated for depression were at a two sigma level (580,000 per million), and eligible heart attack survivors who failed to receive β-adrenergic blockers were at a one sigma level (790,000 per million). In contrast, Chassin found that anesthesiology was the one health care specialty that approached the six sigma level, with deaths caused by anesthesia as low as 5.4 per million.[17] In comparison with health care, airline fatalities were a two sigma process (230 per million) and a traditional company operated around four sigma, the equivalent of 6200 errors per million.[17] Considering that errors are often tied directly to cost, this error rate has significant financial implications.

Six Sigma is similar to the Model for Improvement in that it makes use of a simple framework to guide improvement, in this case using Define, Measure, Analyze, Improve, Control (DMAIC).[16] The DMAIC steps are described in Table 6-2. As mentioned earlier, many organizations have found the greatest benefit by combining elements of different methodologies in their CQI work. One popular example of this is Lean-Six Sigma, which combines improvements in flow and value with reduction in error and variation. Furthermore, individual tools from these strategies, such as PDSA cycles or DMAIC processes, can be applied where appropriate.

TABLE 6-2 STEPS IN THE LEAN OR SIX SIGMA PROCESS

Step	Description
Define	Define the goals of the improvement project. Obtain necessary support and resources and put together a project team.
Measure	Establish appropriate metrics. Measure baseline performance of the current system.
Analyze	Examine the system for possible areas of improvement.
Improve	Improve the system through implementation of ideas. Statistically validate improvements.
Control	Institutionalize the new system and monitor its stability over time.

QUALITY IMPROVEMENT MEASURES AND TOOLS

The concept of using measurement to drive improvement has its origins in both medicine and industry. The use of data to improve the health of patients originated in the mid-1800s with two pioneers, Florence Nightingale and John Snow. Nightingale used data on mortality among British soldiers to drive improvements in sanitation in field hospitals. Similarly, Snow used data on the incidence and geographic location of cholera to make the connection between the incidence of the disease and water obtained from the Broad Street water pump. In the early 20th century, Ernest Codman, a surgeon at Massachusetts General Hospital, was the first to advocate tracking of patient outcomes so that adverse events could be identified and improvements in care made for future patients. In the 1970s, Avedis Donabedian emphasized the importance of measurement and described a model for evaluating quality of health care based on structure, process, and outcomes—*structure* being the environment in which health care is provided, *process* being the method by which it is provided, and *outcomes* being the result of the care provided. More recently, in 1991, Paul Baltaden and Don Berwick developed the IHI, one of the leaders in the application of improvement science to health care.[18]

In QI, measurement can serve many purposes. It can be used to identify problems and establish baseline performance, inform and guide QI projects, select and test changes for improvement, and assess and align progress with organizational goals. Selecting and developing measures that are useful can be challenging. Optimal measures must be comprehensive, carefully defined, tailored to the target audience, and involve minimal measurement burden. Target audiences usually include clinical staff, so measures should address and align with clinical targets for specific patient populations with whom the staff work. Measures should pass the face validity test with clinical practitioners delivering care. National or organizational measures, if applicable, can also be used, but they may not always be relevant or credible to the local target audience. Within an organization, target audiences should include system leaders, so measures should also align with organizational priorities and strategic goals.

PROCESS AND OUTCOME MEASURES

Measures should include the following:

1. Process measures that address the processes of health care delivery (e.g., perioperative β-adrenergic blocker administration for patients, antibiotic administration for prevention of surgical site infection)
2. Outcome measures that address patient outcomes from delivery of these services, such as clinical and functional outcomes or satisfaction with services (e.g., morbidity, mortality, length of stay, quality of life, or perceptions of care)
3. Balancing measures that address the possible consequences of changes in the process (e.g., when process improvements are made to improve efficiency, other outcomes, such as patient satisfaction, should not be adversely affected)

Each of these measures has advantages and limitations.[19] A comprehensive set of measures should include at least one process, outcome, and balancing measure. In addition, structural measures, such as ICU nurse-to-physician staffing ratios, can be important to include when appropriate.[20,21]

Health care providers readily accept process measures because they demonstrate the degree to which caregivers can influence a process with the intention to improve patient outcomes. Practitioners generally feel more accountable for the process of care than its outcomes, because outcomes may be affected by many other variables.[19] An obstacle to using process as a measure of quality is sustainability; frequent updating is required as the science of medicine advances.

Process measures, which evaluate how care is delivered, may be easier to measure and implement than outcome measures and can provide important insight into care.[22] Process measures can provide immediate feedback regarding performance, allowing for rapid improvements in care. Process measures have two other important advantages: first, they generally have face validity for providers, meaning that providers believe they can use the data to improve care; and second, because risk adjustment is less important, broad implementation is feasible. Moreover, joint efforts among providers, professional societies, and external government or payer agencies have made process measures more feasible.[22]

To be valid, process measures should have causal links to important outcomes; a change in the process should produce a desired change in outcome. One of the best opportunities to improve patient outcomes may well come from discovering how to deliver therapies (processes) that are known to be effective in producing a desired outcome.[23] For example, hand hygiene and application of chlorhexidine to sterilize the skin site before insertion of a central venous catheter (CVC) are two of five processes known to reduce catheter-related bloodstream infections (CRBSI).[24] Process measures such as these are indicators of whether patients reliably receive evidence-based interventions known to prevent complications.

When measuring processes, patient factors, measurement bias, and interventions already in place as part

of standard practice all play a role in outcomes. The linkage of process to outcomes must be demonstrated scientifically or widely accepted by peers, although the latter risks the linkage being accepted but wrong. In general, a balanced set of process and outcome measures helps inform improvement efforts and provides evidence that efforts have made a difference in the lives of patients.

The need for risk adjustment and long-term follow-up is complex. If an outcome occurs infrequently, providers will obtain meaningful feedback on a timely basis. For example, evidence of improved rates of CRBSI (an outcome measure) may require 3 months of data (because few patients develop infections), whereas improved adherence to evidence-based practices to reduce infections (process measures) may be observed within a week (because all patients can be evaluated to determine whether they received the intervention). Nevertheless, consumers and employers are increasingly requesting outcome measures both to improve care and decrease cost. The relative focus on outcome and process measures will depend on balancing the collection of data between that which is scientifically sound and that which is feasible.

For measurement to be effective, the following principles are important. First, measures should focus on something that the improvement team has the power to change and should initially be simple, small-scale measures that focus on the process itself and not on people. Second, measures should be practical, seek usefulness—not perfection—and fit the work environment and cost constraints. Third, data for measurement should be easy to obtain; finding ways to capture data while the work is getting done allows measures to be built into daily work. Fourth, qualitative data (e.g., reasons for patient dissatisfaction) are often highly informative and easy to obtain and should complement quantitative data (e.g., percentage of patients satisfied with care). Finally, when using measures, balance is key; a balanced set of measures can help answer the question, Are we improving parts of our system at the expense of others?

Measurement should not overwhelm the change process. Improvement teams should minimize the burden of measurement whenever possible. Measurement can have both direct and indirect consequences on resource use, provider behaviors, and patients.[25] Measurement of performance and outcomes of care can be costly, especially if the data collection process is manual and involves chart reviews. The burden of measurement is reduced with an electronic medical record system and computerized order entry, although these information technology systems are costly to implement and maintain. Additionally, these resources may not be equally available throughout a system or organization, leading to disparities in the care provided.

Measurement fixation is an unintended consequence on health care staff behavior that may occur with the use of process measures. For example, when a process measure such as "the percentage of diabetic patients who received an action plan" is used rather than an outcome measure such as "improved patient understanding about diabetic management," the measure is perceived by the clinician as defining what is important. Thus, measurement of the process becomes the priority, rather than the intended outcome.[25] Alternatively, the clinician may become so focused on what is being measured that different aspects of care are not equally prioritized. In addition, a predominance of process rather than outcome measures can stifle innovation by scripting a process, thus inhibiting process-level innovation. Practice variation does have some utility because medical practice is dynamic, and it is through the trial of new methods of care that innovation occurs. Finally, QI performance measures may not match patient preferences for clinical care. Performance measures that do not take patient preference into account can lead to decreased patient satisfaction, trust, and confidence in their health care practitioners and system.[25] Thus, selection of a set of appropriate measures with the attributes described previously can be a balancing act that includes weighing the tradeoffs involved.

ANALYSIS AND DISPLAY OF QUALITY IMPROVEMENT DATA

Interpretation of data and understanding of process variation are fundamental to QI work. Data elements central to improvement are first and foremost—those data are collected as a basis for action. Second, interpretation of data is made within the context of the process. Last, the analysis technique should filter out noise in the process. Aggregate data or summary statistics typically do not filter out noise in the system and do not present a broad enough context to point practitioners in the direction of proper action or process improvement.

Shewhart postulated that data contain both signal and noise; to be able to learn, one must separate the signal from the noise.[26] CQI science defines two types of variation within a process: random variation and specific variation. Random variation, also known as common-cause variation, results from differences in the inputs that a process receives or inherent factors in the process itself. Random variation is the random background noise within a system and occurs in the process all the time. Specific variation, also known as special-cause or attributable variation, is not present all of the time as background noise, but rather arises from one or more specific causes that are not part of the system. A process is considered to be unstable when specific variation exists, and efforts should be made to learn about the special causes for this variation. A stable process exists when specific variation no longer occurs, leaving only random or common variation.[9] CQI aims to eliminate specific variation for every process so that only random variation remains. A standards-based QA system fails to distinguish random cause from special cause and attempts to correct all variation. Attempts to correct random variation will necessarily fail—a process CQI defines as "tampering." When a process exhibits only random variation, the process should be evaluated to determine whether it is functioning at an acceptable level. If it is not, the process will need to be changed so that the average is moving in the desired direction. Standardization of a process is often the key to reducing random variation and improving a process.

Run Charts and Control Charts

Run charts and control charts are graphic displays of data that enable observation of trends and patterns over time. They are the best tools for determining whether improvement strategies have had an effect. A run chart (see Fig. 6-2), also called a time series chart, plots the variable or measure being studied on the vertical axis and plots the time on the horizontal axis. The average, or centerline, is the median. At least 12 data points are required to establish a baseline, and at least 20 to 25 data points are required to detect trends and patterns. Run charts should be annotated with tests of change to provide the context within which data can be interpreted. Four rules can be used with run charts to determine whether nonrandom patterns exist or to detect whether the change has led to an improvement:

1. A shift is indicated by six or more consecutive points above or below the median.
2. A trend is indicated by five or more points all increasing or all decreasing.
3. A run is defined as a series of consecutive points on the same side of the median line.
4. An astronomical data point is an unusual point that is obviously different in value (an outlier).[11]

Because change is by nature temporal, run charts in which data are presented over time are powerful tools for interpreting data within the context of the process.

A control chart (see Fig. 6-3),[27] also known as a Shewhart chart,[11,12] is an extension of a run chart and is used to distinguish between specific and random variation. As on a run chart, the variable is plotted on the vertical axis and time on the horizontal axis. However, with a control chart the centerline or average is the mean, rather than the median, and the upper control limit (UCL) and lower control limit (LCL) are calculated. The UCL and LCL correspond to ± 3 sigma from the mean. A process is considered to be "in control," or stable, when data points are within these control limits.[11] Random variation, or variation that is the result of the regular rhythm of the process, produces a stable process. However, in an unstable process that contains variation from special causes, data points exceed the UCL or LCL.[28]

Dashboards and Scorecards

A dashboard of measures functions like an instrument panel for an aircraft or automobile and provides real-time feedback on what is happening. Balanced *scorecards,* or "whole system measures," are similar to dashboards and are used to provide a complete picture of quality. Developed by Kaplan and Norton, the balanced scorecard is defined as a "multidimensional framework for describing, implementing, and managing strategy at all levels of an enterprise by linking objectives, initiatives, and measures to an organization's strategy."[29] A set of measures should reflect the culture and mission of an organization. Viewed collectively, this set of measures provides a gauge of current performance and can also guide the direction for future organizational improvement efforts. A balanced set of measures is critical to ensure that improvement efforts in one area do not adversely affect outcomes in other areas.

Additional QI Evaluation and Communication Tools

In most situations, QI frameworks such as the Model for Improvement or Lean Sigma are sufficient to help guide the development, testing, implementation, and spread of improvement. However, to better understand problems within a system or process, QI professionals have developed or adapted a number of methods and tools. Some of these methods and tools help with viewing systems and processes and organizing and communicating information. These are described in the following section.

Understanding how a process or system works is fundamental to improving it. Process mapping is a method to gain this understanding. A flow diagram, or flow chart, is an improvement tool used during process mapping; it provides a visual picture of the process being studied, wherein the series of activities that define a process is graphically represented. Flow charts identify and clarify all steps in the process. They also help the team understand the complexity of the process and identify opportunities for improvement.

Failure mode and effects analysis is a systematic, proactive method of identifying and addressing problems associated with a process. It uses a standardized approach to analysis that includes identifying the various steps in a process and addressing their failure modes, effects, and possible interventions.

Key Driver Diagram (KDD) (Fig. 6-4)[30] is another approach to organizing the theories and ideas for improvement that a team has developed. The KDD presents the aim or outcome of the project with both the theories (key drivers) behind the improvement and ideas for test of change.[11] Initially, the driver diagram helps lay out the descriptive theory behind the improved outcomes. As these theories are tested, the driver diagram is updated and enhanced to develop a predictive theory. KDDs are extremely useful because they provide a shared mental model for the team during its improvement efforts.

IMPROVEMENT INTERVENTION TOOLS

Efforts in QI and patient safety have produced tools with which to reorganize the way care is delivered. QI intervention tools are used to improve communication and teamwork. Examples of these tools include daily goals sheets, briefings/debriefings, and checklists.

Daily Goals Sheet

Since July 2001, the daily goals sheet has been used to improve communication during multidisciplinary rounds in the ICU at Johns Hopkins Hospital.[31] A one-page checklist, this tool is completed every morning to establish the care plan, set goals, and review potential safety risks for each patient (Fig. 6-5). The goals sheet stays with the patient, is updated as needed, and is used as an information sheet for all staff involved in the patient's care. It can be modified for use on other nursing units or during operating room (OR) sign-out or emergency department rounds (also see Chapters 101 and 102).

Before implementation of the daily goals sheet, an initial survey showed that ICU team members were unable

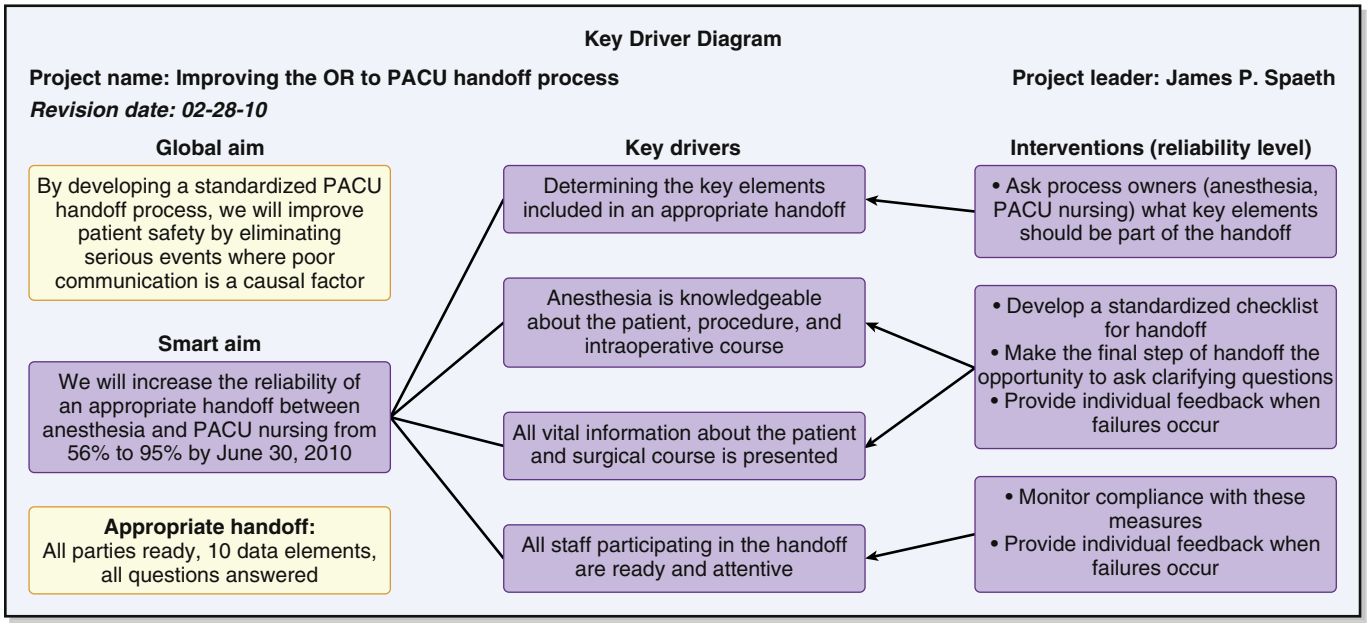

Figure 6-4. Example of a key driver diagram (KDD) developed to improve the operating room (OR) to postanesthesia care unit (PACU) handoff process. This diagram incorporates the global and smart aim of the project, the key drivers inherent to the process, and specific interventions targeting each of the key drivers. *(From Spaeth J, Varughese A:* Improving the OR to postanesthesia care unit handoff process: a quality improvement initiative. *Society for Pediatric Anesthesia Meeting Abstract, San Diego, CA, 2011.)*

to answer two simple questions after rounding at each patient's bedside: "Do you understand the patient's goals for the day?" and "Do you understand what work needs to be accomplished on this patient today?" Fewer than 10% of the residents and nurses knew the care plan for the day—a finding that was not surprising because traditional bedside rounds tended to focus on teaching the staff about disease processes rather than focusing on the work that was necessary to treat the patient. Approximately 4 weeks after the daily goals sheet was implemented, 95% of residents and nurses understood the goals for each patient. Moreover, after the daily goals sheet was implemented, length of stay in a surgical ICU at Johns Hopkins decreased from a mean of 2.2 days to only 1.1 days.[31]

Briefings and Debriefings

Similar to the daily goals sheet, briefing and debriefing tools are designed to promote effective interdisciplinary communication and teamwork. Both have been used in the OR, during sign-out from the ICU nursing staff to the intensivist, and between OR nursing and anesthesia coordinators.[32-34] A briefing is a structured review of the case at hand that takes place among all team members before the start of an operative procedure. A debriefing occurs after the procedure; the team reviews what worked well, what failed, and what could be accomplished better in the future (Fig. 6-6).

An example of an OR briefing includes introduction by name (first and last) and role of each team member, confirmation of the correct patient, confirmation of the site/side and procedure (time-out), and a verbal assurance that all team members agree that they understand the procedure and what is required to ensure its success. A check of all necessary equipment, medications (e.g., appropriate antibiotic), and blood availability is performed. The question, "If something were to go wrong, what would it be?" is asked, and plans to mitigate or respond to the potential hazard are discussed (also see Chapter 3).

Checklists

Checklists have been used in health care and other industries to ensure that important steps in a process are not forgotten. The Food and Drug Administration recommends that a checklist be used when checking out and inspecting an anesthesia machine before use to ensure that the equipment and monitors are functioning properly.[33,35] As part of a QI project to reduce CRBSI at Johns Hopkins, care providers implemented a checklist as one of several interventions to reduce complexity and to introduce a redundant safety check. The checklist, typically completed by a nurse, was attached to the CVC insertion cart to ensure compliance with the best practices for CVC placement. The nurse was empowered to stop the procedure if the checklist was not followed or if sterile technique was compromised. This intervention resulted in a 66% reduction in the overall CRBSI rate; the median rate was reduced from 2.7 per 1000 catheter days before the intervention to 0 by month 3 and through month 18 of the postintervention.[36] In general, these QI tools seek to standardize both communication and technical work.

Haynes and colleagues[37] described the use of a checklist to guide the perioperative time-out, briefing, and debriefing process. They showed that implementing the World Health Organization (WHO) Surgical Safety Checklist (Fig. 6-7)[38] reduced mortality and inpatient complications.[37]

	Room Number _____	Shift: ❒ AM / ❒ PM
Safety	What needs to be done to d/c patient from the ICU?	
	Patient's greatest safety risk? How can we ↓ risk?	
	What events or deviations need to be reported? ICUSRS issues?	
Patient Care	Pain & Sedation Management	Pain goal ____ /10
	Cardiac Review ECGs	HR goal ____ ❒ at goal ❒ ↑ ❒ ↓ β-blockade
	Volume status Net goal for midnight	Even ❒ Pos ❒ Neg ___ Net ___ (cc) ❒ Patient determined
	Pulmonary: Ventilator, ventilator bundle, HOB ↑, wean	❒ OOB/pulmonary toilet/ambulation
	SIRS/Infection/Sepsis evaluation Temp >38°C or <36°C; HR >90 RR >20 or $Paco_2$ <32 WBC >12000 < 4000 or >10% bands	❒ No current SIRS/sepsis issues ❒ Known/suspected infection ❒ Culture blood ×2/urine/sputum ❒ Antibiotic changes ❒ Discontinue sepsis bundle
	Can catheters/tubes be removed?	Y/N
	GI/Nutrition/Bowel regimen: TPN catheter, ND tube PEG needed?	❒ TPN ❒ NPO/Advance diet
	Is patient receiving DVT/PUD prophylaxis?	Y/N
	Can meds be discontinued, changed to PO, adjusted?	
To Do	Tests/Procedures today	
	Scheduled labs	
	AM labs needed/CXR?	
	Consultations	
Description	Has primary service been updated?	
	Has family been updated? Social issues addressed? Long-term/Palliative care

SOURCES OF QUALITY IMPROVEMENT INFORMATION

Development of a QI program first requires that an issue be identified; then baseline data are collected and an improvement intervention instituted. Data are re-collected after the intervention. If the intervention is found to be effective, ongoing monitoring or audits are instituted to ensure that the change is sustained. As part of the audits, feedback must be given to the providers. Health care providers traditionally have had limited ability to obtain feedback regarding performance in their daily work, in part because of a lack of information systems and a lack of agreement on how to measure quality of care.[39]

Ideas for QI programs can be identified from a multitude of sources, but they typically start with surveys and input from local medical staff and reviews of reported incidents. Additional information is gathered from the literature, review of national guidelines and quality metrics, and information obtained from external or internal reviews.

Sources of QI data that span both the clinical and administrative arenas include evidence-based medicine (EBM) and evidence-based clinical practice guidelines, alerts from accrediting agencies and nonprofit safety organizations, standards and guidelines put forth by medical specialty associations, closed claims databases, and government agency administrative databases. United States governmental agencies, including the Agency for Healthcare Research and Quality (AHRQ), Centers for Medicare and Medicaid (CMS), and the National Quality Forum (NQF), promote the development and reporting of health care quality measures.[40]

INCIDENT REPORTING

Voluntary incident reporting that captures hazardous systems has been successfully used to improve patient care and foster QI programs.[41] As the potential of voluntary incident reporting is being realized in health care, this reporting has become less punitive and more focused on systems rather than on individuals. Voluntary incident reporting, when appropriately applied, helps identify hazards to patients that can then become the focus of QI efforts that seek to mitigate those hazards.[42] Unlike other methods that evaluate harmed patients, voluntary incident reporting provides the potential to also learn from near misses—incidents that did not lead to harm

	Briefing: Before Every Procedure
	Team introductions: First and last names, including roles; write names on board
	Verify: Patient ID band, Informed Consent (read out loud), site marking, OR posting, patient's verbalization of procedure (if patient awake), H&P or clinic note
	Are there any safety, equipment, instrument, implant, or other concerns?
	Have antibiotics been given, if indicated?
	What are the anticipated times of antibiotic redosing?
	Is glucose control or β-blockade indicated?
	Is the patient positioned to minimize injury?
	Has the prep solution been applied properly, without pooling, and allowed to dry?
	Have the goals and critical steps of the procedure been discussed?
	Is the appropriate amount of blood available?
	Is DVT prophylaxis indicated? If yes, describe.
	Are warmers on the patient?
	Is the time allotted for this procedure an accurate estimate?
	Have the attendings reviewed the latest laboratory and radiology results?
	Debriefing: After Every Procedure
	Could anything have been done to make this case safer or more efficient?
	Has the Surgical Site Infection data collection form been completed?
	Are the patient's name, history number, surgical specimen name, and laterality on the paper work? (must be independently verified by the surgeon)
	Did we have problems with instruments? Were they reported?
	Plan for transition of care to postop unit discussed? ❒ Fluid management? ❒ Blood transfusion paperwork in chart? ❒ Antibiotic dose and interval to be continued postop? ❒ Pain management/PCA plan? ❒ New medications needed immediately postop? ❒ β-blockers needed? ❒ Glucose control? ❒ DVT prophylaxis?

Figure 6-6. Example of an operating room briefing and debriefing tool. *DVT,* Deep vein thrombosis; *H&P,* history and physical; *ID,* identification.

but were potentially hazardous. A rich source for QI projects should be these near misses and potential hazards, so that prevention of events is highlighted.

All anesthesiology departments should have a process in place for capturing adverse events and near misses. Although most departments have a process for reporting, many incidents go unreported for a variety of reasons. Departments should encourage voluntary reporting without threat of punishment. Electronic capture of adverse events, near misses, and complaints can provide data that can subsequently be analyzed to identify trends and assess the degree of harm that a hazard poses to patients.

Events that occur frequently with low harm can be just as important as an event that occurs rarely with high harm. At the local level, it is more effective to focus on a more frequently occurring adverse event (e.g., perioperative skin abrasions, mislabeling of laboratory specimens) or on a process that can be measured with high frequency (e.g., hand hygiene, administration of antibiotic prophylaxis). For rarely occurring harmful events, a QI initiative may encompass a more expansive analysis of a national adverse-event database with multicenter participation.

With multiinstitutional event reporting systems, events that would rarely be seen in a single institution can be collected in larger numbers. Such systems allow analysis for common causes that increase our knowledge base for prevention initiatives. Larger multiinstitutional data gathering systems include the University HealthSystem Consortium (www.uhc.edu), which supports event reporting and databases that can be used to develop QI programs, benchmarking, and evidence-based practice. Reporting systems that have been developed specifically to investigate rarely occurring anesthesia-related events include the Anesthesia Incident Reporting System (AIRS) created by AQI (www.aqihq.org/airs/airsIntro.aspx) and Wake Up Safe (www.wakeupsafe.org), a QI initiative of the Society for Pediatric Anesthesia. The AIRS program publishes a learning case each month in the *ASA Newsletter,* including a summary of a reported case with learning points.

More expansive international incident-reporting systems that are anonymous and voluntary have also been analyzed in the literature and have provided important information. Examples are the United Kingdom's Serious Incident Reporting and Learning Framework[43] (www.nrls.npsa.nhs.uk/report-a-patient-safety-incident/serious-incident-reporting-and-learning-framework-sirl/) and the Australian Incident Monitoring Study.[44] These incident registries do not require that the events be considered human error or preventable to merit reporting and are a source of ideas for QI projects.

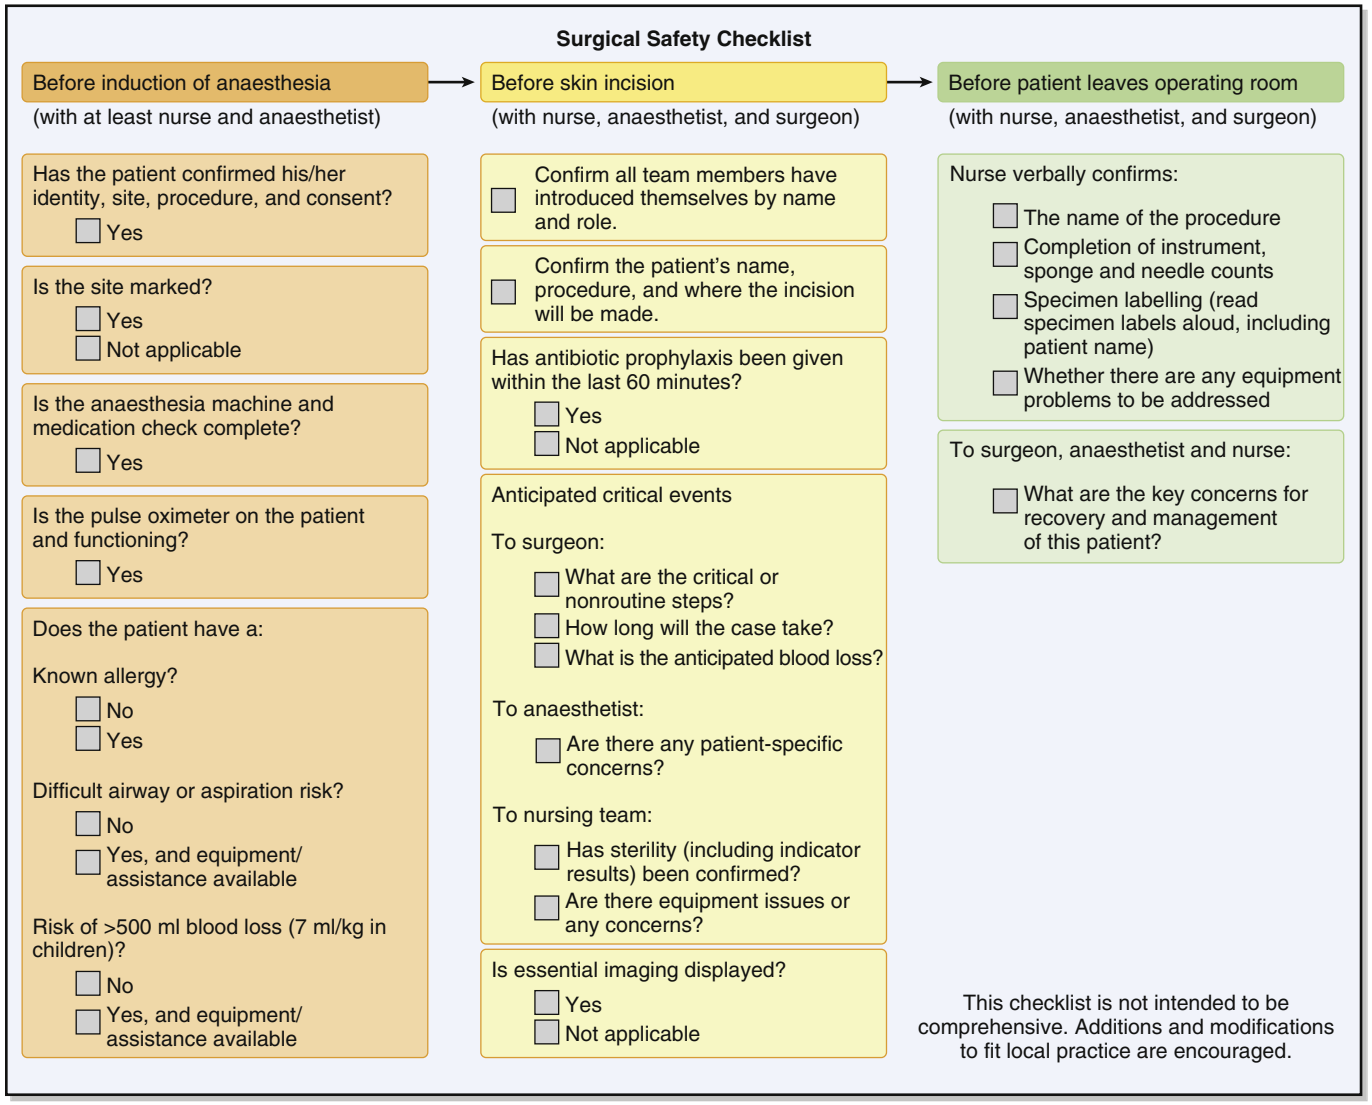

Figure 6-7. WHO Safe Surgery Checklist. *(Reproduced with permission from World Health Organization. WHO Surgical Safety Checklist.* www.safesurg.org/uploads/1/0/9/0/1090835/surgical_safety_checklist_production.pdf.*)*

Although voluntary systems often prove fruitful, many events and near misses still frequently go unreported. One way to capture these incidents is to survey local medical staff members to obtain their thoughts on how the last patient was harmed or how the next patient might be harmed. This process of performing a staff safety assessment survey is described in two later sections of this chapter (see "Collaborative Programs" and "Comprehensive Unit-Based Safety Program"). Staff safety assessment surveys can be particularly helpful for identifying issues for QI projects. Additionally, if staff members identify the issue, the likelihood is greater that they will have a vested interest in participating in the QI efforts.

PUBLISHED LITERATURE

Literature reviews offer ideas for QI topics in specific areas and information to guide interventions. For example, if the QI project plan is to reduce hazards in cardiac anesthesia, a literature review will provide reports of various cardiac anesthesia risks. Once a topic within a clinical area is selected, a literature search should be performed again to determine whether similar QI projects have been performed and whether they were successful. Such information will help with the design of a future initiative. The literature also provides published reports that identify guidelines and/or evidence-based practices that can be the basis for future programs.[45,46]

NATIONAL INITIATIVES AND QUALITY METRICS

The AHRQ is the source for both the National Quality Measures Clearinghouse and the National Guideline Clearinghouse. National professional organizations, such as the American Society of Anesthesiologists (ASA) and the Society for Critical Care Medicine (SCCM), offer guidelines specific to the field. The ASA has supported the review and development of many important guidelines that can serve as a rich source of QI initiatives. These

BOX 6-1 *Surgical Care Improvement Project (SCIP) Process and Outcome Measures*

Surgical Site Infection

- Prophylactic antibiotics
  - Received within 1 hour before surgical incision
  - Appropriately selected for surgical patients
  - Discontinued within 24 hours after surgery end time (48 hours for cardiac surgery)
- Cardiac surgery patients with controlled 6 AM postoperative serum glucose
- Postoperative wound infection diagnosed during index hospitalization (**OUTCOME**)
- Surgery patients with appropriate hair removal
- Colorectal surgery patients with immediate postoperative normothermia

Cardiac Surgery

- Noncardiac vascular surgery patient with evidence of coronary artery disease who received β-blockers during the perioperative period
- Surgery patients on a β-blocker before arrival who received a β-blocker during the perioperative period
- Intraoperative or postoperative acute myocardial infarction diagnosed during index hospitalization and within 30 days of surgery (**OUTCOME**)

Venous Thromboembolism (VTE)

- Surgery patients with recommended VTE prophylaxis ordered
- Surgery patients who received appropriate VTE prophylaxis within 24 hours before surgery to 24 hours after surgery
- Intraoperative or postoperative pulmonary embolism diagnosed during index hospitalization and within 30 days of surgery (**OUTCOME**)
- Intraoperative or postoperative deep vein thrombosis diagnosed during index hospitalization and within 30 days of surgery (**OUTCOME**)

Respiratory

- Number of days ventilated surgery patients had documentation of HOB being elevated from recovery end date (day 0) through postoperative day 7
- Patients diagnosed with postoperative VAP during index hospitalization (**OUTCOME**)
- Number of days ventilated surgery patients had documentation of stress ulcer disease prophylaxis from recovery end date (day 0) through postoperative day 7
- Surgery patients whose medical record contained an order for a ventilator weaning program (protocol or clinical path)

Global

- Mortality within 30 days of surgery
- Readmission within 30 days of surgery

Vascular Access

- Proportion of permanent hospital end-stage renal disease vascular access procedures that are autogenous arterial venous fistulas

HOB, Head of bed; *VAP,* ventilator-associated pneumonia; *VTE,* venous thromboembolism.

guidelines cover a range of practices and include guidelines for the placement of central venous access,[47] management of patients with obstructive sleep apnea,[48] and management of preoperative fasting.[49] For those who are also involved in critical care medicine, guidelines and protocols do improve performance with specific care processes such as sedation and ventilator weaning protocols in ICUs. Such protocols decrease the duration of mechanical ventilation and ICU length of stay[50,51] (also see Chapters 101 and 102).

Review of national quality metrics is another source of ideas for QI topics. National initiatives from CMS, such as the Physician Quality Reporting System (PQRS) and Surgical Care Improvement Project (SCIP), provide quality metrics and are associated with pay for performance. The Joint Commission (TJC) website (www.jointcommission.org) lists national patient safety goals and national quality core measures that are surveyed during site visits for accreditation. In 2004, TJC partnered with CMS to align measures common to both organizations in an initiative called Hospital Quality Measures. These measures are also endorsed by the NQF, a private, nonprofit membership organization created to develop and implement a national strategy for health care quality measurement and reporting (www.qualityforum.org). One of NQF's functions is to endorse certain quality and safety measures (consensus standards), which are then incorporated into other national quality initiatives. The goal for NQF-endorsed standards is that they become the primary standards used to measure the quality of health care in the United States. Increasingly, anesthesia programs are focusing on the standards that are relevant to the specialty because facilities are being evaluated on compliance with regulations and are required to report their performance regarding these standards to the governing bodies.

SCIP, a national collaborative of public and private entities that has outlined perioperative QI goals, is in partnership with TJC and CMS in a national initiative (www.qualitynet.org). This initiative uses both process and outcome measures (Box 6-1) to focus on key clinical areas, including surgical site infection, perioperative myocardial infarctions, venous thromboembolism, mortality, and readmission.

An increasing number of regional and national organizations are developing initiatives that are stimulating the reporting of specific evidence-based practices and outcomes. These initiatives are also determining the local selection of areas for QI (Table 6-3). Reporting of these measures to CMS is being incentivized by pay for performance and performance-based payment. National professional organizations such as the ASA are developing metrics specific to the field.

OUTCOMES RESEARCH

The comparison of outcomes associated with different process decisions, or variations in care delivery, is the basis for outcomes research. Outcomes research[52] offers a potential to identify these variations in care and to determine whether they improve outcomes for patients undergoing anesthesia. One of the key issues in outcomes research is risk adjustment, a challenging goal

TABLE 6-3 **NONPROFIT AND GOVERNMENTAL QUALITY IMPROVEMENT ORGANIZATIONS PERTINENT TO ANESTHESIA**

Quality Improvement Organization	Website	Description
Agency for Healthcare Research and Quality (AHRQ)	www.ahrq.gov	Lead federal agency charged with improving the quality, safety, efficiency, and effectiveness of health care

Anesthesia Patient Safety Foundation (APSF)	www.apsf.org	Promotes investigations and programs that will provide a better understanding of anesthetic injuries
Centers for Disease Control (CDC)	www.cdc.gov	One of the major operating components of the U.S. Department of Health and Human Services
Emergency Care Research Institute (ECRI)	www.ecri.org	Uses applied scientific research to discover which medical procedures, devices, drugs, and processes are best
Institute for Healthcare Improvement (IHI)	www.ihi.org	Health care improvement organization based in Cambridge, Massachusetts
Institute for Safe Medication Practices (ISMP)	www.ismp.org	The nation's only 501(c)(3) organization devoted entirely to medication error prevention and safe medication use
Medicare Quality Improvement Community (MedQIC)	www.medquic.org	A national knowledge forum for health care and quality improvement professionals
National Quality Forum	www.qualityforum.org	Created to develop and implement a national strategy for health care quality and reporting
National Patient Safety Foundation (NPSF)	www.npsf.org	An independent 501(c)(3) organization with a mission to improve the safety of patients

that requires a robust dataset. Using administrative data to identify patient risk factors has many limitations. Registries designed specifically for research, benchmarking, and QI are good sources for this purpose.

The Society of Thoracic Surgeons (STS) and the National Surgical Quality Improvement Programs (NSQIP) are examples of outcomes research registries. Established in the early 1990s, the STS database now includes participation by nearly all U.S. cardiac surgery centers and has developed robust risk-stratification models. Findings from this database have led to initiatives associated with significant reductions in mortality; examples include the use of β-adrenergic blockers and aspirin perioperatively (also see Chapter 3) and the use of internal mammary arteries for coronary artery bypass grafting. NSQIP is a newer registry that was developed by the U.S. Department of Veterans Affairs (VA). Findings from this risk-adjusted outcomes database were used to identify variations in care. The changes that were instituted based on these findings resulted in improved outcomes throughout the VA network. NSQIP has been adopted by the American College of Surgeons (ACS) to provide comparisons among hospitals. Currently, more than 350 general surgery centers participate.[53] Hospitals that participate submit detailed data on a sample of general surgical patients for a number of common surgical procedures. They then receive a graphic display that compares their outcomes with those of the entire cohort. Surgery centers then use these data to identify areas in which they might be able to make improvements and initiate QI projects with that focus. As an example, the Kaiser Permanente group used this information to develop a QI program focused on reducing the percentage of patients with prolonged perioperative intubation.[53]

The ASA created the Anesthesia Quality Institute (AQI) and the National Anesthesia Clinical Outcomes Registry (NACOR) with the goal of improving anesthesia outcomes through capture of case-specific data directly from electronic anesthesia data systems. These resources are still evolving and moving forward to improve outcomes in anesthesia. Another important effort in anesthesia is the Multicenter Perioperative Outcomes Group (MPOG), which is led by researchers at the University of Michigan. MPOG has established a national network of anesthesia practice groups that contribute data to a unified database. The goals of MPOG are to develop a structure for multiinstitutional collaboration and data sharing, to develop the information technology infrastructure to pool a wide variety of perioperative data for patient-centered research, to develop the statistical infrastructure to analyze the data, and to provide an academic venue in which faculty from multiple institutions will be able to collaborate in outcomes research (http://mpog.med.umich.edu).[52]

INTERNAL OR EXTERNAL INSTITUTIONAL REVIEWS

Internal or external institutional reviews of health care processes can provide important insights and ideas for QI initiatives. In addition to the external regulatory reviews, institutions are expected to perform internal reviews of quality and identify areas for improvement. These reviews are often used for QI projects at the institutional level.

PRIVATE INSURERS

Many private insurers now collect data on certain quality elements. The Leapfrog group is one such entity. The Leapfrog Hospital Quality and Safety Survey assesses hospital performance based on three evidence-based safety practices: (1) use of computerized physician order entry, (2) evidence-based hospital referral, and (3) ICU physician staffing. In 2010, the NQF Safe Practices were added as a Leapfrog Safe Practices score (a fourth leap), which is based on the level of performance of other NQF-endorsed practices (www.leapfroggroup.org). Leapfrog reports the results and rankings of its survey, allowing employers to

use the results to guide their choices in selecting health care coverage for their employees.

Public and private insurers are demanding increased accountability secondary to rising health care costs and threatened budgets. In response, performance-based payments, such as those used successfully in business, are being introduced as a means of improving quality. Pay for performance (P4P) refers to financial incentives that reward practitioners for the achievement of a range of payer objectives, including efficiency (quality care at a smaller cost), submission of data and measures to payers, and improved quality and patient safety (www.ahrq.gov/qual/pay4per.htm#1). Measures that are incorporated into P4P and performance-based measures must be evidence-based, consistent with national goals, or based on consensus in the absence of evidence. Furthermore, it is important that measures be reliable, valid, and feasible and that the programs be voluntary. Although the strategy of P4P is to align quality of care and payment, the impact of P4P on quality of care has thus far been modest. Currently, some Medicare programs also withhold payment for certain hospital-acquired conditions.

The PQRS is a reporting program that uses a combination of incentive payments and payment adjustments to promote reporting of quality information to CMS by eligible professionals. Physicians (anesthesiologists) and practitioners (certified registered nurse anesthetists and anesthesia assistants) can earn a 2% bonus from CMS by reporting their compliance with measures. Most anesthesia groups report through their billing software on the following measures: appropriate timing of prophylactic antibiotics to prevent surgical site infection, normothermia at the time of postanesthesia care unit admission (or documentation of active warming efforts), and observation of a bundle of sterile precautions when inserting a central line (use of the central line checklist). An additional 0.5% is awarded to those who participate in the maintenance of a certification program for their specific specialty board. An initial step in this program was payment for participation; ultimately, successful compliance with the clinical measures will be the basis for bonus payments. One question is whether payments may be decreased to those with less-than-desirable outcomes or nonparticipation in the reporting programs listed earlier. Additional measures are being evaluated, and the methods by which they will be incorporated into national initiatives and/or P4P will continue to evolve.[54, 55]

EXAMPLES OF QUALITY IMPROVEMENT PROGRAMS

Examples of QI frameworks and tools have been discussed. This section addresses broad initiatives for quality and safety improvement that have used some of the methodologies and tools detailed earlier in this chapter.

COLLABORATIVE PROGRAMS

Use of a collaborative is one approach to improving broad areas of care. A quality improvement collaborative involves the participation of two or more health care teams working toward a shared goal. In health care, a set of multidisciplinary representatives (from all of the clinical and administrative areas that are linked to the area of focus) should participate in the collaborative. A collaborative can be developed within a single organization and/or across multiple health care organizations. Collaborative programs are typically led by a team that is responsible for the following:

1. Determining the evidence-based interventions to be used and presenting these to the participants (if evidence-based interventions are not available, the team will generate interventions based on local and broad expert consensus)
2. Establishing the data collection approach (defining measures, collection methods, and feedback mechanism)

A key element to the success of collaboratives is an established process for educating members and for sharing interventions and obstacles. Through group discussions (meetings and/or conference calls), teams can learn about best practices and innovative methods used by other teams to approach a problem. In addition, collaboratives bring a shared momentum and enthusiasm that can increase sustainability.[21,56,57]

IHI has used collaboratives for more than a decade to improve patient care. In 2003 they introduced their Breakthrough Series Collaboratives in 2003,[58] which are characterized by these key standard steps: topic selection, expert faculty recruitment, enrollment of participating teams, learning sessions, action periods, the model for improvement, summative congresses and publications, and measurement and evaluation (Fig. 6-8).

Sawyer and associates[59] reported the success of a collaborative that incorporates a "mechanism to move evidence to the bedside and foster a culture where the focus is the patient."[59] The collaborative includes an emphasis on translating evidence into practice (TRIP) and the Comprehensive Unit-Based Safety Program (CUSP). This methodology has been reproduced and validated in several large collaborative efforts (Fig. 6-9).[59-61]

The TRIP model incorporates the following key steps and emphasizes the importance of measurement and feedback of data to teams.

1. Identify evidence-based interventions associated with an improved outcome through review of peer-reviewed publications.
2. Select goal-oriented interventions that have the most impact on outcomes and transform them into behaviors. In selecting behaviors, focus on interventions with the strongest treatment effect (smallest number needed to treat) and the lowest barrier to use.
3. Develop and implement measures that evaluate either the interventions (processes) or the outcomes.
4. Measure baseline performance and establish databases to facilitate accurate data management and timely feedback to teams.
5. Ensure that patients receive evidence-based interventions through four basic steps: engagement, education, execution, and evaluation (Table 6-4).

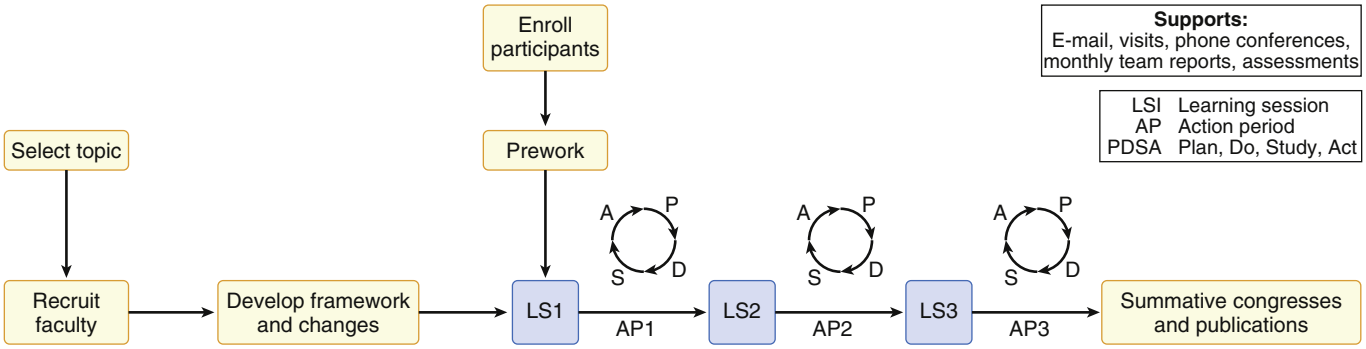

Figure 6-8. Breakthrough Series Collaborative Model. *(Reproduced with permission from Institute for Healthcare Improvement: The Breakthrough Series: IHI's Collaborative Model for Achieving Breakthrough Improvement. IHI Innovation Series white paper, Boston, 2003.* http://www.ihi.org/knowledge/Pages/IHIWhitePapers/TheBreakthroughSeriesIHIsCollaborativeModelforAchievingBreakthroughImprovement.aspx.*)*

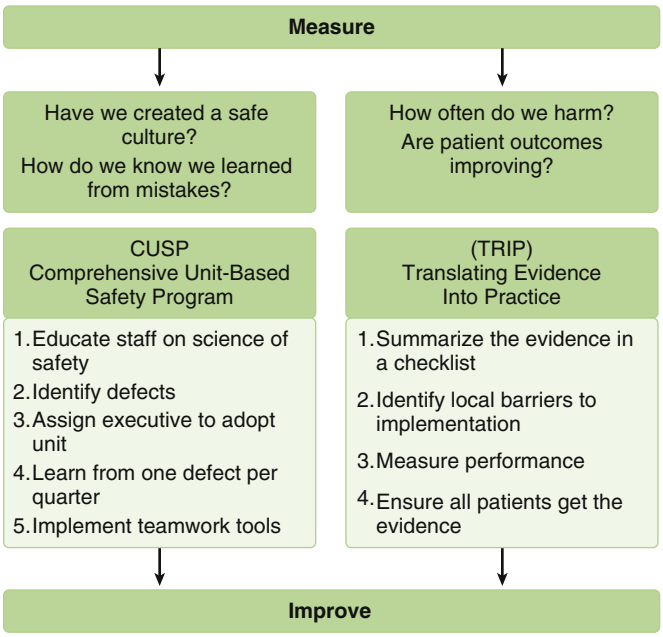

Figure 6-9. Translating evidence into practice (TRIP): four basic steps to ensure patients receive evidence-based care. *(Reproduced with permission from Sawyer M: Using evidence, rigorous measurement, and collaboration to eliminate central catheter-associated bloodstream infections,* Crit Care Med *38:S292-298, 2010.)*

The format for the collaborative also includes annual face-to-face meetings with the participating teams and periodic conference calls, which focus on education about the actual processes being implemented, the evidence base to support these processes, and the sharing of experiences. First, weekly immersion calls provide an initial overview of the program, describe the roles and responsibilities of each of the individuals, and introduce the tools that are to be used. Once the collaborative is introduced, monthly content calls are held throughout the program and are typified by a slide presentation of the evidence base for the intervention or of other components of the program to be implemented. The monthly coaching calls offer an opportunity for teams to share how well or how poorly they are implementing the interventions and share ideas for overcoming barriers.

TABLE 6-4 FOUR STEPS THAT ENSURE PATIENTS RECEIVE EVIDENCE-BASED INTERVENTIONS THROUGH A COLLABORATIVE USING THE EXAMPLE OF CATHETER-RELATED BLOODSTREAM INFECTIONS

Step	Action	Example
Engage	Make the problem real	Share information of local CRBSI rate vs. national rate
Educate	Develop an educational plan to reach ALL members of the caregiver team	Present evidence-based practices at grand rounds and multidisciplinary team meetings Present plans to improve care and measure outcome
Execute	Develop a safety culture Reduce complexity of the processes Introduce redundancy in processes Hold regular team meetings	Develop a culture of intolerance for CRBSI Ensure that all equipment and supplies for sterile CVC insertion are in one place and easily available Use checklists that identify key steps to reduce CRBSI Focus on 1 to 2 tasks per week and identify team member responsible for task
Evaluate	Measure and provide feedback	Develop data collection plan and database to track progress Give staff real-time feedback; post progress in highly visible location Identify causes of defects

CRBSI, Catheter-related bloodstream infections; *CVC,* central venous catheter.

Inclusion of the CUSP program in the collaborative provides a structured approach to improve safety culture and identify and mitigate hazards (i.e., learn from mistakes).[31,34] CUSP is a five-step program that has been tested and used successfully to improve quality and safety in ICUs (Table 6-5).[62,63]

Safety culture is assessed before the implementation of CUSP and reassessed after 1 year to evaluate the impact of the program. Multiple culture assessment tools are available.[64,65] The AHRQ offers a free survey online (www.ahrq.gov). The initial measure provides a baseline

TABLE 6-5 FIVE-STEP COMPREHENSIVE UNIT-BASED SAFETY PROGRAM

	Step	Description
1	Present educational material	Educate staff on science of safety though lectures and other educational materials
2	Complete forms that identify patient safety issues	Ask the following questions: • How will the next patient be harmed? • How can this harm be prevented? • Establish voluntary incident reporting
3	Assign senior executive responsible for specific area	Senior executive meets with all staff of the clinical area to: • Help prioritize safety efforts • Remove barriers for system changes • Provide resources • Demonstrate hospital commitment to patient safety • Foster relationship between senior leadership and staff
4	Learn from defects	Implement projects focused on two to three safety issues Keep goals simple: • Reduce complexity in the process • Create independent redundancies to ensure critical steps are accomplished
5	Implement teamwork tools	Implement programs such as checklists, training, and daily goals targeted at improving teamwork and communication

assessment of staff perceptions of safety culture in their clinical areas and their perceptions of the organization's commitment to patient safety.

Education is a crucial aspect of CUSP; it provides staff with a new set of lenses through which to identify hazards and recommend system changes to improve care. The objectives of these educational efforts are to ensure that staff: (1) understand that safety is a system property, (2) learn concepts for reliable health care design, and (3) understand the basics of change management. After an educational lecture on the science of safety, staff members are requested to identify patient safety hazards in their clinical areas and suggest improvement interventions. For this process, staff members review incident reports, liability claims, and sentinel events from their unit. In addition, two questions are asked: "How do you think the next patient will be harmed?" and "How can we prevent it from happening?"

After the completion of the survey and educational component, a senior leader of the institution (e.g., hospital president, vice president, director) is partnered with a unit or clinical area. This leader attends rounds on the unit monthly to help staff members prioritize safety efforts, to ensure that they have the resources to implement improvements, and to hold them accountable for evaluating whether safety has improved. Staff members are asked to learn from one defect per month and to implement one tool per quarter designed to improve care delivery.[31,34]

CUSP was pilot-tested in ICUs and subsequently implemented throughout Johns Hopkins Hospital and in the Michigan Keystone project.[60] In the pilot, a patient-safety team that consisted of staff from the clinical area was responsible for oversight of the program. To be most effective, this team included the ICU director as the ICU physician safety champion, the nurse manager, another ICU physician and nurse, a risk manager or patient-safety officer, and a senior executive from the institution. The program worked best if the physician and nurse who led the program dedicated at least 20% of their time to improving quality and patient safety. The first unit was the beta site; subsequent teams from other clinical areas would learn from its successes and failures. The ultimate goal was to have every area in the hospital organizing and managing safety through CUSP.

CUSP has been associated with significant improvements in safety culture. The percentage of staff reporting a positive safety climate increased from 35% before CUSP to 60% after CUSP.[63,66] In addition, teams identified and mitigated several specific hazards through CUSP. As a result of asking staff members to speculate on how the next patient might be harmed, the ICU created a dedicated ICU transport team, implemented point-of-care pharmacists, implemented the daily goals sheet, clearly labeled epidural catheters to prevent inadvertent intravenous connection, and standardized the equipment in transvenous pacing kits.[67] Moreover, the use of CUSP decreased the length of stay and nurse turnover.

In summary, CUSP provides several benefits for improving safety culture and is a primer for staff compliance in implementing any safety or QI intervention or project. It provides enough structure to convert the often-vague goals of improving safety into a focused strategy; yet it is flexible enough to allow units to work on issues most important to them. CUSP provides a venue to introduce rigorous research methods, acts as a learning laboratory to identify and mitigate hazards, and has the potential to improve patient outcomes.

CHALLENGES AND BARRIERS TO QUALITY IMPROVEMENT PROJECTS

Multicentered and/or single-hospital projects can fail because of inadequate resources, lack of leadership support, vague expectations and objectives for team members, poor communication, complex study plans, inadequate management of data collection, and wasted efforts to "reinvent the wheel" rather than adopting practices proven to be effective. Successful collaboratives require a local culture (the set of values, attitudes, and beliefs of the group) that is ready for change and participants who have a shared view of safety and who understand the science of patient quality and safety (i.e., the technical components of how care is organized and delivered).

THE FUTURE: RESEARCH, EDUCATION AND ETHICS

Much remains to be accomplished in QI research and practice. The opportunity to improve patient care is substantial, and the pressure to improve the quality of perioperative care continues to increase. Improving quality of care requires the ability to measure and improve

performance. Research is needed to develop measures of quality that clinicians believe are valid and to learn how to ensure that all patients reliably receive recommended interventions. Innovation is needed to develop information systems that can be used by multiple disciplines. Anesthesiologists and professional societies may need to partner with experts in quality measurement to develop and implement quality measures. Future efforts should balance the feasibility and validity of quality measures and develop integrated approaches to improving quality, including strategies to develop care bundles, decrease complexity, and create independent redundancies.

Clinicians now need the skills necessary to improve quality. Health care will cross the quality chasm only when all view quality and safety as their primary job, rather than as an added activity, and health care organizations provide the infrastructure to monitor and improve performance. Frontline health care providers must understand the science of quality and safety and evaluate safety risks as hazardous systems, not incompetent people. Integral to this is the education of our trainees. CQI in anesthesia residency training programs has been touted for well over a decade.[68] In recent years, residents in training were presented with six core competencies to master, mandated by the Accreditation Council of Graduate Medical Education,[69] and the IOM put forth their six Aims for Improvement[4] (Table 6-6). In an effort to link these two sets of goals and apply them to the clinical setting for training purposes, Bingham and colleagues[70] developed a framework called the Healthcare Matrix that can be used as both an educational tool and a research tool for improvement.

With the increasing amount of intellectual focus and health care resources being directed toward QI programs, the ethics of QI have come to light. QI projects have generally been exempt from the rigorous review of human-subjects research. However, a Hastings Center Report on the ethics of using QI methods to improve health quality and safety suggests that some QI projects may involve risk to patients and should undergo a formal review.[71] This report lists QI initiatives that may trigger the need for a review as those that have a randomized design, use novel treatments, involve researchers, have delayed feedback of monitoring, or are funded by external sources. The reporting of QI activities should be encouraged, as should requiring approval by an internal review board and following a standardized format for reporting the results. All of these practices support the premise that delivery of quality care is a science as well as an art.

TABLE 6-6 ACCREDITATION COUNCIL OF GRADUATE MEDICAL EDUCATION (ACGME) SIX CORE COMPETENCIES AND INSTITUTE OF MEDICINE (IOM) SIX AIMS FOR IMPROVEMENT

	ACGME Core Competencies	IOM Aims for Improvement
1	Patient care	Safe
2	Medical knowledge	Timely
3	Interpersonal and communication skills	Effective
4	Professionalism	Efficient
5	System-based practice	Equitable
6	Practice-based learning and improvement	Patient-centered

SUMMARY

Health care organizations need a systematic approach to three areas of patient safety: (1) translating evidence into practice, (2) identifying and mitigating hazards, and (3) improving culture and communication. The underlying principle for all of the approaches discussed in this chapter is that improvement of the quality of care dictates that practitioners must be able to measure their performance. Health care practitioners traditionally have had limited ability to obtain feedback regarding performance in their daily work, in part because of the absence of information systems and a lack of agreement on how to measure quality of care.[39] As a result, many in health care do not have access to performance data and consequently do not know what results they achieve (or fail to achieve). As consumers, payors, regulators, and accreditors increasingly require evidence regarding quality of care, the demand for quality measures will grow. To meet these demands, anesthesiologists must be prepared to use valid measures to evaluate the quality of care that they provide and to implement evidence-based best practices in the perioperative care of patients.

Acknowledgment

This chapter greatly benefited from the thoughtful editing of Claire Levine.

Chapter 7

Human Performance and Patient Safety

MARCUS RALL • DAVID M. GABA • STEVEN K. HOWARD • PETER DIECKMANN

Key Points

- Clinical excellence is not achieved by the use of sound medical knowledge alone. Human factors and the interaction of team members, as well as organizational conditions in the system of care, also play major roles. Therefore, the study of human performance and related organizational matters is very important.
- The health care system in general and clinical institutions in particular must provide appropriate organizational characteristics to allow and foster safe patient care practices (e.g., improve safety culture, integrate effective incident reporting and analysis systems).
- High-reliability organization theory describes the key features of systems that conduct complex and hazardous work with very low failure rates. Errors do occur in such organizations, but their systems make them more impervious to errors and their sequelae (resilience).
- In dynamic domains such as anesthesia, continuous decision making, as described in the cognitive process model, is critical to achieving safe patient care.
- Several error mechanisms have been demonstrated through human factors research. Understanding these psychological "traps" (e.g., "fixation errors") can help anesthesia professionals to avoid or mitigate them.
- The introduction and spread of crisis resource management (CRM) training, including the application of realistic simulation exercises, are starting to improve patient safety in anesthesia and other acute care domains.
- As for all human beings, the performance of individual anesthesia professionals can be adversely influenced by "performance-shaping factors," including noise, illness, aging, and especially sleep deprivation and fatigue.
- A particular technique of human factors research called task analysis has been useful in understanding the work of anesthesia professionals.
- Observation of anesthesia professionals during routine operations or in the handling of adverse events (by using realistic patient simulators) has improved our knowledge of critical decision making, team interactions, and the impact of using cognitive aids such as checklists or emergency manuals.
- Future progress on patient safety in anesthesia will require interdisciplinary research and training, improvements in systems safety and organizational learning, and the involvement of all levels of the health care industry.

IMPACT OF HUMAN PERFORMANCE ON PATIENT SAFETY

The most important component of every anesthetic regimen is the human performance of the anesthesia professional and its relation to patient safety. More than 70% of accidents are caused by "human factors." Because the performance of the anesthesia professional—embedded in a larger system of care—is such a critical and most determining aspect of patient safety, education and training of health care professionals in this area need improvement. This chapter aims to provide an overview of the importance of human performance and systems safety in anesthesia and to provide start-up knowledge of key safety factors and methods.

Anesthesia is an intrinsically hazardous undertaking, but as hazardous activities go, its track record is indeed a model of patient safety for the rest of health care.[1,2] The Institute of Medicine (IOM) asserts: "Anesthesia is an area in which very impressive improvements in safety have

been made."[3,4] However, the theory of organizational safety teaches us that safety is a never-ending process; any patient harmed by an anesthetic is one patient too many (in concert with the "zero vision" statement of the U.S. Anesthesia Patient Safety Foundation [APSF]: "That no patient shall be harmed by anesthesia"). Cooper and Gaba wrote:

Anesthesiologists should remain aware of the hazards they still face, take pride in having been the leaders in patient safety efforts, and stay motivated to continue the pursuit of "no harm from anesthesia" with the passion it still demands.[1]

Because most of the work on human performance (and also on simulation) has been started and has focused on anesthesiology in the operating room (OR), this chapter deals primarily with aspects of performance and safety in the OR setting. Nevertheless, most of the same principles and issues are relevant to the postanesthesia care unit (PACU), the intensive care unit (ICU), emergency medicine, and to a lesser degree, pain therapy and other domains of importance to anesthesiologists. For readers with a special interest in the ICU, a selection of references is given as a starting point.[5-22]

Safe conduct of anesthesia depends on the appropriate application by skilled anesthesia professionals of knowledge concerning surgical procedures, the physiology of patients during and after anesthesia, the characteristics of anesthetic and adjuvant drugs, and the means of monitoring the patient and the life-support equipment throughout the perioperative period. In this chapter, we use "anesthesia professional" to refer to any anesthesia clinician taking care of a patient, whether a physician, certified registered nurse anesthetist (CRNA), or anesthesia assistant (or to similar positions in other countries).

Traditionally, an adequately trained anesthesia professional automatically was assumed to perform appropriately. Deviations from optimal outcomes were understood to result from imperfections in the art and science of anesthesia, which led to heavy emphasis on the scientific and technical aspect of anesthesia training and care. More rarely, adverse outcomes were ascribed to negligence or incompetence on the part of the anesthesia professional. Today, a more complete understanding exists that anesthesia professionals themselves, both as a profession and as individuals, have strengths and vulnerabilities pertaining to their work environment. The performance of human beings is incredibly flexible and powerful in some aspects but very limited in others. Humans are vulnerable to distractions, biases, and errors. This chapter surveys some of the human characteristics that define the performance of anesthesia professionals. These characteristics (also termed human factors) are by no means constant; for example, a person may communicate very effectively in one instance and fail to close the loop in the next challenging communication role.

The domain of the anesthesia professional is very challenging; it is at least as difficult as other domains that more readily capture the public's imagination, such as aviation. Since the 1980s, research has been conducted on the nature and limitations of professional judgment and decision making in this dynamic and complex world. Chapter 8 explores developments in the methods of using simulations and simulation technologies that have contributed to this research and that may open new opportunities to prepare anesthesia professionals to handle the challenges they face in their work.

The literature related to human performance and patient safety is vast. Standard reference works are available[23-34] (Appendix 7-1), and this chapter samples only a portion of this literature as it most closely relates to the work of anesthesia professionals. Moreover, this chapter does not address human-machine interactions and the physical design of the work environment in depth. These aspects of human factors, or ergonomics, in anesthesia have considerable importance in their own right. The reader is referred to several publications that review these issues in detail.[35-46]

NATURE OF THE OPERATIONAL DOMAIN OF ANESTHESIOLOGY

The operational domain of anesthesia is a complex, dynamic world with a cognitive profile common to many real-world task domains. Analysis of complex dynamic worlds since 2000 has departed sharply from previous conceptions of decision making.[47] Classic decision-making approaches, such as decision theory and multiattribute utility theory, are mathematic techniques that were traditionally used as the dominant framework for understanding human performance. They worked well in simplified laboratory experiments on decision making and action, yet some investigators had significant difficulty in applying these approaches to real-world decision and action settings.[47] Orasanu and colleagues identified eight factors that characterize such naturally occurring complex dynamic worlds.[47] These factors apply to anesthesia as follows:

1. **Ill-structured problems.** Unlike traditional decision experiments, there is not just a single decision to be made. Rather, a variety of interrelated decisions must be made by the anesthesia professional and surgeon. The patient's physiologic behavior is not an independent random variable but is causally linked to previous decisions and actions.
2. **Uncertain dynamic environment.** Dynamism stems from the frequency of routine and anomalous changes or events, the rapidity with which they evolve, and the unpredictability of the patient's physiology and response to interventions. An anesthetized patient is in a constant state of change during surgery, with many events outside the anesthesia professional's control. Although preventive measures can reduce the likelihood of some events, other events cannot be avoided because they are inevitable side effects of medically necessary procedures (e.g., surgical blood loss). Unpredictable and dynamic occurrences compete with the preplanned aspects of the case and drive the anesthesia professional's actions. The true state

of the patient cannot usually be measured directly. It must be inferred from ambiguous patterns of clinical observations and data from electronic monitors. These data are imperfect because, unlike industrial systems that are designed and built with sensors in key areas to measure the most important variables, patients are typically instrumented to measure the variables that are easiest to monitor, predominantly with the use of noninvasive methods. Most physiologic functions are observed indirectly through weak signals available at the body surface and thus are prone to various types of electrical and mechanical interference. Invasive measurements are also vulnerable to artifacts and uncertainties of interpretation. Even if the anesthesia professional knew the exact state of the patient, the patient's response to interventions would be unpredictable.

3. **Time stress.** Because the OR is a scarce resource, an incessant overall time pressure exists to use the OR efficiently. An even more intense immediate time stress occurs within each case and is generated by dynamic situations that evolve rapidly and must be dealt with in timely fashion.
4. **Shifting, ill-defined, or competing goals.** Multiple goals of case management (e.g., hemodynamic stability, good operating conditions for the surgeon, rapid emergence from anesthesia) may compete with each other. The surgeon's goals may sometimes compete with those of the anesthesia professional. All these goals shift as the patient's situation changes dynamically throughout the procedure.
5. **Action-feedback loops.** The time constants of actions and their effects are very short, on the order of seconds to minutes. Complete intermixing of decision making and action occurs; these functions are not performed in separate cycles. Most decisions and actions are implemented and evaluated incrementally, with the effect of one cycle assessed before deciding on further possible actions.
6. **High stakes.** The stakes are high because even for elective surgery in healthy patients, there is an ever-present and very real risk of injury, brain damage, or even death. A catastrophe is often the end result of many pathways that begin with seemingly innocuous triggering events. Each intervention, even if appropriate, is associated with side effects, some of which are themselves serious. Some risks cannot be avoided. Unlike an event such as a commercial flight, which can be delayed or aborted if a problem occurs, during an event in the OR this is not usually possible, and immediate surgery may be necessary to treat a medical problem that is itself life-threatening. Analogous to military aviation, balancing the risks of action (anesthesia and surgery) against those of inaction is often extremely difficult.
7. **Multiple players.** Anesthesia domains involve multiple players from different professional backgrounds. Each individual has a set of goals, abilities, and limitations. In some situations, interpersonal interactions, among anesthesia personnel and between them and other OR team members, dominate the work environment.
8. **Organizational goals and norms.** The anesthesia professional works within the stated and unstated norms of the OR suite, the anesthesia department, the institution, and the profession as a whole. Decisions are sometimes made to conform to these norms even though they are not wholly subscribed to by the anesthesia professional.

Although many of these features apply to other domains of medicine, anesthesiology is unique in that all eight factors are prominent. In particular, what sets anesthesia apart from clinic- or ward-based medicine is the intensity of the dynamism, time pressure, and uncertainty, with danger lurking just below the surface.

SAFETY CULTURE OF THE OPERATING ROOM AND INTENSIVE CARE ENVIRONMENT

ANALYZING THE ANESTHESIA PROFESSIONAL'S DOMAIN: THE OPERATIONAL WORLD VERSUS THE ORGANIZATIONAL WORLD

Psychologists and cognitive engineers who study real work environments describe each field as a domain. Each domain has specific characteristics that set it apart from others, including the nature of the tasks to be performed, the relationships among the tasks, the time scale over which they must be executed, and the criteria for their successful performance. This chapter deals mainly with the operational domains in which anesthesia care is delivered, primarily the OR, the PACU, and the ICU (see also Chapters 4, 109, and 110). However, as pointed out by Reason,[48-51] as well as by Cook, Woods, and McDonald,[52] what goes on in the operational domain is extensively shaped by the organizational and managerial environment in which it is located, even to the point that operational personnel believe themselves to be the "victims" of problematic decisions further back in the system.

In everyday practice, these distinctions are hidden or blurred. The positive and negative contributions of the organizational and management elements are often so embedded in the normal routine that they are difficult to isolate. Interesting information about the system often comes from considering abnormal situations, accidents, or near misses instead of normal events. For example, investigation of the loss of the space shuttle Columbia revealed a variety of latent errors within the procedures and safety culture at the National Aeronautics and Space Administration (NASA): "The accident was probably not an anomalous, random event, but rather likely rooted in NASA's history and the space flight program's culture."[53]

The report placed as much weight on these factors as on the direct technical causes of the accident. Traditionally, one speaks of errors arising in decisions and actions that lead to a mishap. However, the term "error" is increasingly considered an inappropriate way to categorize behavior (being a judgment of attribution and blame) and should be thought of merely as a way to identify behavior at the locus of a critical situation. In

this context it must be understood that "errors are not the cause of an accident." Rather, errors are usually the consequence of a combination of several underlying factors. Beyond that, errors must combine with other circumstances to result in an accident or adverse outcome.[54] This concept is illustrated in Figure 7-1. Some errors are actively produced in the operational domain, whereas others are introduced by the organizational environment. James Reason, a psychologist at the University of Manchester, England, described the latter by using the concept of "latent errors":

... errors whose adverse consequences may lie dormant within the system for a long time, only becoming evident when they combine with other factors to breach the system's defenses. [They are] most likely to be spawned by those whose activities are removed in both time and space from the direct control interface: designers, high-level decision makers, construction workers, managers and maintenance personnel.[54]

Latent errors probably exist in all complex systems, and Reason adopted a medical metaphor to describe them as "resident pathogens." Like microorganisms in the body, the resident pathogens remain under control until sets of local circumstances "combine with these resident pathogens in subtle and often unlikely ways to thwart the system's defenses and bring about its catastrophic breakdown" (Fig. 7-2). This "threat and error model" was also articulated by the noted aviation-oriented psychologist Robert Helmreich at the University of Texas (Fig. 7-3).[55]

A variety of latent failures can exist in the anesthesia environment. They may include such issues as how surgical cases are booked, how cases are assigned to specific anesthesia professionals, what provisions are made for preoperative evaluation of outpatients, and what relative priority is given to rapid turnover between cases or avoiding cancellation of cases as opposed to avoiding risk. Latent errors can also result from the design of anesthesia equipment and its user interfaces, which in some cases lead clinicians to err or are unforgiving of errors. Manufacturing defects and routine maintenance failures are also types of latent failure.

Investigation of untoward events must address both latent and active failures and both the organizational and managerial environment and the operational domain. One risk of focusing solely on active failures is that operational personnel may be "victims of the system" in a "catch-22"–type situation and be pushed to maximize production while admonished to "be safe." Addressing only their actions—and not the latent pressures under which they must work—can make them defensive and uncooperative. Cook, Woods, and McDonald pointed out that if one looks at the chain of events in an accident sequence, one can always find a failure on the part of an operator.[52] If the analysis stops at this point, the operator (i.e., the anesthesia professional) may be wrongly blamed for a failure, the real roots of which go back to latent failures in the organization. If the underlying latent errors are never identified or never fixed, they will remain in the system and will probably induce another accident chain in the future. This situation is visualized in Reason's accident trajectory, shown in Figure 7-2.

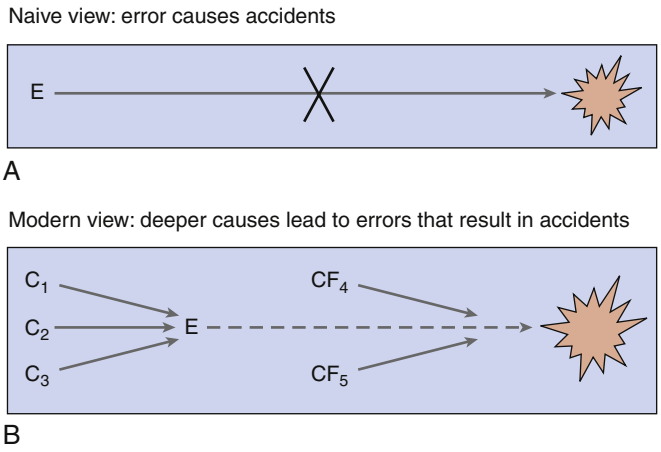

Figure 7-1. Relationship between errors (E) and adverse events. **A,** Errors are not the cause of accidents but in rare cases they lead directly to the adverse event. Multiple root causes (C_1, C_2, C_3) lead to the error (**B**). For the most part, additional contributing factors (CF_4, CF_5) are necessary to allow the error to evolve into an adverse event. Incident reporting systems should try to identify as many of the root causes and contributing factors before an accident happens and try to influence these factors in such a way that no accident will happen. *(Modified from Rall M, Manser T, Guggenberger H, et al: Patient safety and errors in medicine: development, prevention and analyses of incidents [in German],* Anasthesiol Intensivmed Notfallmed Schmerzther *36:321-330, 2001 with permission.)*

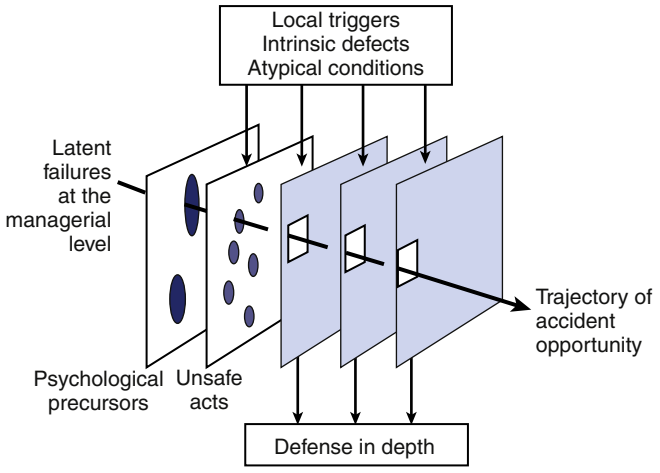

Figure 7-2. James Reason's model of the causation of accidents. Latent failures at the managerial level may combine with psychological precursors and event triggers at the operational level to initiate an accident sequence. Most accident sequences are trapped at one or more layers of the system's defenses. The unforeseen combination of organizational or performance failures with latent errors and triggers may lead to breach of the system's defenses and allow the accident to take place. The diagram should be envisioned as being three-dimensional and dynamic — with " shields " moving around and holes in the defenses opening and closing. *(Redrawn from Reason JT:* Human error, *Cambridge, 1990, Cambridge University Press.)*

ASYMMETRY BETWEEN SAFETY AND PRODUCTION

An additional difficulty in achieving optimal safety is an inherent asymmetry of information and concern about safety versus production (Table 7-1).[54] Investments for

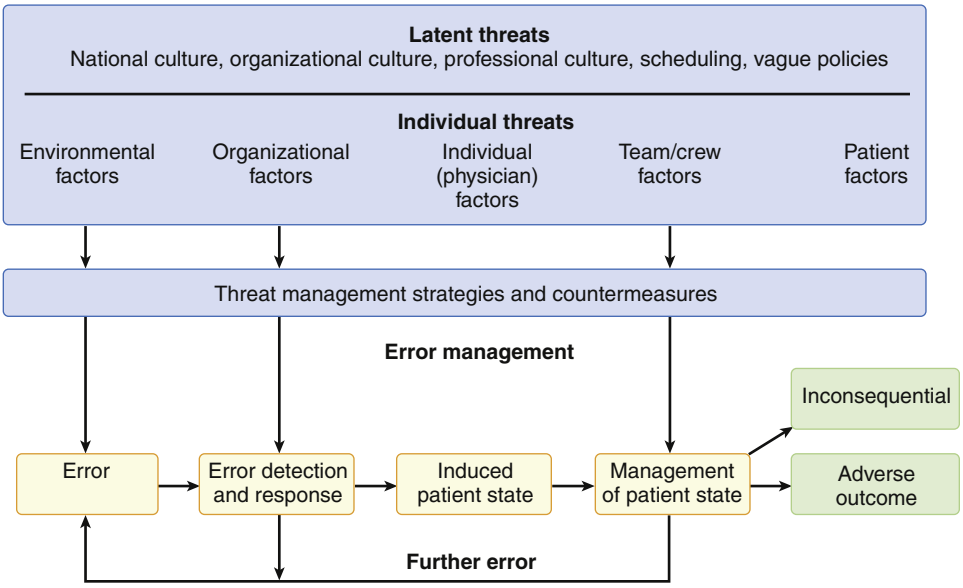

Figure 7-3. University of Texas threat and error model.[55] This model, which illustrates the evolution of errors, is used in the analysis of incidents and accidents.

TABLE 7-1 ASYMMETRY OF SIGNALS OF SAFETY VERSUS SIGNALS OF PRODUCTION

Production	Safety
Feedback about production is easy to measure reliably and nearly continuously ("revenue," "earnings," "expenses") and indicates success in a positive fashion	Traditional measures of "safety" are indirect and discontinuous, thus making them noisy and difficult to interpret or even deceptive
Success is indicated "positively" (e.g., increasing earnings), is obviously reinforcing, and has high salience (the bottom line is the "bottom line" for a firm)	Feedback is provided "negatively" (fewer accidents or incidents) and has little reinforcement value in itself. High salience is achieved only after an accident or a scary near miss
The relationship between the application of resources (money, effort, time) and production goals is relatively certain, thus making it easy to use feedback	Even when interpreted correctly, the relationship between application of resources and safety goals is relatively uncertain, thus making it difficult to use the feedback

Modified from Reason JT: Human error, *Cambridge, 1990, Cambridge University Press.*

BOX 7-1 ***Recommendations of the Institute of Medicine Report*** **To Err Is Human**

- Make patient safety a declared and serious aim.
- Provide strong, clear, and visible attention to safety.
- Implement nonpunitive systems for reporting and analyzing errors.
- Incorporate well-understood safety principles, such as standardizing and simplifying equipment, supplies, and processes.
- Establish interdisciplinary programs to improve teamwork and communication by using modalities proven in other industries, including simulation.

From Kohn LT, Corrigan JM, Donaldson MS: To err is human: building a safer health system, *Washington, DC, 1999, National Academy Press.*

production are easy to plan for and measure; feedback about production is easy to obtain and to interpret. Investments for safety are more difficult to plan for, and the costs are more difficult to measure. Most importantly, feedback about safety is inherently weak and ambiguous. How can one measure the accidents that could have occurred but did not? Only after a catastrophe takes place do the costs of a safety failure become apparent.

ORGANIZATIONAL SAFETY

Since the 1990s, many landmark publications and activities have addressed patient safety and the organizational aspects of reducing errors.[3,30,50,56-62] The report of the IOM in 1999, *To Err Is Human,*[3] was a highly publicized awakening in the United States about the problems of patient safety. Summarizing the primary literature, the report stated that "tens of thousands die each year from errors in their care and hundreds of thousands suffer or barely escape from nonfatal injuries that a truly high-quality care system would largely prevent." The most important recommendations of this report, which led to nationwide activities to promote patient safety, are shown in Box 7-1.

The subsequent report of the IOM Committee on Quality of Health Care in America, entitled *Crossing the Quality Chasm: A New Health System for the 21st Century,*[56] took a systematic approach to improvement of the entire health care system. It stated that "between the healthcare we have and the care we could have, lies not just a gap, but a chasm" because the health care system today harms too frequently yet routinely fails to deliver its potential benefits. The report concluded: "The current care system cannot do the job. Trying harder will not work. Changing the systems of care will." In the following text we consider the organizational and systems aspects of anesthesia care and patient safety.

Several schools of thought about organizational safety in highly hazardous activities exist. Two theories, normal accident theory (NAT) and high-reliability organization

TABLE 7-2 **COMPLEMENTARY VIEWS OF HIGH-RELIABILITY ORGANIZATION THEORY VERSUS NORMAL ACCIDENT THEORY**

HROT	NAT
Accidents can be prevented through good organizational design and management	Accidents are inevitable in complex and tightly coupled systems
Safety is the priority organizational objective	Safety is one of a number of competing objectives
Redundancy enhances safety; duplication and overlap can make a reliable system out of unreliable parts	Redundancy often causes accidents because it increases interactive complexity and opaqueness and encourages risk taking by social shirking and cue-taking behavior
Decentralized decision making is needed to permit prompt and flexible field-level responses to surprises	Organizational contradiction: decentralization is needed to handle the distributed complexity, but centralization is needed to manage tightly coupled systems
A "culture of reliability" will enhance safety by encouraging uniform and appropriate responses by field-level operators	A military model of intense discipline, socialization, and isolation is incompatible with democratic values
Continuous operations, training, and simulations can create and maintain high-reliability operations	Organizations cannot train for unimagined, highly dangerous, or politically unpalatable operations
Trial-and-error learning from incidents (through effective incident reporting) can be effective and supplemented by anticipation and simulations	Denial of responsibility, faulty reporting, and biased reconstruction of history frequently cripple learning efforts

Modified from Sagan SD: The limits of safety, *Princeton, NJ, 1993, Princeton University Press.*
HROT, High-reliability organization theory; *NAT,* normal accident theory.

theory (HROT), have dominated the discussion of safety in many domains and have been applied individually to health care with increasing frequency since the 1980s.[51-60,63] NAT was originally promulgated by the sociologist Charles Perrow in the wake of the Three Mile Island (Pennsylvania) nuclear accident,[64] and the theory has been applied by him and others to such diverse fields as commercial aviation, maritime transport, and the handling of nuclear weapons. HROT was put forth initially by a group of researchers at the University of California at Berkeley. It has also been applied to diverse domains, including aircraft carrier flight decks, offshore oil platforms, air traffic control, nuclear power production, and the financial transaction industry (Karlene Roberts, personal communication). These workers' complementary views of organizational safety are summarized briefly here and in Table 7-2.

NORMAL ACCIDENT THEORY

NAT focuses primarily on two features of a system: (1) the complexity of interactions among the system's elements and (2) the presence of tight coupling among the system's elements. A system is tightly coupled when a change in one part of the system rapidly alters other parts of the system. For example, some physiologic systems are buffered from changes in others, whereas certain core components, such as oxygen delivery and blood flow, are tightly coupled and interact strongly. The patient's physiology may become tightly coupled to external systems such as ventilators and infusions of hemodynamically active drugs. When complexity and tight coupling coexist, abnormal sequences of events can sometimes be hidden and have complex or unpredictable consequences. Typically, active errors in the system do not result in an accident because they are trapped at some point by the system's multiple layers of checks and defenses (see Fig. 7-2). Even a minor perturbation can cause normal system behavior to be out of control when complex interactions and tight coupling are present. Perrow called this a "normal accident" because the perturbations are common and arise out of otherwise normal system operations.[64] He suggested that attention should be directed at strengthening the recovery pathways by which small events can be properly handled before they evolve into a serious accident.

COMPLEXITY AND TIGHT COUPLING: LATENT ERRORS IN ANESTHESIA

Clearly, the anesthesia domain involves complex interactions with tight coupling.[65] The complexity stems to some degree from the variety of devices in use and their interconnections, but these are, in truth, vastly simpler than those found in an oil refinery, a 747 aircraft, or a space shuttle. A more important source of complexity is the "uncertainty complexity" of the patient.[65] The human body is an incredibly complex system containing numerous components, the interactions of which are only vaguely understood. Because many body systems affect each other, the patient is a major site of tight couplings. Furthermore, the anesthetic state tends to ablate the buffers between some of these interconnected systems, thereby strengthening the coupling between them and between the patient and external mechanical supports. Galletly and Mushet studied anesthesia "system errors" and observed tight coupling associated with "the use of neuromuscular blocking drugs, the presence of cardiorespiratory disease, certain types of surgical procedures, and the effect of general anesthetic agents.[66] Looser coupling was observed with the use of high concentrations of oxygen and air mixtures, preoxygenation, and spontaneous breathing techniques."

According to the NAT view, we delude ourselves by believing that we can control our hazardous technologies and forestall disaster; in reality, many of the efforts we make at management and design tend only to increase the opacity and complexity of the system (making more holes in the barriers), thereby increasing the likelihood of accidents. The combination of these factors provides fertile ground for the occurrence of accidents—indeed, according to NAT it makes it inevitable that some of the

"normal" everyday faults, slips, and incidents will evolve into tragic accidents. NAT is often considered a "pessimistic" view of the ability of organizations to conduct highly hazardous operations without harmful errors.

The very concept of risk is constructed and negotiated. This was perhaps expressed most clearly by Dianne Vaughan in her powerful analysis of the explosion of the Challenger space shuttle:

Risk is not a fixed attribute of some object, but constructed by individuals from past experience and present circumstance and conferred upon the object or situation. Individuals assess risk as they assess everything else—through the filtering lens of individual worldview.

Vaughan's main thesis is that the Challenger exploded not because "risk-taking" managers "broke the rules" but because the system evolved to make excessive risk a part of "following the rules." This happened in response to the system's "culture of production" with ingrained production pressure; it was a regular occurrence that aberrant findings be explained away ("normalization of deviance"), and "structural secrecy" was enforced between departments, between manufacturers and NASA, and between engineers and managers. Sadly, many of these same phenomena occurred yet again and led to the Columbia accident.[53] Unfortunately, each of these system characteristics is also present in perioperative settings.

HIGH-RELIABILITY ORGANIZATION THEORY

In contrast to these rather pessimistic views of the organizational challenges to safety is the HROT view that although it is not easy, proper organization of people, technology, and processes can handle complex and hazardous activities at acceptable levels of performance.[61,67] Even though accidents can never be totally eliminated, high-reliability organizations (HROs) (Fig. 7-4) must be judged by the benefits that we derive from their activities and their small absolute risk of failure. This view seems particularly appropriate in anesthesiology because forgoing surgical treatment is not a viable option for many patients, and challenges to safety must often be met head-on. Although the concepts of HROT have varied over the years, the core characteristics of HROs are shown in Boxes 7-2 and 7-3.[68-70]

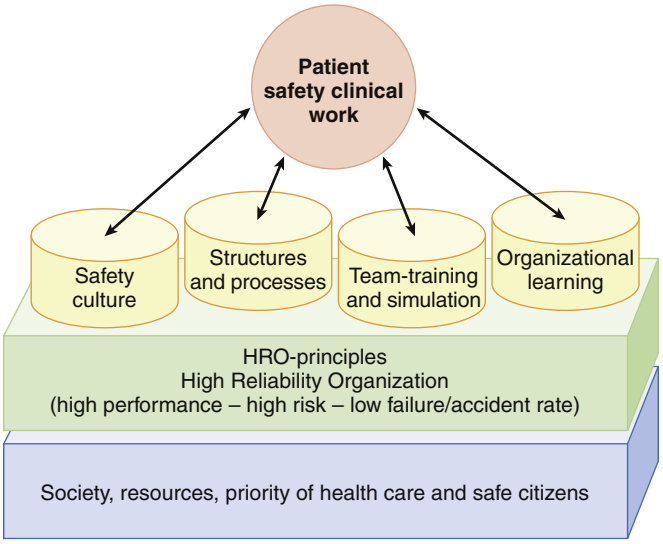

Figure 7-4. High-reliability organization.

A key aspect of HROT is that of a culture of safety (or "safety culture"). Since publication of the reports from the IOM, health care has begun paying attention to certain elements of "culture." However, most of the attention has been devoted to the "culture of blame" in a system whereby problems are addressed largely in terms of who is to blame rather than what can be done to prevent these problems. Safety culture goes beyond the issue of blame by dealing with a host of aspects related to how individuals and groups conduct their work. Culture is made up of values (what is important), beliefs (how things should work), and norms (the way things work). These elements are shown in Box 7-2. It is equally important that the culture be highly uniform throughout the organization and be continually reinforced by peers, more so than by enforcement of rules.

High-Reliability Organization Theory in the Specialty of Anesthesiology

Anesthesiology has traditionally been strong at some elements of an HRO, particularly in redundancy and technical safety measures. A movement is growing in anesthesia to implement HRO philosophies and techniques more fully.[63] In fact, anesthesiologists not only have been promoters of the patient safety movement in general but also have been leaders at applying HROT principles to health care. In 2003, the APSF began initiatives in high-reliability perioperative health care (see the special issue of the *APSF Newsletter,* summer 2003, at www.apsf.org).

BOX 7-2 ***Elements of a Culture of Safety****

VALUES

- Safety is the most important goal, overriding production or efficiency.
- The preoccupation is with possible "failures," rather than past "successes."
- Necessary resources, incentives, and rewards are provided for optimal safety, not only for optimal production.

BELIEFS

- Safety must be actively managed.
- Processes and routines of care are as (or more) important to safety as individual dedication, skill, or effort.
- Openness about safety and errors is essential; learning from normal and adverse events should be thorough.

NORMS

- Low-ranking personnel raise safety issues and challenge ambiguity regardless of hierarchy or rank.
- Calling for help is encouraged and occurs frequently, even (or especially) by experienced personnel.
- Explicit communication is frequent.
- The hierarchy is flat—leaders listen to juniors; juniors speak up; and calling for help is routine regardless of rank.
- People are rewarded for rationally erring on the side of safety, even when their credible concerns turn out to be wrong.

Modified from Weick KE: Organizational culture as a source of high reliability, Calif Manage Rev *29:112-127, 1987.*

*Part of high-reliability organization theory as described in Box 7-3.

Box 7-3 summarizes key elements of an HRO adapted to health care.

TEAMS AND COMMUNICATION

Unlike teams in aviation, the military, and police and fire services, the OR team is unusual in that the command structure is ambiguous. Physicians (surgeon and anesthesiologist) are nominally superior to nursing and technical staff, but physicians are coequally responsible for the patient during the immediate perioperative period. Surgeons were historically considered the "captain of the ship," with even a legal doctrine giving them responsibility for the actions of all other OR team members. Although this legal doctrine has formally fallen by the wayside, remnants of it remain in aspects of the organizational structure and culture of OR environments. Nonetheless, when both an anesthesiologist and a surgeon are caring for a patient, they are coequally responsible, and this situation can lead to complex issues of command authority, hierarchy, and control.

Each physician, as well as the nurses and technicians, has a primary territory of knowledge, skill, and responsibility, but considerable overlap exists among them.

Strictly speaking, a team is defined as "a distinguishable set of two or more people who interact, dynamically, interdependently, and adaptively toward a common and valued goal/objective/mission, who have each been assigned specific roles or functions to perform, and who have a limited life-span of membership." A team is distinct from a group in that a group is an ad hoc collection of individuals without a specific mission and without specific roles. In the OR, all team members have the common goal of a good outcome for the patient. However, considerable disagreement can exist on how to achieve this goal and which elements of patient care have the highest priority. These differences are probably traceable to the fact that the OR team is itself made up of several "crews" (i.e., surgery, anesthesiology, nursing, perfusionist, radiology), each of which has its own command hierarchy, its own global properties (professional standing, culture, traditions, and history), and its own set of local goals and objectives for management of the patient. The differences among the crews can be so striking that we sometimes refer to them as separate tribes (transcript of the Conference on Human Error in Anesthesia, Asilomar, Calif., 1991).

Each "crew" has one or more members who must work effectively together, and crews combine to form a team. A critical component of the success of this process comprises the establishment and maintenance of a shared mental model of the situation. To the degree that these objectives can be accomplished, the different individuals will be able to tailor their efforts toward a common goal. Experience working together as a crew or team will improve the likelihood of generating a shared mental model.

Cooke and Salas and their associates made some interesting statements on teams and team knowledge (Box 7-4).[71,72] In their view, "team knowledge" is more than the sum of individual team members' knowledge, and these investigators demonstrated the need for new methods to elicit team knowledge (e.g., a collective holistic approach). In team knowledge, Cooke and Salas distinguished between "team mental model" and "team situation model." To judge team knowledge, information is also needed on the broader aspect of "team cognition," which involves team knowledge itself, team decision making, team situation awareness, and team perception. Figure 7-5 reflects these components of team cognition and team knowledge.[71]

BOX 7-3 *Key Elements of a High-Reliability Organization in Medicine*

Established Culture of Safety (See Box 7-2)

Optimal Structures and Procedures

- Decision making rests with those with greatest knowledge or experience about specific issues regardless of rank or job type.
- The unit integrates crews from different departments (e.g., cardiac surgery, cardiac anesthesia, OR nursing, perfusion, ICU) into a coherent clinical team. Teamwork and resiliency are emphasized.
- Formal procedures are in place to maximize transfer of information to all team members before a case (e.g., briefings or time-out procedures).
- Schedules are designed to keep work hours and duty periods at reasonable levels to avoid undue fatigue. Personnel under excessive stress are supported or replaced as needed.
- Standardized procedures, techniques, and equipment are adopted whenever possible so that similar tasks or operations are performed similarly regardless of the personnel involved; conversely, when necessary (in an emergency or adverse event), the team is resilient and responds as needed to the situation without slavish dependence on standard routines.
- The use of preplanned algorithms, checklists, and cognitive aids is actively encouraged.
- Easy access to current information systems is available at all times and all locations.

Training and Practice in Routine Procedures and Simulations

- Debriefings are conducted after each case.
- Nonpunitive assessment instruments are used on a regular basis to provide current feedback and identify elements requiring special training.
- Initial and recurrent simulation-based single-discipline and multidisciplinary training in crew resource management occurs (see Chapter 8).
- Actual clinical crews and teams conduct periodic drills or simulations of critical situations in the real OR, PACU, and ICU.
- Resident training uses a guided curriculum; training goals and the level of responsibility assigned to a resident match the current proficiency level of the trainee with the complexity of the procedure.

Organizational Learning

- Robust mechanisms are in regular use for organizational learning, both prospectively (considering in advance how to optimize protocols and procedures, such as failure mode and analysis of effects) and retrospectively (from analyzing reports of adverse events, near misses, or problems such as root cause analysis).
- Problems are analyzed primarily to determine what can be improved, rather than whom to blame. Altered procedures are assessed and adopted as appropriate. Process changes reflect appropriate analysis.

ICU, Intensive care unit; *OR,* operating room; *PACU,* postanesthesia care unit.

Status and Hierarchy Effects

Status and hierarchy effects are important in team performance. Especially in crisis situations, the lower-status crew member tends to defer to the higher-status individual, even if that individual is performing poorly. In aviation, some airplane crashes have occurred in which overbearing captains were combined with unassertive subordinates (first officer copilot and flight engineers). The team was not able to respond effectively, even when the subordinates knew that something was wrong.

In aviation, as in academic anesthesia practice, training is an ongoing activity in the domain. Although the captain is in charge of the flight, the captain and the first officer (who is essentially in training to become a captain) traditionally alternate the roles of "pilot flying" and "pilot not flying" on each leg of a flight. Each of these roles is carefully defined and involves separate but interrelated tasks (the pilot flying handles the flight controls, whereas the pilot not flying handles radio communications and other tasks). In anesthesiology, the roles of the trainee and the faculty member during patient care are rarely made explicit. The trainee is often expected to do all tasks with only occasional assistance from the supervisor (part of a training method known as cognitive scaffolding). The exact responsibility for different tasks in a crisis is not predefined. It is interesting that two factors frequently found to be associated with critical incidents in anesthesia have been "teaching in progress" and "inadequate supervision."[73]

A particular issue of hierarchy is known as *cue giving and cue taking,* in which people give off cues (often without even knowing it) that are taken up by others.[74] Those people not at the top are very sensitive to cues emitted by their superiors. The cues sent by high-status personnel can inhibit action or even questions from lower-status people. One effect of this phenomenon is that dyads and teams that expect to have redundancy from "multiple sets of eyes" on a patient may not achieve this goal because the views of a single person dominate the thinking of the group.

BOX 7-4 *Teamwork Principles*

- Team leadership matters.
- Team members must have clear roles and responsibilities.
- Shared understanding of the task, teammates, and objectives goes a long way.
- Take time to develop a discipline of prebriefing, performance, and postbriefing.
- Teamwork effects matter.
- Clinical expertise is necessary but insufficient for patient safety; cooperation, communication, and coordination skills matter.
- Teams must have clear and valued visions.
- Learning from mistakes, self-correction, and adaptability are the hallmarks of high-performance teams.

From Salas E, Rosen MA, King H: Managing teams managing crises: principles of teamwork to improve patient safety in the emergency room and beyond, Theoret Issues Ergonomics Sci *8:381-394, 2007.*

PRODUCTION PRESSURE

The social and organizational environment may also act as a source of production pressure on anesthesia professionals (see also Chapters 3, 4, and 6). *Production pressure* encompasses the economic and social pressures placed on workers to consider production, not safety, their primary priority.[64] In anesthesiology, this typically means keeping the OR schedule moving speedily, with few cancellations and minimum time between cases. In principle, safety and efficiency can go hand in hand. Many aspects of high reliability, such as standard operating procedures, preprocedure briefings, and flattening the hierarchy, may smooth operation of the system, as well as make it safer. Frequently, however, the pressure for throughput can erode safety.

For example, when anesthesia professionals succumb to these pressures, they may skip appropriate preoperative evaluation and planning, or they may fail to perform adequate pre-use checkout of equipment. Even when preoperative evaluation does take place, overt or covert pressure from surgeons (or others) can cause anesthesia professionals to proceed with elective cases despite the existence of serious or uncontrolled medical problems. Production pressure can cause anesthesia professionals to choose techniques that they would otherwise believe to be inadvisable.

Figure 7-5. Components of team cognition and team knowledge.

Gaba and associates reported on a randomized survey of California anesthesiologists concerning their experience with production pressure.[75] These investigators found that 49% of respondents had witnessed a situation in which patient safety was compromised by pressure on the anesthesiologist. Thirty percent reported strong to intense pressure from surgeons to proceed with a case that they wished to cancel. Notably, 20% agreed with the statement that "If I cancel a case, I might jeopardize working with that surgeon at a later date."

Production pressure also leads to haste by the anesthesia professional, a psychological precursor to the commission of unsafe acts. In the survey, 20% of respondents answered "sometimes" to the statement that "I have altered my normal practices in order to speed the start of surgery," whereas 5% answered "often" to this statement. Twenty percent of respondents rated pressure by surgeons to hasten anesthetic preparation or induction as strong or intense. Repeated exposure to these conflicts can cause the anesthesia professional to internalize pressures; 38% of survey respondents felt strong to intense internal pressure to "get along" with surgeons, and 48% reported strong internal pressure to avoid delaying cases. Anesthesia professionals may then feel impelled to go ahead with cases against their better judgment, even in the absence of overt pressure.

Investigating these aspects of the work environment is difficult because such relationships are driven by economic considerations, as well as by the complex organizational and interpersonal networks linking the different medical cultures. Changing the environment will be equally challenging.

ASSESSING RISK FACTORS IN ANESTHESIA

An innovative attempt was made by a team of engineers and anesthesiologists to apply a technique called *probabilistic risk analysis* (PRA) to model cascading risks and the effects of different types of organizational interventions.[76,77] PRA has been used extensively in nuclear power and other highly hazardous industries (e.g., it was used for analysis of the risks to the space shuttle from thermal tile failure). Complete PRA models are very complex and extensive. In the anesthesiology study, a highly simplified PRA model was used to assess the feasibility of applying this technique to health care. The PRA analysis of organizational changes in anesthesia suggested that patient risk could be reduced best by closer supervision of residents, the use of patient simulators for training and periodic recertification, and regular medical examination of anesthesia professionals for fitness for duty. As yet it has not been possible to develop comprehensive PRA models of anesthesia risk because the number of decision and action elements is very large, and knowledge of the probability of success or failure for each of the decisions or actions is very limited. The PRA approach may be a useful heuristic to help clinicians lay out critical decision-making and therapy issues, but it may never make any meaningful contribution as a quantitative safety management technique.

Interest has been growing in applying process-oriented systems analysis to patient care flows and processes. For example, a group in Tübingen, Germany, performed a process-oriented systems analysis at a medical university hospital to assess the anesthesia work system's ability to regulate variances and disturbances in the work process.[78] These investigators showed that the internal work process can be regulated well but that the high interdependence of the anesthesia work system with other systems requires extensive coordination activities.

CHARACTERISTICS OF SUCCESSFUL INCIDENT REPORTING SYSTEMS

INCIDENT REPORTING SYSTEMS FOR LEARNING FROM PROBLEMS

An important strategy for improving patient safety (and a core tenet of HROT) is *organizational learning*. Such learning can be both prospective (deliberating in advance of process changes how they could affect safety) and retrospective (learning from events that have already transpired). Most high-hazard and high-reliability industries have made special efforts to create systems for retrospective organizational learning, often by concentrating on the reporting, investigation, and analysis of both frank accidents or errors and near-miss events with no negative outcome.[30,54,55,79-82] The details of successful incident reporting systems (IRSs) are covered in a number of publications (see also Chapter 6).[5,7,22,50,60,83-102]

Historically, investigation of errors in the health care system has been hindered by a "culture of blame,"[100-104] in which naming, blaming, and shaming are the main features of event reporting and review, rather than analysis by experts and focus on the development of systematic countermeasures. A culture of blame in which it is posited that errors, accidents, and near misses primarily result from a lack of knowledge, a bad attitude, or a lack of commitment to patients leads to a heavy burden on those involved in adverse events. It may also compound internalized negative feelings over having contributed to harming a patient.[104,105]

Anesthesiology as a specialty has played a leading role in the attempt to turn this culture of blame into a safety culture—putting safety first[1,2] and trying to understand how errors, incidents, and adverse events evolve.*

Errors Per Se Are Not the Cause of Accidents

Only a minor fraction of errors will lead to a negative patient outcome. However, the "harmless" error may well point to a systematic weakness (latent problem) in the system that, if investigated further, can lead to a systematic change. Unfortunately, the reverse is often true. The lack of a negative outcome is interpreted as "success" of the system, and the underlying vulnerabilities are ignored. In most cases, errors in complex systems are not the sole causes of accidents and rarely lead inevitably to an adverse event (see Fig. 7-1, *A*). In actuality, there are probably underlying reasons (C_1 to C_3 in Fig. 7-1, *B*) as to why someone commits an error initially, and then

*References 5, 30, 50, 63, 82, 83, 85, 106-115.

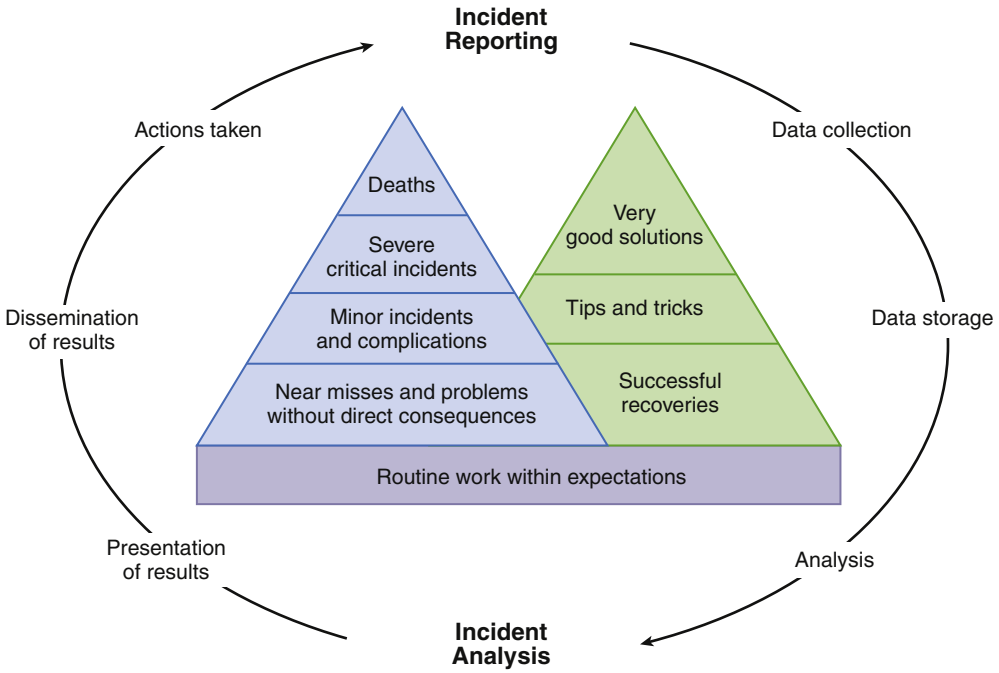

Figure 7-6. Process model of an incident reporting system that is constructed as a complete system. The data must be collected, saved securely, and analyzed independently, and the results must be visualized in a relevant way, distributed to stakeholders in an applicable way, and produce concrete action by the reporting organization. It should be possible to report all incidents and errors, independent of the outcome. Innovative systems should even include positive reports. *(Figure by P. Dieckmann.)*

additional contributing factors (CF_4, CF_5) are "needed" to allow an accident to develop. The main idea of modern IRSs is to identify the factors that make errors more likely to occur, as well as additional factors that allow a negative outcome to ensue. By reporting and analyzing factors C_1 to C_3 and CF_4 and CF_5 in Figure 7-1 regardless of the outcome, it may be possible to eliminate or reduce the probability or the harm potential of the accident long before it ever happens.

If reporting is safe and provides useful information from expert analysis, it can measurably improve safety.[90]

IRSs, if well-structured and operated, can make a substantial difference in system safety (Fig. 7-6). The knowledge about weaknesses and strengths of the health care system that is "out there" already can finally be extracted and made available for others. IRSs are often referred to as "learning systems," similar to the National Reporting and Learning System of the National Patient Safety Agency in the National Health Service (NHS) of the United Kingdom.

Effective IRSs allow insights into the health care system that are otherwise very difficult to acquire. In this sense IRSs can open "windows to the system."[106]

Merely having a reporting form or a database of information does not constitute an effective reporting system. These forms or databases can be effective only when they are constructed, established, and maintained as an entire system (Fig. 7-7; see also Fig. 7-6) and are successfully embedded in the organization or industry. Omission of or faults in any of the requirements in Box 7-5 will limit the success of the system.[98]

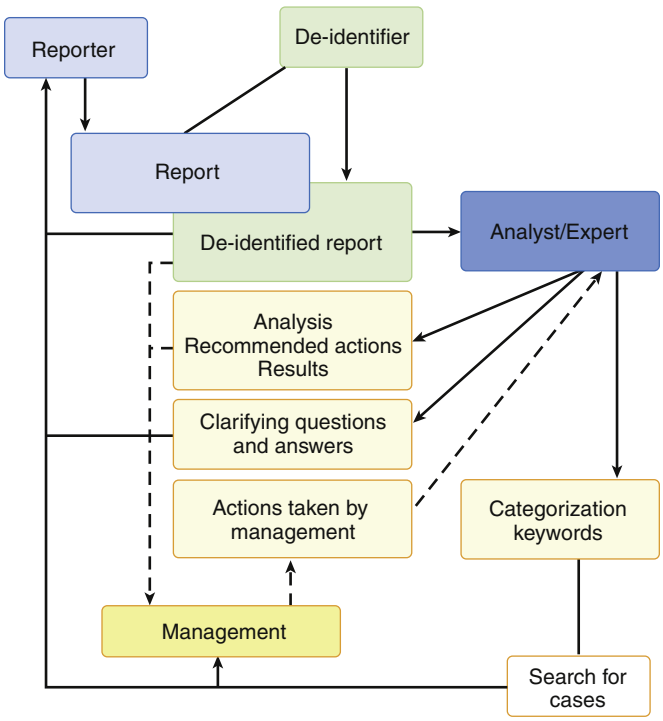

Figure 7-7. Data handling in a modern incident reporting system with de-identification. The incoming reports are first completely de-identified by a trained de-identifier. Only after this step is the report ready to be analyzed. It is important that the reports are analyzed by a multiprofessional team and that recommendations be fed back to the management of the organization from which the report came. The analysis and feedback should be transparent for all stakeholders.

BOX 7-5 ***Important Characteristics of Effective Incident Reporting Systems***

- Integration of the incident reporting system into the organization and full support by management
- The absence of negative sanctions for reporters and people involved
- Confidential or anonymous reporting option, with active de-identification (domain expertise required)
- Legal protection and state-of-the-art data security
- Independence of the organizational hierarchy: reports are sent to a trusted subunit outside the hierarchy of the organization or outside the organization (external trust center, e.g., NASA for the ASRS)
- Orientation to a system that enables all stakeholders of patient safety, including physicians, nurses, and technicians, to file reports easily
- Easy and fast reporting
- Training of stakeholders to file valuable reports (e.g., focusing on human factors issues, as well as medical-technical aspects)
- Timely feedback about reception of the report, its analysis, and proposed measures to be taken from it
- Analysis of each report by experts (a multiprofessional team that has a background not only in the medical domain but also in issues of human performance and analysis methods)
- Deep analysis of selected cases by using root cause analyses or failure modes and effect analyses with the aim of improving systems safety in the future
- Timely implementation of improvements to confirm the "reactivity" of the system and to *make a difference*
- Evaluation of improvements and special care to avoid "improvements for the worse" (quick fixes without improving the underlying latent dangers)
- Organizational support of reporting and analysis of cases, as well as the implementation of improvements
- Supports continuous improvement of the positive proactive safety culture in the department (systems perspective!)

Data from references 30, 87, 90, 116.
ASRS, Aviation Safety Reporting System; *NASA,* National Aeronautics and Space Administration.

What Should Be Reported?

Uncertainty about *what* should be reported is one of the barriers for an IRS.[117] In aviation, it has been necessary to create a reporting system for "incidents" (without negative outcome) that is distinct from systems for reporting or analyzing accidents. Of course, in aviation the occurrence of an accident is usually known immediately, and such events are never "supposed to happen." Yet in health care every human being will get sick and will die; in fact, most people will die in proximity to medical care. Thus, negative outcomes are inherent to the progression of disease, so determining which outcomes are the result of "errors" or "accidents" is much more difficult in health care settings. For this reason many experts believe that for health care event reporting systems, it should be possible to report all critical incidents, with or without a negative outcome. In fact, the system may also solicit reports of "positive events" in which the outcome was good despite challenging clinical circumstances. In general, the invitation to report should be very broad and cast a "wide net" to find all interesting occurrences.

What Should Report Forms Look Like?

Reporting systems that rely primarily on an array of checkboxes for the reporter to choose from regarding the "causes" of the incident have not proved to be useful. In fact, it is thought in the Aviation Safety Reporting System (ASRS), for example, that "counting incidents is a waste of time" (quote from Charles Billings, a founder of the ASRS). In a voluntary reporting system, one has no way to estimate the true number of specific problems. Similarly, trend analysis is not feasible because the frequency of events and the frequency of reporting are confounded. A free-text description of the reported incident has been more helpful in identifying what can be learned from the report. This view is also supported by the World Health Organization's guidelines for incident reporting[87]:

However, much of what promotes learning in patient safety lacks crisply defined data elements, so most authorities believe it is important for reports to include narrative to convey meaning. Narrative reports provide the opportunity to capture the rich context and storyline that allow the conditions that contributed to the error to be explored and understood.

Indeed, some believe that only narrative reports are capable of providing information that provides meaningful insight into the nature of the underlying systems defects that caused the incident (Richard Cook, personal communication).

Clearly, no reporting system can detect all the problems in a clinical institution, even ones that create a severe vulnerability. For one thing, it is known that between 50% and 96% of critical incidents are not reported with current systems,[118,119] although newer thrusts in incident reporting hope to increase the percentage of events reported.

Legal Issues of Reporting Systems

Especially in jurisdictions for which medical liability litigation is common, certain legal issues affect reporting systems. First, for some kinds of events in some settings, legal requirements to report the event to a governmental body are in place. This is true in the United States for certain kinds of adverse drug events or for certain failures of medical devices. Moreover, some states have started mandatory reporting programs about so-called never events that are thought should never occur in the absence of systems failure. In general, voluntary IRSs operate completely in parallel with any other types of reporting systems.

An important question for most reporters is whether the report will be confidential or anonymous and whether the report will confer any immunity to the reporter. Anonymous reporting provides maximum protection for reporters but limits the amount of information that can be acquired about any given event and the cogency of that information. Confidential reporting can allow confidential interaction between analysts and the reporter to acquire all the information and context needed concerning the event, but the linkage between the report and the identity of the reporter exposes a risk even if confidentiality is formally provided. The ASRS—on which many reporting systems have been modeled—operates as a confidential system but with subsequent de-identification of the reports to make them anonymous. Furthermore, the ASRS was able to offer

BOX 7-6 ***Characteristics of the German National Anesthesia and Intensive Care Incident Reporting System PaSOS (www.pasos-ains.de)***

- The system is provided by the two German anesthesia societies and run by a professional interdisciplinary group.
- Every anesthesia department and ambulatory anesthesia unit in Germany is entitled to take part. The basic functionality, software, server storage, and updates are free of charge (a service by the societies).
- The system is Web-based with an anonymous secure login (SSL). No data are stored locally in the hospitals, but users work directly on the central secure server with php technology.
- The reports are primarily sent outside one's own institution for de-identification by the system's own independent and interdisciplinary patient safety group (TuPASS), which increases trust of employees in the safety of the system.
- All reports undergo a professional four-eye active anonymization and de-identification process by domain experts trained in incident reporting and using checklist protocols to prevent any lapses in de-identification.
- After de-identification, most reports can be read in full text by all employees. This is meant to sensitize all by reading all the cases and to stimulate discussion about patient safety in the department and to report your own cases. It also provides very powerful feedback to the reporter, who can read "his" or "her" report in the Web.
- Every department has a unique department login that is provided to all employees (e.g., physicians, nurses, technicians).
- This login allows you to separate "your" reports from the national reports. So every department has its own "local" incident reporting system inside the big national system. No personal logins are provided because the system is anonymous.
- Most reports are readable in the national IRS, open to all anesthesiologists. This should contribute to the national spread of important critical safety information. Of course, on this level, nobody can see where the reports came from. (You can select "your" reports with your department login, but you cannot identify the origin of reports once they are in the national database).
- All reports are manually tagged with key words for meaningful search results; they are classified according to the U.K. NHS NPSA contributory factors framework,[52,94,95] and they are also categorized with the CRM key points (see text).[63,122]
- A local de-identifier does not exist and can therefore not be interviewed by any legal authorities.
- An optional module, "feedback and analysis suggestions," is available on request; it provides expert feedback about every report from the IRS provider team back to the organization's risk management, including systems safety analysis and suggestions for countermeasures.
- Several organizational prerequisites must be fulfilled by departments to take part (organizational embedding before starting to report). For example, all departments must send their PaSOS representatives to an initial workshop for briefing about the do's and don'ts of IRS. They also receive a set of slides and information material to spread the messages in their local departments (snowball effect).
- Departments that do not comply with the minimal requirements, especially prerequisites such as the written "no-blame assurance" to their employees, are not allowed to take part or may even be excluded from the system.

limited immunity from administrative actions for those who filed a report. This was a major incentive for reporting events. In health care, physicians largely fear malpractice litigation, and it is not possible to offer immunity from litigation to reporters, although offering immunity from administrative action (e.g., an official reprimand) within the hospital itself could be an incentive to report.

Statutory Protection. The United States now provides both federal and state statutory protection (shield) from discovery of any voluntary event reports that may be available (depending on the locale and many other circumstances). The U.S. Congress passed the Patient Safety and Quality Improvement Act of 2005 (Public Law 109-41). This authorized the Department of Health and Human Services to certify patient safety organizations (PSOs) to collect confidential reports about events and to analyze the information. The act provides strong legal protection (privilege) from any compelled release of the information, as in the process of discovery in a lawsuit.

Internal reporting systems within hospitals may be protected as quality improvement activities in states that provide privilege from discovery of such reports and deliberations. State laws vary widely on this matter. In addition, the quality improvement protections are often questioned during litigation, and whether the privilege will be applied depends on the ruling of a judge in each individual case.

Reporting systems in other countries have used other strategies. For example, in Germany, national IRSs have constituted themselves as a "press office" (informing the anesthesia public as a journal would); this then brings them under the protection of the "free press act and rights" and makes it almost impossible to use its data in litigation.

De-identification Before Information

A common strategy of confidential reporting systems is to convert the data quickly to anonymous status by "de-identification." To do this, it is necessary to edit the reports and delete all information that could be used to identify persons or organizations. Systems vary by what stage of analysis they conduct de-identification and where they set the balance between acquiring needed information and deleting possibly identifying data. One issue in all reporting systems, especially in health care, is that the key facts of many events may be unique and may thereby lead to a high risk of "intrinsic identification" even when all objective identifiers are stripped.

Many countries have IRSs with various designs and operational processes (see Appendix 7-1).[5,7,50,60,83-100] Many systems are installed locally, but more and more national systems, or at least systems with a national common data set, are being installed.[120] Box 7-6 shows some of the features of and lessons learned from different German national IRSs.

The Anesthesia Incident Reporting System in the United States. In 2011 the Anesthesia Quality Institute, affiliated with the American Society of Anesthesiologists (ASA), initiated the Anesthesia IRS (AIRS) to collect reports of critical events in anesthesia (see also Chapter 6). Incidents can be reported by secure Web-based data collection, either confidentially or anonymously. Confidential reporting allows the AIRS analyst to contact the individual for clarification or follow-up. Legal protection is provided by 2005 US federal legislation that makes reports to, and analysis work products of, approved PSOs free from "discovery" in legal proceedings. The law also imposes strict guidelines on how confidentiality of the work must be preserved. The AIRS publishes a monthly column in the *ASA Newsletter,* in which it describes—in de-identified form—an interesting case report and its analysis by the AIRS Committee. As of January, 2013, 713 total reports had been received (95% "confidential"), with 16 published cases in the *ASA Newsletter.*

AN INDEPENDENT ORGANIZATION FOR ACCIDENT INVESTIGATION IN HEALTH CARE (MEDICAL NATIONAL TRANSPORTATION SAFETY BOARD)?

In the United States, transportation accidents are investigated by the National Transportation Safety Board (NTSB; http://www.ntsb.gov/), an independent federal government organization. Similar agencies exist in most countries. Suggestions have been made for several decades for N NTSB-like body to investigate accidents in health care. In the Past few years, new calls have been made to establish such an organization. The complexities and pitfalls of such a system (including the fact that adverse outcomes are several orders of magnitude more common in health care than in commercial aviation) have so far obstructed any progress toward creating such a program. Nevertheless, the results of such professional interdisciplinary investigations, directed toward how such accidents can be prevented in the future, could be very beneficial. The debate about the feasibility and advisability of such high-level investigating organizations will probably continue for a long time.

PERSONNEL SELECTION TO IMPROVE SAFETY

Each profession has special requirements of personnel so that they are able perform tasks optimally. Selection of the right people to do the job is among a few core human factors issues. In most countries personnel selection in health care puts a high premium on education and knowledge-based test scores, but very little emphasis on measuring underlying cognitive abilities. Unlike the situation in military aviation, there are few formal selection criteria for entry into anesthesia practice. Instead, the criteria are decided on by each department's trainee selection committee. Nearly every student who chooses anesthesia as a specialty will be accepted by some training institution. Moreover, few trainees are terminated from their anesthesia training—and then usually only because of normative failures (e.g., drug abuse; ill-treatment of patients or co-workers; failure to show up) rather than lack of performance in doing anesthetic work.

Some work has attempted to define the underlying ability characteristics of a successful anesthesia professional. Greaves and Grant presented an inventory of 16 characteristics of "good" anesthetic practice—knowledge, skill, perception, confidence, prudence, vigilance, fluency, decisiveness, anticipation, organization, flexibility, responsiveness, good manner, assertiveness, good management, and good communication.[26] This inventory can serve as a basis for discussion of anesthesia professionals' education and training. The authors of the inventory recommended its use for formalized consultant feedback to trainees while noting the inventory's unproven validity and reliability. An interdisciplinary group in Germany conducted an evaluation of another list of critical abilities for anesthesia professionals that was published in German.[121]

HUMAN FACTORS

This section of the chapter deals with human factors in the broadest sense of the meaning. In contrast to the previous section, which covered aspects of the health care system and organizational matters, the human factors portion is related to the performance of individuals and teams and to factors influencing their performance and promoting or preventing active or passive errors. Because more than 70% of all errors in medicine can be attributed to problems with human factors rather than problems with knowledge or practical skills, the impact of human factors cannot be overestimated. On this basis, perhaps human factors should take 70% of the whole book. Given that this chapter cannot deal with human factors in a comprehensive way, many topics can be touched on only briefly, and the reader is directed to the available literature. We focus on the most important aspects of human factors that are directly relevant to practicing anesthesia professionals.

NONTECHNICAL SKILLS IN ANESTHESIA

Since the 1980s, the health care professions have become more aware of the importance of "nontechnical" skills in the delivery of safe, high-quality medical care. This recognition has brought an increased need for assessment, evaluation, and training of these skills. Patient simulators were perhaps the first opportunity to show and train these skills under realistic stressful conditions.[122-125] The introduction of simulators and the associated training concepts accelerated understanding of these human factors by the medical community.[2] Some of the needed "crisis management skills"[25,126] can be trained for without the use of simulators, as shown in other domains (aviation, oil platforms, military).[81,127-129] The baseline level of crisis resource management (CRM) performance is somewhat low.[130] Helmreich stated that as a first step in establishing error management programs, it is necessary to provide formal training in teamwork, the nature of error, and the limitations of human performance.[55]

Different ways exist to group the nontechnical skills that are at the heart of CRM training. One approach is to distinguish between two categories of nontechnical

TABLE 7-3 NONTECHNICAL SKILLS IN ANESTHESIA: CLASSIFICATION, MARKERS, AND TEACHING POINTS

	Anesthesia Nontechnical Skills (Fletcher et al[164])		Performance Markers (Gaba et al[142])	Key Teaching Points in Anesthesia Crisis Resource Management (Howard et al[165], Gaba et al[166])
Concepts	**Elements**	**Categories**	**Markers**	**Reminders**
Cognitive and mental skills	Planning and preparing Prioritizing Providing and maintaining standards Identifying and using resources Gathering information Recognizing and understanding Anticipating Identifying options Balancing risks and selecting options Reevaluating	Task management Situation awareness Decision making	Orientation to case Leadership (also a social and interpersonal skill) Planning Workload distribution Anticipation Vigilance Preparation Reevaluation	Anticipate and plan Know your environment Exercise leadership Set priorities dynamically Use cognitive aids Distribute the workload Mobilize all available resources Use all available information Allocate attention Anticipate and plan Prevent and manage fixation errors Reevaluate repeatedly
Social and interpersonal skills	Coordinating activities with team Exchanging information Using authority and assertiveness Assessing capabilities Supporting others	Team working	Inquiry and assertion Communication feedback Group climate Followership	Communicate effectively Teamwork Communicate effectively Exercise leadership and followership Exercise followership
Overall assessment	Not applicable Assessments are made only at the element and category level		Overall nontechnical performance of the primary anesthetist Overall nontechnical performance, not who is right of the whole team	Teamwork! Concentrate on what is right, not who is right

skills: (1) cognitive and mental skills, including decision making, planning, and situation awareness (Table 7-3); and (2) social and interpersonal skills, including aspects of teamwork, communication, and leadership. Another approach is to split nontechnical skills into five major groups, as shown in Figure 7-8.

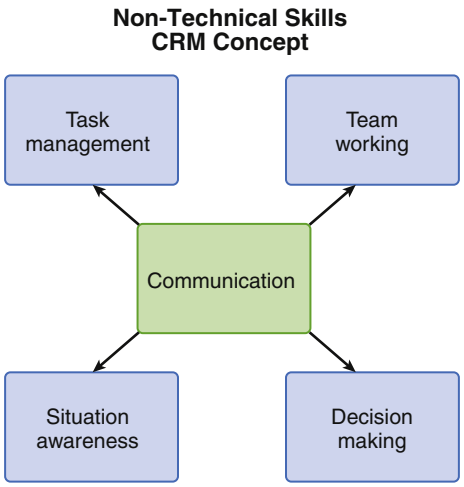

Figure 7-8. Five main groups of nontechnical skills. In this approach, effective communication is like the glue that holds all the other components together. *CRM,* Crisis resource management.

CRISIS RESOURCE MANAGEMENT

What Exactly Is Crisis Resource Management?

Cockpit (later "crew") resource management was introduced in aviation in the mid-1980s and is considered to be successful in that industry and other industrial and military settings (although admittedly, there is not what evidence-based medicine would call "level 1 evidence" for this success).[29,30,49,131-134] Crew resource management is now taught systematically to crew members of all major U.S. airlines and at many airlines around the world.[135] A similar program in anesthesiology was first developed by Gaba, Howard, and associates at the Veterans Affairs (VA) Palo Alto Health Care System and Stanford School of Medicine in Palo Alto, California,[4,117,122,125,136] originally as Anesthesia Crisis Resource Management (ACRM). The ACRM curriculum and its variants have since been adopted by training centers worldwide. A detailed description of the ACRM course is provided.

In overview, CRM means to coordinate, use, and apply all available resources to protect and help the patient as best as possible. Resources include all the personnel involved, along with all their skills, abilities and attitudes—albeit also with their human limitations. Machines, devices, and information sources, including cognitive aids, are also critical resources.

BOX 7-7 ***Crisis Resource Management—Key Points in Health Care***

1. Know the environment.
2. Anticipate and plan.
3. Call for help early.
4. Exercise leadership and followership with assertiveness.
5. Distribute the workload (use the 10-seconds-for-10-minutes principle).
6. Mobilize all available resources.
7. Communicate effectively—speak up.
8. Use all available information.
9. Prevent and manage fixation errors.
10. Cross check and double check (never assume anything).
11. Use cognitive aids.
12. Reevaluate repeatedly (apply the 10-seconds-for-10-minutes principle).
13. Use good teamwork—coordinate with and support others.
14. Allocate attention wisely.
15. Set priorities dynamically.

Modified from Rall M, Gaba DM: Human performance and patient safety. In Miller RD, editor: Miller's anesthesia, *ed 6. Philadelphia, 2005, Churchill Livingstone.*

Figure 7-9. Crisis resource management (CRM) cards for training. The cards are given to each participant during simulation training sessions. One side shows the 15 CRM key points of Rall and Gaba; the other side shows a tool for formalizing decision making to reach better decisions and avoiding fixation errors. It also shows a short graphic version of the "10-seconds-for-10-minutes" concept, reminding participants to take the necessary time to organize into a team, whenever appropriate. *(Photograph by M. Rall.)*

Although it is termed crisis management, CRM principles actually also apply before a crisis ensues. CRM includes preventing and intercepting threats and errors and minimizing their negative consequences to the patient.

The key points of CRM as they apply to anesthesia care have been steadily updated and expanded over time (Box 7-7). During simulation training sessions, little cards with CRM key points are usually given to the participants to keep the memory of these points alive when the participants are back in the real world (Fig. 7-9). Some of the principles may seem obvious or self-evident. However, from our experience in simulation training, it is in fact *not* trivial to apply these principles whether during routine work or during crises. More theoretic background on the principles can be found in the textbook on ACRM by Gaba, Fish, and Howard,[137] as well as in related safety literature.[†]

As with nearly all principles of sound human factors, application of CRM key points to patient care must be supported by top leadership and reinforced in the actual work environment. It is of no worth to study these principles (or even practice them in simulations) only to find that the pressures and culture of the "real OR" make them impossible to implement for real patients. Fully integrating these key points into the structures and processes of clinical practice has proved to be a significant challenge.

Know the Environment! (CRM Key Point 1). CRM begins before the crisis starts. One of the prerequisites for CRM is to *know the available resources and the details of the specific working environment.* Resources are *personnel, equipment* (software, hardware, or cognitive aids), and *supplies*. It is important to know who can be asked for help, who is available at different times of the day, how to call those helpers quickly, and how long it will take them to arrive. Regarding equipment, it is necessary to not only know *what* is available and *where to find it* but also *how* to operate it. The anesthesiologist is responsible for being well versed in the operation of all relevant equipment and should also use manuals and other cognitive aids to learn to use the gear and as a backup source of information during patient care.

Anticipate and Plan (CRM Key Point 2). Anticipation is key for goal-oriented behavior. Anesthesia professionals must consider the requirements of a case in advance and plan for the key milestone. They must imagine what could go wrong and plan ahead for each possible difficulty. Savvy anesthesia professionals expect the unexpected, and when it does strike, they then anticipate what could happen next and prepare for the worst. People often talk about "staying ahead of the game" or, conversely, "falling behind" or "being behind the eight ball."

Call for Help Early (CRM Key Point 3). Knowing one's own limitations and calling for help are signs of a strong character and a competent person. Trying to handle everything alone or toughing out a critical situation is dangerous and unfair for the patient, who should not suffer to protect the anesthesia professional's pride or ego. In case of an emergency or even a suspected emergency, help should be called early rather than late. Some typical triggers for calling for help that apply to any anesthesia professional at any level are (1) when there are too many tasks to do, (2) when the situation is already catastrophic (e.g., cardiac arrest, difficulty securing the airway), (3) when serious problems are becoming worse or are not responding to the usual maneuvers (or both), and (4) when you do not know what is going on. It is important to know in advance who is available and how to call for help and to plan for how best to use the help when it arrives.

Exercise Leadership and Followership With Assertiveness (CRM Key Point 4). A team needs a leader. Someone has to take command, distribute tasks, collect

[†]References 30, 49, 51, 54, 55, 80-82, 138-142.

information, and make key decisions. Leadership rarely means knowing more than everybody else, doing everything alone, or putting other people down. Leadership is about planning, deciding, and distributing tasks by clear communication. Followership is also an important skill. Followers are key members of the team who listen to what the team leader says and do what is needed. However, it does not mean shutting off their own brains. Followers should be assertive if they think that the team leader is making wrong decisions. It is their responsibility to make sure that the leader is aware of their concerns. Whenever people work together, conflict can ensue; anyone on the team may need to diffuse conflicts to focus the team on care of the patient. Get everyone to concentrate on *what* is right, not on *who* is right.

Distribute the Workload—10-Seconds-for-10-Minutes Principle (CRM Key Point 5). One of the main tasks of a team leader is distribution of the workload. Someone is needed to define the necessary tasks and ensure that they are fulfilled properly and that everything fits together. If possible, the team leader should remain free of manual tasks to observe, gather information, and delegate tasks. Team members should also look actively for things that need to be done. It is not a good team if the team leader has to express every idea and nothing is done before it is explicitly ordered.

A corollary is known as the "10-seconds-for-10-minutes principle,"[143] which posits that if a team can slow its activities down just a little, it can gain more than enough benefit in rational decision making and planning to offset the delay. The need to slow down appears to be greatest in critical situations such as the beginning of the diagnosis and treatment planning or when the team "feels stuck" because the usual treatment is not working (Fig. 7-10).

A prehospital emergency service in Germany, after being trained by Rall and having more than 2 years of ongoing simulation team training, reported that they frequently used the "10-for-10" principle in the field with a high subjective improvement of team decisions and team work (Sascha Langewand, EMS Cooperation, Schleswig-Holstein Ltd, www.rkish.de, personal communication).

Mobilize All Available Resources (CRM Key Point 6). Everyone and everything that could help deal with the problem at hand should be mobilized, including humans and technology embedded in organizational processes. On the human side, the anesthesia professional's knowledge and skills (mitigated by knowledge of one's human deficiencies) are the most important resources, complemented by the human helpers who can be brought to bear. Equipment and supplies are the means by which knowledge is translated into action. Some equipment will be readily available, but other equipment will need time to be mobilized.

Communicate Effectively—Speak Up (CRM Key Point 7). Communication is key in crisis situations. Good team work depends on everybody's being on the same page and coordinating their efforts; communication is the glue that holds the disparate members together (see Fig. 7-8). Effective communication is challenging to accomplish. Several aspects

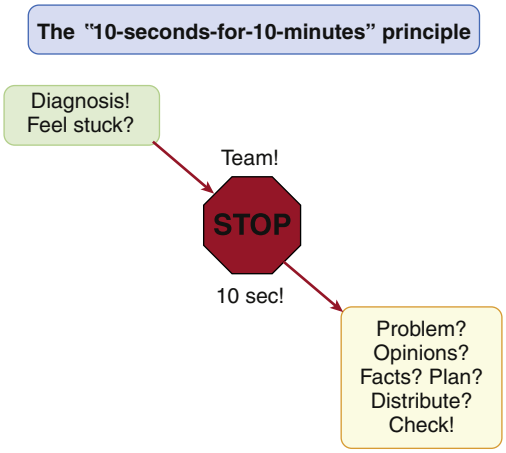

Figure 7-10. The "10-seconds-for-10-minutes principle." When making a *diagnosis* or *feeling stuck*, perform the 10-second team time-out and check to see "what the biggest problem is (the most dangerous aspect right now)" (*Problem*). Clarify this with all available team members (*Opinions*). Gather the information available (*Facts*). Plan the treatment, including the desired sequence of actions. Distribute the workload by assigning tasks and responsibilities. *Check* with all team members about any further concerns or suggestions.

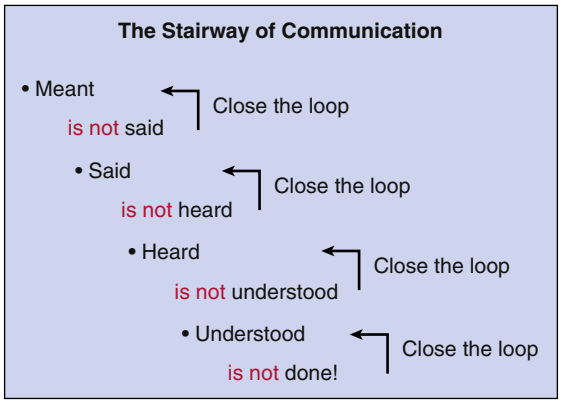

Figure 7-11. Model showing the importance of proper communication. When dealing with complex situations under time pressure, people tend to "mean" a lot but "say" little. It is important to let other team members know what you think (mental model). Not everything that is said is necessarily heard by those who should hear. This is often not the "fault" of the receiving end; acoustic hearing and mental understanding are not the same. It is important for the sender and receiver of a message to close the communication loop. Some tasks need time to be completed and may fail. Let the team know.

make communication difficult sometimes; for example, saying something is meaningful communication only if the messages are received and understood (Fig. 7-11).

Use All Available Information (CRM Key Point 8). Anesthesiology is particularly complex because information must be integrated from many different sources. Every bit of information can assist in understanding a patient's status better and in arriving at the correct diagnosis. Information sources include those immediately at hand (the patient, monitors, the anesthesia record), secondary sources such as the patient's chart, and external sources such as cognitive aids (see later) or even the Internet.

Prevent and Manage Fixation Errors (CRM Key Point 9). Human actions are based on an instantaneous mental model of the current situation. If the model of the situation is erroneous, the actions will probably be wrong.

The term *fixation error* describes a model that is persistently faulty despite sufficient evidence to correct it. A fixation error is the persistent failure to revise a diagnosis or plan in the presence of readily available evidence suggesting that a revision is necessary. This type of error is extremely common in dynamic situations. Three main types of fixation errors are recognized.[144,145]

One type of fixation error is called *this and only this*—sometimes also called *cognitive tunnel vision.* In this type of error, attention is focused on only one possibility, and other (possibly or actually correct) alternatives are not taken into account. Another fixation error is *everything but this,* which is the persistent search for irrelevant information and failure to treat a probable cause, with serious consequences.

Perhaps the most insidious fixation error is the persistent claim that *everything is OK,* in which all information is attributed to artifact, and possible signs of a catastrophic situation are otherwise dismissed. Another form of "everything is OK" is the failure to transition from routine mode to emergency mode when the situation demands it.

One principle of managing fixation errors is to obtain a new view—a second opinion—on the situation from someone unaware of the faulty previous assumptions. Although it is appropriate to brief the new person on the situation, it is best to avoid biasing the person with the conclusions already drawn. Even when working alone, the anesthesia professional can deliberately change perspectives (physically or mentally) and look for information not fitting the picture of the situation, as though entering the room for the first time.

The aforementioned 10-for-10 principle (CRM key point 5) may also be helpful in managing fixation errors. More information on fixation error is provided later in the section on core process.

Cross Check and Double Check—Never Assume Anything (CRM Key Point 10). Cross checking means to correlate information from different sources. There are often three independent sources of information on the patient's heart rate (electrocardiogram [ECG], pulse oximetry, and blood pressure monitor), for example, and two on the rhythm (ECG and pulse oximetry).

Another aspect of cross checking involves reviewing the status of actions that have been done or are under way. Human memory of actions performed is vulnerable, especially when interruptions have occurred. Moreover, although we often attempt to check things "at a glance," such fleeting observations are prone to error. Checking numbers and settings on equipment by actually touching them and looking carefully may be worth the effort. In general it is best to "never *assume* anything"; make sure and double check important information.

Use Cognitive Aids (CRM Key Point 11). Cognitive aids—such as checklists, handbooks, calculators, and advice hotlines—come in different forms but serve similar functions. They make knowledge "explicit" and "in the world" rather than only being implicit, in someone's brain. Memory and cognitive functioning are vulnerable to error or complete failure, especially in stressful situations. Cognitive aids offload memory and safeguard the recall of critical items. They also help ensure the use of current best practices because during a crisis, people sometimes revert to what they originally learned as the best, not what is the latest recommendation. The use of cognitive aids rather than memory alone is another sign of strength. Cognitive aids are discussed in more detail later in this chapter.

BOX 7-8 ***Reevaluation Questions—Maintaining Situation Awareness***

- Was the initial assessment of the situation or diagnosis correct?
- Did the actions have any effect? (e.g., Did the drug reach the patient?)
- Is the problem getting better, or is it getting worse?
- Does the patient have any side effects resulting from previous actions?
- Are there any new problems or other problems that were missed before?
- What further developments can be expected in the (near) future?

Reevaluate Repeatedly—Apply the 10-Seconds-for-10-Minutes Principle (CRM Key Point 12). Acute medicine is dynamic. What is correct now may be wrong in the next minute. Some parameters may change slowly over time, and subtle changes can be difficult to perceive. Trend monitoring can be helpful to detect slow, but insidious changes.

Furthermore, the dynamic nature of critical events makes it necessary to repeatedly reevaluate the situation. Box 7-8 shows a set of questions that should be raised repeatedly to check whether one is still treating the most serious problem most effectively.

Implement Principles of Good Teamwork—Coordinate With and Support Others (CRM Key Point 13). Teamwork in multidisciplinary teams is at the heart of much patient management in the OR and ICU. Key principles of teamwork in dynamic situations have been delineated, especially in the work of Eduardo Salas and colleagues at University of Central Florida (see Fig. 7-5). Coordination within a team ideally begins before a team gathers. If all members know about the tasks to be done and their roles during these tasks, coordination is easier. Short briefings at the beginning of a task are common in aviation and are worth the time spent. During the acute phase of a crisis situation, it is valuable to spend a small amount of time to coordinate the team's activities (see 10-for-10 earlier in CRM key point 5). "Dream teams" support each other continuously, with everybody looking after each other.

Allocate Attention Wisely (CRM Key Point 14). Human attention is very limited, and multitasking is very difficult. Attention must be dynamically allocated where it is needed. One can develop rhythms and scan

patterns to do this. The "ABC equals airway, breathing, circulation" mnemonic is based on this principle. Other strategies are to alternate between focusing on details and focusing on the big picture and to offload certain responsibilities, tasks, or information streams to other qualified team members, provided these teams members periodically update the team leader about the situation.

Set Priorities Dynamically (CRM Key Point 15). Dynamic situations demand dynamic measures with decisive, purposeful preliminary decisions and actions that are constantly reevaluated and modified as new information becomes available or the results of treatment are apparent. What was not a right move at one time may become the right move at another. In addition, having one solution to an obvious problem does not guarantee that it is the best solution to the one problem or that only one problem exists. However, one priority is always paramount—ensuring adequate oxygenation and perfusion of critical organs.

HOW CAN CRISIS RESOURCE MANAGEMENT SKILLS BE LEARNED AND TRAINED?

CRM is taught in many different ways. Seminar-based training on human factors and CRM principles has become popular in health care (e.g., programs called TeamSTEPPS, MedTeams, Medical Team Training, LifeWings),[146-153] although the role of such activities versus simulation-based CRM approaches has not yet been fully delineated. Seminars use didactic sessions, group exercises, and sometimes discussion and analysis of "trigger videos."

Such training seems useful for learning about CRM principles and articulating how they could apply to anesthesia professionals' work environments. Newer studies even show an improvement in patient outcomes.[154-156] Given the experience in the airline industry, it is likely that to address CRM skills for both trainees and experienced personnel completely, a combination of seminars and simulation-based exercises will be needed. We believe that practicing the execution of CRM skills requires exposure to challenging clinical situations in realistic simulation scenarios, followed by detailed group debriefings (often using video of the simulations) to analyze what transpired. As detailed in Chapter 8, such CRM-oriented simulation training may be available in dedicated simulation centers or as in situ simulation training in actual work environments. Many simulation centers also offer mobile training, which means that they can bring the simulator and everything else needed (e.g., audio/video equipment) to any facility to train the staff in institutions that do not have a simulator or staff capable of conducting the training.

HOW CAN CRISIS RESOURCE MANAGEMENT SKILLS CONTRIBUTE TO PATIENT SAFETY?

Although 70% of all errors in anesthesia may be attributable to human factors, interventions to improve this picture have only partially penetrated the fabric of the industry. CRM-oriented training is one component of a comprehensive approach to addressing human factors issues in anesthesia safety, but it is not yet a standard part of clinical training. Meanwhile, some definitive evidence indicates that CRM training improves patient outcomes,[154,156-158] even though it is often functionally very difficult to acquire such evidence. Nevertheless, CRM training is an integral and accepted part of training in aviation, nuclear power, and other industries in which human errors can lead to catastrophic events. There is no reason to assume that anesthesia professionals would be less error prone or would benefit less from human factors–based CRM training than the professionals in other high-hazard industries.

ASSESSING NONTECHNICAL SKILLS IS MORE SUBJECTIVE THAN ASSESSING TECHNICAL SKILLS

A study by Morgan and Cleave-Hogg concluded that "the simulator environment is somehow unique and allows different behaviors to be assessed."[159] As Glavin and Maran stated, "Any scoring system that attempts to address the assessment of clinical competence clearly has to address both technical and non-technical skills."[160] Consequently, there is still a long road ahead in measuring performance.

Two research groups (VA-Stanford and the University of Basel in Switzerland) studied adaptations of the anchored subjective rating scales developed by the NASA/University of Texas Aerospace Crew Performance Project. The VA-Stanford group published preliminary data reviewing the interrater reliability of subjective ratings of behavior on five-point anchored scales.[142,161] Using a fairly stringent test of interrater reliability (the topic is quite complex in the statistical literature), these investigators found only moderate reliability when 5 trained raters used a 5-point scale to score 14 anesthesia teams, each managing 2 different complex critical events in the simulator (malignant hyperthermia and cardiac arrest). Despite some difficulty in agreement on the operational definitions of each type of behavior, the investigators stated that the largest problem in achieving agreement was the high variability of each behavior over the course of a simulation. For example, an anesthesia crew could show evidence of good communication at a particular instant, only to be shouting ambiguous orders into thin air at the next instant. Aggregating such behavior into a single rating was extremely difficult, even for the bounded time segments of the scenario. These data demonstrate the importance of evaluating performance by more than one rater, who, no matter how well trained, may produce scores that differ significantly from another single rater. The investigators suggested combining scores from a minimum of a pair of raters inasmuch as it was shown that the mean of scores from two raters had a very low probability of differing from the mean of five raters by more than a single rating point. The behavioral markers of their score are shown in Table 7-3 and are compared with Fletcher's anesthesia nontechnical skills (ANTS) score and the ACRM key teaching points (see Box 7-7).

The Anesthesia Nontechnical Skills System

Fletcher, from the Industrial Psychology Group of Aberdeen, Scotland (a group headed by Rhona Flin) and working with clinicians from the Scottish Clinical Simulation Centre (Glavin and Maran), performed an in-depth review of the role of nontechnical skills in anesthesia. Fletcher stated that nontechnical skills had not been explicitly addressed in the traditional education and training of anesthesiologists, even though they have always been demonstrated and used during clinical work. The group analyzed incident reports and observations of real cases, as well as attitude questionnaires and theoretic models.[162] Like others, these investigators recognized that simulation offers the opportunity to identify, develop, measure, and train nontechnical skills in a safe learning environment, so they also included significant observations during realistic simulations.[163]

Incident reports proved very limited because they did "not provide the finer-grained level of information necessary to understand where the skills broke down."[164] These workers defined nontechnical skills as "attitudes and behaviours not directly related to the use of medical expertise, drugs or equipment." Although nontechnical skills can be seen under the heading of "human factors," it is preferred that they be addressed as "nontechnical skills," which is more specific.

As in the ACRM instructional paradigm,[122,165,166] Fletcher and colleagues identified two categories of nontechnical skills:

- Cognitive and mental skills, including decision making, planning, and situation awareness
- Social and interpersonal skills, including aspects of team working, communication, and leadership

Fletcher's ANTS scheme is shown in Table 7-4, along with the behavioral markers of Gaba's team and the ACRM key teaching points. A description of the ANTS categories and elements, including examples of good practice and poor practice, is presented in Table 7-4.

The structure of the new ANTS scheme was derived from a system of behavioral markers that had been developed for aviation in a European project called "NOTECHS," which itself was an evolution of the UT-Markers of the University of Texas (Helmreich). A summarized comparison of the aviation systems and explanations about using nontechnical markers for training and evaluation can be found in the book, "Group Interaction in High Risk Environments," written by an international group of human factors specialists.[166a] Several comments about the ANTS approach are appropriate.

ANTS' intent is to score only those skills that can be identified unambiguously through observable behavior. Such restriction may enhance the reliability of the scoring but could exclude relevant personal factors such as self-presentation, stress management, and maintaining perspective. ANTS assumes that "communication" is included or "even pervades" all other categories and does not score communication as a separate skill. This

TABLE 7-4 EXAMPLE OF A DESCRIPTION OF THE ANESTHESIA NONTECHNICAL SKILLS SYSTEM (ANTS SYSTEM V1.0)

Task Management—skills for organizing resources and required activities to achieve goals, be they individual case plans or longer-term scheduling issues; four skill elements: planning and preparing, prioritizing, providing and maintaining standards, and identifying and using resources

Planning and preparing—developing primary and contingency strategies in advance for managing tasks, reviewing these tasks, and updating them if required to ensure that goals will be met; making necessary arrangements to ensure that plans can be achieved

Behavioral Markers for Good Practice	*Behavioral Markers for Poor Practice*
Communicates plan for case to relevant staff	Does not adapt plan in light of new information
Reviews case plan in light of changes	Does not ask for drugs or equipment until the last minute
Lays out drugs and equipment needed before starting case that are suitable for the patient	Does not have emergency or alternative drugs available
Makes postoperative arrangements for patient	Fails to prepare postoperative management plan

Prioritizing—scheduling tasks, activities, issues, information channels, and so on, according to importance (e.g., because of time, seriousness, plans); being able to identify key issues and allocate attention to them accordingly; and avoiding being distracted by less important or irrelevant matters

Behavioral Markers for Good Practice	*Behavioral Markers for Poor Practice*
Discusses priority issues in case	Becomes distracted by teaching trainees
Negotiates sequence of cases on list with surgeon	Fails to allocate attention to critical areas
Conveys order of actions in critical situations	Fails to adapt list to changing clinical conditions

Providing and maintaining standards—supporting safety and quality by adhering to accepted principles of anesthesia; following, when possible, codes of good practice, treatment protocols or guidelines, and mental checklists

Behavioral Markers for Good Practice	*Behavioral Markers for Poor Practice*
Follows published protocols and guidelines	Does not adhere to emergency protocols or guidelines
Cross-checks drug labels	Does not check blood with patient and notes
Checks machine at beginning of each session	Breaches guidelines such as minimum monitoring standards
Maintains accurate anesthetic records	Fails to confirm patient's identity and consent details

From Fletcher GCL, Flin R, Glavin RJ, Maran NJ: Framework for observing and rating anaesthetists' non-technical skills: anaesthetists'non-technical skills (ANTS) system V1.0, *version 22, Aberdeen, Scotland, 2003, University of Aberdeen.*

approach is in contrast to that of others who believe that communication is a specific skill that should be rated separately.[127,167] The category "task management" of the ANTS includes the element "providing and maintaining standards," which may be a point of discussion if it can be an observable behavior "not directly related to medical expertise" as stated in the definition. In addition, a problem may arise because there are not so many well-accepted standards in medicine (in strong contrast to, e.g., aviation).

Flin's group, meanwhile, adapted nontechnical skills scoring systems for several other medical fields, such as for surgeons and ICU care.[30,82,135,140-142,168-175] These investigators have not yet made adaptations that fully describe multidisciplinary crews and teams.

Not all nontechnical skills will be expected to be observed during every scenario or clinical situation. It is important to delineate between "required behaviors" in a given scenario and the generic set of behaviors. If a required behavior is not observed, the rating system advises that one rate that behavior as poor nontechnical skills, whereas the absence of a given nontechnical skill behavior otherwise has no particular meaning and should be rated as "not observed." As in all subjective nontechnical performance systems, training plus calibration of raters is necessary.

Fletcher and co-workers evaluated ANTS by using scripted videotapes taken in a realistic simulator.[164] Fifty consultant anesthesia professionals were given 4 hours of training as raters and then rated 8 test scenarios ranging from 4 to 21 minutes each. They rated performance at the level of specific elements and also at the broader level of category (see Table 7-3) by using a 4-point scale (they could also enter "not observed"). Three investigator anesthesia professionals also rated the scenarios and agreed on a "reference rating" to be used as the benchmark for the study. In questionnaires, the ANTS system was evaluated by raters as relatively complete, possibly with superfluous elements. Raters found that nontechnical skills were usually observable, and most thought that it was not difficult to relate observed behavior to ANTS elements. The interrater reliability, accuracy, and internal consistency of the ratings were good to acceptable and are presented in Table 7-5.

Although well performed, some caveats about these data are in order. Because scripted videos were used as the basis for ratings, it is possible that the observability or scorability of the desired sets of behavior was greater than in actual simulation scenarios. The scripted scenarios were rather short (4 to 21 minutes), which perhaps made it relatively easy to remember certain aspects of the performance and reduced the likelihood that the raters would encounter the problem of aggregating a score from fluctuating behavior over time. The window of "accuracy" as "±1 point" on a 4-point scale seems to be rather wide.

On the whole, the ANTS system appears to be a useful tool to enhance assessment of nontechnical skills in anesthesia and other medical fields further, and its careful derivation from a current system of nontechnical assessment in aviation (NOTECHS) may even allow some inter-domain comparisons.[21,171]

PERFORMANCE-SHAPING FACTORS

With a few exceptions, the foregoing discussion of the performance of skilled anesthesia professionals has assumed that they are normally fit, rested, and acting in a standard working environment. Experience in human performance in the laboratory and other domains suggests that internal and external performance-shaping factors exert profound effects on the ability of even highly trained personnel. The degree to which performance-shaping factors affect the overall performance of anesthesia professionals and the outcome of patients is highly uncertain. In extreme cases, such as profound fatigue, no question exists that these factors can result in severe degradation of the anesthesia professional's performance or even complete incapacitation. However, these extreme conditions are quite unusual, and it is unclear whether the levels of performance decrement likely to be induced in typical work situations have any significant effect. Although the practice of anesthesia does require an attentive and skilled individual, it does not require peak human performance. It would be unrealistic to expect peak performance for every anesthetic regimen because on the order of 60,000 anesthetics are administered each day in the United States by a total of approximately 40,000 to 60,000 anesthesia professionals. Although it is unrealistic to expect peak performance for every case, society expects anesthesia professionals to come to work prepared—not impaired. As stated in the ASA guidelines for the ethical

TABLE 7-5 **RESULTS OF AN EVALUATION STUDY OF ANESTHESIA NONTECHNICAL SKILLS BY FLETCHER AND COLLEAGUES**

Measure	Score	Range	Maximum/Minimum	Element/Category
Interrater agreement	Element level	0.55-0.67	Highest element	Identifying/using resources
	Category level	0.56-0.65	Lowest element	Recognizing/understanding
			Highest category	Task management
			Lowest category	Team working
				Situation awareness
Accuracy relative to the reference rater's score	% within ±1 point	88%-97%	Highest element	Identifying options
	Mean absolute deviation	0.49-0.84, depending on elements	Lowest element	Assessing capabilities
			Highest element	Authority/assertiveness
			Lowest element	Providing standards

From Fletcher R, Flin P, McGeorge R, et al: Anaesthetists' non-technical skills (ANTS): evaluation of a behavioural marker system, Br J Anaesth *90:580-588, 2003.*

practice of anesthesiology, anesthesiologists have ethical responsibilities to themselves. The guideline goes further by stating the following:

the practice of quality anesthesia care requires that anesthesiologists maintain their physical and mental health and special sensory capabilities. If in doubt about their health, then anesthesiologists should seek medical evaluation and care. During this period of evaluation or treatment, anesthesiologists should modify or cease their practice.

With these caveats in mind, however, several performance-shaping factors are potentially of sufficient magnitude to be of concern. Ambient noise, music, fatigue and sleep deprivation, aging, illness, drug use, and attitudes are discussed later. Several other issues that are not discussed include the level of illumination and environmental temperature. These factors can be shown to have a performance-shaping effect in the laboratory, but it is uncertain how much they affect performance in the OR. Currently, the responsibility for ensuring fitness for duty rests solely with the individual clinician. In HROs, the institution implements measures to mitigate performance-shaping factors.

Ambient Noise and Music in the Operating Room

The OR is a relatively noisy work environment (see also Chapter 6).[176-180] Mean sound levels are considerably higher than in most offices or control rooms (continuous movement of air through an open surgical suction tip is a common source of continuous noise), and peak sound levels can be quite high. Some sources of noise are uncontrollable, such as surgical drills, monitor alarms, and inadvertently dropped instrument pans; other sources are controllable, such as conversation and music (see later). Evidence in the general literature indicates that noise can adversely affect human performance.[176] Furthermore, studies by Murthy and colleagues demonstrated that volume-accurate replay of recordings of OR noise significantly interfered with the speech discrimination ability of anesthesia residents during laboratory testing.[181,182] The OR noise also caused a significant reduction in residents' performance on psychometric tests of mental efficiency and short-term memory.[181] The potential interference of noise with communication and situation awareness among personnel in the OR is particularly worrisome to those concerned with optimizing teamwork in this complex work environment.

The use of music in the OR is now widespread. Many health care professionals believe that music enlivens the workday and can build team cohesiveness when all team members enjoy the music. A controversial study by two social psychologists, Allen and Blascovich, suggested that surgeon-selected music improved surgeons' performance on a serial subtraction task and reduced their autonomic reactivity (i.e., "relaxed" them) when compared with control conditions consisting of experimenter-selected music or no music at all.[183] The methodology of this study has been criticized.[184]

In response to Allen and Blascovich, several anesthesiologists challenged the notion that the surgeon's preference for the type or volume of music can or should override the needs of other members of the team.[184,185] This issue generated considerable controversy among surgeons and anesthesiologists. In a reply to some of the letters to the editor commenting on their study, Allen and Blascovich stated the following:

The letters here suggest that not everyone on the surgical team always appreciates the type of music chosen by the surgeon, and anesthesiologists in particular appear to prefer silence in surgery. When we asked the surgeons in our study about this issue, we were told that the environment of surgery does not lend itself to the democratic process, and music was part of the environment in which they felt most comfortable.[186]

Murthy and colleagues[181] studied the effect of OR noise (80 to 85 dB) and music on knot-tying ability in a laparoscopic skill simulator. They found no difference in time or knot quality in the conditions tested and concluded that surgeons can effectively block out noise and music. Invited commentary that accompanied the article brings up important issues: what impact does noise have on other members of the surgical team, how does noise affect communication between team members, does noise affect judgment, and other unanswered questions.

The question of the proper role of music in the OR has no simple answer. Clearly, optimal patient care is the primary goal. Some surgical and anesthesia personnel explicitly forbid any type of music in the OR. A more common approach of many OR teams is to allow any team member to veto the choice or volume of music if they believe that it interferes with their work.

Reading in the Operating Room and Other Distractions

The observation that some anesthesia professionals were observed to read journals or books casually during patient care led to a vigorous debate of the appropriateness of such activity.[187] Although it is indisputable that reading could distract attention from patient care, a study by Slagle and Weinger in 2009 suggested that when the practice of reading is confined to low-workload portions of a case, it has no effect on vigilance[188] (see later). In their opinion, blanket policies against reading nonessential materials are both doomed to failure and possibly detrimental because reading could counteract boredom in some situations. Furthermore, reading as a distraction is not necessarily any different from many other kinds of activities not related to patient care that are routinely accepted, such as idle conversation among personnel. Many comments about the issue were related not to the actual decrement in vigilance induced by reading but rather to the impact of the negative perception of the practice (and of those who do it) by surgeons and by patients (if they were aware of it). Slagle and Weinger also wondered about the impact of Internet use during anesthesia care, a growing phenomenon. Wax and colleagues looked at electronic anesthesia records from more than 1000 cases by 171 anesthesia professionals, all of whom used a record-keeping computer system that also allowed, and tracked, access to the Internet.[189] These investigators correlated

hemodynamic variability and adverse hemodynamic outcomes versus the extent of Internet use both within and between cases. They found no significant impact of Internet use on these variables. However, this methodology does not assess the vigilance of the anesthesia professional directly. As Domino and Sessler point out in an accompanying editorial, it is well established that cell phone use and texting reduce vigilance while driving automobiles (or trains) and increases the risk of accidents.[190]

As pointed out by nearly all authors on these topics, the bottom line is as follows, to quote Slagle and Weinger: "(1) the patient must be the foremost priority and (2) being distracted or performing noncritical tasks during critical or unstable situations is inappropriate and dangerous." In our training course on ACRM, we teach that the anesthesia professional is responsible for modulating all controllable distractions—for example, allowing music during routine work (if all agree), reading, or Internet use, but eliminating it when the workload increases or a situation becomes more complex or urgent. Similarly, although our own institutions do not have a fixed policy against reading in the OR (or against casual conversation, for that matter), everyone expects the anesthesia professional to have a very low threshold for abandoning any potential distractions to provide maximum attention to patient care.

The issue of potential distractions in general, which include "all the various stimuli that could prevent someone from concentrating," was studied by Campbell and associates.[191,192] These investigators also looked at interruptions—"a stimulus that briefly requires the attention of the anesthesia professional." With such broad definitions, the distractions and interruptions in this study varied widely: from work-related or unrelated conversations; maneuvering within the OR suite or OR; music, pagers, phone calls, and noise; and even conversation with a patient to reassure him or her. Distractions occurred, on average, between once every 2 minutes to once every 7 minutes, depending on the phase of the anesthetic case. Slightly more than 20% of distractions—particularly interruptions—were associated with an observable negative impact. Such events are particularly problematic when they disrupt prospective memory, which is the memory to do something in the future. Disruptions in prospective memory are known to be an issue in aviation safety and health care safety,[193-200] and this study reinforced the special risk of interruptions in anesthesia safety.

Sleep Deprivation and Fatigue*

General Principles. Scientists are discovering the importance of adequate sleep to allow normal human performance. A consensus report by leaders in the field of sleep medicine stated the following:

[we] evaluated scientific and technical reports on the distribution throughout the 24-h day of medical incidents (such as heart attack and stroke) and performance failures (such as vehicular accidents and human errors in industrial and technical operations that can affect public safety). We found that these events occur most often at times of day coincident with the temporal pattern of brain processes associated with sleep. It thus appears that the occurrence of a wide range of catastrophic phenomena are influenced by sleep-related processes in ways heretofore not fully appreciated.[201]

This report goes on to give many examples of catastrophes that have occurred at least in part because of the effects of sleep deprivation and fatigue.

Investigations in other complex industries (aviation, nuclear power, maritime, long-haul trucking) have identified fatigue as the probable cause of or a contributing factor in many accidents. Unlike health care, the transportation industries have a body—the NTSB—that actively evaluates accident causation, including performance-shaping factors such as fatigue and sleep deprivation. By formal analysis, fatigue has been implicated in many famous accidents. For example, fatigue was a contributing factor in the Exxon Valdez grounding (in Alaska), the nuclear disasters at Three Mile Island (in Pennsylvania) and Chernobyl (in the Ukraine), and the decision-making process that led to explosion of the space shuttle Challenger. We have no such mechanism for evaluating fatigue causation in medical error, so what is not looked for will not be found.

Based on these findings, however, it is likely that chronic sleep deprivation, circadian rhythm abnormalities, and fatigue can be blamed for some iatrogenic adverse patient outcomes. As previously mentioned, the IOM report published in 1999 revealed that thousands of patients are harmed each year by preventable error. Some of these errors may have fatigue as a causative factor, and this should be an area of active study. However, it is difficult to determine the degree to which this is true because no blood test equivalent exists for level of impairment secondary to fatigue. Although these factors have long been minimized or ignored by health care professionals, an understanding of them is critical to maximize patient safety, as reflected in these reviews.[202,203]

The process of ignoring this issue may be coming to an end. In December 2011, The Joint Commission published a "Sentinel Event Alert" documenting the impact of fatigue on patient safety.[204] The Joint Commission suggested actions for organizations aimed to mitigate fatigue-related safety breaches (Appendix 7-2; www.jointcommission.org/assets/1/18/sea_48.pdf).

Normal Sleep. Carskadon and co-workers referred to sleep as a reversible behavioral state of perceptual disengagement from and unresponsiveness to the environment that is usually accompanied by postural recumbency, quiescence, closed eyes, and other indicators commonly associated with sleeping.[205] Sleep can be thought of as a physiologic drive state similar to hunger or thirst and is necessary for maintenance of alertness, performance, and overall well-being (see also Chapter 14). The intensity of this drive can be inferred by noting how quickly an individual falls asleep. Just as eating and drinking satiate hunger and thirst states, sleeping reverses the desire to sleep.

The amount of sleep required by any individual is genetically determined and is the amount that allows

*This section was edited by Steve Howard, Veterans Affairs Palo Alto Health Care System and Stanford University.

that individual to be awake and alert throughout the day. The average sleep time for young adults is 7 to 8 hours per 24-hour period, with an approximately 15% interindividual variation. These sleep requirements do not change with age, and humans can do little to train their physiology to function optimally on less sleep than required.

Sleep Debt. If adequate sleep is not obtained for whatever reason, daytime sleepiness and impaired performance ensue. Sleep loss is cumulative and results in what is referred to as sleep debt. An individual who has obtained an optimal amount of sleep is better prepared to perform long periods of sustained work than one who is operating from a sleep debt.

Because of the additive effects of chronic partial sleep loss, even minor sleep restriction on a nightly basis can insidiously accumulate into a substantial sleep debt.[206] The only way to pay back a sleep debt is with sleep.

Sleep debts are commonplace in our culture. The National Sleep Foundation's annual survey continues to reveal that Americans chronically undersleep by 60 to 90 minutes each day (http://www.sleepfoundation.org/article/sleep-america-polls/national-sleep-foundation-bedroom-poll). Shift work, long and irregular work hours, and the demands of family and recreation lead to irregular sleep patterns and prevent restful sleep. This is particularly true for physicians, who often work in shifts, have long duty periods, and must frequently care for patients for long periods.

Circadian Rhythms. Rhythms that fluctuate on a 24-hour time scale are known as circadian rhythms. The biologic clock that is responsible for these rhythms is located in the suprachiasmatic nucleus in the human brain. The best-known circadian rhythms are those of body temperature, hormone secretion, metabolism, and the sleep-wake cycle. The circadian system is synchronized to the 24-hour day by external stimuli referred to as "zeitgebers," the most influential of which is the light-dark cycle of day and night.

The circadian system is biphasic in that it produces a state of increased sleep tendency and decreased performance capacity during two periods throughout the 24-hour day—from 2 AM to 6 AM and from 2 PM to 6 PM. These periods are sometimes referred to as circadian lulls or low points. These are periods when we are more vulnerable to incidents and accidents because our body clock is "turned off." The circadian clock is very resistant to alterations, and it does not adjust rapidly to changes such as those produced by jet lag or shift work. Disruption of the normal circadian rhythm or incomplete circadian adaptation leads to acute and chronic sleep deprivation, decreased alertness, increased subjective fatigue, and decreased physical and mental performance.[207]

Sleepiness and Alertness. Sleepiness and alertness are at opposite ends of a continuum. Daytime sleepiness is the most obvious effect of failing to obtain adequate sleep. Healthy adults are maximally alert by midmorning. This is sequentially followed by a circadian lull in the early afternoon (causing some cultures to incorporate an afternoon "siesta"), increased alertness in the early evening, and finally increased sleepiness that normally results in falling asleep at night.

The most extreme periods of sleepiness become manifest when one is out of sync with the circadian clock (either staying awake and working when our clock is pressuring sleep or attempting to sleep when our clock is pressuring wakefulness). Data from the U.S. Department of Transportation reveal that the greatest number of single-vehicle accidents takes place during the early morning hours when people are at a circadian lull of alertness. These accidents are thought to result from inadvertent lapses in driver attention brought about by extremes of sleepiness.[208]

Determinants of Sleepiness. The major factors causing sleepiness are decreased quantity of sleep, poor quality of sleep (sleep fragmentation resulting from multiple awakenings or abnormal progression of sleep states and stages), disrupted circadian rhythms, and the use of certain medications. The amount of sleep obtained is directly related to daytime sleepiness. If sleep is restricted in healthy adults, daytime sleepiness can be demonstrated the following day.[206] If one is allowed to extend sleep beyond the usual sleep time, increased alertness can be demonstrated in the laboratory.[4] Sleep quality is affected by many factors. Sleep fragmentation affects older adults and patients with sleep disorders such as sleep apnea and periodic limb movements. Sleep fragmentation commonly occurs in physicians who are awakened from sleep to care for patients while in the hospital.

Caffeine and other stronger stimulants are known to reduce nocturnal sleep if ingested close to bedtime, hence decreasing sleep quantity and quality.[209] Potent stimulants such as amphetamines do produce increased alertness and performance, but they have significant side effects and are not an option for health care personnel (e.g., the individual must undergo a substantial amount of recovery sleep ["crash"] after their effect is gone). Newer, nonamphetamine alertness-enhancing drugs (e.g., modafinil) are currently under study and are being used in shift workers, including health care workers (see the later section on fatigue countermeasures).

Mood. Long work hours, fatigue, and sleep deprivation have also been shown to bring about consistent and dramatic changes in mood and emotions.[210,211] Depression, anxiety, irritability, anger, and depersonalization have all been shown to increase during testing of chronically fatigued house staff. These emotions are an obvious source of stress between anesthesia professionals and their coworkers, patients, and families. The relationship of mood, performance, and patient safety has yet to be determined.

Vigilance. Vigilance, the centerpiece of the ASA logo, is defined as "alert watchfulness." Vigilance is critical, although studies of the performance of anesthesiologists make it clear that vigilance is not the only key characteristic of careful anesthesiologists. Vigilance is a necessary but not sufficient condition to permit the safe passage of a patient through the perioperative period. If vigilance and other aspects of decision making are impaired by performance-shaping factors such as sleep deprivation and fatigue, the likelihood of an adverse patient outcome is greater.

Monitoring of slowly changing stimuli is a classic vigilance task that makes up a significant proportion of the anesthesia professional's work. This type of task is most sensitive to the degrading effects of sleepiness and fatigue. During the performance of lengthy vigilance tasks, the most common types of decrements include increased reaction time, lapses (transient periods of unawareness), and a reduction in the probability of detecting an alarm. This type of performance impairment has been documented after as little as 30 minutes of time on a task, and the decrement is even more pronounced if the individual is physiologically sleepy at the beginning of the task.

Microsleep Events. The most extreme cause of impaired vigilance is the occurrence of actual sleep episodes (microsleeps) encroaching into periods of wakefulness. Microsleep events typically last a few seconds to a few minutes. They are intermittent in onset, and their impending occurrence is difficult for the individual to predict. Most individuals underestimate their level of sleepiness when they can be objectively shown to be extremely sleepy, thus making this problem even more insidious. In other words, one can fall asleep and not be perceptually aware of it. This has significant meaning in the workplace and when driving home after long work periods. Microsleep episodes are the probable cause of many single-vehicle crashes.

Microsleeps are a sign of extreme sleepiness and are harbingers of the onset of longer sleep periods. Typically, they occur during periods of low workload or stimulation and when an individual is maximally sleepy. In addition, an individual's performance between microsleep episodes is impaired. Frequent and longer microsleeps increase the number of errors of omission.

Driving while drowsy may be less forgiving than practicing medicine while drowsy. It is easy to imagine that if a driver has a microsleep for only seconds while traveling at 60 miles per hour, the likelihood of an accident will be high. Although the anesthesia professional's work environment does not (usually) evolve as fast as that of the driver, the safety implications of falling asleep while providing care are similarly obvious.[212]

Scientists at the NASA Ames Research Center in Mountain View, California studied the occurrence of microsleep episodes in pilots during transmeridian flights.[213] These flights involve multiple time zone changes with long, irregular work schedules and resultant disruption of circadian rhythms. This situation causes fatigue, sleepiness, and decreased performance, which are believed to have an impact on flight safety. This particular protocol compared two pilot groups flying equivalent flights: a control (non-nap) group and a nap group. Electroencephalographic monitoring of the pilots was performed to determine the extent of microsleep episodes and also to document whether pilots were actually able to nap if given the opportunity. In brief, the study revealed that (1) crew members were able to nap seated in the cockpit if given the opportunity, (2) the non-nap crew had significantly more microsleep episodes during critical phases of flight than did the crew that had napped, and (3) performance on a standardized test of visual reaction time was worse in the non-nap group than in the group that had napped. This study demonstrated that microsleeps do occur even in a work environment in which sleep is strictly forbidden and in which work hours are tightly regulated. Napping appears to be a reasonable countermeasure to decrease the likelihood of microsleeps and improve performance. Other work on napping supports these conclusions.

Do anesthesia professionals suffer microsleep events? The answer almost certainly is yes. Anecdotal evidence, as well as unpublished reports from our own surveys, suggests that these events do occur from time to time. Microsleeps occurred in a study of anesthesiologists performing work in a simulated environment.[214] Studies from the Harvard Work Hours and Safety group revealed that interns working traditional shifts in the ICU were more prone to microsleeps during their work shifts (they used the term "attentional failures") than individuals who worked shortened shifts.

Shift Work. From a practical standpoint, shift work will remain a common method to provide 24-hour care in the hospital setting.[215-217] Workers and managers should learn how circadian factors, sleep-related factors, and social factors affect the lives of workers and their families. Hospital organizations should make it a priority to establish that workers are appropriately rested, just as they try to ensure that workers are not impaired by drugs or alcohol on the job. Given current knowledge concerning shift work and the many factors that affect an individual's ability to cope, no single "best" schedule for shift work exists. Some workers tolerate systems that others find excessively onerous. If given a choice, many workers choose suboptimal shift work rotations when doing so gives them increased pay or more time off work.

Methodologies for Assessing Sleepiness. Various methods are used for assessing an individual's level of sleepiness, including behavioral indicators, subjective measures, and physiologic measures (see also Chapter 14). Behavioral indicators of sleepiness include yawning, ptosis, decreased social interaction, and microsleep events. Many of these behaviors are difficult to quantify.

Subjective measures include various types of numeric or visual analog scales that attempt to measure how sleepy the individual *feels*. These methods are used frequently in studies of sleepiness because they are very easy to implement; however, subjective feelings of fatigue and sleepiness are often underestimated by individuals in comparison to their level of physiologic sleepiness. Both behavioral and subjective sleepiness can be masked by a stimulating environment, even though the individual remains physiologically sleepy. When environmental stimuli wane, physiologic sleepiness manifests itself as an overwhelming propensity to fall asleep. A person who is physiologically alert does not experience sleepiness as environmental stimuli decrease. For example, without physiologic sleepiness, an individual may become bored during a lecture but does not fall asleep.

Physiologic (objective) measures of sleepiness have been used extensively in sleep research and sleep medicine. Richardson, Carskadon, Dement, and colleagues developed the Multiple Sleep Latency Test (MSLT), which is the standard method for quantifying daytime

sleepiness.[218,219] The MSLT tests the propensity of an individual to fall asleep in a sleep-inducing environment during the daytime. A short sleep latency (i.e., falling asleep quickly) is a sign of increased sleepiness, whereas a long sleep latency is a sign of decreased sleepiness. A normal MSLT score is greater than 10 minutes, whereas pathologic daytime sleepiness is defined as 5 minutes or less. Pathologic levels correspond to the daytime sleepiness typically seen in patients with narcolepsy or sleep apnea or in healthy individuals deprived of sleep for 24 hours.

Evaluation of Physiologic Sleepiness in Anesthesia Residents. Using the MSLT, Howard and colleagues evaluated the physiologic daytime sleepiness of anesthesia residents under three different conditions: (1) "baseline" (daytime shift, no on-call duty period in the previous 48 hours), (2) "post-call" (immediately after a 24-hour work and in-house on-call period), and (3) "sleep extended."[203,220] In the sleep-extended condition, residents were told to maximize sleep and were allowed to arrive for work at 10 AM (3 to 4 hours later than normal) for 4 consecutive days before testing. They were not on call during this time. The sleep-extended condition was included to provide a true control state of maximal rest and optimum alertness.

In this study, anesthesia residents had an MSLT score of 6.7 ± 5.3 minutes in the "baseline" condition and 4.9 ± 4.7 minutes in the "post-call" condition; both scores revealed the nearly pathologic levels of daytime sleepiness seen in patients with narcolepsy or sleep apnea. The "baseline" group slept an average of 7.1 ± 1.5 hours per night, whereas the "post-call" group reported an average of 6.3 ± 1.9 hours of sleep during their night on call. Ironically, although the on-call periods occurred during rotations that often have very busy call nights, only a few subjects were, in fact, awake most of the night. In the "sleep-extended" condition, the subjects extended their sleep to an average of more than 9 hours per night, and MSLT scores were in the normal range (12.0 ± 6.4 minutes). These results clearly demonstrate that medical personnel who have not been on call cannot be assumed to be "rested" when compared with "fatigued" post-call residents. These data also indicate that under "normal" working conditions, the resident physicians studied were physiologically sleepy to nearly pathologic levels. This finding documents a previously unknown level of chronic sleep deprivation in this population. Notably, these data cast substantial doubt on previous studies of the performance of medical personnel that have relied on the assumption that individuals working under "normal" conditions are truly rested (see also Chapter 9).

Evaluation of Subjective Sleepiness. In the previously discussed study, Howard and colleagues also investigated the degree of discrepancy between the residents' subjective sleepiness (how sleepy they felt) and their physiologic sleepiness (how easily they fell asleep). Subjective sleepiness was measured with a validated numeric scale (Stanford Sleepiness Scale); physiologic sleepiness was measured with the MSLT, as described earlier. Subjects' self-reported sleepiness immediately before each sleep opportunity during the MSLT did not, in general, correlate with their MSLT score. As in previous studies, subjective sleepiness correlated better with physiologic sleepiness when subjects were extremely alert or extremely sleepy.

The authors also found that subjects demonstrated little ability to determine whether they had actually fallen asleep during the MSLT sleep opportunities. For example, in 51% of trials in which the electroencephalographic and electro-oculographic measurements showed that the subject had fallen asleep, the subjects thought they had remained awake throughout the test. These results support the contention that medical personnel are physiologically vulnerable to degraded alertness yet are unable to perceive this decrement. Thus, an anesthesia professional could, in fact, fall asleep during a case, awaken, and be totally unaware of the lapse in vigilance.

Sleep Deprivation and Fatigue in Medical Personnel. Human error represents a significant risk to hospitalized patients,[3] and it has been estimated to play a role in more than 70% of anesthesia mishaps.[221] This is similar to the error rate seen in cognitively similar work environments such as aviation.[222] Clearly, the physiologic capabilities and limitations of the human operator in complex work environments remain central to safe and productive performance. The 24-hour demands of medical care parallel the physiologic challenges present in other operational domains; nevertheless, minimal data are available to quantify the fatigue-related risk to performance and alertness in medical personnel.

Providing quality health care requires physicians to attend to details critical for life, such as monitoring of changing vital signs, administering the correct type and dose of medications, and in general, making crucial decisions to achieve optimal patient care. Physicians, like other workers, are affected by all the physiologic, psychological, and behavioral demands that characterize work environments requiring continuous, around-the-clock operation. However, whereas much of the health care system (e.g., nursing) relies on multiple work shifts to cover the 24-hour day (which is also not a perfect system), physicians more typically work long duty periods and frequently experience sleep loss, circadian disruption, and fatigue. Even minimal levels of sleep loss (e.g., obtaining as little as 2 hours less sleep than an individual requires) can lead to lapses in performance, increased physiologic sleepiness during the daytime (including microsleeps), and altered moods.[223] This level of degraded performance and alertness almost certainly contributes to medical error and health care mishaps.[202]

Work Hour Regulations. In July 2003, The Accreditation Council for Graduate Medical Education (ACGME) in the United States instituted the first set of common duty hour requirements for all accredited residency training programs. In 2011, the ACGME published a revised set of guidelines in response to the 2008 IOM report entitled *Resident Duty Hours: Enhancing Sleep, Supervision, and Safety*.

The current ACGME requirements can be found at www.acgme.org and are as follows:

- Eighty hours per week are averaged over a period of 4 weeks (including all in-hospital call).

- One day (continuous 24-hour period) in 7 is free of all duties (clinical and educational) averaged over a 4-week period.
- Postgraduate year 2 (PGY-2) residents and above must be scheduled for in-house call no more frequently than every third night (when averaged over a 4-week period).
- Maximum duty periods:
  - Duty periods of PGY-1 residents must not exceed 16 hours in duration.
  - Duty periods of PGY-2 residents and above may be scheduled to a maximum of 24 hours of continuous duty in the hospital. Programs must encourage residents to use alertness management strategies in the context of patient care responsibilities. Strategic napping, especially after 16 hours of continuous duty and between the hours of 10:00 PM and 8:00 AM, is strongly suggested.
  - Residents must not be assigned additional clinical responsibilities after 24 hours of continuous in-house duty.
- In-hospital call is not to exceed 24 hours; residents may remain on duty for 6 additional hours to participate in educational activities, transfer care of patients to another team, conduct outpatient clinics, and maintain continuity of care.
- No new patients are accepted after 24 hours of continuous duty.
- Residents must not be scheduled for more than 6 consecutive nights of night float.
- Residents should have a 10-hour period between all daily duty periods and must have 8 hours free of duty. They must have at least 14 hours free of duty after 24 hours of in-house duty.
- Moonlighting hours are to be included as part of the 80-hour limit and must not interfere with the ability of the resident to achieve the goals and objectives of the educational program.
- Exceptions: a residency review committee may grant exceptions for up to a 10% increase in the 80-hour limit to individual programs on a case-by-case basis (maximum increase to 88 hours per week).

The most significant change with the revised requirements affect interns, so anesthesia training programs that have categorical positions (interns as well as anesthesia trainees) will be required to maintain these work hour requirements. Training programs were never given direction on how to accomplish the work hour restrictions, but most anesthesiology training programs have been able to adopt them successfully. Interestingly, no work hour restrictions are given for practitioners or any other care providers beyond residency training. There is no proof that the change has had a positive or negative impact on patient or provider safety, although pundits continue to debate both sides of the issue.[224,225] Studies showed that the number of hospitalwide adverse drug events remained constant after the limitations,[226] and postoperative outcomes were not affected in the programs studied.[227]

Compliance rates for the common program requirements have been tracked by Landrigan and co-workers.[228] In a survey of interns, these investigators found that more than 80% reported some kind of work hour violation during 1 or more months of the study. Average work duration decreased and sleep time increased when compared with an equivalent time before duty hour limits. Reporting of compliance by individual residents is complicated by many factors, so the true amount of work being performed is not known. Many surgical programs have requested and been given a 10% work hour extension, but it is not known how many of these requests have been turned down.

European and Australian Regulations. Work hour regulations in the European Union and in Australia or New Zealand are much more stringent than they are for trainees in the United States. In 2009, the maximum hours that junior medical staff in the NHS in the United Kingdom work was reduced from 58 to 48 under European law. This is a major challenge for the health service and will require new ways of working to be adopted. The NHS National Workforce Projects has been appointed as the lead organization to help support the NHS in finding and implementing solutions to the changes in the work environment (http://www.healthcareworkforce.nhs.uk/). The results of these restrictions on patient and provider safety are still being evaluated, and these findings may have an impact on any further restrictions that may occur in the U.S. system. Empiric studies documenting the effect of the European Union changes are lacking, although several arguments for and against the directive have been presented.[229,230]

Harvard Work Hours, Health, and Safety Group Studies. A series of interesting studies was published by a group from the Brigham and Women's Hospital in Boston.[231,232] The investigators conducted a randomized study comparing interns working in an ICU on a traditional schedule (every third night on call with shifts longer than 24 hours in duration) and an intervention schedule that reduced work shift duration (to less than 17 hours) and the number of hours worked per week. Interns made 35.9% more serious medical errors and had twice as many attentional failures (microsleeps) during the traditional schedule. Those on the traditional schedule worked more hours per week (85 versus 65 hours) and slept less (5.8 hours), which led the investigators to conclude that elimination of long work shifts reduced errors and decreased manifest sleepiness.

This group also conducted a monthly prospective nationwide survey of interns' first postgraduate year to evaluate the risk for motor vehicle accidents with extended work shifts.[233] They found an increased likelihood of motor vehicle accidents and near-miss accidents after extended work shifts and an increased monthly risk with increasing number of shifts.

The Harvard group also conducted a survey of house staff on percutaneous injuries during work.[234] They found that from a total of 17,003 monthly surveys with interns, 498 percutaneous injuries were reported (0.029/intern-month). Among other factors, lapses in concentration and fatigue were the most commonly reported contributing factors (64% and 31% of injuries, respectively). Percutaneous injuries were more frequent during extended work compared with nonextended work (1.31 in 1000 opportunities versus 0.76 in 1000 opportunities, respectively. Injuries were more frequent during the nighttime than during

the daytime (1.48 in 1000 opportunities versus 0.70 in 1000 opportunities, respectively). It is easy to conclude from the science that fatigue can harm both the patient and the practitioner.

Sleep and Performance. Previous studies addressed the effects of sleep deprivation and fatigue on physician performance and well-being (see also Chapter 14). Major reviews of this literature identified little consensus.[235,236] Several methodologic flaws are present in the existing literature:

1. The degree of acute sleep deprivation of subjects was poorly defined, and no assessment of chronic fatigue was made. Typically, studies relied on only the previous night's sleep as a level of "fatigue," and subjects could well have been chronically fatigued during baseline (control) trials, which could mask the degree of impairment resulting from the acute fatigue of being on call. This continues to be the greatest weakness in studies of fatigued health care providers.
2. Measuring actual clinical performance is difficult and was not attempted. Most studies had to rely on simple cognitive tasks that probed only short-term memory, immediate recall, and simple reaction time; the validity of using such simple tests to probe complex performance has been challenged because these simple tests do not assess the higher-level cognitive functions most critical to skilled medical care.
3. Most of the performance tests were of very short duration (3 to 5 minutes). Studies have shown that if sufficiently motivated, even fatigued subjects can perform well on short-duration tasks.
4. Practice effects were not adequately accounted for. If subjects have not learned a particular performance test sufficiently to achieve maximum performance, subsequent trials will almost certainly show improvement in performance because of further learning of the task.

Some studies requiring subjects to perform sustained vigilance tasks of long duration have, in fact, shown impairment in the performance of fatigued physicians. Tasks of this type, which require sustained attention to detail, are highly relevant to the anesthesia professional's tasks, and they are the most sensitive to the effects of sleep loss and fatigue.

Do Anesthesiologists Perceive Fatigue As a Problem? The survey by Gaba and associates revealed that more than 50% of respondents believed that they had made an error in clinical management that they thought was related to fatigue.[237] In another survey of anesthesiologists and CRNAs, the majority (61%) of respondents recalled having made an error in the administration of anesthesia that they attributed to fatigue.[238] Data from these surveys and others reveal that issues of sleepiness and fatigue are perceived by anesthesia practitioners as being important causative factors in reducing anesthesia-related patient safety.[239]

Howard and colleagues conducted a study of rested versus sleep-deprived anesthesiology residents by using a realistic patient simulator.[214] Multiple measures of performance were collected during this 4-hour experiment (e.g., psychomotor tests, reaction to secondary task probes, response to clinical events). In the rested condition, subjects had 4 consecutive days of sleep extension (showing up at work at 10:00 AM), whereas in the sleep-deprived condition they had remained awake for 25 hours (during a "pseudo"–on-call period) before performing the simulated anesthetic. Subjects in the rested condition were able to increase their total sleep time more than 2 hours from baseline. Psychomotor tests revealed progressive impairment of alertness, mood, and performance over the course of the pseudo–on-call period, as well as on the experimental day, when compared with the well-rested condition. Secondary task probe response times were slower after sleep deprivation, although this reached statistical significance in just one of three probe types. No statistical difference in case management between conditions was reported—in fact, subjects in both conditions made significant errors. The behavioral alertness scores in the sleep-deprived condition were different from those of subjects who had increased their sleep time. Even when well rested, the subjects in this experiment did not perform perfectly; however, they did not show any of the behavior indicative of being sleepy (e.g., head nodding, eyes closing). Sleep-deprived subjects cycled (often rapidly) in and out of sleepy behavior, and the most impaired individuals showed such behavior for more than 25% of the experiment (60 minutes).

Fatigue Countermeasures. Studies such as the ones described previously are establishing the true picture of sleepiness and fatigue in medical personnel. From studies of the performance of fatigued individuals in other domains, we know that professionals become increasingly vulnerable to the degrading effects of sleepiness as the sleep debt accumulates. It may be difficult to determine a causal relationship between anesthesia professional fatigue and patient outcome. However, it is clear that if anesthesia professionals are not awake, they cannot possibly be aware. Such a lapse in vigilance is unacceptable. Furthermore, anesthesia professionals cannot prevent sleep by willpower alone because it is a fundamental physiologic drive. Demands for clinical services must be balanced against the potential for reduced vigilance and error by seriously fatigued practitioners, anesthesia professionals, and surgeons alike.

Because fatigue is such a widespread and insidious problem, it is important to determine ways to counteract its effects. Strategies that institutions or practitioners can use to minimize the negative effects of sleepiness and fatigue on performance include the following:

- Education
- Improved sleep habits
- Rest breaks at work
- Strategic napping
- Medications
- Light therapy

Education. The first step in addressing sleepiness and fatigue of medical personnel is to educate practitioners and the administrators of health care institutions about the impact of sleep issues on work performance, mood,

job satisfaction, and health (see Chapter 9). Education is a relatively simple and inexpensive countermeasure that can be implemented immediately. Educational programs covering sleep deprivation, circadian disruption and fatigue, and countermeasures have been enthusiastically adopted by an increasing fraction of the aviation community.[240,241] Similar programs should be developed for the health care community. Education alone is sufficient for some individuals and institutions to change their work and sleep habits or their organizational and scheduling procedures. However, it is clear at both the individual and organization level that education will not be sufficient to address this issue fully. Other competing forces (e.g., measures of production versus safety) are very powerful and difficult for practitioners to manage.

Improved Sleep Habits. The most important factor is to obtain adequate sleep—most adults need at least 8 hours. Good sleep habits include the following: regularity of bedtime and wake-up time; sufficient time for sustained and individually adequate sleep; restriction of alcohol, caffeine, and nicotine before bedtime; and use of exercise, nutrition, and environmental factors so that they enhance rather than disturb sleep. A regular sleep schedule is an important part of optimal sleep hygiene, but it is often not possible for medical personnel, given the requirement to cover clinical needs on a 24-hour basis. Medical personnel should make greater effort to maintain as constant a sleep schedule as possible and to maximize sleep opportunities before and after periods of reduced sleep.

Social drug use can have profound effects on sleep. Physicians frequently use caffeine to stay awake during on-call periods, but often its use could be more strategic. Strategic use (i.e., use when its alerting effects are needed) of caffeine requires knowledge about its onset and duration of action. Besides its alerting effects, caffeine produces an increase in awakenings and decreases the total nocturnal sleep time if ingested close to sleep opportunities. Individuals who ingest large amounts of caffeine and who have nocturnal sleep disturbances should limit or cease their intake of caffeine. Long-term use of caffeine, common in our culture, produces tolerance to the alerting effect of the drug and hence should be avoided when using caffeine strategically. Nicotine is a stimulant that produces effects similar to those of caffeine. Alcohol is often used successfully to initiate sleep, but its effect on sleep architecture after sleep onset can be devastating. After ingestion of alcohol, frequent awakenings from sleep occur that can be associated with increased sympathetic nervous system activity, often manifested as headache, sweating, and tachycardia. Clearly, use of these substances should be restricted near bedtime.

Physicians often lack good nutritional habits, especially during long duty periods. Meals may be skipped or ingested quickly whenever there is adequate time. If one is hungry before bedtime, it is best to avoid eating or drinking heavily because this, too, can disturb sleep.

The effects of age can make optimum sleep habits difficult to achieve because sleep requirements do not change once reaching adulthood. The number of awakenings per night rises after the age of 45 years and results in decreased sleep efficiency (time in bed versus total sleep time). The ability to initiate sleep at any time during a 24-hour day is diminished after the age of 25 years, and "sleeping in" to make up for lost sleep is more difficult as individuals grow older. Sleep-related disorders such as breathing disruptions (obstructive sleep apnea) and periodic limb movements also become more common with age.

Ideally, the sleep setting should be a dark, quiet room devoid of sources of interruption such as pets, telephones, pagers, and children. The sleeping surface and environmental temperature should be comfortable. Psychological stressors increase baseline physiologic arousal and can impair the quality and quantity of sleep. For example, reviewing the previous day's events or attempting to plan tomorrow's activities while trying to fall asleep is not conducive to sleep. Effort should be made to separate the work of the day with a period of relaxation before attempting to initiate sleep.

Rest Breaks at Work. Although other industries have openly recognized the reality of decrements in vigilance resulting from fatigue and sleepiness, the health care system has not. Rest breaks and rotation of task duties are mandatory for air traffic controllers and are part of naval ship command procedures in an attempt to prevent potential lapses in vigilance. Short breaks have been shown to increase productivity and job satisfaction, and they probably also help alleviate boredom. In anesthesia training programs, residents are frequently given rest breaks during the daytime, but this is often not the case with private practitioners. Private practice anesthesia typically does not provide the mechanisms for rest breaks or task duty rotation, in part because of fiscal issues. An "extra" anesthesia professional would be necessary to provide these opportunities on a regular basis.

The optimal timing and length of breaks are unknown, but periodic relief from duty should be taken when possible. Cooper and co-workers studied the effects of intraoperative exchange of anesthesia personnel.[242,243] Although in some cases the process of relieving OR personnel caused a problem, it more frequently was associated with the discovery of a preexisting problem. The positive effect of relief of personnel probably depends on the quality of the handover briefing conducted by anesthesia professionals. Studies are currently being performed to address standardized handover of intraoperative care of patients.

If anesthesia professionals are unable to obtain a break during long work periods, they can take other measures to remain alert. They can engage other OR personnel in conversation (although this, too, can be distracting), thereby increasing the level of stimulation in the environment. Walking around and standing up are also techniques that decrease subjective (but not physiologic) sleepiness. If anesthesia professionals are having microsleep events, which may be noticed by other personnel rather than by the anesthesia professionals themselves, fatigue is already very severe, and complete sleep is imminent. In such a situation, the practitioner must secure additional assistance in surveillance of the patient and, if necessary, obtain relief to allow time for sleep.

Strategic Napping. If adequate sleep during the night cannot be obtained, naps can be used to decrease sleepiness and improve performance. The optimal nap length for most individuals is about 45 minutes; this duration

acutely improves alertness, allows improved performance, and minimizes the possibility of sleep inertia on awakening. Naps as short as 10 minutes have beneficial effects on alertness. A nap of 90 to 120 minutes allows a full sleep cycle and can additionally boost alertness and performance over that of shorter nap periods. Data from NASA studies of flight crews demonstrate that on the whole, napping is a useful countermeasure to fatigue and sleep deprivation.[213]

Smith-Coggins and associates studied the effect of naps during the night shift on health care providers working in a busy suburban university emergency department.[241] Workers were randomized to work a night shift without rest (as was the norm in this facility) or to receive a 40-minute nap opportunity at 3 AM. The investigators found that a nap taken at this time improved performance on some (but not all) measures. The most important result of this study may be the fact that the subjects were able to (1) use this strategy successfully in the real workplace and (2) improve alertness and performance.

Investigators at the VA Hospital at Palo Alto, California, have developed a Strategic Nap Program that has been successfully piloted at two sites within the Veterans' Affairs system. This program has been implemented in ICU settings but is equally applicable to other high-risk, dynamic domains such as the OR. Components of the program include a formal educational program, program guidelines for the individual practitioner and the facility, and other guidance for implementation.

Certain issues complicate the appropriate use of naps by medical professionals. Physicians have an individual and cultural tendency to ignore or to minimize the effect of fatigue and sleep deprivation. The culture of medicine views work breaks and naps as signs of weakness. The military has addressed similar attitudes with the concept of "power napping." Troops are strongly encouraged to take naps of 10 minutes to 1 hour when the situation permits to increase their strength and performance. This approach appropriately presents the idea of napping in a positive light as a sign of wisdom and strength rather than one of cowardice and frailty.

Sleep Inertia. Sleep inertia corresponds to the period of reduced ability to function optimally immediately on awakening.[226,244] This phenomenon usually occurs when individuals are awakened out of slow-wave sleep and is manifested as grogginess and impaired performance lasting as long as 15 to 30 minutes after awakening. Sleep inertia can also occur after being awakened from normal sleep and is most common during the early morning circadian trough (2 to 6 AM). Depending on the preexisting level of sleepiness, individuals who take naps longer than 40 minutes are at greater risk for sleep inertia on awakening. Sleep inertia can be important to health care professionals who may be awakened out of deep sleep to provide emergency care to patients (e.g., emergency cesarean section or emergency intubation). If urgent work can be anticipated, the sleeping individual should be awakened with sufficient time (at least 15 minutes) to minimize the fogginess and decrement in performance associated with sleep inertia. If sleep inertia is unavoidable, it would be wise for the affected person to ask for help until the grogginess dissipates.

Medications. A few studies have evaluated the use of sedative-hypnotics for promotion of sleep during nonduty hours by nonmedical personnel (e.g., to assist in daytime sleep after a night shift). Many questions remain unanswered regarding the quality of sleep obtained after using hypnotics, the severity of hangover effects, and the potential risk of abuse. Melatonin, which is a hormone secreted by the pineal gland, may have promise as a nonaddictive daytime sleep-inducing agent, but the results of existing studies are controversial.

Stimulants may have a role in the maintenance of alertness during periods of extreme sleepiness. Modafinil is a nonamphetamine alertness-enhancing drug that has been approved for use in narcolepsy and shift work sleep disorder.[245] The side effect profile of this drug is so promising that it has been studied extensively by the military and shift workers as a nonaddicting adjunct for alertness management. Its use in health care is also being studied but cannot be sanctioned at this point.[246] The use of sedatives and potent stimulants to manipulate sleep is not considered an appropriate option for anesthesia professionals. Caffeine is used frequently to increase alertness temporarily, but caveats about its use exist, as discussed earlier. Caffeine should be used strategically to maximize its effect when needed. Strategic use of caffeine includes (1) knowledge of its onset (15 to 30 minutes) and duration of action (3 to 4 hours) and (2) use when alertness is required and the opportunity to sleep is minimal.

Countermeasures should be studied and implemented in health care. Major financial incentives support maintaining the status quo.[202] If anesthesiologists know that they are impaired (from fatigue or for any other reason), the assistance of a colleague should be enlisted so that patient safety is not negatively affected.

Light Therapy. Timed cycles of bright light and darkness have been used in certain circumstances to facilitate adaptation to shift work. Exposure to bright light (>7000 to 12,000 lux) and darkness at the appropriate points in the circadian cycle has been shown to reset the circadian pacemaker by 12 hours over a period of 2 to 3 days.[247] This important finding demonstrates the ability to make significant changes in the circadian system relatively quickly. However, resetting the circadian timekeeper is critically dependent on the timing, intensity, and duration of exposure to light and to "total" darkness. Being off by only an hour can prevent the desired effect. Adhering to such time-critical schedules for this treatment is probably impractical for anesthesia professionals, given the many work-related and social factors that affect their activities. Research on light treatment continues and may eventually result in more practical treatment regimens.

Aging

All individuals understand that their abilities cannot be maintained indefinitely as they age (see also Chapter 80). On average, performance on laboratory tests of discrete sensory-motor and cognitive skills can be shown to decrease with increasing age.[248] However, large differences are noted among individuals. Again, except at extreme points of performance failure (e.g., severe impairment of vision or hearing), the contribution of isolated

changes in physiologic or cognitive performance is difficult to relate to real work situations.[249] For one thing, the work environment is often rich with redundant cues involving multiple sensory modalities. For another, technologic compensation may be possible, as with the use of hearing aids or glasses. Finally, along with possible physiologic changes of age typically comes greater experience with a variety of situations. For many individuals, the lessons learned from experience more than offset the modest degree of physiologic impairment that they face as they grow older. This compensation has, in fact, been documented for skilled typists, chess players, and bridge players. Middle-aged individuals can use their experience to solve everyday problems better than young individuals can; however, for older adults (on average), compensation by experience is no longer sufficient to offset cognitive slowing.[249] Age takes a toll on short-term (or "working") memory,[250] and evidence indicates that aged workers are more sensitive to the interruptions in attention that are so prevalent in dynamic environments. Nevertheless, few of these deficits have been documented in complex work settings, largely because it is so difficult to measure performance in these domains. The issue of the aging anesthesiologist has raised considerable controversy among anesthesiologists.

What do other industries do about this issue? From 1959 until the end of 2007, U.S. and aviation regulations forced airline pilots to retire at 60 years of age regardless of their health or competence. When the "Age 60 Rule" was put in force, the rationale was that the "increased speeds and passenger loads of commercial airliners placed greater demands on pilots with respect to their physical fitness and piloting skills." Some experts may argue that the increasingly challenging nature of anesthesia practice also places greater demands on anesthesia professionals than ever before.

After intense debate and many studies since the 1980s,[251,252] with partially contradictory studies and few data suggesting that pilots between the ages of 60 and 65 years are at greater risk, the Age 60 Rule was modified by law (HR 4343) at the end of 2007. The new rule allows airline pilots to continue flying until age 65 years, although for captains in international operations, a pilot younger than 60 years must be the copilot.

Federal Aviation Administration (FAA) regulations do require air transport pilots to pass "class I" medical examinations every 6 months. However, the medical examination process appears to be largely aimed at identifying individuals with chronic medical conditions that place them at risk for sudden incapacitation (e.g., significant coronary heart disease). Pilot incapacitation during high-workload phases of flight has been shown in simulator testing to lead to a significant rate of crashes, even when a second pilot is at the controls. These physical examinations may weed out pilots with severe cognitive or sensory-motor deficiencies, but they are not designed to assess subtle aspects of changes in performance resulting from age. Of course, no requirements whatsoever exist for medical examination or certification of anesthesia professionals, nor is there any limitation on the practice of anesthesia at any age.

It is likely that age alone does not independently cause a significant decrement in performance, but age correlates with other factors that are likely to affect performance. The concern about aging professionals revolves more around the loss of knowledge and skill as one becomes farther removed from initial training than around the loss of fundamental mental capacity. Thus, the originally well-trained practitioner who keeps abreast of the changing standard of care and who exercises emergency skills frequently is less likely to be affected by advancing age than is a marginal practitioner whose knowledge and skills were frozen immediately after completion of training and who practices in a low-complexity environment. The FAA regulations deal with this issue for air transport pilots by requiring frequent (every 6 months) evaluation of performance by FAA-certified check pilots. These evaluations are performed during actual flights and in realistic simulators, and they, in essence, check fitness for duty regardless of age. Currently, no similar program exists in anesthesia to assess the competency of practitioners at any age, except for initial board certification, which is voluntary. Periodic maintenance of certification in anesthesiology is required by the American Board of Anesthesiology for diplomates attaining certification after the year 2000, but it is not mandatory to be board certified to practice anesthesia, and the recertification examinations are not as intense, as thorough, or as frequent as those required for air transport pilots. Thus, the issue of age-related effects on anesthesia professional performance is likely to continue to be raised periodically for the foreseeable future.

Illness and Drug Use

Every anesthesia professional is vulnerable to transient illnesses, which in some cases probably reduce performance ability (see Chapter 110). All personnel are vulnerable to chronic medical conditions that could directly or indirectly affect their fitness and performance capability. The culture of the caring professions often leads individuals to continue to work with illnesses that would cause other professionals to stay at home or to seek medical advice. The performance-shaping effects of the illness can be exacerbated by the use of either over-the-counter or prescribed medications. The degree to which illnesses and medications affect professional performance in anesthesia is unknown.

A serious problem for anesthesia professionals is that of drug abuse (see Chapter 110).[253-258] It is estimated that up to 8% of physicians could be classified as having alcoholism. In an anonymous survey of anesthesia personnel from one institution, 75% of respondents reported drinking alcohol on a regular basis. They reported drinking an average of 1.6 drinks per day 2.7 days per week. Just less than 10% of subjects reported having been "hung over" while conducting anesthesia, and 40% reported having given anesthesia within 12 hours of alcohol consumption; 84% stated that alcohol use never adversely affected their clinical performance.

The degree to which small doses of alcohol or hangovers affect the performance of complex, real-world tasks is uncertain. Some studies of general aviation and navy pilots suggested that hangover effects can degrade performance even when more than 8 hours has elapsed since alcohol consumption and no blood alcohol level

is detectable.[251,259-261] Nonetheless, although statistically significant, the changes in performance seen in these studies may not have been functionally significant. These studies also suggested interactions among age, workload, and hangover in causing decrements in performance.[251,259-261] However, the "aged" cohort was defined as 31 years or older and was compared with a cohort of pilots in their early 20s. Extrapolating these results to the anesthesia domain is difficult.

Nevertheless, the natural history of serious abuse of alcohol, cocaine, sedatives, or narcotics by anesthesia professionals is such that cognitive performance will at some point be seriously compromised. However, addiction specialists frequently report that job performance is one of the last areas of life to become impaired.[262,263] For this reason, the period of time in which an addicted anesthesia professional's performance in the OR is significantly impaired is a relatively small fraction of the total time during which drugs are abused. Although this in no way excuses the practice of conducting anesthesia while under the influence of drugs, it may account for the fact that reports of addicted anesthesiologists are, unfortunately, common, whereas reports of overt patient risk or harm resulting from an addicted physician's errors are unusual.

Anesthesiology has been at the forefront in dealing with impaired medical personnel. Management of personnel discovered with a drug impairment is fairly standardized,[256,264] but the question whether to return these individuals to anesthesia practice is increasingly controversial, even when they return under carefully monitored reentry protocols.[256] The main risk appears to be to the addict's own safety, although questions about patient safety can never be eliminated.

Ultimately, in the current medical system the responsibility rests with anesthesia professionals to ensure that their own performance level is sufficient for the work at hand. Pilots use a mnemonic checklist to review the effects of potential performance-shaping factors and are instructed not to fly if they are impaired for any reason. The difficulty in anesthesiology (and to some degree in aviation) is that the real-world organization and incentives of many practice settings do not provide mechanisms for personnel to excuse themselves if they are temporarily impaired. Ironically, better means may be available to identify and support a practitioner with a serious addiction than for the more common occurrences of profound sleep deprivation or impairment by a transient or chronic illness.

THE STUDY OF HUMAN PERFORMANCE

Study of human performance involves research paradigms different from those typically used in the science of anesthesia. Many obstacles exist to obtaining hard, statistically valid data on human performance. There are no animal models for expert human performance and no "Sprague-Dawley anesthesiologists" to be studied in detail, nor can studies of professional performance be conducted with the psychologist's typical experimental subject, the university undergraduate student. Recruiting expert anesthesia professionals to be the subjects of study is difficult and raises issues of selection bias concerning those who do volunteer. Especially if conducted during actual patient care, investigations of human performance are strongly influenced by concerns about litigation, credentialing, and confidentiality, thus making it difficult to execute optimal studies.

Furthermore, variability among individual anesthesia professionals is quite striking because different anesthesia professionals respond to the same situation in different ways, and each individual may act differently on different days or at different times of the same day. The magnitude of this intraindividual variability is often nearly the same as the interindividual variability.

"Performance" itself is an intuitively meaningful concept that is difficult to define precisely. No universal standards are available for the clinical decisions and actions of anesthesia professionals. They depend heavily on the context of specific situations. In addition, determining how anesthesia professionals perform their jobs, whether successfully or unsuccessfully, means delving into their mental processes. This cannot be measured easily. Experimental designs can involve artificial laboratory tasks for which performance can be objectively measured, but these tasks will then be far removed from the real world of administering anesthesia. Conversely, investigating the actual performance of trained practitioners in the real world yields primarily subjective and indirect data. Understanding the anesthesia professional's performance must be seen as analogous to solving a jigsaw puzzle. Pieces of the puzzle probably come from a variety of sources, none of which by itself captures the entire picture. These pieces include objective data from artificial laboratory tasks, prospective observation of routine patient care, analysis of retrospective reports of near misses or anesthetic mishaps, and prospective observation of the response to simulated events. To achieve the best possible understanding of the situation, it is necessary to accept many data that seem uncomfortably subjective to the physical or biologic scientist. Because the research methodologies may be unfamiliar to anesthesia professionals, some pioneering studies of anesthesia professional performance are described in detail in this chapter.

WHY STUDY HUMAN PERFORMANCE IN ANESTHESIA?

How can improved understanding of the human performance of anesthesia professionals help them provide patient care more safely, in a wider variety of clinical situations, with greater efficiency, and with increased satisfaction to both patients and practitioners? The possibilities include the following:

1. Improved operational protocols and enhanced training of anesthesia professionals. The way in which individuals conduct anesthesia is based, in part, on knowing the limits of their performance envelope. Anesthetic techniques and OR practices should draw on anesthesia professionals' abilities and should mitigate their weaknesses. Anesthesia professionals' abilities are strongly affected by training. Understanding the required performance

characteristics and inherent human limitations will lead to improved training, which will most fully develop the strengths and counter the existing vulnerabilities of the anesthesia professional. This process should make patient care safer, less stressful, and more efficient.
2. A more rational view of professional work and legal responsibility (see Chapters 10 and 11). Modern medicine, especially in the United States, is strongly influenced by medicolegal concerns. The litigation system has a major selection bias in that every case that comes before it involves an adverse outcome for a patient. The duty of the practitioner is to render care as a "reasonable and prudent" specialist in the area of anesthesia. What is reasonable and prudent? What type of performance is to be expected from appropriately trained human beings in a complex and dynamic environment? By understanding human performance, it may be possible to generate a more rational view of what is and is not within the standard of care.
3. A more effective work environment. Anesthesia professionals now perform their tasks by using an array of technologies, most of which have not been designed to support the anesthesia professional's work optimally. By understanding the anesthesia professional's tasks and performance requirements, the workspace and tools could be improved for better support of the most difficult tasks. This, too, can lead to greater safety and to greater efficiency and work satisfaction.
4. A more efficient organizational system (see Chapter 4). Anesthesia is embedded within a larger system of organized medical care that involves interactions among numerous institutions, organizations, and professional domains. Understanding how the anesthesia professional's work relates to the larger system may enable the development of more rational and efficient flow of information and organizational control.

Although anesthesiologists have been basing analysis of human performance on individual actions, decisions, and mental models and the influence of organizational factors and safety culture for some time (see survey articles[1,2,265]), their importance to health care in general has only relatively recently been appreciated.[3,56]

COGNITIVE PROCESS MODEL OF THE ANESTHESIA PROFESSIONAL

The empiric data can best be interpreted in accordance with an explicit model of the cognition involved in an anesthesia professional's performance. Several investigators have written about the cognitive elements in anesthesiology.[52,65,125,162,266-275] The model developed here is explicit, comprehensive, and specific to anesthesia. It is described in detail as a framework for understanding the empiric data and provides a vocabulary for discussing the elements of both successful and unsuccessful performance by anesthesia professionals. This model draws heavily on the work of a number of other investigators who studied human performance in a variety of complex, dynamic worlds.[138,275-278]

DECISION MAKING INVOLVES MULTIPLE LEVELS OF MENTAL ACTIVITY

The entire model, which is shown in Figure 7-12, depicts the anesthesia professional as working at five different interacting cognitive levels to implement and control a core process of observation, decision making, action, and reevaluation (Box 7-9). The core process must then be integrated with the behavior of other team members and with the constraints of the work environment.

The division of mental activities into levels follows the work of Rasmussen and Reason.[277,279,280] Having multiple levels supports parallel processing (performing more than one task at a time) and multitasking (performing only one task at a time but switching very rapidly from one task to another). The anesthesia task analyses,[281-285] as well as the direct observations of anesthesia professionals in Toronto[266] and Tübingen,[286-289] have provided clear evidence for the occurrence of parallel processing and multitasking. Table 7-6 gives an overview of the mental activity levels.

At the sensorimotor level, activities involving sensory perception or motor actions take place with minimal conscious control; they are smooth, practiced, and highly integrated patterns of behavior. At the procedural level, the anesthesia professional performs regular routines in a familiar work situation. These routines have been derived and internalized from training and from previous work episodes. A level of abstract reasoning is used during preoperative planning, and intraoperatively it is used in unfamiliar situations for which no well-practiced expertise or routine is available from previous encounters.

Dynamic Adaptation of the Anesthesia Professional's Thought Processes

Rasmussen's model[277] was extended by the explicit addition of two additional levels of mental activity that provide for dynamic adaptation of the anesthesia professional's own thought processes. This ability to "think about thinking" to control one's own mental activities strategically is called metacognition by psychologists, and it is thought to be an important component of working in complex, dynamic domains. Supervisory control is concerned with dynamically allocating finite attention between routine and nonroutine actions, among multiple problems or themes, and among the five cognitive levels. Resource management deals with the command and control of available resources, including teamwork and communication.

CORE PROCESS

An overview of the core process and its elements is given in Box 7-9. The elements are explained in detail in the following sections.

Observation

Management of rapidly changing situations requires the anesthesia professional to assess a wide variety of information sources, including visual observation of the patient and the surgical field, visual inspection of a multitude of displays from electronic monitors, visual observation of

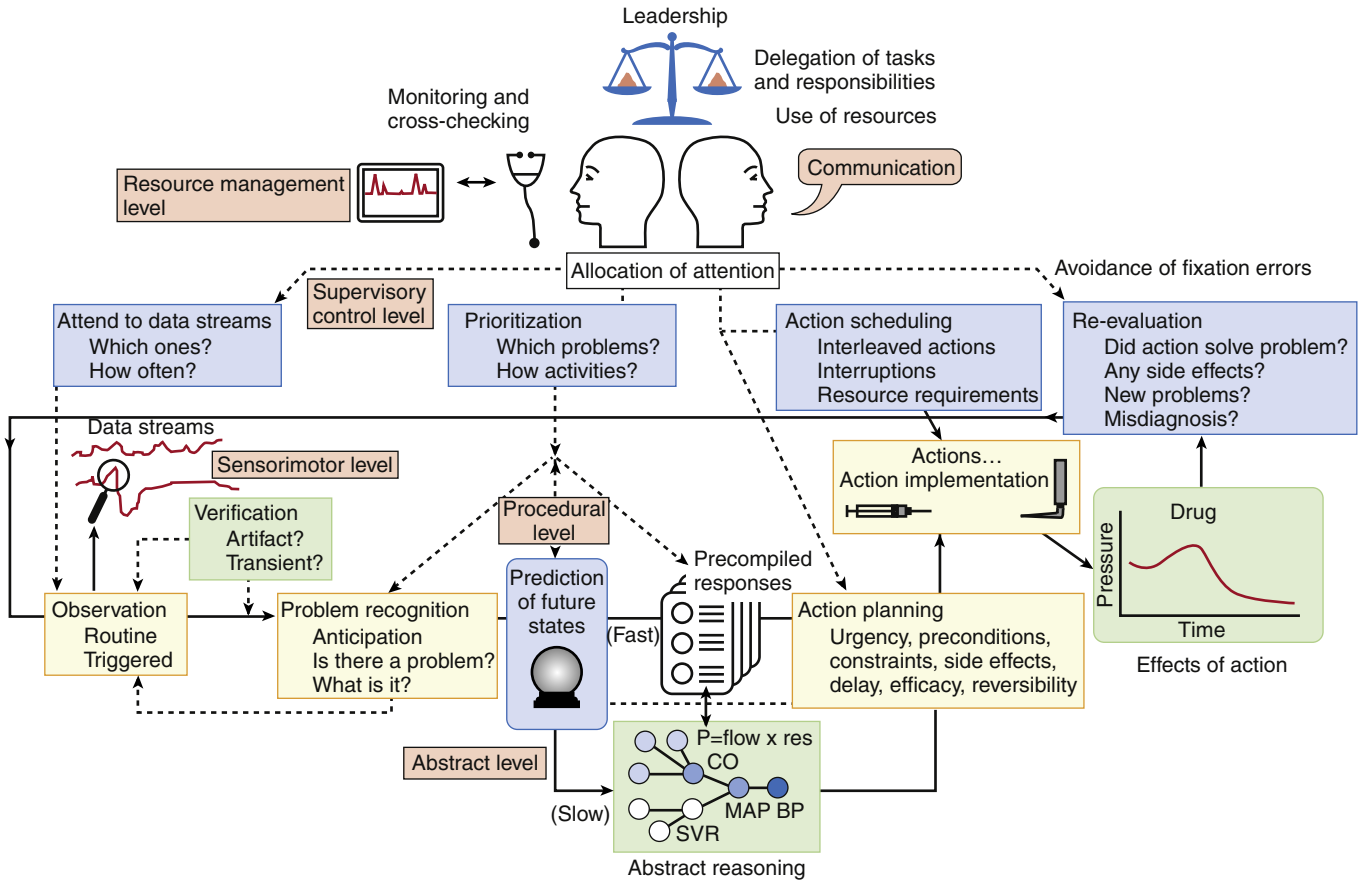

Figure 7-12. Cognitive process model of the anesthetist's real-time problem-solving behavior (see text for a detailed description). Five levels of cognition operate in parallel. The core process involves a main loop (*solid arrows*) of observation, decision, action, and reevaluation. The core process is managed by two levels of metacognition that involve supervisory control, allocation of attention, and resource management (above the core process). Each component of the model requires different cognitive skills, and each component is vulnerable to a different set of performance failures or "errors." *BP,* Blood pressure; *CO, cardiac* output; *MAP,* mean arterial pressure; *SVR,* systemic vascular resistance. *(From Gaba DM, Fish KJ, Howard SK:* Crisis management in anesthesiology. *New York, 1994, Churchill Livingstone.)*

the activities of nurses and the contents of suction canisters and sponges, listening for normal and abnormal sounds from the patient and equipment, interpretation of radiographs, and reading of reports of laboratory test results. Because the human mind can attend closely to only one or two items at a time, the anesthesia professional's supervisory control level must decide what information to attend to and how frequently to observe it.

The multitasking involved in observing multiple data streams was probed by experiments measuring secondary task performance and vigilance. The realistic simulation studies demonstrated the large number of information sources actually used during the response to a critical event. Routine parts of the core process operate primarily at the sensory, motor, and procedural levels and are executed repetitively throughout the course of an anesthetic regimen. Results from the University of California, San Diego (UCSD), and from the Department of Veterans Affairs and Stanford University (UCSD/VA-Stanford group) concerning the vigilance of experienced anesthesia professionals versus novices suggested that novices had not fully developed their core process as a highly automated function and thus were required to devote more mental resources to routine activities.

BOX 7-9 ***Elements of the Core Mental Process***

1. Observation
2. Verification
3. Problem recognition
4. Prediction of future states
5. Decision making
   a. Application of precompiled responses (recognition-primed decision making)
   b. Decision making using heuristics and probability
   c. Decision making including abstract reasoning
6. Action implementation
7. Reevaluation (avoiding fixation errors)
8. Start again with 1 (loop continues)

Verification

In the OR environment, the available information is not always reliable. Most monitoring is noninvasive and indirect and is susceptible to artifacts (false data). Even direct clinical observations such as vision or auscultation can be ambiguous. Brief transients (true data of short duration) can occur that quickly correct themselves. To prevent them from triggering precipitous actions that may have

TABLE 7-6 **LEVELS OF MENTAL ACTIVITY**

Level of Control	Explanation	Comments
Resource management level	Command and control of all resources, including teamwork and communication	Incident analysis shows a huge contribution of lack of resource management and communication skills to the development of incidents and accidents; the importance of these factors is reflected in the ACRM principles and simulation training courses (see Chapter 8)
Supervisory control level	Metacognition: thinking about thinking	Dynamic adaptation of the thought process, decision making (e.g., avoiding fixation errors), scheduling, and remembering actions (e.g., prospective memory tasks)
Abstract reasoning level	Use of fundamental medical knowledge, search for high-level analogies, deductive reasoning	Often in parallel with other levels; in emergency situations often too slow and too sensitive to distractions in high-workload situations
Procedural level	Precompiled responses, following algorithms, heuristics, "reflexes"	Recognition-primed decision making—experts are more often on this level; special errors may occur as a result of not checking for the appropriateness of the "procedure"; less experienced personnel may misuse this level for ill-considered, unadapted "cookbook medicine"
Sensorimotor level	Use of all senses and manual actions; "feeling, doing, hearing"; sometimes subconscious control of actions	Experts perform smooth action sequences and control their actions by direct feedback from their senses (e.g., action sequences of placing an intravenous line or endotracheal intubation; skill-based errors such as slips and lapses may occur)

ACRM, Anesthesia crisis resource management.

significant side effects, critical observations must be verified before the clinician acts on them. Verification uses a variety of methods, shown in Table 7-7.

If in doubt, it should always be assumed that the patient is at risk and that the parameter in question is real ("rule out the worst case"). The assumption of a technical artifact should be the last step.

Knowing when and how to verify data is a good illustration of strategic knowledge (metacognition). For example, the anesthesia professional must decide under what conditions it is useful to invest time, attention, and energy in establishing a new information source (e.g., a pulmonary artery catheter) in the middle of a case rather than relying on more indirect information sources that are already in place.

Problem Recognition

Anesthesia professionals are taught the importance of scanning their instruments and environment, but they must use these observations to decide whether the patient's course is "on track" or whether a problem is occurring. If a problem is found, a decision must be made regarding its identity and its importance. This process of problem recognition (also known as situation assessment) is a central feature of several theories of cognition in complex, dynamic worlds.[162,290-292]

Problem recognition involves matching sets of environmental cues to patterns that are known to represent specific types of problems. Given the high uncertainty seen in anesthesia, the available information sources cannot always disclose the existence of a problem, and even if they do, they may not specify its identity or origin. The experiment by Westenskow and colleagues with the intelligent alarm system mainly probed these parts of problem recognition.[293] In this experiment, subjects were already alerted to the existence of a problem by an alarm, so they could immediately focus their attention specifically on information sources concerning ventilation. In 11 cases, the fault could not be identified, but compensation for the fault was successful, as described in the next paragraphs.

The supervisory control level mediates the decision when a clear-cut match or "diagnosis" cannot be made. Anesthesia professionals and other dynamic decision makers use approximation strategies to handle these ambiguous situations; psychologists term such strategies *heuristics*.[294] One heuristic is to categorize what is happening as one of several "generic" problems, each of which encompasses many different underlying conditions. Another is to gamble on a single diagnosis (frequency gambling[279]) by initially choosing the single most frequent candidate event. During preoperative planning, the anesthesia professional may adjust a mental "index of suspicion" for recognizing certain specific problems anticipated for that particular patient or surgical procedure. The anesthesia professional must also decide whether a single underlying diagnosis explains all the data or whether these data could have multiple causes. This decision is important because excessive attempts to refine the diagnosis can be very costly in terms of allocation of attention. By contrast, a premature diagnosis can lead to inadequate or erroneous treatment.

The use of heuristics is typical of expert anesthesia professionals and often results in considerable time savings in dealing with problems. However, it is a double-edged sword. Both frequency gambling and inappropriate allocation of attention solely to expected problems can seriously undermine problem solving when these gambles

TABLE 7-7 **METHODS FOR VERIFICATION OF CRITICAL OBSERVATIONS**

Method	Explanation and Example
Repeating	The observation or measurement is repeated to rule out a temporary wrong value (e.g., motion artifacts during noninvasive blood pressure measurement)
Checking trend information	The short-term trend is observed for plausibility of the actual value. Trends of physiologic parameters almost always follow curves, not steps
Observing a redundant channel	An existing redundant channel is checked (e.g., invasive arterial pressure and cuff pressure are redundant, or heart rate from an ECG and pulse oximeter)
Correlating	Multiple related (but not redundant) variables are correlated to determine the plausibility of the parameter in question (e.g., if the ECG monitor shows a flat line and "asystole" but the invasive blood pressure curve shows waves)
Activating a new monitoring device	A new monitoring modality is installed (e.g., placing a pulmonary artery catheter). This also adds another parameter for the method of "correlating"
Recalibrating an instrument or testing its function	The quality and reliability of a measurement are checked, and its function is tested (e.g., if the CO_2 detector shows no values, the anesthetist can exhale through it to see whether the device works). Observation of redundant channels can also help verify a value (see above)
Replacing an instrument	If doubt exists about the function of a device, an entirely new instrument or an alternative backup device may be installed
Asking for help	If the decision on the values remains unclear, help should be sought early to obtain a second opinion from other trained personnel

ECG, Electrocardiogram.

do not pay off if the reevaluation component of the core process does not correct the situation.

Prediction of Future States

Problems must be assessed in terms of their significance for the future states of the patient.[162,290] Problems that are already critical or that can be predicted to evolve into critical incidents receive the highest priority. Prediction of future states also influences action planning by defining the timeframe available for required actions. Cook and colleagues described "going sour" incidents in which the future state of the patient was not adequately taken into account when early manifestations of problems were apparent.[295] It is also known from research in psychology that the human mind is not very well suited to predict future states, especially if things are changing in a nonlinear fashion. Under such circumstances, which are not uncommon for natural systems such as the human body, the rate of change is almost invariably underestimated, and people are surprised at the outcome.[51] Slow but steady and sustained blood loss in a child during surgery may result in few or subtle changes in hemodynamics for some time until rapid decompensation occurs. If the weak signs of the developing problem were not detected, the ensuing catastrophe may seem to have occurred "suddenly."

Decision Making

Having recognized a problem, how does an expert anesthesia professional respond? The classic paradigm of decision making posits a careful comparison of the evidence with various causal hypotheses that can explain them.[47] This is then followed by a careful analysis of all possible actions and solutions to the problem. This approach, although powerful, is relatively slow and does not work well with ambiguous or scant evidence. In complex, dynamic domains such as anesthesia, many problems require "decisions under uncertainty,"[273,296] with quick action to prevent a rapid cascade to a catastrophic adverse outcome. For these problems, deriving a solution through formal deductive reasoning from "first principles" is too slow.

Precompiled Responses and Abstract Reasoning

In complex, dynamic domains, the initial responses of experts to the majority of events stem from precompiled rules or response plans for dealing with a recognized event.[279] This method is referred to as recognition-primed decision making,[276,297] because once the event is identified, the response is well known. In the anesthesia domain, these responses are usually acquired through personal experience alone, although there is a growing realization that critical response protocols must be codified explicitly and taught systematically. Experienced anesthesia professionals have been observed to rearrange, recompile, and rehearse these responses mentally based on the patient's condition, the surgical procedure, and the problems to be expected.[298] Ideally, precompiled responses to common problems are retrieved appropriately and executed rapidly. When the exact nature of the problem is not apparent, a set of generic responses appropriate to the overall situation may be invoked. For example, if a problem with ventilation is detected, the anesthesia professional may switch to manual ventilation at a higher fraction of inspired oxygen (FiO_2) while considering further diagnostic actions.

However, experiments involving screen-only[298] and realistic[161,299-301] simulations have demonstrated that even experienced anesthesia professionals show great variability in their use of response procedures to critical situations. This finding led these investigators to target simulator-based training in the systematic training of responses to critical events.[122,266,302-304]

Even the ideal use of precompiled responses is destined to fail when the problem does not have the suspected cause or when it does not respond to the usual actions. Anesthesia cannot be administered purely by precompiled

"cookbook" procedures. Abstract reasoning about the problem through the use of fundamental medical knowledge still takes place in parallel with precompiled responses, even when quick action must be taken. This seems to involve a search for high-level analogies[279] or true deductive reasoning using deep medical and technical knowledge and a thorough analysis of all possible solutions. Anesthesia professionals managing simulated crises have linked their precompiled actions to abstract medical concepts.[298] It is unclear whether this represents merely self-justification as opposed to true abstract reasoning, in part because the particular simulated crises they faced did not require novel abstract solutions. At this time, the degree to which abstract reasoning is necessary for optimal intraoperative crisis management is unknown.[125,266,296]

Taking Action

A hallmark of anesthesia practice is that anesthesia professionals do not just write orders in a patient's chart; they are directly involved in implementing the desired actions.

Although such direct involvement has many benefits in timeliness and flexibility of action, it also poses risks. Implementation of action can usurp a large amount of the anesthesia professional's attention and can be distracting. This is particularly an issue when other tasks have been interrupted or temporarily suspended. The "prospective memory" to complete these tasks can be erased. (For a more detailed explanation of prospective memory, see later.) In addition, anesthesia professionals engaged in a manual procedure are strongly constrained from performing other manual tasks, as demonstrated in several of the mental workload and vigilance studies described earlier.

Errors in executing a task are termed *slips*, as distinguished from errors in deciding what to do, which are termed *mistakes*.[278] Slips are actions that do not occur as planned, such as turning the wrong switch or making a syringe swap. Thus, when critical incident[221,305] and quality assurance studies described "technical errors" in using equipment, they were referring to slips, whereas "judgment errors" referred to mistakes. One particular type of execution error, termed a *mode error*,[278] is becoming more frequent in all domains with the increased use of microprocessor-based instrumentation and devices.[267] In a mode error, actions appropriate for one mode of a device's operation are incorrect for another mode. An example in anesthesiology is the "bag/ventilator" selector valve in the anesthesia breathing circuit, which selects between two modes of ventilation. Failing to activate the ventilator when in the "ventilator mode" can be catastrophic. Mode errors can also occur with monitoring or drug delivery devices if they assign different functions to the same displays or switches depending on the mode of operation selected.

Particularly dangerous slips of execution can be addressed through the use of engineered safety devices that physically prevent incorrect actions.[54] For example, newer anesthesia machines have interlocks that physically prevent the simultaneous administration of more than one volatile anesthetic drug. Other interlocks physically prevent the selection of a gas mixture containing less than 21% oxygen.

Certain very complex issues concerning human-machine interactions and the ways in which technology affects behavior in complex patient care environments are beyond the scope of this chapter. Other publications address these issues.[‡]

Reevaluation and Situation Awareness

To cope with the rapid changes and profound diagnostic and therapeutic uncertainties seen during anesthesia, the core process must include repetitive reevaluation of the situation. Thus, the reevaluation step returns the anesthesia professional to the observation phase of the core process, but with specific assessments in mind (as shown in Box 7-7 at CRM key point 12, "Reevaluate repeatedly").

The process of continually updating assessment of the situation and monitoring the efficacy of chosen actions is termed *situation awareness*.[290-292,307,308] Situation awareness is a very interesting and important topic in analyzing performance and reasons for errors.[162,309,310] A review of situation awareness issues in anesthesiology has been published.[162]

MANAGEMENT AND COORDINATION OF THE CORE PROCESS

Empiric studies have clearly demonstrated that attention sharing is needed among cognitive levels, among tasks, and often among problems. The intensive demands on the anesthesia professional's attention could easily swamp the available mental resources. Therefore, the anesthesia professional must strike a balance between acting quickly on every small perturbation (which requires a lot of attention) and adopting a more conservative "wait-and-see" attitude. This balance must be constantly shifted between these extremes as the situation changes. However, during simulated crisis situations, some practitioners showed great reluctance to switch from business as usual to emergency mode even when serious problems were detected. Erring too far in the direction of wait and see is an error that can be particularly catastrophic.

In addition to the attentional demands of the anesthesia professional's core tasks, the OR environment is full of distractions. Routine events, such as turning the OR table or repositioning the patient, distract attention from the main process of conducting the anesthesia. Noise is prevalent, with peak levels exceeding that of a freeway. Practitioners find false auditory alarms from monitors or other equipment extremely distracting.[311-313] Other distractions include teaching in progress,[314] incoming telephone calls, background music, and conversation with OR personnel. Expert anesthesia professionals modulate the distractions by eliminating them when the workload is high and allowing them to occur when the workload is low (to improve morale and team building).

Active Management of Workload

One major aspect of strategic control of attention is the active management of workload. Rather than passively dealing with rising or falling workload, the anesthesia professional actively manages it. Schneider and Detweiler[187] and Gopher (position paper, Conference on Human Error in Anesthesia, Asilomar, Calif., 1991) described the

[‡]References 35, 37, 39-43, 45, 46, 267, 306.

theoretic basis for a variety of strategies of workload management. These strategies were addressed specifically for anesthesiology by several investigators.[266,268] The anesthesia professional actively manages workload by the following techniques.

Avoiding High-Workload Situations. Experts may choose techniques and plans that reduce the workload (especially when their individual and team resources are limited), even when those plans are marginally inferior from a technical standpoint. For example, a single anesthesia professional may choose not to use a high-tech, high-workload monitor such as transesophageal echocardiography (TEE) because of the high workload required to use it properly.

Distributing Workload over Time. The anesthesia professional can prepare for future tasks when the current load is low (preloading) and can delay or shed low-priority tasks when the workload is high (offloading). Resources that require a significant amount of workload to prepare, such as intravenous infusions, are often made ready before the case starts. Multitasking is also a way to distribute work over time. Every task is made up of several subtasks, each of which has a finite duration. Because close attention may not be required during each of these subtasks, they can be interleaved with a fixed amount of attention (multiplexing). Multiplexed tasks must be scheduled and coordinated in real time at the supervisory control level.

Distributing Workload Over Personnel. When workload cannot be distributed over time and when additional resources are available, tasks can be distributed to them. Some resources are internal to the individual anesthesia professional, whereas others require additional personnel. For example, a single anesthesia professional can simultaneously ventilate the patient by hand, assess cardiac rhythm, and discuss patient care with the surgeon. A single anesthesia professional cannot simultaneously insert a pulmonary artery catheter and ventilate the patient's lungs by hand. If these tasks are to be performed at the same time, they must be assigned to different individuals.

Changing the Nature of the Task. The nature of a task is not fixed. Surgery and anesthesia can sometimes be postponed or aborted. Tasks can be executed to different standards of performance; as standards are loosened, the workload required to perform them is reduced. For example, during periods of massive blood loss, the anesthesia professional focuses primarily on administering blood and fluids and on monitoring blood pressure. In such cases, less critical tasks such as writing on the anesthesia record are offloaded to lessen the workload. The acceptable limits of blood pressure will also be widened.

Action Selection and Scheduling

At any time during an anesthetic regimen there may be multiple things to do, each of which is intrinsically appropriate, yet they cannot all be done at once. Simulator experiments have shown that anesthesia professionals sometimes have difficulty selecting, planning, and scheduling actions optimally. The anesthesia professional must consider the following factors:

1. Preconditions are necessary for carrying out the actions (e.g., it is impossible to measure a thermodilution cardiac output if no pulmonary artery catheter is in place).
2. Constraints are placed on the proposed actions (some actions are incompatible with other aspects of the situation; e.g., it is impossible to check the diameter of the pupils when the head is fully draped in the surgical field).
3. Side effects of the proposed actions often play a controlling role in choosing among possible drug therapies.
4. The rapidity and ease of implementation of proposed actions are factors; those that are easily and rapidly performed are preferred over those that require more time, attention, and skill.
5. Certainty of success of the actions is often traded off against rapidity and ease of implementation (under some circumstances, the higher certainty of success of a set of actions justifies the investment of time, attention, and resources needed to implement them).
6. The reversibility of the action and the cost of being wrong are considered, with rapidly reversible actions preferred over those that cannot be reversed, especially when potential side effects are significant.
7. The cost of the action in terms of attention, resources, and money is taken into account.

Experts in other complex, dynamic domains (specifically tank commanders and fire chiefs) have been observed to conduct a mental simulation of the actions that they are contemplating to determine whether their plans have hidden flaws.[315] Anesthesia professionals have been observed to rehearse a plan mentally in advance of a case,[268] but the degree to which this is done in real time is not known. Because most actions can be executed incrementally, as in titrating a drug in small aliquots, adverse consequences can often be discovered through repetitive reevaluation.

Resource Management

The ability of the anesthesia professional to command and control all the resources at hand to execute the anesthetic regimen as planned and to respond to problems that arise is termed *resource management* (another concept first described in aviation that applies equally well to anesthesiology; see the earlier section on CRM key points). Resource management involves translating the knowledge of what needs to be done into effective team activity by taking into account the limitations of the complex and ill-structured OR, PACU, or ICU domain. Resource management explicitly requires teamwork and crew coordination. It is not enough for the anesthesia professional to know what to do or even to be able to do each task alone. The anesthesia professional can accomplish only so much in a given time, and some tasks can be performed only by other skilled personnel (e.g., laboratory tests, taking radiographs). When the task load exceeds the resources available, the anesthesia professional must mobilize help and distribute the tasks among those present. Many issues concerning optimum resource management and crew coordination are not yet well understood and are the focus of active research by cognitive scientists and experts

in many complex and dynamic domains.[29,127-129,316-318] Research in aviation has already demonstrated that many aircraft accidents are linked to failures on the part of crews with appropriate technical skills to manage the flight deck effectively.[222] The hallmarks of resource management derived from these studies are discussed in detail in the earlier section on CRM key points.

Dynamic Prioritization of Tasks. Complex multiple-personnel simulations of anesthetic crises have been used to address the issue of resource management. Although the data from these simulations are still preliminary, it appears that poor supervisory control and resource management were substantial components of suboptimal management of the simulated crises.[301] In other words, like the pilots, anesthesia professionals had the knowledge and technical skill to manage the patient, but they failed to manage their environment properly to achieve success (hence termed CRM skills or nontechnical skills). (In aviation, such situations have often resulted in what is called "controlled flight into terrain.")

Prospective Memory

Prospective memory describes one's ability to remember in the future to perform an action.[319] It is particularly prone to disruption by concurrent tasks or interruptions. Disruption of intentions or ongoing tasks is common in everyday life and has also been described in pilots and air traffic controllers.[320-324] In anesthesia, for example, if the anesthesia professional suspends ventilation temporarily (say to allow a radiograph to be taken), the intention to restart the ventilator depends on prospective memory and can be easily forgotten. Chisholm and associates performed a study in an emergency department and looked for "interruptions" and "breaks in task." They found that during a 3-hour period, the emergency physician was faced with more than 30 interruptions and more than 20 breaks in task. It is likely that similar results would be found in the ICU.[325]

A variety of methods may preserve prospective memory of intentions. Visual or auditory reminders can be used (physiologic monitor alarms often serve this purpose whether intended or not), although the effectiveness of such methods seems to be less than one would expect. Special actions—such as leaving one's finger on the ventilator switch—can be used to indicate that an important intention is pending.

FIXATION ERRORS

Faulty reevaluation, inadequate adaptation of the plan, or loss of situation awareness can result in a type of human error termed a *fixation error*.[144,145] Fixation errors have been described by all the investigators conducting experimental studies of responses of anesthesia professionals to abnormal situations.[300,301,326] Avoiding fixation errors in the field of anesthesia is CRM key point 9 and is covered in the section on CRM key points.

HAZARDOUS ATTITUDES

Attitudes are important components of ability that can affect performance as strongly as can physiologic performance-shaping factors. Psychologists studying judgment in aviators have identified five types of attitude as being particularly hazardous, and they have developed specific antidote thoughts for each hazardous attitude.[231] These attitudes as related to anesthesia are shown in Table 7-8. Aviation psychologists instruct pilots to verbalize the antidote thought whenever they find themselves thinking in a hazardous way.

TABLE 7-8 **EXAMPLES OF HAZARDOUS ATTITUDES AND THEIR ANTIDOTE THOUGHTS**

Hazardous Attitude	Antidote Thoughts
Antiauthority: "Don't tell me what to do. The policies are for someone else."	"Follow the rules. They are usually right."
Impulsivity: "Do something quickly—anything!"	"Not so fast. Think first."
Invulnerability: "It won't happen to me. It's just a routine case."	"It *could* happen to me. Serious problems can develop even in routine cases."
Macho: "I'll show you I can do it. I can intubate the trachea of anyone."	"Taking chances is foolish. Plan for failure."
Resignation: "What's the use? It's out of my hands. It's up to the surgeon."	"I'm not helpless. I can make a difference. There is always something else to try that might help."

The *invulnerable* and *macho* attitudes are particularly hazardous for anesthesia professionals. They are compounded by production pressures to handle more cases in less time with fewer cancellations and less opportunity for preoperative evaluation. The feeling that a catastrophe "cannot happen to me" and that perfect performance can always be called on to avert a disaster can lead to cavalier behavior and poor planning. It can alter thresholds for believing that abnormal data represent a problem, thereby leading to the fixation error of "everything's OK." In 1984, Cooper wrote the following about studies of critical incidents in anesthesia:

Perhaps the most insidious hazard of anesthesia is its relative safety. The individual anesthesia professional rarely, on average, will be responsible for a serious iatrogenic complication. It is our impression from the process of collecting incidents, that most seemingly minor errors are not taken seriously and that risk management depends almost solely on the anesthesia professional's ability to react instinctively and flawlessly every time a problem arises.[314]

Expert human performance is the anesthesia professional's most powerful tool to safeguard the patient. However, planning to avoid catastrophe is likely to be more successful than battling to avert it.

THE ANESTHESIA PROFESSIONAL'S TASKS

Investigation of a complex work environment typically starts with task analysis (reviews of this technique were published in the journal *Human Factors*[327]). One can perform an abstract analysis of the work goals

and constraints and then derive the tasks required to achieve the goals. Alternatively, one can observe what skilled practitioners actually do in their work and classify these actions into task elements. Often the techniques are combined. In this section the anesthesia professional's tasks are examined in the abstract, and then the empiric task analysis approach is reviewed. The two distinct phases of anesthetic care are as follows: (1) preoperative evaluation, planning, and preparation; and (2) conduct of the anesthetic regimen and immediate postoperative care.

PREOPERATIVE EVALUATION AND PLANNING

Few data are available on how well anesthesia professionals identify important patient conditions through history taking and physical examination (see also Chapter 38). A frequent organizational obstacle to the anesthesia professional's evaluation task is difficulty obtaining the patient's previous medical records. The performance of anesthesia professionals in selecting appropriate laboratory tests has been found to be relatively poor. Roizen and associates stated the following:

Even when physicians agree to reduce testing by using specific, agreed upon criteria for selectively ordering tests based on history and physical examination, they still make a surprising number of mistakes when ordering tests. Approximately 30% to 40% of patients who should have certain tests … do not get them, and 20% to 40% of patients who should not have tests are subjected to them.[328]

Roizen has argued for automation of routine patient questioning and selection of laboratory tests and has participated in the development of commercial devices to do so. Whether these devices, in combination with human follow-up for patients with medical problems, will improve the efficiency and accuracy of preoperative evaluation remains to be determined. The performance of anesthesia professionals in interpreting ECGs and chest radiographs also appears to be poor relative to specialists in these fields. The extent to which this factor influences the design of anesthetic plans or patient outcomes is unknown.

ANESTHETIC PLAN

In constructing the plan, the anesthesia professional uses the preoperative evaluation of the patient to match the technical requirements of the surgical procedure and the physiologic characteristics of the patient to the mental, physical, and technologic resources available. A typical anesthetic plan contains several elements. For example, the plan for general anesthesia includes choices for the means of inducing anesthesia, securing the airway and ensuring proper ventilation, maintaining anesthesia, conducting emergence from anesthesia, and controlling postoperative pain. Skilled planning is as critical as skilled execution in safe patient care. If a significant feature of the situation is missed in formulating the plan, it can leave the patient vulnerable, regardless of how adeptly the plan is implemented.

The technical requirements of most surgical procedures are well known. Most patients do not have medical problems that could significantly alter the anesthetic plan, although Gibby and associates found that 20% of outpatients, most of them with ASA physical status 1 or 2, had conditions identifiable through an anesthesia professional's history and examination that required changes from a "standard" anesthetic plan.[329] When a procedure is new or challenging, when the patient has significant underlying disease, or when needed resources are not available, creative planning may be needed to identify a set of physiologic goals for the anesthetic regimen. Routine anesthetic plans can be modified or combined to produce a compromise plan that best fits the goals and constraints of the situation.

The process of constructing anesthetic plans has been studied very little. Most of the existing literature on preoperative planning concentrates only on narrow medical and physiologic aspects of underlying diseases and their anesthetic ramifications. No systematic research has been conducted on how various tradeoffs are made or on how normal anesthetic processes are adapted to suit the needs of specific situations.

PRE-USE PREPARATION AND CHECKOUT OF EQUIPMENT

After the plan is established, the anesthesia professional must prepare the work environment. This involves obtaining the necessary equipment and supplies, assembling infusions, preparing syringes of needed drugs, and conducting pre-use checkouts of life-support equipment (see Chapter 44). The performance of anesthesia professionals at these tasks is not optimal. Buffington and co-workers demonstrated that only 3% of anesthesia professionals examining an anesthesia machine could identify all five faults with which it had been rigged; most practitioners found only two of the five.[330] Nearly 30% missed such major faults as complete absence of both unidirectional valve disks in a circle anesthesia breathing system and swap of the nitrous oxide and oxygen cylinders (made possible by a fault in the pin-indexing system).

The Food and Drug Administration (FDA), in cooperation with the ASA, the APSF, and experts from academics and industry, developed a set of recommendations for checkout of the anesthesia apparatus.[331] This checklist was widely disseminated by the ASA and the APSF. However, it was found that use of the checkout procedure was minimal and that the extent of pre-use checkout by practitioners was extremely variable. A newer study was conducted to compare the checkout of anesthesia machines by practitioners with and without use of the FDA checkout procedure.[332] Most of the faults were detected by 50% or fewer participants, regardless of the checkout procedure used. Only for one fault, failure of the oxygen–nitrous oxide ratio protection system, did the FDA checklist offer significant advantages; when using it, the detection rate increased to 65%. Interestingly, 34% of the faults that were not detected were missed by practitioners who had in fact correctly answered three out of three written test questions concerning that fault.

This finding suggests that although some of the performance deficit may be related to lack of knowledge, a substantial proportion of it results from the inability to apply abstract knowledge to the practical performance of equipment checkout.

The original checklist was widely criticized, particularly for its complexity.[333] A streamlined version of the original checklist was published by the FDA in 1994.[334] A study of the new checklist, however, showed no significant benefit from its use and a disturbingly low rate of detection of machine faults (≈50%).[335] In another study, anesthesia professionals using a highly interactive electronic checklist (developed by Blike and Biddle) improved their detection of "easy faults" but still missed a high proportion of difficult faults.[336] A study performed more recently to measure the influence of fatigue on performance in a simulator showed that subjects in both the rested and fatigued conditions left out significant portions of the machine checkout.[214]

In early 2013 the APSF issued a request for proposals to study the large-scale implementation of a more general preinduction checklist for anesthesia professionals that is aimed to catch a variety of preventable problems before the anesthetic is begun. The intention of the APSF is to make such preinduction checks adopted by the anesthesia community as a universal practice.

EMERGENCY CHECKLISTS OR EMERGENCY MANUALS

One aspect of preparedness to handle possible emergencies is to rehearse their management mentally in advance (see also Chapters 33 and 102). Another approach consists of the readiness and ability to use emergency cognitive aids, particularly emergency checklists or emergency manuals (also known by similar terms, including emergency response protocols, critical event algorithms, and so on). Despite many advances, the use of such cognitive aids is still not a regular part of the culture of medical work in many locales.

In 2003 the U.S. Department of Veterans Affairs National Center for Patient Safety developed a set of emergency checklists, in concert with the VA Palo Alto-Stanford group, and derived from the catalog of critical incidents in the book *Crisis Management in Anesthesiology*. The VA Health Administration had placed a set of these checklists on plastic laminated sheets in every OR of 105 hospitals. Other emergency checklists have been made available electronically.[337,338] A study of the use of the VA cognitive aids suggested that they were beneficial to VA anesthesia professionals.[339] Other research has demonstrated that (1) medical and technical performance is better during simulated crisis malignant hyperthermia when a cognitive aid is used[340] and (2) it can be very helpful to the anesthesia professional leading the team if a "reader" is present whose job is to read the relevant aid to the team and keep track of whether the relevant tasks have been performed.[341] A group from Boston has published two articles about simulation testing of 12 "crisis checklists" that demonstrated a substantial reduction in failure to adhere to well-recognized critical steps in patient management when the checklists were used.[342,343]

The Stanford Anesthesia Cognitive Aid Group (SACAG) has conducted many years of simulation testing of cognitive aids meant for real-time intraoperative use,[340,341] with increasing levels of optimization through graphic design. SACAG has produced the *Emergency Manual: Cognitive Aids for Perioperative Critical Events* comprising 23 optimized emergency checklists (Fig. 7-13). (Much of the work in the *Emergency Manual* was adapted from cognitive aids originally published in "Appendix of Crisis Management Algorithms in Anesthesia" in the *Manual of Clinical Anesthesiology*, edited by Stanford anesthesiologists Larry Chu and Andrea Fuller and published by Lippincott Williams & Wilkins in 2011). In 2013 these cognitive aids were placed in all anesthetizing locations

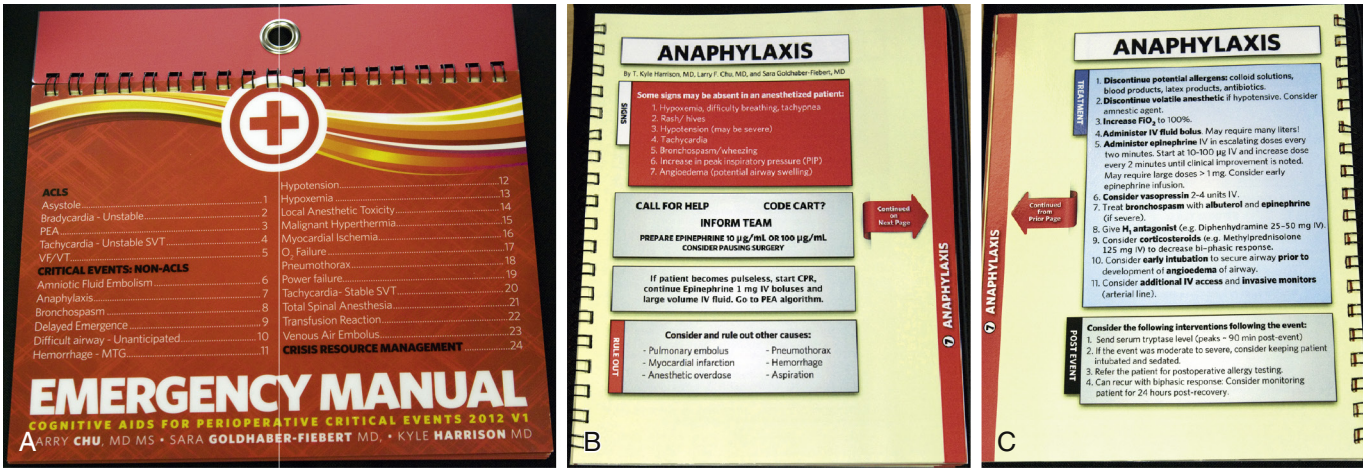

Figure 7-13. A, Front cover of the Stanford Anesthesia Cognitive Aid Group (SACAG) *Emergency Manual.* To reduce cost, the manual is printed on sealed paper; only the front and back pages are laminated. It can be hung by its strong metal grommet. On the front page, it shows the emergency events, thus making it easy to jump to the right page. Experience shows that clinicians must be familiarized with the manual in advance for optimal use. **B** and **C,** Two pages of the *Emergency Manual* checklist for "Anaphylaxis": The content and the layout have been optimized through graphic layout and careful choice of words for easy and ergonomic use in actual operating room emergencies. *(Photographs by D. Gaba.)*

in the Stanford family of teaching hospitals. The *Emergency Manual* is now available free electronically throughout the world as a downloadable portable document format (PDF) file under a Creative Commons Attribution; Non-Commercial; No-Derivatives License. Users are able to choose to print out the *Emergency Manual* locally, and instructions are given on choices of printing paper (e.g., nonflammable and able to be wiped with disinfectant), binding, and placement in perioperative patient care settings. The movement for the dissemination and use of such cognitive aids is growing. An *Emergency Manual* Implementation Collaborative has been started bringing together several leading centers in this arena to facilitate the development, testing, dissemination, adoption, and use of these resources.

EXECUTION AND ADAPTATION OF PLANS

Anesthetic plans are dynamic. The anesthesia professional must monitor the plan as it is executed and must adapt it in response to dynamically changing events. The key features of this task are (1) checking for the achievement of milestones and (2) reactive plan adaptation. These features are shown schematically in Figure 7-14. At various points of a procedure, critical milestones must be achieved to keep the original plan unaltered. If a milestone is not achieved, the anesthesia professional must decide whether to delay the next action in the sequence, modify the plan, or suspend or abort the procedure. On some occasions, the milestones are explicitly identified in advance, whereas in others the milestones are implicit.

The anesthesia professional must also react to a large number of other contingencies, some of which can be predicted in advance based on the patient's history and the type of surgery, whereas others cannot be anticipated. Incoming data streams must be constantly scrutinized (see the "police cars" in Fig. 7-14) to determine whether an expected or unexpected contingency is occurring. If so, the existing plan may have to be modified. As plans are changed, actions may be taken that invalidate other aspects of the previous plan, thereby

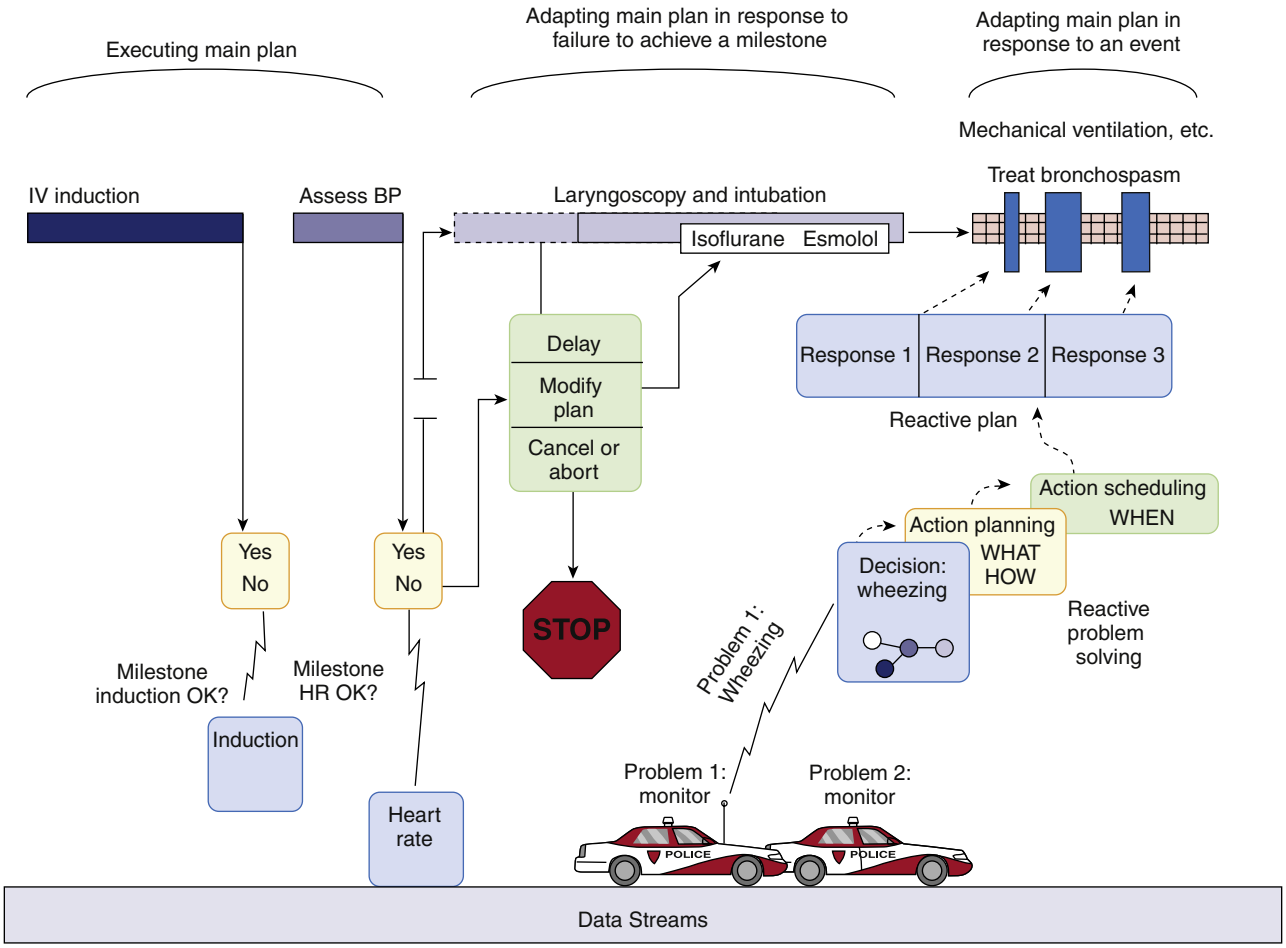

Figure 7-14. Schematic diagram of the dynamic adaptation of preoperative plans. The anesthetist begins with intravenous (IV) induction of anesthesia as planned *(top left)*. On achieving the milestone of successful induction of anesthesia, blood pressure (BP) is checked before proceeding with laryngoscopy and intubation *(center)*. If BP is not satisfactory, the next step may be delayed and the plan amended to optimize BP. If necessary, the procedure may even be aborted at this stage. Throughout the procedure, the anesthetist is vigilant for the occurrence of new problems ("police cars"). If a problem is detected, a process of reactive problem solving takes place that may result in new adaptations to the plan (in this case, treatment of bronchospasm). *HR,* Heart rate. *(From Gaba DM:* Human error in dynamic medical environments. *Hillsdale, NJ, 1994, Lawrence Erlbaum, pp 197-224.)*

requiring further adaptation of the plan. In some cases, even the original goals of the anesthetic plan may need to be adapted.

FREQUENCY OF EVENTS REQUIRING ACTIVE INTERVENTION BY THE ANESTHESIA PROFESSIONAL

The preceding analysis of Figure 7-14 suggests that anesthesia professionals must be prepared to react dynamically to changing events. How frequent is this requirement? In the Multicenter Study of General Anesthesia,[344] 86% of patients had at least one undesirable outcome. Although most events were minor and caused no injury to the patient, more than 5% of patients had one or more severe events requiring "significant therapy, with or without full recovery." This incidence is probably a lower limit for severe events because the entry criteria of the study precluded the enrollment of critically ill patients or emergency surgical procedures, for which the likelihood of severe problems requiring intervention would be expected to be high.

In another study by Cooper and associates,[345] impact events, defined as "undesirable, unexpected, and which could cause at least moderate morbidity," occurred in 18% of patients either in the OR or in the PACU, and 3% of all cases involved a "serious" event. These figures are also probably lower limits because for technical reasons the study excluded patients going directly from surgery to an ICU.

Moller and coauthors reported 4439 "impact events" in 10,312 patients either in the OR (2441) or in the PACU (1998).[346] Here again, some patients had several events, whereas others had none. The investigators did not compute the frequency of severe events, but overall, these data appear to be consistent with those from earlier studies.

MODEL OF EVENT EVOLUTION

The findings just discussed, as well as the larger system issues raised by Reason and Perrow, can be summarized in a model of event evolution (Fig. 7-15).[65,125,266]

Similar models incorporating some of the same features have also been described.[66,347] Underlying aspects of the system can generate latent failures. Either by random chance or because of interactions between the latent failures, an event may be triggered by one of four components of the operational system in the OR: the anesthesia professional, the surgeon, the patient, or the equipment. Anesthesia professionals have traditionally been most interested in events that they trigger

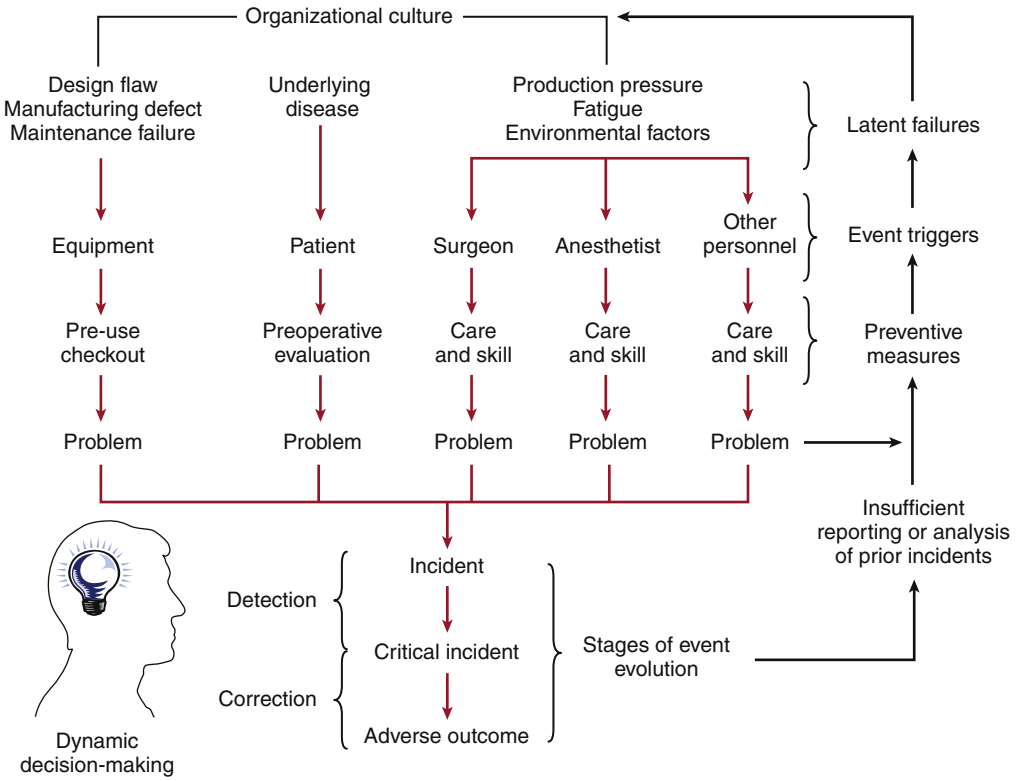

Figure 7-15. Chain of accident evolution in anesthesia. As in Reason's model, underlying latent failures (and the organizational culture) predispose to triggering of an accident sequence by equipment, the patient, the surgeon, the anesthesiologist, and other personnel. This sequence can be prevented by prophylactic measures such as preoperative evaluation and treatment of patient diseases or pre-use checkout of life-support equipment. Once a problem occurs, it may remain self-limited or evolve further down the accident chain. Using dynamic decision making, the anesthetist must detect and correct the problems that do occur at the earliest possible point in the chain of evolution. Interruption of the accident chain is made more difficult when tight coupling exists within the system, when multiple interacting problems are present, or when problems disrupt recovery processes. Efficient use of incident analysis may make it easier in the future to prevent or interrupt problem evolution. *(Redrawn with modification from Gaba DM, Fish KJ, Howard SK:* Crisis management in anesthesiology. *New York, 1994, Churchill Livingstone.)*

themselves (e.g., esophageal intubation), but in fact, most events are initiated by a combination of underlying patient disease and another of the triggering factors. Most problems are not directly harmful to the patient unless they evolve further. Possibilities for evolution of the problem include the following:

1. A single problem worsens and by itself evolves into an adverse outcome.
2. The problem begins to evolve but remains self-limited without any intervention.
3. Multiple small problems combine to trigger a problem that can evolve into an adverse outcome; the original problems by themselves would not have evolved further.
4. A single problem triggers another problem that evolves into an adverse outcome.
5. An evolving problem should be able to be stopped, but the recovery pathway is faulty.
6. Two problems are triggered. Attention focused on one (minor) problem distracts attention from the (serious) evolution of another.

The system has a variety of interruption points at which the occurrence of problems can be prevented (preoperative evaluation of patients and pre-use checkout of equipment). Moreover, although anesthesiology is far more dynamic than many medical domains, it is relatively slow in comparison with many human activities such as sports, driving, and combat flying. Thus, events often evolve slowly enough that the process of accident evolution can be thwarted before an adverse patient outcome actually occurs. The interruption of accident evolution corresponds to the "defense-in-depth" in Reason's "Swiss cheese" model[80] and to recovery from a normal accident in Perrow's paradigm (see Figs. 7-2 and 7-3 and the overview on NAT in Table 7-2).

In the prospective studies of intraoperative events cited earlier, the incidence of undesirable situations was surprisingly high, whereas the rate of actual patient harm was quite low. The patient's safety was frequently protected only by the skilled intervention of a trained anesthesia professional. This is a markedly different picture from that in commercial aviation, although the accident rate in aviation is very low. Approximately 30,000 airline flights take place each day in the United States, and very few serious incidents or accidents occur, although the exact number is unknown. The *total* accident rate from *all causes* (not including terrorist acts) for scheduled airline flights from 2002 through 2011 was 0.29 per 100,000 departures. Air carrier accidents with one or more fatalities occurred at a rate of 0.009 per 100,000 departures. In fact, according to the National Transportation Safety Board, in the years 2007 to 2011 there was only a single fatal airline accident (http://www.ntsb.gov/data/table6_2012.html).

The actual number of events in aviation matching the "impact event" criteria given earlier is not known, but it is probably at least 100 times greater than the number of accidents. Even so, this still makes aviation incidents far less frequent than the 3% to 5% rate of "significant" impact events in anesthesia. Based on these data, it is clear that the intraoperative management of abnormal, dynamically changing events remains the critical locus of anesthesia skill.

EMPIRIC STUDIES OF ANESTHESIA PROFESSIONALS' TASKS

Since the 1970s, numerous studies of anesthesia professionals' intraoperative activities have been conducted.[§] In addition, an increasing number of studies have been performed in realistic simulation environments.[2,21,24,220,352-368]

The earliest studies used time-lapse photography of a handful of anesthetic cases with a frame-by-frame analysis of tasks. One major finding of the first task analysis, by Drui and associates in 1973, was that "the anesthesiologist's attention was often directed away from the patient-surgical field."[369] In subsequent studies, it was found that approximately 40% to 50% of the time the anesthesia professional's gaze was directed away from the patient or surgical field.[281-283] McDonald and Dzwonczyk, studying cases from 1981, classified direct patient activity as "one during which the anesthesia professional had contact with the patient and a view of the surgical field."[282] These investigators explicitly noted "observation of skin color," "palpation of pulse," and "auscultation of heart and breath sounds" as direct patient activities. Observing arterial pressure or the ECG and observing or adjusting the anesthesia machine or intravenous infusions were classified as indirect patient activities. In this study, 83% of the anesthesia professional's time was spent on activities that were not direct patient activities. The same group repeated its study for cases from 1985 and demonstrated a much higher rate of direct patient monitoring than obtained in 1981 (44.8% versus 16.8%).[283] This group attributed the difference to the change from manual ventilation in 1981, which took up much of the anesthesia professional's visual attention, to the use of mechanical ventilators in 1985, which freed the anesthesia professional to watch the patient.

It is true that looking at the patient and at the surgical field is a hallmark of an excellent clinician. Opponents of technology decry the degree to which monitors and therapeutic devices distract the anesthesia professional's gaze from the patient. However, an important distinction must be made between the anesthesia professional's attention, which surely must be directed to the patient's needs, and the anesthesia professional's gaze, which in fact may best serve the patient by being directed elsewhere. Many of the tasks cited in the study by McDonald and Dzwonczyk and their co-workers were highly related to management of the patient,[283] even though they did not involve direct visualization of or contact with the patient. The critical question, which task analysis by itself cannot answer, is when anesthesia professionals gaze at the surgical field, how often are they gathering information, and how often are they just "watching the scenery"? Put more generally, what is the information content of the various observations being made, and what is their relation to action tasks and to the goals of conducting a safe anesthetic regimen?

[§]References 39, 43-46, 48, 214, 235, 275, 348-351.

Intriguingly, Drui and associates had asked physicians who were helping code their films, "What information, if any, do you gain from the direct performance of this activity?"[369] However, these investigators never described what information was available from each activity, although they seem to have assumed that turning the anesthesiologist's gaze away from the patient and surgical field was bad. Boquet and co-workers not only studied the gaze of anesthesia professionals (by using a sophisticated eye-tracking system) but also asked consultant anesthesia professionals to grade the importance of different visual targets and manual tasks.[281] "The patient" was assigned the maximal importance on the scale. However, "the surgical field," which occupied 25% of the anesthesia professional's time, was apparently not listed by the consultants. Perhaps, in their minds, the surgical field was lumped together with the patient.

Another key finding of the study by Drui and co-workers was that 40% of the anesthesia professional's time was coded as "idle," meaning that no obvious task was seen on that frame of film.[369] In 1988, McDonald and Dzwonczyk stated that this and other "studies showed that the anaesthetist spends most time performing tasks that are either secondary or unrelated to patient care."[282] However, in their original article, Drui and associates correctly recognized that the absence of visually apparent activity did not mean that the anesthesia professional was truly idle; in fact, these investigators hypothesized that this time was used by anesthesia professionals to make the decisions on which the observable tasks were based.[369]

The most detailed task analyses took place in a series of studies carried out by the UCSD/VA-Stanford group.[235,275,284,285,350,370] These analyses used progressively more task categories (11 to 28 to 32) to analyze the activities of novice and experienced anesthesia professionals in day surgery cases and the activities of senior residents during cardiac surgery. The studies showed that a small number of tasks, repeated frequently, occupied the majority of case time. Four tasks (observing monitors, recording, conversing with attending staff [for novice residents], and adjusting monitors) accounted for 50.1% of the total case time in one study. Specific activities such as airway management (e.g., bag ventilation, laryngoscopy) occurred in brief, but intense clusters (Fig. 7-16). Given the larger number of task categories, the anesthesia professional was rarely seen to be idle.

Studies by this group have attempted to determine whether a difference exists in task patterns between novice and experienced anesthesia professionals. Confirming a priori expectations, the investigators found that novices perform many of the same tasks as do experienced personnel at specific phases of an anesthetic regimen; however, the novices had a longer dwell time, on average, for each task. These studies also showed that experienced providers had lower heterogeneity of tasks and greater efficiency of tasks per unit time.[371]

Of note (but also not unexpected), novice residents spent more time speaking to their attending staff (11% of preintubation time) than did experienced residents or CRNAs. Experienced personnel observed the surgical field more than did the novices. The implications of this finding are not clear. Novices did take longer to complete patient preparation and induction of anesthesia, but it appeared that some of the extra time taken by novices working under supervision was offset by the efficiency of offloading other concurrent tasks to the attending anesthesiologist such that preintubation time was increased by only 6 minutes for novices.[371] This group also reported that as the density of tasks per unit time increased, the dwell time on each task decreased, and vice versa. This finding has important implications for how anesthesia professionals allocate their attention (see the earlier section on management and coordination of the core process).

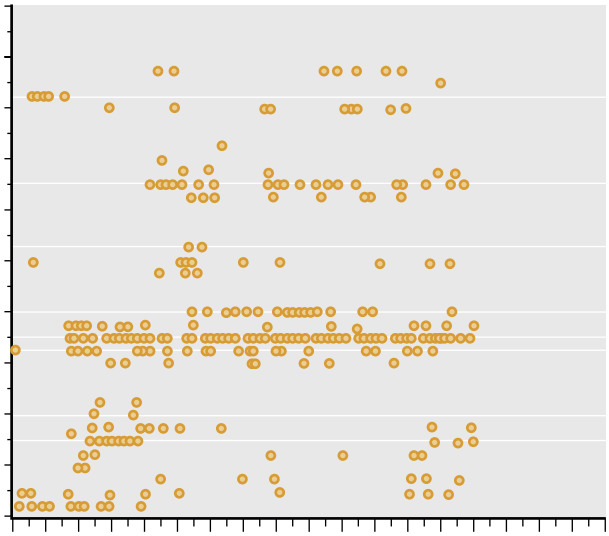

Figure 7-16. Distribution of the anesthetist's tasks during an actual ambulatory surgery procedure. The anesthetist was directly observed by an investigator who recorded a code number for each task as it was performed (there were 28 task codes). Certain tasks, such as bag ventilation, were clustered in specific phases of the case, whereas others, such as observing monitors, were repeated frequently throughout the procedure.

Task Analysis and Action Density

An interdisciplinary research group consisting of the Work and Organisational Psychology Department of the Swiss Federal Institute of Technology in Zurich and the Center for Patient Safety and Simulation of the Department of Anaesthesiology of the University of Tübingen performed several task analysis studies using the Flexible Interface Technique (FIT) system[372] (Fig. 7-17), which facilitates analysis of multiple parallel and overlapping actions.[286] The group produced a set of 41 observation codes—representing a single action (Table 7-9). Because the method allowed true capture of overlapping actions, it was possible to describe a valid task density in the analysis of anesthesia professionals' action sequences.

Figures 7-18 and 7-19 show examples of observations of 24 real OR studies. The observation data contain many short-term fluctuations (*dots*); the moving average of action density of the previous 5 minutes was charted as well (*line*). Figure 7-18 shows a complete anesthesia procedure with obvious increases in action density during induction and emergence from anesthesia. Figure 7-19 shows 2 final phases of cardiac cases involving cardiopulmonary bypass. The described task analysis technique

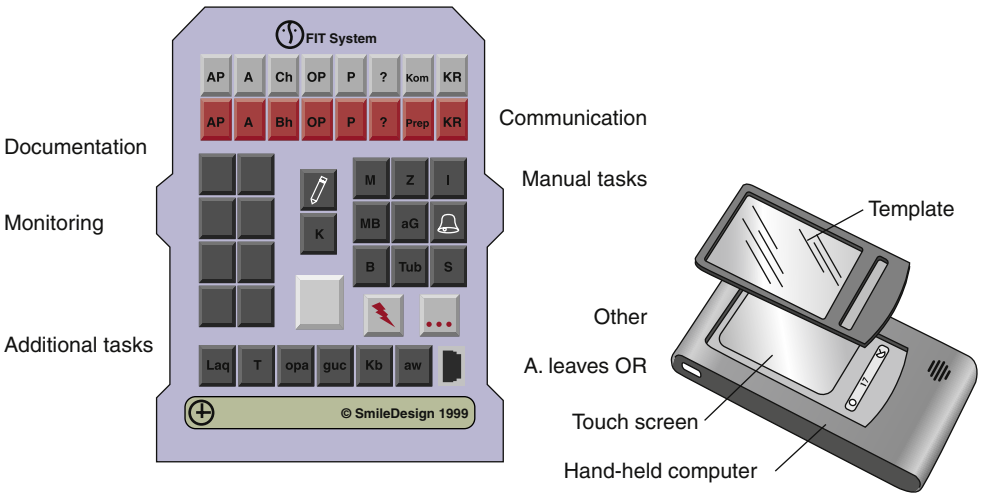

Figure 7-17. Flexible Interface Technique system. The system allows easy reorganization of task analysis items and categories and can properly resolve overlapping actions. *OR,* operating room.

TABLE 7-9 OBSERVATION CODES USED TO CLASSIFY TASKS AND ACTIONS

Task Group	Actions
Monitoring	Reading of patient record, observation of patient, observation of patient monitors, observation of anesthesia machine, observation of intravenous drip, observation of syringe pumps, measurement, scanning of area
Measures	Placement of IV, drug administration, adjustment of IV, mask ventilation, intubation or extubation, adjustment of anesthesia machine, use of other equipment, quitting alarms, suctioning
Communication	(1) Active conversation with nurse anesthetist, attending anesthetist, surgeon, OR nurse, patient, others; (2) responsive conversation with nurse anesthetist, attending anesthetist, surgeon, OR nurse, patient, others; and (3) response to pager
Documentation	Patient chart labeling (drugs, drips, laboratory results)
Additional operations	Positioning of patient, patient transfer, tasks of others (circulating nurse, orderly), arrangement of workplace, conversation with observer ("just looking"), miscellaneous, leaving OR (with possible audiovisual contact with OR)

IV, Intravenous line; *OR,* operating room.

was also used successfully by the Tübingen group to study action sequences in a simulator and compare them with findings in the real OR to demonstrate and evaluate the ecologic validity of simulators (see Chapter 8).

Automation

Early task analyses identified repetitive tasks that did not appear to offer substantial information content or therapeutic benefit as candidates for automation. Drui and associates identified filling out anesthesia records, measuring blood pressure, and adjusting intravenous infusions.[369] Kennedy and colleagues identified data display and trend plotting.[373] Many of these tasks have in fact been automated since the 1990s. Loeb, from the University of California, Davis (UCD), showed that anesthesiologists typically observed monitors for approximately 1 to 2 seconds every 10 to 20 seconds and that it usually took several observing cycles before they detected a subtle cue on the monitor.[374] Gurushanthaiah and co-workers studied the effect of more sophisticated display modalities on detection of signals by anesthesiologists and found that histogram and polygon formats improved response latency in the laboratory setting over formats using raw numbers only.[375] However, the applicability of these laboratory finding to the more complex signal detection that must occur during patient care is uncertain. Incidentally, the experience in the field of aviation suggests that automation of both monitoring and therapeutic devices produces its own problems in human-machine interactions and may well be a causative or contributing factor in some adverse anesthetic events. Some of the same types of automation-related adverse events seen in aviation are now observed in anesthesiology.[267]

The impact of automation on task distribution is uncertain. The change to mechanical ventilation did affect the analyses of McDonald and Dzwonczyk,[282] as detailed earlier. A study by Allard and co-workers showed no reduction in time spent recording when automated record-keeping devices were used.[376] However, the UCSD/VA-Stanford collaboration published data demonstrating a 20% reduction in the time spent record keeping when automated record keeping was in use during cardiac anesthesia.[371] The investigators noted a slight, but not significant increase in time spent on direct patient care activities when electronic record keeping was in use. No clear evidence indicates that electronic record keeping will yield a marked enhancement of the anesthesia professional's ability to perform other patient care tasks, although automated record keeping may yield other benefits. The UCD and UCSD/VA-Stanford groups demonstrated that electronic automated record keeping does not significantly reduce the vigilance of anesthesia professionals.[377,378]

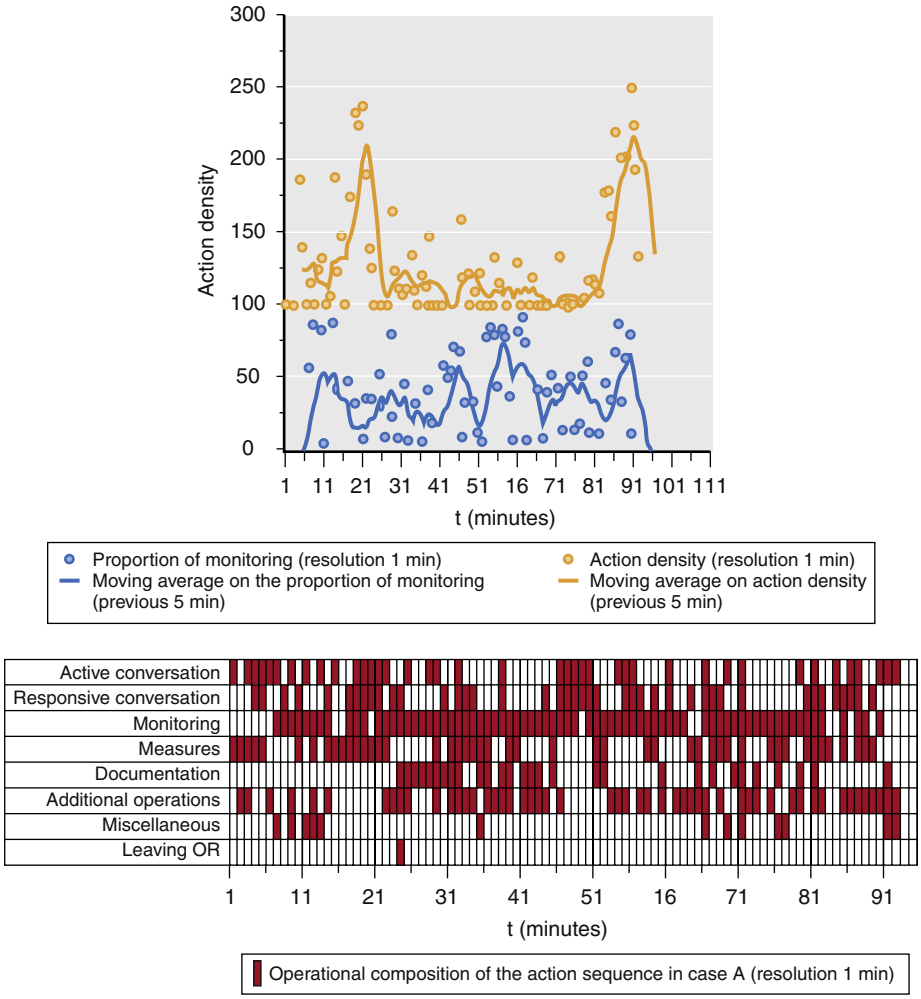

Figure 7-18. Action density diagram illustrating the derived parameter "action density" from induction of anesthesia to emergence in a real anesthetic case. The *yellow line* in the graph shows the overall action density and the *dots* show the moving average of the density. The *blue line* shows the contribution of one task group, "monitoring," as an example. The table in the lower graph shows the composition of the data for all eight task groups from the same case. *OR,* Operating room.

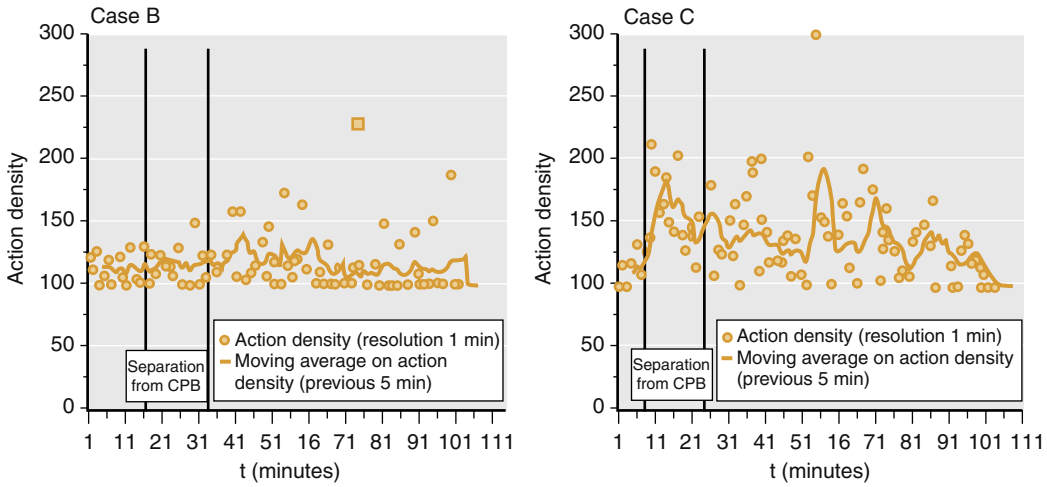

Figure 7-19. Action density during separation from cardiopulmonary bypass (CPB) without and with complications. The graph on the *left* is the density diagram of an uncomplicated case (case B) with a "flat" action density diagram during (between the two *vertical lines)* and after separation from CPB. In contrast, case C, shown in the graph on the *right,* had a complicated weaning from CPB; a very high action density is followed by an elevated density with further peaks after separation.

MENTAL WORKLOAD OF ADMINISTERING ANESTHESIA

The observable tasks do not tell the whole story of what the anesthesia professional is doing. As Drui and co-workers suggested, mental activity is going on even when the anesthesia professional appears idle.[369] What, then, is the mental workload of administering anesthesia? Mental workload is another concept that is readily understood but difficult to define precisely. Various ways exist to measure mental workload, none of which are ideal.

Primary Task Performance Measure

The primary task performance measure assesses the subject's performance on standard work tasks as they are made progressively more difficult by increasing the number of tasks, task density, or task complexity. At first the subject is able to keep up with the increasing task load, but at some point the workload exceeds the ability to manage it, and performance on the standard tasks decreases. The disadvantage of the primary task performance measure is that in many complex task domains no accepted way exists to measure the subject's performance on the primary work tasks objectively except by loading to the point of catastrophic performance failure, which is easily detected. In actual high-risk domains, one cannot allow primary task performance to degrade, and one certainly cannot allow it to fail catastrophically. Although experiments of this type are in principle feasible with anesthesia simulators, they have not yet been attempted.

Secondary Task Probing

A more useful technique, secondary task probing, tests the subject with a minimally intrusive secondary task that is added to the primary work tasks. The secondary task is a simple one for which performance can be objectively measured, and the subject is instructed that the primary tasks of patient care take absolute precedence over the secondary task. Therefore, assuming that the secondary task requires some of the same mental resources as the primary task, the performance of the subject on the secondary task is an indirect reflection of the spare capacity available to deal with it; thus, it is an inverse measure of primary task workload (the greater the spare capacity, the lower the primary workload). Secondary tasks such as reaction time (with or without choice), finger tapping, and mental arithmetic have been used for this technique in the psychology laboratory, in high-fidelity simulators, and in some field studies of actual work situations.

Gaba and Lee presented two-digit addition problems on a computer screen placed in the anesthesia workspace at random approximately every 45 seconds.[379] The delay in responding to problems and the number of problems skipped were logged over time and correlated with a concurrent six-category task analysis. The dynamic ebb and flow of mental workload during cases of varying complexity was documented. For example, cardiopulmonary bypass was confirmed as a time of very low workload for the anesthesia professional, whereas induction of anesthesia was confirmed as a period of high workload. Manual tasks and conversing with the attending physician were correlated with a delayed or absent response to the secondary task.

Subsequent studies by the UCSD/VA-Stanford group[284,285] and the UCD group[374,378,380] used the reaction time to a changing display in or around the clinical monitors as a secondary task to assess mental workload, vigilance, or both. For the UCSD/VA-Stanford group, the display was a red light placed next to the main physiologic monitor. This secondary task was analogous to but totally separate from the standard tasks of clinical work. When the secondary task was embedded in the regular work tasks, it was called an embedded task. The UCD group used a secondary task involving recognition of changes in the alphanumeric display of an unused channel of an actual clinical monitor (a parameter labeled "Vig" on the monitor changed values from "5" to "10"). This task was only partially embedded because although it did involve an actual clinical monitor, it displayed on an otherwise unused channel and was not of clinical significance. The VA-Stanford group has experimented with fully embedded secondary tasks during simulator anesthetic cases in which the values of actual clinical variables can be manipulated at will to evaluate the subject's response time to the excursion of data values beyond predefined reporting thresholds.

The mean response time to the red light used by the UCSD/VA-Stanford group was markedly less than 60 seconds for experienced subjects in both the induction and postinduction (maintenance) phases, but it was much higher for novice residents during the induction phase (Fig. 7-20). The probe was not given frequently enough to track the ebb and flow of workload. The response to the UCD task typically (56%) occurred within 60 seconds, but 16% of stimuli overall (27% during the induction period) were not responded to within 5 minutes. The conclusion was that spare capacity may be limited by the workload of the case during certain periods of anesthesia care.

These workload studies have several problems. One is interference with the "response channel." If responding

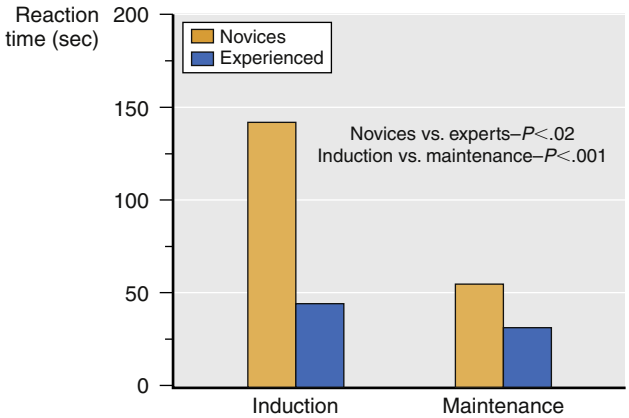

Figure 7-20. A test of the anesthetist's vigilance. Shown is the mean reaction time of novice residents and experienced anesthetists in response to the illumination of a red light placed next to the electrocardiogram monitor display during actual ambulatory surgery procedures. In both groups the reaction was faster in the maintenance phase than during induction of anesthesia. Novices reacted significantly more slowly than did experienced anesthetists. Because the distribution of reaction times was skewed and nongaussian, error bars are not shown, and nonparametric statistics were used for hypothesis testing.

to the probe requires manual activity with a mouse or keyboard (as in the studies of Gaba and Lee and the UCD group), it cannot be performed whenever the subject is occupied with a manual task. This is especially true during a sterile procedure. Therefore, it may be impossible to distinguish between a high primary task load (i.e., no spare capacity to address the secondary task) and a low primary task load that happens to usurp the manual response channel. However, in the study by Gaba and Lee, 37% of the problems that were skipped for lack of spare capacity did not occur during a manual task.[379] All the UCSD/VA-Stanford studies have allowed multiple response channels (manual, voice, and gesture), so there was no response channel interference; however, the potential for interference remains in the UCD studies.

An additional problem with these studies is that even these simple secondary tasks were intrusive when repeated frequently. Thus, a tradeoff was seen between temporal resolution of the measurement and its intrusiveness. Controversy also exists about whether these probes measure "vigilance" or "workload," although the same techniques probably measure both aspects of performance. When probes occur infrequently, are subtle, have multiple response channels, and are performed with a low level of existing workload, they are more likely to measure vigilance; when they are frequent, readily detectable, require a manual response, and are performed during a high-workload period, they probably are more indicative of spare capacity and workload.

Slagle and colleagues carried out an assessment of an established clinical task analysis methodology regarding intrarater and interrater reliability.[349] These investigators had a trained observer rating 20 routine anesthesia cases, by first rating cases in the OR and then rating the same cases from a videotape, with another observer rating the same videotapes twice. A computerized task analysis program with 38 task categories was used. The results showed good intrarater reliability and also high concordance between real-time and video analyses. This finding is important because real-time observation is unfeasible in many circumstances. This study had problems in analyzing parallel tasks because the technique of "toggling between the task categories at a rate proportional to the time spent on each task" resulted in large differences in "task duration" and "task occurrences" between the two raters. This problem of recording parallel tasks (two or more) was solved by Manser and colleagues in Tübingen.[286,287,381]

Subjective Measures

A third modality of workload assessment consists of subjective measures in which individuals are asked, either in retrospect or in real time, how much load they were or are under during actual work situations. Subjective measures complement objective measurements because the subjective perceptions of the anesthesia professional may be an important source of stress and anxiety; conversely, an anesthesia professional may subjectively underestimate the workload in settings in which objective measurements demonstrate a marked reduction in spare capacity.

Various scales have been proposed to measure dimensions of mental workload that are, in theory, different. However, Gaba and Lee adapted a set of workload scales from those used at NASA and showed that workload ratings on each of the scales were highly correlated.[379] In subsequent studies by the UCSD/VA-Stanford group, a single dimension of overall load was assessed by using an asymmetric numeric scale that minimized biases caused by a tendency to group responses at the middle and extremes of symmetric scales. This group demonstrated that a neutral observer can estimate the subjective workload of the anesthesia professional in real time with high correlation to the self-rated workload of the subject.[284] Again, as could be expected, subjective workload was highest during induction and emergence from anesthesia, especially for novices.

Physiologic Measures

The final set of techniques for assessing workload consists of physiologic measures. Visual or auditory evoked potentials have been used successfully to assess mental workload, but this technique can be used only in a static laboratory environment. Heart rate is a relatively easily measured variable that may be altered by mental workload. Toung and associates showed that the anesthesia professional's heart rate increases at the time of intubation, and the amount of increase is inversely related to the amount of overall medical training.[382] Azar and co-workers found that anesthesia faculty members' heart rate and blood pressure increased during induction of anesthesia, and significant ST-segment depression developed in one individual.[383] Bitetti and colleagues confirmed that heart rate changes occurred during anesthesia but did not always correlate with contemporaneous self-recordings of "stress."[384]

Because of the many factors that affect heart rate, the beat-to-beat variability of the heart rate is thought to be a better indicator of mental workload. The frequency components of heart rate variability can be separated by spectral analysis; a component at 0.1 Hz has been linked to mental workload. Although several groups have acquired heart rate data on anesthesiologists, none has reported an analysis of the workload-related frequency components.

APPLICATIONS OF TASK ANALYSIS AND WORKLOAD METHODOLOGIES

The results of task analyses and workload measurements have primarily provided objective confirmation of several intuitive beliefs about anesthesia practice. The real importance of these studies is that a coherent methodology has been developed that may be useful for studying a variety of interesting questions.[287,385] The question of the impact of electronic automated record-keeping systems was addressed earlier. Another question concerns TEE. This monitoring modality has become commonplace during cardiac anesthesia and anesthesia for other patients with cardiovascular disease who undergo complex operations. It is widely recognized that evaluating TEE images and manipulating the TEE probe require substantial visual and mental attention.

The UCSD/VA-Stanford group has published data suggesting that vigilance (as measured by response latency to illumination of a red light) was substantially lower when the anesthesiologist was involved in manipulating,

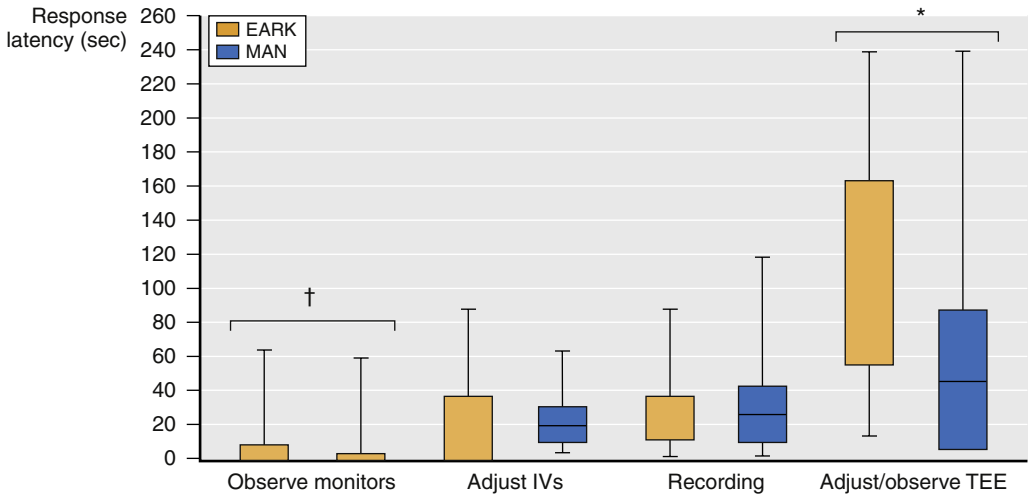

Figure 7-21. Vigilance test data during anesthetic tasks with and without automated record keeping. The range of data is shown for each of four task categories in electronic automated record keeping (EARK) and manual record keeping (MAN). Each box contains 50% of the data for that subgroup (the upper limit of the box is the 75th percentile; the lower limit is the 25th percentile), whereas the maximum and minimum are shown by the upper and lower *horizontal bars.* The response latency during record keeping was not significantly different between EARK and MAN. In both record-keeping groups, subjects had significantly slower responses when observing or adjusting the transesophageal echocardiogram (TEE) than when recording, observing monitors, or adjusting intravenous lines (IVs). Subjects in both groups had faster response latency when observing the monitoring array, which contained a red light, than when performing the other three tasks. $^{*}P < .05$; $^{\dagger}P < .05$. *(From Weinger MB, Herdon OW, Gaba DM: The effect of electronic record keeping and transesophageal echocardiography on task distribution, workload, and vigilance during cardiac anesthesia,* Anesthesiology *87:144-145, 1997.)*

adjusting, or examining the TEE images than when other patient care tasks were being performed (Fig. 7-21).[377] This finding may reflect, in part, the layout of the workspace. The TEE machine is large and is often placed near the left side of the head of the OR table, whereas the anesthesia machine and attendant monitors, by convention, are typically placed near the right side of the head of the table. Remote displays slaved to the primary monitor are also more likely to be on the patient's right side. This arrangement makes it physically difficult to glance from one modality to another. The degree to which the mental concentration required to use TEE itself detracts from vigilance for other signals remains to be determined explicitly.

It is important to differentiate the various uses of TEE. When TEE is used to answer specific clinical questions triggered by events or milestones during the procedure, the value of the information may be worth an investment of effort despite the reduction in overall vigilance. When TEE is used as a continuous monitor for myocardial ischemia or during a detailed routine examination, the reduction in vigilance must be considered when evaluating the potential benefits of the technology. Some practitioners describe special ways to handle the attention required for TEE, including tightening alarm thresholds (to provide audio warnings of changed values) and assigning specific patient monitoring functions to another individual while conducting the initial TEE placement and examination.

Many other interesting questions on the performance of anesthesia professionals are still unanswered and can be addressed with the techniques of task analysis and workload and vigilance assessment, including the following:

1. How do task load and task density differ between private practice settings and academic settings?
2. Do characteristic "patterns" for experts and novices (or should we say for "good" and "bad" anesthesiologists?) exist in the analysis of tasks and their densities? And if yes,
   a. How do the work patterns of novices change to become those of "experts"? How can the training of novices be focused to support these changes best? Is suboptimal performance of novices detectable through analysis of task distributions and mental workload?
   b. Can work patterns be linked to safe anesthetic practice, or can special patterns be linked to unsafe behavior? Perhaps this could be done by assessing high-workload simulator scenarios. In a proactive safety culture, this would allow us to identify such colleagues and train them individually.
3. How much task load can the average anesthesia professional handle? How are tasks distributed among personnel (e.g., between resident and faculty, between CRNA and supervisor, and among staff anesthesia professionals) during the high-workload periods of patient care? This question is just beginning to be addressed by applying the task analysis techniques described earlier to videotapes of actual anesthetic cases. With use of these tapes, the task sequences of multiple anesthesia personnel can be elicited separately, as can the communications used to coordinate their activities.

OTHER STUDIES OF "VIGILANCE" AND DECISION MAKING BY ANESTHESIA PROFESSIONALS

STUDIES OF "VIGILANCE"

The dominant metaphor for the mental activity of the anesthesia professional has been that of a vigilance task.

"Vigilance" is the motto on the seal of the ASA. What is vigilance, and to what degree does it capture the complex nature of the anesthesia professional's work? "Vigilance, or sustained attention, refers to the ability of observers to maintain their focus of attention and to remain alert to stimuli for prolonged periods of time" (J. Warm, presentation at the Panel on Vigilance, ASA annual meeting, 1992). The literature concerning vigilance is abundant. Many laboratory studies have demonstrated decrements in vigilance during prolonged vigilance tasks that are exacerbated or ameliorated by a variety of factors. These studies have generated considerable controversy. Some psychologists believe that the results of laboratory studies of vigilance have little application to complex real-world task domains.[386,387] Certainly, the anesthesia professional's work involves vigilance as a necessary component because no meaningful work can be accomplished if new stimuli are not perceived. However, the anesthesia professional's task is much more complex than just vigilant alertness to stimuli. Therefore, vigilance is a necessary but not sufficient condition for appropriate performance.[65]

Several studies have attempted to quantitate the vigilance of anesthesia professionals to changes in clinically important variables by using low-fidelity simulation. Beatty and associates had anesthesia professionals watch for changes in displays of six vital signs on a video monitor.[388] Denisco and colleagues used videotapes containing abnormal changes in anesthesia flow meter settings and physiologic monitor displays.[389] The raw reaction times were not reported—only the "vigilance scores." Such studies purported to demonstrate a degradation in performance for sleep-deprived and fatigued residents, but these studies had methodologic flaws. For example, in the study of Denisco and colleagues, the subjects were never told the threshold of change for them to report.[389]

In addition, the work environment of the anesthesia professional is much more complex than that presented in these low-fidelity simulations. Although it can be argued that complexity will worsen vigilance, such is not necessarily the case. Complexity can combat boredom, which is a distinct possibility in vigilance experiments. In addition, the real work environment often provides redundant data cues on changes that offer multiple possibilities for their detection.

A study of rested anesthesia professionals using realistic anesthesia simulation measured detection times (first awareness of a problem) for a variety of intraoperative events embedded within a realistic case situation.[214] An event that caused alarms to sound immediately, such as ventricular tachycardia or fibrillation, was detected in 10 seconds or less (thus confirming its veracity, but acting on it took longer in many instances). Another event, occlusion of the intravenous line, was detectable only by visual observation in the direction opposite the anesthesia machine and monitors. This event took several minutes (on average) to detect, but it was corrected quickly after detection. The redundancy of cues in the task domain was confirmed in that 6 different observational modalities were used by at least 1 of the 19 residents studied to detect endobronchial intubation initially.

Other vigilance studies have focused on detecting the loss of an existing monitoring modality during actual patient care. In one study,[390] the esophageal stethoscope was occluded with a clamp after a staged distraction (conversation or a loud noise). Subjects most commonly detected the occlusion by observing the clamp, rather than by noting a loss of sound. Although this study purported to show a difference in vigilance related to the use of automatic blood pressure measurement devices, the artificial distraction could have biased the results; the subjects typically failed to hear the loss of sounds, and a significant result was reported for only one group of residents, arbitrarily stratified by length of training. Another study,[391] which evaluated reaction time to loss of esophageal stethoscopy more carefully, showed that 13% of occlusions were detected after 1 minute. However, this study required a manual response, and the investigators noted that in some instances of delay, the subject was involved in a manual clinical activity such as administering blood or drugs.

Apparent reductions in vigilance could result either from a reduction in "spare capacity" to attend to the stimuli immediately or from a reduction in the overall alertness of the anesthesia professional. Enhancements in the display and annunciation of relevant information would be a useful ameliorative strategy in the first case, whereas this strategy would not be useful if the anesthesia professional's overall alertness were impaired, such as by sleep deprivation or illness. The influence and impact of fatigue and possible countermeasures are covered in the earlier section on performance-shaping factors.

EMPIRIC STUDIES OF COMPLEX DECISION MAKING AND ACTION BY ANESTHESIA PROFESSIONALS

Traditional concepts of decision making in medicine have concentrated on relatively static, well-structured decisions. For example, should patient A with an elevated blood pressure be treated for hypertension with drug X, or should no treatment be started? Other investigators have looked only at "diagnosis" as an isolated task (specifically, "diagnostic explanation") both in internal medicine[392-394] and in radiology. These approaches to decision making have not captured the unique aspects of dynamism, time pressure, and uncertainty seen in anesthesiology. Since the 1980s, a paradigm has emerged regarding decision making and action in complex real-world situations.[47,276,290] The cognitive model of dynamic decision making was described previously. Several teams from inside the anesthesiology profession and from the human performance community have been striving to develop a more comprehensive understanding of the complex performance of anesthesia professionals. Their work has been based on a small number of new experiments (often involving medium- or high-fidelity anesthesia simulators), reinterpretation of previous experiments, direct and indirect observation of the conduct of anesthesia, and extrapolations from other industries to anesthesiology. Each experiment has probed several aspects of decision making and action, which are described in the following section.

Responding to Simulated Critical Incidents

Many studies using simulations have been performed and published. Because the results of later studies are largely in accord with those of the original studies, we describe

the original studies as examples that also represent some of the more recent literature.[20,21,395-404]

Using a realistic hands-on anesthesia simulator, Gaba and DeAnda studied the response of anesthesia trainees and experienced anesthesia faculty and private practitioners to six preplanned critical incidents of differing type and severity[123,300,405]:

1. Breathing hoses too short to turn the table 180 degrees, as requested by the surgeon
2. Endobronchial intubation (EI) resulting from surgical manipulation of the tube
3. Occlusion of intravenous tubing
4. Atrial fibrillation (AF) with a rapid ventricular response and hypotension
5. Disconnection between the endotracheal tube and the breathing circuit
6. Ventricular tachycardia or fibrillation

These investigators measured the detection time (as described in the section on vigilance) and the correction time (the time from the event's onset until any one of a predefined set of corrective actions was first taken). They assessed the information sources by which subjects detected the incidents and then confirmed and diagnosed the problem. They asked subjects to "think aloud" to permit subjective analysis of their decision-making strategies. A summary of the data is shown in Figure 7-22. Major findings from this set of studies included the following:

1. Events differed from each other in their inherent ease of solution. Some events (e.g., airway disconnection) were detected rapidly and corrected. Some problems (e.g., intravenous occlusion) were difficult to detect, but once they were detected, diagnosis and therapy were achieved rapidly. Other problems (EI, AF) were easy to detect by using one of several redundant information sources as

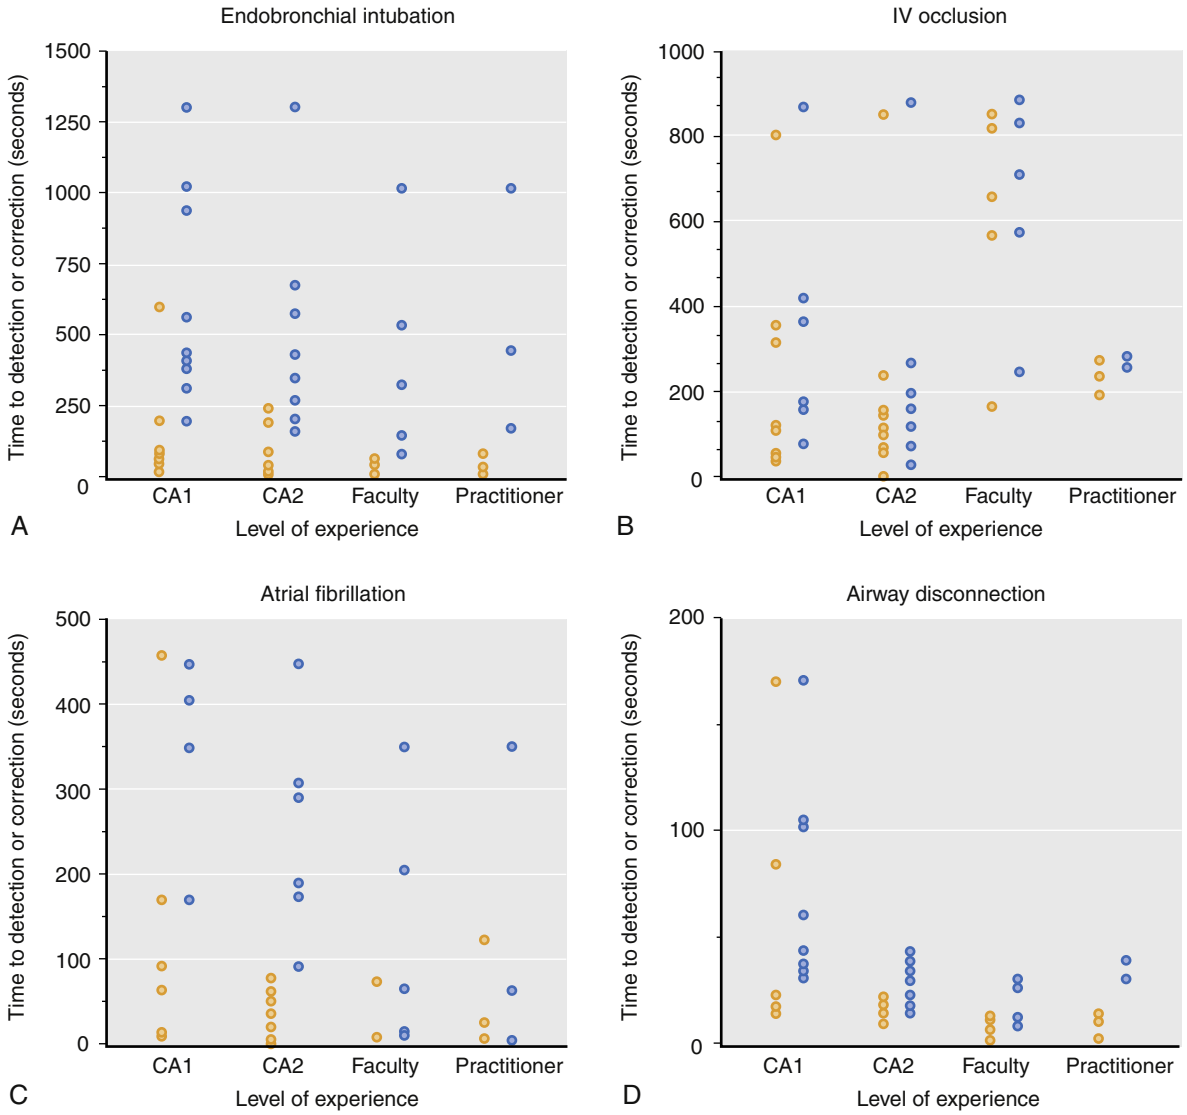

Figure 7-22. Response times of anesthesiologists with different levels of experience to four simulated critical incidents: **A,** endobronchial intubation; **B,** intravenous (IV) occlusion; **C,** atrial fibrillation; and **D,** airway disconnection. Detection time is represented by *yellow circles* and correction time by *blue circles* (see text for definitions of these times). Unless an overlap exists between response times, each circle represents a single individual. The scale of response times is different for each event. Variability among incidents and among individuals is substantial. Despite a trend to better performance with increased experience, major errors were made by individuals in all groups. *CA1,* First-year clinical anesthesia residents; *CA2,* second-year clinical anesthesia residents. *(From DeAnda A, Gaba DM: Role of experience in the response to simulated critical incidents,* Anesth Analg *72:308-315, 1991.)*

the first clue (6 for EI; 4 for AF), but they required additional time (7 to 8 minutes for EI; 1.5 to 4.5 minutes for AF) to confirm the abnormality, establish a diagnosis, and initiate appropriate therapy. Diagnosis and planning and monitoring of therapy used a large number of information sources (11 for EI; 9 for AF).
2. For each incident, considerable interindividual variability was found in detection and correction times, in information sources used, and in actions taken. Each experience group contained some who required excessive time to solve the problem or who never solved it. In addition, in each experience group at least one individual made major errors that could have had a substantial negative impact on a patient's clinical outcome. For example, one faculty member never used electrical countershock to treat ventricular fibrillation. One private practitioner treated the EI as though it were "bronchospasm" and never assessed the symmetry of ventilation. One resident never found the airway disconnection.
3. The average performance of the anesthesia professionals tended to improve with experience, although this varied by incident. The performance of the experienced groups was not definitively better than that of the second-year residents (who were in their final year of training at that time). Many (but not all) novice residents performed indistinguishably from more experienced subjects.
4. The elements of suboptimal performance were both technical and cognitive. Technical problems included choosing defibrillation energies appropriate for internal paddles when using external paddles, ampule swap, and failure to inflate the endotracheal tube cuff that resulted in a leak. Cognitive problems included failure to allocate attention to the most critical problems and fixation errors.

Schwid and O'Donnell, from the University of Washington, used the Anesthesia Simulator Consultant (ASC) screen-only simulator (Anesoft Corp., Issaquah, Wash.) (Table 7-10) to perform an experiment similar to those of Gaba and DeAnda with a realistic simulator.[298] This method enabled them to evaluate some elements of anesthesia professional behavior more carefully, albeit with the limitations imposed by presenting the OR "on the screen." After working on several practice cases without critical incidents, each subject was asked to manage 3 or 4 cases involving a total of 4 serious critical events (esophageal intubation, myocardial ischemia, anaphylaxis, and cardiac arrest). The progression of each event was mediated by the interaction of physiologic and pharmacologic models with the actions taken by the subject. The anesthesiologists studied had varying experience levels. One group was made up of 10 anesthesia residents with at least 1 year of anesthesia training, whereas the other 2 groups contained 10 anesthesia faculty members and 10 private practitioners, respectively.

Major findings of the study included the following:

1. Significant errors in diagnosis or treatment were made in every experience group. The errors occurred in both diagnosis of problems and in deciding on and implementing appropriate treatment. For example, 60% of subjects did not make the diagnosis of anaphylaxis despite available information on heart rate, blood pressure, wheezing, increased peak inspiratory pressure, and the presence of a rash. In managing myocardial ischemia, multiple failures occurred (Table 7-11).
2. Thirty percent of subjects did not compensate for severe abnormalities while considering diagnostic maneuvers.
3. Fixation errors in which initial diagnoses and plans were never revised were frequent, even when they were clearly wrong.

Westenskow and colleagues used a test lung and remotely activated faults in the breathing circuit to test the anesthesia professional's ability to identify faults related to ventilation and the anesthesia breathing circuit after hearing an alarm.[293] One group of subjects used standard alarms, set to factory defaults, on an anesthesia machine, which included a capnograph. The other group used the same anesthesia machine with the alarms disabled along

TABLE 7-10 INCIDENCE OF TOTALLY CORRECT DIAGNOSIS OR TREATMENT OF SIMULATED CRITICAL INCIDENTS WITH USE OF THE ANESTHESIA SIMULATOR CONSULTANT

Incident	Anesthesia Residents (%)	Anesthesia Attendings (%)	Anesthesiologists in Practice (%)
Diagnosis of esophageal intubation	80	100	100
Treatment of myocardial ischemia	20	40	20
Diagnosis of anaphylaxis	20	60	40
Treatment of cardiac arrest	40	30	20

TABLE 7-11 FAILURE RATE IN THE MANAGEMENT OF SIMULATED MYOCARDIAL ISCHEMIA WITH THE ANESTHESIA SIMULATOR CONSULTANT

Incident	Anesthesia Residents (%)	Anesthesia Attendings (%)	Anesthesiologists in Practice (%)
Untreated tachycardia	30	50	70
Untreated hypotension	40	60	20
Inappropriate drug	20	10	0
Inability to recall infusion dose	50	20	10
Inability to calculate infusion rate	70	40	40

From Schwid HA, O'Donnell D: Anesthesiologists' management of simulated critical incidents, Anesthesiology *76:495-501, 1992.*

with a neural network–based intelligent alarm and fault identification system. The mean "human response time," which was the time between sounding of the first alarm and identification of the event, ranged from approximately 15 seconds for airway disconnection to approximately 90 seconds for an endotracheal tube cuff leak. The 10 anesthesiologists tested with the standard alarm setup were unable to identify the fault within 2 minutes on 11 occasions—5 cuff leaks, 3 airway obstructions, and 3 stuck-open expiratory valves. However, in such circumstances they did take appropriate compensatory actions while continuing to search for the cause (e.g., increasing fresh gas flow to compensate for a cuff leak).

The intelligent alarm apparatus used data from three sensors (in-line capnograph, spirometer, and airway pressure). A neural network determined whether any of seven faults was present and, if so, displayed a text message specifying the fault, as well as an animated diagram of the lung, airway, and anesthesia breathing circuit with the faulty component highlighted in red. The smart alarm system took slightly longer on average to detect a fault than did the conventional alarm system (25 versus 21 seconds), but the human response time was markedly reduced for three of the seven faults. No statistically significant differences were noted between anesthesia residents and faculty members with either alarm system.

The investigators suggested that the more specific alarm messages in their intelligent alarm system could direct the attention of the anesthesia professional to the occurrence of specific problems and in so doing would decrease workload and reduce the likelihood of fixating on inappropriate information. They stated that such a system's advantages would be even greater in a more realistic clinical environment in which the anesthesia professional has multiple complex tasks and not just detection and identification of ventilation-related events.

Loeb and Fitch developed and tested an auditory display of six physiologic variables.[406] Encouraged by the popularity of the pulse oximeter's pulse tone,[407-409] these workers investigated whether the addition of auditory cues would enhance the rate and speed of detection of predefined events. The results showed that the combined display (visual and auditory) lead to faster detection of events, even though the rate for correct identification of the event was slightly higher in the "visual only" display (80% versus 88%). It seems a potential exists to improve the rate of detection of changes in physiologic variables with more sophisticated display modalities, thereby enhancing the "effective vigilance" of anesthesia professionals.

Complex, Multiple-Personnel Simulations of Anesthetic Crises

Once again, the literature now contains numerous studies of more complex simulations of intraoperative events with multiple anesthesia professionals interacting either with "confederate" actors in the roles of other clinicians (e.g. surgeons, nurses), or in some cases with actual clinicians in those roles. Again, because much of the more recent literature recapitulates findings of the pioneering studies, we describe those studies but refer the reader to newer studies.[339,343,400,401,410-413]

In the process of evaluating a new type of training for anesthesia professionals involving crisis management, Howard and colleagues collected anecdotal data on the responses of teams of anesthesia professionals, surgeons, and nurses to planned (and unplanned) critical events.[122] These experiments largely confirmed the results of the studies described earlier and extended them to include more complex management issues and team interactions. Howard and colleagues found a substantial incidence of difficulties managing multiple problems simultaneously, applying attention to the most critical needs, acting as team leader, communicating with personnel, and using all available OR resources to best advantage.

Botney and associates analyzed similar videotapes from 18 different simulator training sessions on crisis management.[414] In a single event, a volatile anesthetic vaporizer had been left on at 4% and was hidden beneath a printout from the noninvasive blood pressure monitor. Simultaneously, a mechanical failure of the capnograph occurred and made it impossible to confirm endotracheal intubation with carbon dioxide measurements. This event purposefully presented an invitation to become fixated on the endotracheal tube while ignoring other relevant information. Five of 18 subjects never discovered the volatile anesthetic overdose despite catastrophic effects on blood pressure and heart rate and clear evidence that the endotracheal tube was correctly placed. Of those who did detect the vaporizer setting, the average time to detection was nearly 4 minutes, with some subjects taking longer than 12 minutes.

In the second event studied, a loss of pipeline oxygen supply occurred while an anesthesia professional was assuming the care of a critically ill patient who required an FiO_2 of 100% to achieve satisfactory blood oxygenation. The oxygen cylinder on the machine was empty (i.e., it had not been checked by the initial anesthesia professional, who had left the case after becoming ill). The pipeline failure was quickly detected (19 seconds), but the responses to it were extremely variable and showed a variety of problems. Five of 18 anesthesia professionals closed the anesthesia circuit (which preserves the existing oxygen in the circuit), but all 5 subsequently switched to ventilation with a self-inflating bag using room air or to mouth-to-tube ventilation. Five of 18 could not open the reserve oxygen cylinder because they could not locate the tank wrench attached to the machine (it tended to rest between two gas cylinders). Several teams had trouble mounting a new oxygen tank on the anesthesia machine; problems with the gasket disk were frequent. The individuals did not appear to have a well-formulated plan for managing this event, and they did not optimally coordinate their actions with their assistants or with the other OR personnel.

A study by Byrne and Jones looked at differences in the performance of experienced and less experienced anesthesia professionals.[356] Using a self-developed patient simulator system, these investigators measured time to treatment and deficiencies in patient care in 180 simulations. The results showed significant differences only between the first and second year. As seen in other studies,[365] significant errors occurred at all levels of experience, and most of the anesthesia professionals deviated

from established guidelines. These studies underscore the importance of recurrent training for experienced anesthesia professionals and the truism that experience is not a substitute for excellence.

The reader is referred to Chapter 8 for discussion of newer studies with the use of patient simulators and performance assessment as such.[¶]

Indirect Observation of Anesthesia Professionals Involved in Difficult Cases

An unusual approach involving indirect observation of actual cases was used by Cook and colleagues at the Ohio State University in Columbus.[295] Rather than collecting data on the case itself, these investigators transcribed the discussions of interesting cases occurring at a weekly quality assurance conference. These investigators argued that this approach allowed them to apply a "neutral observer criterion" to the behavior of the anesthesia professional. The investigators acknowledged the risks of hindsight bias and selection bias with this methodology, but they suggested that their technique provided a unique window on human performance issues.

Fifty-seven cases were analyzed, 21 of which had a full cognitive analysis in the final report. From the presentation and discussion of a case, the investigators classified evolution of the events into 1 of 5 categories: acute incident, going-sour incident, inevitable outcome incident, difficult-airway incident, and no-incident incident. For each case, the cognitive analysis was "based on using knowledge about the cognitive demands of the task domain and data about practitioner activities to analyze the practitioner's information-processing strategies and goals, given the resources and constraints of the situation." The investigators postulated a cognitive cycle as a component of data-driven activation of knowledge and knowledge-driven observation and action.

Cook and colleagues called attention to several issues that surfaced in their cognitive analysis of these cases, including the following[295]:

1. Multiple themes. Many cases involved several lines of concern simultaneously, each of which could have interacted with another (e.g., tight coupling). Each theme had multiple means available to deal with it. Maintaining "situation awareness" was important. The multiple themes sometimes generated competing or conflicting goals. Adaptive planning (as described in the section on abstract task analysis) was sometimes required.
2. Unusual situations. The greatest expertise was seen with infrequent or unusual situations rather than with typical situations.
3. Allocation of attention. Allocation of attention to relevant stimuli or to the most important "theme" was an important issue. The attentional shifts were not always well supported by existing alarm and display technologies.
4. Cognitive workload. Anesthesia professionals attempted to reduce their cognitive workload whenever possible.
5. Team interaction. Cooperative work, team interaction, and communications issues were problems in several cases. These stemmed from both individual and organizational failures to coordinate information and efforts from different organizational components (e.g., ICU and OR, surgeons and anesthesiologists).

Direct Observation of Anesthesia Professionals

A team of cognitive scientists and anesthesiologists at the University of Toronto conducted direct observations of anesthesiologists and obtained verbal "think aloud" protocols during actual case management.[266] The group in Tübingen also performed direct observations for their task analysis studies.[287,377] Devitt and co-workers performed a study to assess the validity of performance assessment during simulated scenarios.[24]

Video Analysis of Actual Trauma Resuscitation and Anesthesia

Mackenzie and Xiao and their colleagues pioneered in the analysis of actual clinical care of anesthesia professionals captured on videotape, with a focus on trauma resuscitation and anesthesia for trauma patients at the Maryland Shock Trauma Unit in Baltimore.[420-424] Their sophisticated recording system captures audio, video, and vital signs data and requires only that the clinicians insert a videotape to start the whole system.[425] Analysis of these cases has revealed inadequacies in the availability and arrangement of monitoring equipment, as well as nonexistent or ambiguous communication. Meanwhile, a few groups around the world have started to use video for task analysis and assessment of performance for research and training, which are not detailed here.[168,214,311,349,381,426-432]

Problems faced by all investigators are the lack of an accepted standard for objective or subjective evaluation of anesthesia professional performance and the absence of an agreed-on methodology for analyzing and describing anesthesia professional performance. Several of the previously mentioned groups are working on methodologies for evaluating technical and behavioral aspects of performance.[#] Measurement of complex performance is a difficult problem, and it is likely to be some time until a metric for assessment of performance is well established.

APPENDIX 7-2 *The Joint Commission Sentinel Event Alert*[*]
HEALTH CARE WORKER FATIGUE AND PATIENT SAFETY

The link between health care worker fatigue and adverse events is well documented, with a substantial number of studies indicating that the practice of extended work hours contributes to high levels of worker fatigue and reduced productivity. These studies and others show that fatigue increases the risk of adverse events, compromises patient safety, and increases risk to personal safety and well-being.[1-5] While it is acknowledged that many factors contribute to fatigue, including but not limited to insufficient staffing and excessive workloads, the purpose of this Sentinel Event Alert is to address the effects and risks of an extended work day and of cumulative days of extended work hours.

The Impact of Fatigue

Fatigue resulting from an inadequate amount of sleep or insufficient quality of sleep over an extended period can lead to a number of problems, including:

- Lapses in attention and inability to stay focused
- Reduced motivation
- Compromised problem solving
- Confusion
- Irritability
- Memory lapses
- Impaired communication
- Slowed or faulty information processing and judgment
- Diminished reaction time
- Indifference and loss of empathy[6]

Contributing Factors to Fatigue and Risks to Patients

Shift length and work schedules have a significant effect on health care providers' quantity and quality of sleep and, consequently, on their job performance, as well as on the safety of their patients and their individual safety. This fact has been borne out in numerous studies. Findings from a groundbreaking 2004 study of 393 nurses over more than 5300 shifts—the first in a series of studies of nurse fatigue and patient safety—showed that nurses who work shifts of 12.5 hours or longer are 3 times more likely to make an error in patient care.[7] Additional studies showed that longer shift length increases the risk of errors and close calls and is associated with decreased vigilance,[7] and that nurses suffer higher rates of occupational injury when working shifts in excess of 12 hours.[8] Still, while the dangers of extended work hours (more than 12 hours) are well known, the health care industry has been slow to adopt changes, particularly with regard to nursing.

"An overwhelming number of studies keep saying the same thing—once you pass a certain point, the risk of mistakes increases significantly," says Ann Rogers, PhD, RN, FAAN, a nationally renowned sleep medicine expert with Emory University's Nell Hodgson Woodruff School of Nursing. "We have been slow to accept that we have physical limits and biologically we are not built to do the things we are trying to do."

Resident physician duty hours have also been the focus of many studies. While the Accreditation Council for Graduate Medical Education (ACGME) implemented duty hour restrictions in July 2003 that limited work shifts to a maximum of 30 hours and no more than 80 hours of work per week, numerous subsequent studies indicated that risks to patient safety and personal injury remain high for resident physicians working recurrent 24-hour shifts.[9,10] In September 2010, the ACGME published the final version of new standards, which became effective in July 2011 (www.acgme-2010standards.org).

An article in the November 2007 *Joint Commission Journal on Quality and Patient Safety* concluded that evidence strongly suggests that extended-duration work shifts significantly increase fatigue and impair performance and safety.[11] The article reported that residents who work traditional schedules with recurrent 24-hour shifts:

- Make 36% more serious preventable adverse events than individuals who work no more than 16 consecutive hours.[12]
- Make five times as many serious diagnostic errors.[12]
- Have twice as many on-the-job attentional failures at night.[13]
- Experience 61% more needlestick and other sharp injuries after their twentieth consecutive hour of work.[14]
- Experience a 1.5- to 2-standard deviation deterioration in performance relative to baseline rested performance on both clinical and nonclinical tasks.[15]
- Report making 300% more fatigue-related preventable adverse events that led to a patient's death.[16]

A subsequent 2009 study also revealed an increased rate of complications among post-nighttime surgical procedures performed by attending physicians who had slept less than 6 hours.[17]

"We have a culture of working long hours, and the impact of fatigue has not been a part of our consciousness," says Christopher P. Landrigan, MD, MPH, director of the Sleep and Patient Safety Program, Brigham and Women's Hospital. The author of several research studies exploring the effects of provider sleep deprivation on patient and provider safety, Dr. Landrigan stresses the importance of reduced work hours for all health care workers and the need for widespread education of health care providers to recognize their limits. "Most are unaware of sleep and circadian biology and the degree that it affects performance. And, most do not realize how much research supports the need to make changes."[18,19]

Actions Suggested by The Joint Commission

There are some evidence-based actions that health care organizations can take to help mitigate the risks of fatigue that result from extended work hours—and, therefore, protect patients from preventable adverse outcomes.

For all organizations:

1. Assess your organization for fatigue-related risks. This includes an assessment of off-shift hours and consecutive shift work and a review of staffing and other relevant policies to ensure they address extended work shifts and hours.
2. Since patient hand-offs are a time of high-risk—especially for fatigued staff—assess your organization's hand-off processes and procedures to ensure that they adequately protect patients.[20]
3. Invite staff input into designing work schedules to minimize the potential for fatigue.

* From The Joint Commission: *Sentinel Event Alert,* Issue 48, December 14, 2011.

Published for Joint Commission accredited organizations and interested health care professionals, *Sentinel Event Alert* identifies specific types of sentinel events, describes their common underlying causes, and suggests steps to prevent occurrences in the future.

Accredited organizations should consider information in an Alert when designing or redesigning relevant processes and consider implementing relevant suggestions contained in the Alert or reasonable alternatives.

Please route this issue to appropriate staff within your organization. *Sentinel Event Alert* may be reproduced only in its entirety and credited to The Joint Commission. To receive by e-mail, or to view past issues, visit www.jointcommission.org.

The Patient Safety Advisory Group informs The Joint Commission on patient safety issues and, with other sources, advises on topics and content for Sentinel Event Alert. Members: James P. Bagian, MD, PE (chair); Michael Cohen, RPh, MS, ScD (vice chair); Jane H. Barnsteiner, RN, PhD, FAAN; Jim B. Battles, PhD; William H. Beeson, MD; Patrick J. Brennan, MD; Martin H. Diamond, FACHE; Cindy Dougherty, RN, CPHQ; Frank Federico, B.S., RPh; Steven S. Fountain, MD; Suzanne Graham, RN, PhD; Jerril W. Green, MD; Peter Gross, MD; Carol Haraden, PhD; Martin J. Hatlie, Esq; Jennifer Jackson, BSN, JD; Paul Kelley, CBET; Henri R. Manasse, Jr, PhD, ScD; Jane McCaffrey, MHSA, DFASHRM; Mark W. Milner, RN, MBA, CPHQ, FACHE; Jeanine Arden Ornt, JD; Grena Porto, RN, MS, ARM, CPHRM; Matthew Scanlon, MD; Carl A. Sirio, MD; Ronni P. Solomon, JD; Dana Swenson, PE, MBA; Susan M. West, RN.

APPENDIX 7-2 ***The Joint Commission Sentinel Event Alert*** *(Continued)*
HEALTH CARE WORKER FATIGUE AND PATIENT SAFETY

4. Create and implement a fatigue management plan that includes scientific strategies for fighting fatigue. These strategies can include: engaging in conversations with others (not just listening and nodding); doing something that involves physical action (even if it is just stretching); strategic caffeine consumption (don't use caffeine when you're already alert, and avoid caffeine near bedtime); taking short naps (less than 45 minutes).[21,22] These strategies are derived from studies conducted by the National Aeronautics and Space Administration (NASA) that state that people can maximize their success by trying different combinations of countermeasures to find what works for them. The NASA studies stress that the only way to counteract the severe consequences of sleepiness is to sleep.[21] Strategies for determining shift durations and using caffeine to combat fatigue can be found in Chapter 40 of *Patient Safety and Quality: An Evidence-Based Handbook for Nurses.*[23]
5. Educate staff about sleep hygiene and the effects of fatigue on patient safety. Sleep hygiene includes getting enough sleep and taking naps, practicing good sleep habits (for example, engaging in a relaxing presleep routine, such as yoga or reading), and avoiding food, alcohol, or stimulants (such as caffeine) that can impact sleep.[21,22]

Safety culture (for all organizations):

6. Provide opportunities for staff to express concerns about fatigue. Support staff when appropriate concerns about fatigue are raised, and take action to address those concerns.
7. Encourage teamwork as a strategy to support staff members who work extended work shifts or hours and to protect patients from potential harm.[20] For example, use a system of independent second checks for critical tasks or complex patients.
8. Consider fatigue as a potentially contributing factor when reviewing all adverse events.

For organizations with a current policy that allows for sleep breaks for staff defined as essential by the organization:

9. Assess the environment provided for sleep breaks to ensure that it fully protects sleep. Fully protecting sleep requires the provision of basic measures to ensure good quality sleep, including providing uninterrupted coverage of all responsibilities (including carrying pagers and phones, and coverage of both admissions and all continuing care by another provider) and providing a cool, dark, quiet, comfortable room and, if necessary, use of eye mask and ear plugs.

See relevant Joint Commission requirements: LD.01.03.01 element of performance 5, LD.03.06.01 EP 3, LD.04.01.01 EP 2, LD.04.04.05 EP 13, PI.02.01.01 EPs 12-14, (hospital and long-term care); NR.02.01.01 EP 1-6, NR.02.02.01 EP 1-4, (hospital).

Chapter 8

Patient Simulation

MARCUS RALL • DAVID M. GABA • PETER DIECKMANN • CHRISTOPH BERNHARD EICH

Key Points

- Simulators and the use of simulation have become integral parts of medical education, training, and research. The pace of developments and applications is fast, and the results are promising.
- The different types of simulators are either primarily computer screen–based simulators (microsimulators) or mannequin-based simulators. Mannequin-based simulators can be divided into script-based and model-based simulators.
- The development of mobile and less expensive simulator models allowed for substantial expansion of simulator training to areas and locales where this training could not be afforded previously. The greatest obstacles to providing simulation training are not the simulator hardware but rather are (1) obtaining access to the learner population for the requisite time and (2) providing appropriately trained and skilled instructors to prepare, conduct, and evaluate the simulation sessions.
- The anesthesia crisis resource management (ACRM) course model with its ACRM key points (see also Chapter 7) is popular worldwide for human factor–based simulation training in anesthesia. Curricula should use scenarios that are tailored to the stated teaching goals, rather than focusing solely on achieving maximum "realism."
- Simulation training has been adapted by many other fields outside anesthesia (e.g., emergency medicine, neonatal care, and intensive care, as well as for medical and nursing students).
- Simulation has proved valuable in research to study human factors and failure modes during anesthesia care, in the development of new treatment concepts (e.g., checklist use and telemedicine), and in the support of bioengineering system development (e.g., device beta-testing, educating the manufacturers' workforce).
- Research continues on the use of simulation for performance assessment.
- Assessment of nontechnical skills (or behavioral markers) has evolved considerably and can be accomplished with a reliability that matches that of many other subjective judgments in patient care. Systems for rating nontechnical skills have been introduced and tested in anesthesia and other fields
- The most important component of high-fidelity simulation training is the self-reflective (often video-assisted) debriefing session after the clinical scenario. The quality of debriefing strongly depends on the skills and experience of the instructor. Most methods of debriefing stress open-ended questions and inquiry to trigger insightful analysis by the learner group
- A simulator is just a tool to accomplish learning objectives that are difficult to achieve during real patient care. The design of curricula and scenarios and the ability of instructors to create appropriate learning situations are the factors that determine whether the simulation tool is effective in achieving the relevant goals.

How can clinicians experience the difficulties of patient care without putting patients at undue risk? How can we assess the abilities of clinicians as individuals and teams when each patient is unique? These questions have challenged medicine for years. These and related questions have begun to be answered in health care by the application of approaches relatively new to medicine but borrowed from years of successful service in other industries facing similar problems. These approaches focus on *simulation,* a technique well known in the military, aviation, space flight, and nuclear power industries.

Simulation refers to the artificial replication of sufficient elements of a real-world domain to achieve a stated goal. The goals can include understanding the domain better, training personnel to deal with the domain, or testing the capacity of personnel to work in the domain.

The *fidelity* of a simulation refers to how closely it replicates the domain and is determined by the number of elements that are replicated and the discrepancy between each element and the real world. The fidelity required depends on the stated goals. Some goals can be achieved with minimal fidelity, whereas others require very high fidelity.

Simulation has probably been a part of human activity since prehistoric times. Rehearsal for hunting activities and warfare was most likely an occasion for simulating the behavior of prey or enemy warriors. Technologic simulation probably dates back to the dawn of technology itself. Good and Gravenstein pointed to the medieval quintain as a technologic device that crudely simulated the behavior of an opponent during sword fighting.[1] If the swordsman did not duck at the appropriate time after striking a blow, he would be hit by a component of the quintain. In modern times, preparation for warfare has been an equally powerful spur to the development of simulation technologies, especially for aviation, shipping, and the operation of armored vehicles. These technologies have been adopted by their civilian counterparts, but they have attained their most extensive use in commercial aviation.

SIMULATION IN AVIATION

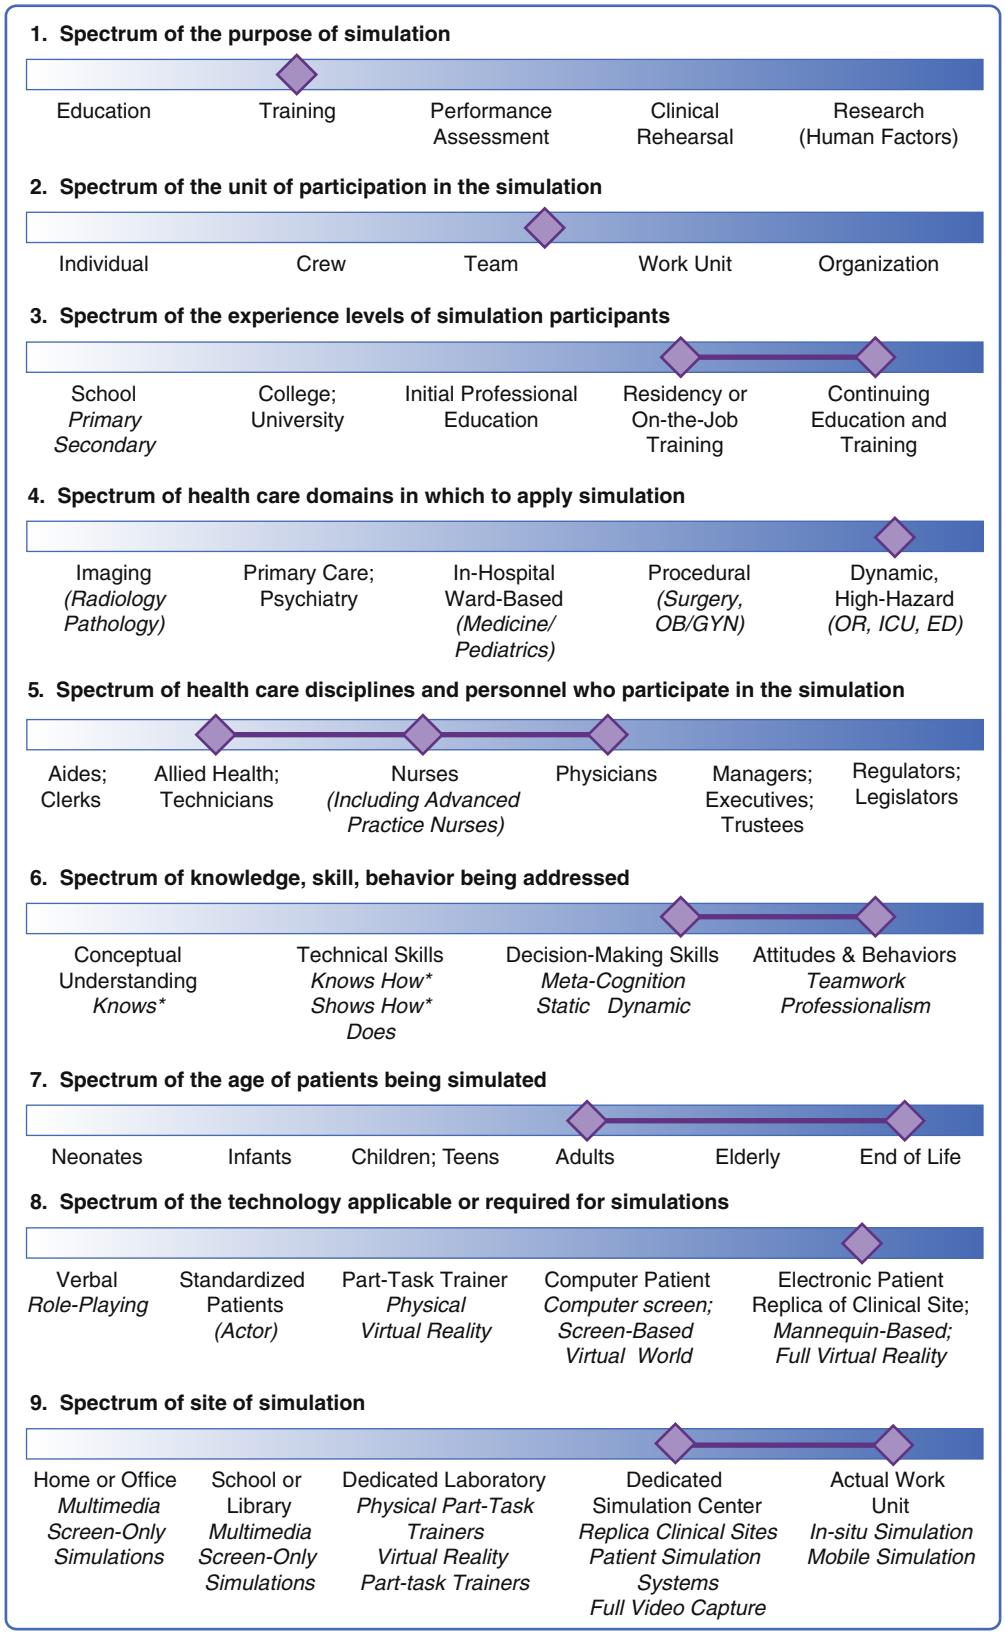
Although some aircraft simulators were built between 1910 and 1927, none of them could provide the proper feel of the aircraft because they could not dynamically reproduce its behavior. In 1930, Link filed a patent for a pneumatically driven aircraft simulator. The Link Trainer was a standard for flight training before World War II, but the war accelerated its use and the further development of flight simulators. In the 1950s, electronic controls replaced pneumatic ones through analog, digital, and hybrid computers. The aircraft simulator achieved its modern form in the late 1960s, but it has been continuously refined. Aviation simulators are so realistic now that pilots with experience flying one aircraft are routinely certified to fly totally new or different aircraft, even if they have never flown the actual aircraft without passengers on board. Similar stories of the development of simulators can be told for numerous other industries.

USES OF SIMULATORS

Although simulators originally were used to provide basic instruction on the operation of aircraft controls, the variety of uses of simulators in general has expanded greatly. Box 8-1 lists possible uses of simulators in all types of complex work situations. Simulation is a powerful generic tool for dealing with human performance issues (e.g., training, testing, and research) (see Chapter 7), for investigating human-machine interactions, and for the design and validation of equipment. As described later in this chapter, each of these uses is potentially relevant to anesthesiology. A few books are devoted solely to the topic of simulation and its use in and outside of anesthesia.[2-4]

BOX 8-1 ***Use of Simulators in Complex Work Environments***

- Team training, as human factor or crisis resource management training
- Training in dynamic plant control
- Training in diagnostic skills
- Dynamic mockup for design evaluation
- Test bed for checking operating instructions
- Environment in which task analysis can be conducted (e.g., on diagnostic strategies)
- Test bed for new applications (e.g., telemedicine tools such as the Guardian Angel System)
- Source of data on human errors relevant to risk and reliability assessment
- Vehicle for (compulsory) testing/assessment and recertification of operators



Modified from Singleton WT: *The mind at work.* Cambridge, 1989, Cambridge University Press.

TWELVE DIMENSIONS OF SIMULATION

Current and future applications of simulation can be categorized by 12 dimensions, each of which represents a different attribute of simulation (Fig. 8-1).[5] Some dimensions have a clear gradient and direction, whereas others have only categoric differences. The total number of unique combinations across all the dimensions is very large (on the order of 4^{12} to 5^{12}—4 million to 48 million). Some combinations overlap strongly with others, and some are inappropriate or irrelevant, so the actual number of meaningful combinations is much lower. Nonetheless, although the demonstrated applications of simulation in health care have been quite diverse, the range of possible applications (a large number, although quite a bit smaller than millions) has by no means been fully examined.

DIMENSION 1: PURPOSE AND AIMS OF THE SIMULATION ACTIVITY

The most obvious application of simulation is to improve the education and training of clinicians, but other purposes also are important. As used in this chapter, *education* emphasizes conceptual knowledge, basic skills, and an introduction to work practices. *Training* emphasizes the actual tasks and work to be performed. Simulation can be used to *assess performance* and competence of individual clinicians and teams, both for low-stakes or formative testing and (to a lesser degree) for high-stakes certification testing.[6,7] Simulation *rehearsals* are now being explored as adjuncts to actual clinical practice; for example, surgeons or an entire operative team can rehearse an unusually complex operation in advance by using a simulation of the specific patient.[8-10] Simulators can be powerful tools for research and evaluation with regard to *organizational practices* (patient care protocols) and for the *investigation of human factors* (e.g., of performance-shaping factors, such as fatigue,[11] or of the user interface and operation of medical equipment in high-hazard clinical settings[12]). Simulation-based empiric tests of the usability of clinical equipment already have been used in designing equipment that is currently for

A

Figure 8-1. The 12 dimensions of simulation applications. **A,** Dimensions 1 to 9. *These terms are used according to Miller's pyramid of learning.

Continued

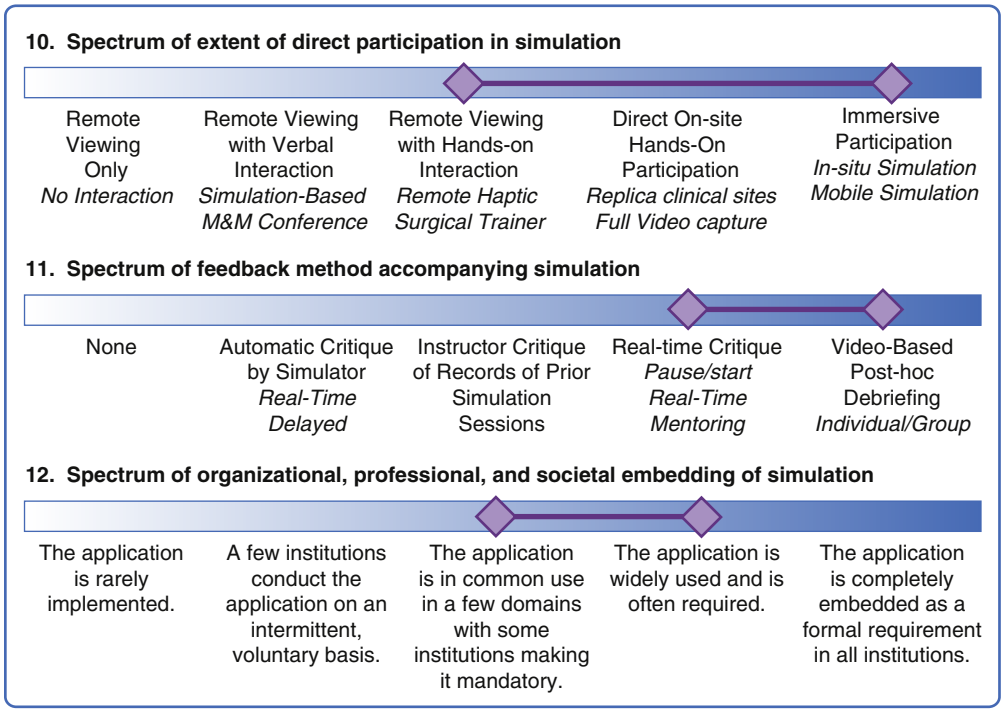


Figure 8-1, cont'd B, Dimensions 10 to 12. Any particular application can be represented as a point or range on each spectrum (shown by *diamonds*). This figure illustrates a specific application—multidisciplinary crisis resource management (CRM)–oriented decision making and teamwork training for adult intensive care unit (ICU) personnel. *ED,* Emergency department; *M&M,* morbidity and mortality; *OB/GYN,* obstetrics and gynecology; *OR,* operating room.

sale; ultimately, such practices may be required by regulatory agencies before approval of new devices.

Simulation can be a bottom-up tool for changing the culture of health care concerning patient safety. First, it allows hands-on training of junior and senior clinicians in practices that enact the desired culture of safety.[13] Simulation also can be a rallying point about culture change and patient safety that can bring together experienced clinicians from various disciplines and domains (who may be captured because the simulations are clinically challenging), along with health care administrators, risk managers, and experts on human factors, organizational behavior, or institutional change.

DIMENSION 2: UNIT OF PARTICIPATION IN THE SIMULATION

Many simulation applications are targeted at individuals. These may be especially useful for teaching knowledge and basic skills or for practice on specific psychomotor tasks. As in other high-hazard industries, individual skill is a fundamental building block, but a considerable emphasis is applied at higher organizational levels, in various forms of teamwork and interpersonal relations (often summarized under the rubric of *crisis resource management* (CRM) adapted from aviation cockpit resource management.) (For more on human factors and CRM concepts, see Chapter 7.)[14,15] CRM is based on empiric findings that individual performance is not sufficient to achieve optimal safety.[16] Team training may be addressed first to crews (also known as *single-discipline teams*), consisting of multiple individuals from a single discipline, and then to teams (or *multidisciplinary teams*).[17] Addressing teamwork in the single-discipline approach that trains crews to work in teams, in contrast to the combined team training of multiple disciplines together, has advantages and disadvantages.[18] For maximal benefit, these approaches are used in a complementary fashion.

Teams exist in actual work units in an organization (e.g., a specific intensive care unit [ICU]), each of which is its own target for training. Growing interest and experience have also been shown in applying simulation to nonclinical personnel and work units in health care organizations (e.g., to managers or executives)[19] and to organizations as a whole (e.g., entire hospitals or networks).

DIMENSION 3: EXPERIENCE LEVEL OF SIMULATION PARTICIPANTS

Simulation can be applied along the entire continuum of education of clinical personnel and the public at large. It can be used with early learners, such as schoolchildren, or with lay adults to facilitate bioscience instruction, to interest individuals in biomedical careers, or to explain health care issues and practices. The major roles of simulation have been, and will continue to be, to educate, train, and provide rehearsal for individuals actually involved in the delivery of health care. Simulation is relevant from the earliest level of vocational or professional education (students) and during apprenticeship training (interns and residents), and it is increasingly

used for experienced personnel undergoing periodic refresher training. Simulation can be applied regularly to practicing clinicians (as individuals, teams, or organizations) regardless of their seniority,[20,21] thus providing an integrated accumulation of experiences that should have long-term synergism.

DIMENSION 4: HEALTH CARE DOMAIN IN WHICH THE SIMULATION IS APPLIED

Simulation techniques can be applied across nearly all health care domains. Although much of the attention on simulation has focused on technical and procedural skills applicable in surgery,[11,18,19,21] obstetrics,[22,23] invasive cardiology,[24,25] and other related fields, another bastion of simulation has been recreating whole patients for dynamic domains involving high-hazard and invasive intervention, such as anesthesia,[26,27] critical care,[28,29] and emergency medicine.[30-33] Immersive techniques can be used in imaging-intensive domains, such as radiology and pathology, and interactive simulations are relevant in the interventional sides of such arenas.[34] In many domains, simulation techniques have been useful for addressing nontechnical skills and professionalism issues, such as communicating with patients and co-workers, or addressing issues such as ethics or end-of-life care.

DIMENSION 5: HEALTH CARE DISCIPLINES OF PERSONNEL PARTICIPATING IN THE SIMULATION

Simulation is applicable to all disciplines of health care, not only to physicians. In anesthesiology, simulation has been applied to anesthesiologists, certified registered nurse anesthetists, and anesthesia technicians. Simulation is not limited to clinical personnel. It also may be directed at managers, executives, hospital trustees, regulators, and legislators. For these groups, simulation can convey the complexities of clinical work, and it can be used to exercise and probe the organizational practices of clinical institutions at multiple levels.

DIMENSION 6: TYPE OF KNOWLEDGE, SKILL, ATTITUDES, OR BEHAVIOR ADDRESSED IN SIMULATION

Simulations can be used to help learners acquire new knowledge and to understand conceptual relations and dynamics better. Physiologic simulations allow students to watch cardiovascular and respiratory functions unfold over time and respond to interventions—in essence bringing life textbooks, diagrams, and graphs. The next step on the spectrum is acquisition of skills to accompany knowledge. Some skills follow immediately from conceptual knowledge (e.g., cardiac auscultation), whereas others involve intricate and complex psychomotor activities (e.g., catheter placement or basic surgical skills). Isolated skills must be assembled into a new layer of clinical practices. An understanding of the concepts of general surgery cannot be combined only with basic techniques of dissecting and suturing or manipulation of instruments to create a capable laparoscopic surgeon. Basic skills must be integrated into actual clinical techniques. Simulation may have considerable power in this process, especially because it can readily provide experience with even uncommon anatomic or clinical presentations. In the current health care system, for most invasive procedures, *novices at a task typically first perform the task on a real patient,* albeit under some degree of supervision. These novices climb the learning curve and work on patients while under varying levels of guidance. Simulation offers the possibility of having novices practice extensively before they begin supervised work on real patients in apprenticeship-like situations.

In this way and others, simulation is applicable to clinicians throughout their careers to support lifelong learning. It can be used to refresh skills for procedures that are not performed often. Knowledge, skills, and practices honed as individuals must be linked into effective teamwork in diverse clinical teams, which must operate safely in work units and larger organizations.[35-37] Perpetual rehearsal of responses to challenging events is needed because the team or organization must be practiced in handling these responses as a coherent unit.

DIMENSION 7: AGE OF THE PATIENT BEING SIMULATED

Simulation is applicable to nearly every type and age of patient, literally from cradle to grave. Simulation may be particularly useful for pediatric patients and clinical activities because neonates and infants have smaller physiologic reserves than do most adults.[38,39] Fully interactive neonatal and pediatric patient simulators are now available. Simulation also addresses issues of older adults and end-of-life issues for every age.

DIMENSION 8: TECHNOLOGY APPLICABLE OR REQUIRED FOR SIMULATIONS

To accomplish these goals, various technologies (including no technology) are relevant for simulation. Verbal simulations ("what if" discussions), paper and pencil exercises, and experiences with actors playing standardized patients[39-41] require no technology, but they can effectively evoke or recreate challenging clinical situations. Similarly, very low technology—even pieces of fruit or simple dolls—can be used for training in some manual tasks. Certain aspects of complex tasks and experiences can be recreated successfully with little technology. Some education and training on teamwork can be accomplished with role playing, analysis of videos, or drills with simple mannequins.[42]

Ultimately, learning and practicing complex manual skills (e.g., surgery, cardiac catheterization) or practicing the dynamic management of life-threatening clinical situations that include risky or noxious interventions (e.g., intubation or defibrillation) can be fully accomplished only using either animals—for reasons of cost and issues of animal rights, this approach is becoming very difficult—or technology to recreate the patient and the clinical environment. The different types of simulation technologies relevant to anesthesiology are discussed later in this chapter.

DIMENSION 9: SITE OF SIMULATION PARTICIPATION

Some types of simulation—those that use videos, computer programs, or the Web—can be conducted in the privacy of the learner's home or office using his or her own equipment. More advanced screen-based simulators may need more powerful computer facilities available in a medical library or learning center. Part-task trainers and virtual reality simulators are usually fielded in a dedicated skills laboratory. Mannequin-based simulation also can be used in a skills laboratory, although the more complex recreations of actual clinical tasks require either a dedicated patient simulation center with fully equipped replicas of clinical spaces or the ability to bring the simulator into an actual work setting (in situ simulation). Performing clinical simulations in situ, as opposed to in a dedicated center, has advantages and disadvantages. Using the actual site allows training of the entire unit with all its personnel, procedures, and equipment. The availability of actual clinical sites is limited, and the simulation activity may distract from real patient care. The dedicated simulation center is a more controlled and available environment, which allows more comprehensive recording of sessions and imposes no distraction from real activities. For large-scale simulations (e.g., disaster drills), the entire organization becomes the site of training.

Video conferencing and advanced networking may allow even advanced types of simulation to be conducted remotely (see dimension 10). The collaborative use of virtual reality surgical simulators in real time already has occurred, even in locations separated by thousands of miles (see later for more on the site of the simulator).

DIMENSION 10: EXTENT OF DIRECT PARTICIPATION IN SIMULATION

Most simulations—even screen-based simulators or part-task trainers—were initially envisioned as highly interactive activities with significant direct hands-on participation virtual on-site setting. Not all learning requires direct participation, however. Some learning can occur merely by viewing a simulation involving others because the viewer can readily imagine being in the shoes of the participants. A further step is to involve remote viewers either in the simulation itself or in debriefings about what transpired. Several centers have been using videoconferencing to conduct simulation-based exercises, including morbidity and mortality conferences.[43] Because the simulator can be paused, restarted, or otherwise controlled, the remote audience can readily obtain more information from the on-site participants, debate the proper course of action, and discuss with those in the simulator how best to proceed.

DIMENSION 11: FEEDBACK METHOD ACCOMPANYING SIMULATION

One can learn a great deal just from simulation experiences themselves, without any additional feedback. For many simulations, specific feedback is provided to maximize learning. On screen-based simulators or virtual reality systems, the simulator itself can provide feedback about the participant's actions or decisions,[44] particularly for manual tasks for which clear metrics of performance are readily delineated.[45,46] More commonly, human instructors provide feedback. This can be as simple as having the instructor review records of previous sessions that the learner has completed alone. For many target populations and applications, an instructor provides real-time guidance and feedback to participants while the simulation is ongoing. The ability to start, pause, and restart the simulation can be valuable. For the most complex uses of simulation, especially when training experienced personnel, the typical form of feedback is a detailed postsimulation debriefing session, often using audio-video recordings of the scenario. Waiting until after the scenario is finished allows experienced personnel to apply their collective skills without interruption and then allows them to see and discuss the advantages and disadvantages of their behaviors, decisions, and actions.

DIMENSION 12: ORGANIZATIONAL, PROFESSIONAL, AND SOCIETAL EMBEDDING OF SIMULATION

The final important dimension is the degree to which the simulation application is embedded into an organization or industry.[47] Being highly embedded may mean that the simulation is a formal requirement of the institution or is mandated by the governmental regulator. Another aspect of embedding may be that—for early learners—the initial (steep) part of the learning curve is required to occur in a simulation setting before the learners are allowed to work on real patients under supervision. In addition, complete embedding of simulation into the workplace means that simulation training is a normal part of the work schedule, rather than being an add-on activity attended in the spare time of clinicians.

CONCEPTUAL ISSUES ABOUT PATIENT SIMULATION

"The key is the program, not the hardware," was a truth about simulation learned early in aviation. Using simulators in a goal-oriented way is at least as much about the conceptual aspects of the technique as it is about the technology of the simulation devices. An understanding of the conceptual and theoretical aspects of the use of simulation techniques can be helpful for determining the right applications of the technique and the important matchups that must be made in the design and conduct of simulation exercises to obtain the best results. When used most effectively, simulation can be—to borrow a line from the band U2—"even better than the real thing."[21] The concepts discussed in this section concern the nature of realism and reality as they apply to simulation and the way that these issues relate to the goals of simulation endeavors to generate a complex social undertaking. The ideas and concepts presented here are largely contributed by Peter Dieckmann and his adaptation of broader psychological concepts to simulation in medicine.

REALITY AND REALISM OF SIMULATION

Unless we are dreaming about it or we are an unrepentant solipsist, a simulation exercise is always real (it is actually happening), but it may or may not be a realistic replication of the reality that is the target of the exercise. Realism addresses the question of how closely a replication of a situation resembles the target. A key distinction is between a *simulator* (a device) and a *simulation* (the exercise in which the device is used). A simulator could be indistinguishable from a real human being (e.g., an actor playing a standardized patient) and yet be used in an implausible and useless fashion. Conversely, certain kinds of realism (see later) can be evoked by simulation exercises that use very simple simulators or even no simulator at all (as in role playing, when the participants in a sense become the simulator). Merely creating a realistic simulation does not guarantee meaning or utility (e.g., learning).[18,19] A closely related aspect concerns the questions of relevance and the social character of simulation.

THREE DISTINCT DIMENSIONS FOR SIMULATION REALISM

Simulator realism and simulation realism, using a variety of terms and concepts, are subtly different and often overlapping. These include *physical fidelity* (the device replicates physical aspects of the human body), *environmental fidelity* (the simulation room looks like an operating room), *equipment fidelity* (the clinical equipment works like or is the real thing), and *psychological fidelity*[22] (the simulation evokes behaviors similar to the real situation), as well as a variety of forms of validity, such as *face validity* (looks and feels real to participants), *content validity* (the exercise covers content relevant to the target situation), *construct validity* (the simulation can replicate performance or behavior according to predefined constructs about work in real situations), and *predictive validity* (performance during a simulation exercise predicts performance in an analogous real situation).[23,24]

The results of studies trying to investigate roots and effects of simulation realism are not conclusive partly because each study may concentrate on a different aspect of this complex whole. It is simply not true that maximum "realism" is either needed or desired for every type of simulation endeavor. For some applications with some target populations, it can be highly advantageous to reduce the realism to heighten the learning experience.[25]

In 2007, we published an article attempting to clarify some issues about realism, reality, relevance, and the purposes of conducting simulations.[18] We applied the model of thinking about reality by the German psychologist Laucken to the realism of simulation.[18] Laucken described three modes of thinking—physical, semantic, and phenomenal, which were renamed physical, conceptual, and emotional and experiential modes by colleagues in Boston.[26]

Physical Mode

The *physical mode* concerns aspects of the simulation that can be measured in fundamental physical and chemical terms and dimensions (e.g., centimeters, grams, and seconds). The weight of the mannequin, the force generated during chest compressions, and the duration of a scenario all are physical aspects of the simulation reality. Existing simulator mannequins have many unrealistic physical elements despite their roughly human shape: they are made of plastic, not flesh and bone; they may have unusual mechanical noises detectable during auscultation of the chest; the "skin" does not change color. Some physical properties are not readily detectable and can be manipulated. Some clinical equipment used in mannequin-based simulation is fully functional and physically identical to the real thing, although in some cases, functional physical limitations may have been introduced for convenience or for safety.[23] Labeled syringes may contain only water instead of opioids, or a real defibrillator may have been modified so that it does not actually deliver a shock (one manufacturer sells a "Hollywood defibrillator"). That certain physical properties and functions have been altered is not usually apparent to participants, at least without special briefings or labels.

Semantic Mode

The *semantic mode* of thinking concerns concepts and their relationships. Within the semantic mode, a simulation of hemorrhage could be described in conceptual terms as "bleeding" of flow rate x beginning at time y occurring at site z and associated with a blood pressure of b that is a decrease from the prior value of a. In this mode of thinking, it is irrelevant how the information is transmitted or represented. The same pieces of *information* could be represented using a vital signs monitor, a verbal description, or the tactile perception of decreasingly palpable pulses. The semantic *recoding* of physical objects is the cornerstone of simulation. It allows the simulation exercise to represent a real situation, and it allows water-filled syringes to be treated as if they contain a drug.

Phenomenal Mode

The *phenomenal mode* deals with the experience, including emotions and beliefs triggered by the situation. For many purposes, providing high phenomenal realism is the key goal, and the physical realism and semantic realism are merely means to this end.

RELEVANCE VERSUS REALITY

A naïve view of simulation would suggest that greater realism in all modes would lead to better achievement of the goals of simulation; this view has been criticized repeatedly.[22,27,28] Simulation is a complex social endeavor, conducted with different target populations for different purposes. The relevance of a simulation exercise concerns the match between the characteristics of the exercise and the reasons for which the exercise is conducted. Different elements of realism are emphasized or sacrificed to maximize the relevance of a simulation exercise. When training on invasive procedures, it is typical to forgo phenomenal realism and emphasize physical and semantic realism so that psychomotor skills can be the focus.

Semantic realism may be sacrificed, especially to help early learners. Situations that could become lethal (e.g., trigger cardiac arrest) very quickly may be slowed

down so that inexperienced clinicians can try to think their way out of the problem. If such a situation were allowed to evolve at its normal speed, it would transition to management of cardiac arrest before the participants could deal with the original problem. Other realism-sacrificing strategies for early learners include cognitive scaffolding, which provides various forms of assistance or cues to help these learners as they struggle with decision making and therapy selection. It is important to select which aspects of the simulation are the most relevant to reach the training goal and should be focused on in terms of optimizing their realism in the different modes.

SETTING OF THE SIMULATION EXERCISE

Simulation exercises have a purpose and are generally integrated into a larger training context (often a course or a series of exercises) that influences how these exercises are conducted, how they are perceived by participants, and what kind of effects they may have. This context has been called the *simulation setting*. The typical elements of the simulation setting are discussed next and are shown graphically in Figure 8-2.

Setting introduction (SI): The introduction delivers general information on how the exercise will be conducted, logistical information, and some of the known pitfalls of the course. Through this introduction and other components of the course, group norms are established explicitly and implicitly.

Simulator briefing (SB) or familiarization: Participants need to be familiar with the simulator and the simulated environment through explanations, demonstrations, and hands-on time. They learn how to use the simulator, what it can and cannot do, what is normal (e.g., normal breath sounds), and how they can interact with the environment (e.g., how to call for help, how to request information about the patient that is not directly available in the simulation environment). The familiarization session also is an opportunity for participants to practice the information gathering they must conduct when first entering a new work environment (e.g., for locum tenens practice).

Theory input (T): Most exercises have didactic and theory components on relevant content information. Sometimes this material is made available in advance through readings or online exercises. It may be presented before or after a simulation session. Sometimes didactic or group-work modules are put in place at different junctures of the course or series.

Breaks (B): For complex courses (e.g., anesthesia CRM [ACRM]), breaks are important for socialization among participants and with instructors. Breaks also provide a venue for informal sharing and storytelling.

Case briefing (C): In many simulation scenarios, participants receive a briefing about the upcoming case. Sometimes this is done explicitly before entering the scenario; sometimes it is embedded into a natural hand-off of the case from one clinician to another.

Simulation scenario (S): Most simulation exercises involve a scenario that posits a given clinical situation and challenges to be posed to participants. Commonly, the possible evolutions of the scenario are delineated in advance by instructors, although occasionally an intrinsically challenging situation is started and then allowed to play out naturally, depending on how the participants react.

Debriefing (D): Most scenarios are followed by some form of debriefing or feedback. In some courses, feedback is only minimal, whereas other courses have a dedicated debriefing session (as long as or longer than the scenario itself) after each scenario (see the later section on debriefing for more detail).

Ending (E): Especially for multiple-scenario courses, a separate final session may be included to end the course. This is an opportunity to summarize issues that were covered, to address questions, and to consider how best to apply the principles covered to real patient care.

Components of a course are expected to have a cumulative effect. Similarly, problems in early portions of a course (e.g., an inability to create an open learning atmosphere during the introduction) can carry over into later

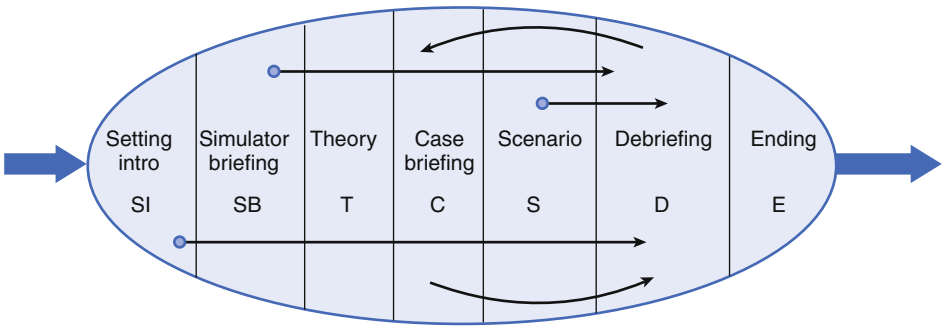

Figure 8-2. The simulator setting. A simulation course consists of different modules or different phases (e.g., setting introduction [SI], simulator familiarization, scenarios [S], debriefings [D]). This figure shows a typical flow for a course with repeated loops back from debriefing to case briefing (C) for each scenario. The different modules are interrelated, and problems arising in one module can affect other modules (*thin arrows*). For example, it could be difficult to conduct an open, constructive debriefing if the scenario were irrelevant, or the simulator briefing insufficient, and or the instructor did not succeed in creating an open atmosphere in the beginning of the course. *E,* Ending; *SB,* simulator briefing; *T,* theory. *(Courtesy P. Dieckmann.)*

phases. Inadequate familiarization briefings leave participants confused as they try to perform "clinical work" with the patient replaced by a mannequin.

SITE OF SIMULATION

Over decades of experience, many different variants of simulation have evolved. One particularly rich set of variations involves the site of simulation. The types of sites currently in use are described; the advantages and disadvantages of each are summarized in Table 8-1. Many of these variants are not mutually exclusive and can be combined in different hybrids. They are often administratively linked—a simulation group that operates a dedicated center often also conducts in situ, mobile, and moving patient simulation exercises at various times for different target populations and applications.

DEDICATED SIMULATION CENTER

One or more simulators may be used in a dedicated simulation facility, typically in rooms that can partially or fully replicate, in a relatively generic fashion, various clinical environments (e.g., operating room, ICU, labor and delivery, emergency department). (For more details see the later section on characteristics of simulation centers.)

IN SITU SIMULATION

In situ simulation is conducted in an actual clinical workplace; the simulator replaces a patient. In situ simulation is a necessity in the absence of a dedicated center, and it can be used in any clinical environment. It is especially useful for unusual workplaces that are difficult to recreate realistically in a simulation center, such as a catheterization laboratory, computed tomography scanner, ambulance, or air rescue aircraft (Figs. 8-3 to 8-9). Most in situ simulation is performed mobile as a temporary setup, but increasingly in situ simulation is established as residential simulation, in which a simulator is permanently installed in a clinical workplace (e.g., creating a simulation-specific room in the actual ICU).

MOVING THE SIMULATED PATIENT FROM ONE SITE OR CARE TO ANOTHER

The advent of completely portable and wireless simulators supports exercises in which the simulated patient can be moved from one clinical site to another (see also

TABLE 8-1 **SITE OF SIMULATION**

Site of Simulation	Explanation	Advantages	Disadvantages
Dedicated center	Fixed facility not part of an actual clinical work unit	Equipment permanently installed	Inability to recreate exact work unit, equipment, supplies of diverse target populations
		Facilitation of complex audiovisual systems	Possible difficulties for clinicians to be free to attend training
		Ease of scheduling	
		Personnel not readily available for clinical work	
		No interference with actual clinical work	
		Multipurpose use	
Temporary in situ	Actual work unit; temporary setup and takedown	Real clinical site	Difficulties in scheduling—may need site for clinical use
		Probing or training of personnel in their actual work unit and using real equipment and supplies	Interference with actual clinical work; personnel readily drafted to return to clinical work
		Ready ability for clinicians to attend in proximity to their work	Great effort of setup and takedown; minimal audiovisual system
Residential in situ	Actual work unit; permanent facility	Same as temporary in situ	High cost of creating a permanent simulation bed in a clinical work unit
			Possible distraction from real clinical work; personnel possibly drafted
Patient movement simulations	Simulated transport from site to site	The challenging clinical work of transport itself	Requirement for multiple simulation sites
		Replication of natural flow of patients and handoffs between teams	Technologic limitations of portable wireless simulators
Mobile simulation	Travel of simulation systems and instructor crew to client (or neutral) sites	Simulation expertise brought to those who cannot or wish not to invest in it themselves	Possibly high transport costs (driver, fuel, vehicle)
		For in situ use, all advantages thereof	For in situ use, all disadvantages thereof plus even greater effort for setup and takedown

Figure 8-3. In situ mobile simulation in a catheterization laboratory. The simulator is placed on the catheterization laboratory tables, surrounded by the x-ray machines, thus complicating treatment of the patient by limiting space. The vital signs monitor is connected to the real monitors, providing relevant data to the catheterization laboratory team. The simulator is controlled from the catheterization laboratory control room. Multiple mobile cameras and a scan converter for vital signs provide a live video transmission to a temporary debriefing area for the nonactive part of the training group and allow for crisis resource management–based debriefings. *(Photograph by M. Rall.)*

Figure 8-4. In situ mobile simulation in a dentist chair. The simulator was equipped with artificial teeth gum and a chalk tooth preparation to drill, thereby simulating the dentist's procedures (administering anesthetic or drilling). Then emergencies developed, and the team response was trained, focusing on crisis resource management key points and important medical aspects, including automated external defibrillator use. *(Photograph by M. Rall.)*

Chapter 90). The patient could be brought into the emergency department by ambulance; taken to a computed tomography scanner, interventional radiology, or operating room; and finally transferred to an ICU. Under what circumstances such movements are worth the effort remains to be determined.

MOBILE SIMULATION: "HAVE SIMULATOR—WILL TRAVEL"

Mobile simulation means that the simulator and the audiovisual gear are moved (made mobile) outside the originating institution for purposes of the simulation event.

Figure 8-5. In situ mobile simulation team training in an ambulance. The limitations regarding space to work and move around inside an ambulance are very important. This situation represents a classic need for in situ training of prehospital teams (in Germany consisting of three paramedics and a prehospital emergency physician). In addition, takeover scenarios (e.g., the helicopter team is taking over a patient from the ground-based team) are a challenge for crisis resource management expertise (e.g., information transfer and continuous patient treatment). *(Photograph taken by M. Rall at an air rescue center in Germany.)*

Figure 8-6. In situ mobile simulation team training in a helicopter. The mobile simulation control room with several cameras and microphones is set up outside the helicopter and also provides a multiperspective view inside to monitor the scenario and react to activities performed. *(Photograph taken by M. Rall at Airmed 2008 with the German Air Rescue (DRF) team.)*

Figure 8-7. A, In situ mobile simulation training in a simulated apartment for prehospital teams. Apartment (living space) scenarios are very common for prehospital teams and require adaptation to local space availability and other circumstances (e.g., bystanders, dogs). **B,** Emergency department simulation with the prehospital team handing over a patient to the hospital staff—always a phase of high-demand and goal-oriented interactions. From a crisis resource management (CRM) training perspective, this scenario is a very good opportunity to highlight problems and unsafe practices (in the sense of high reliability) and to show good team performances using video clips of a scenario. *(**A,** Photograph taken by M. Rall at a CRM training session with the South Tyrolean White Cross in Bolzano, Italy. **B,** Photograph taken by M. Rall during an instructor training course.)*

Figure 8-8. In situ mobile simulation in an intensive care unit (ICU)/intermediate medical care unit location. The training in actual clinical areas also is especially useful for ICU-like surroundings. Crisis resource management–based trainings are very important to showcase these highly complex problems and the interactions needed to coordinate high-performing ICU teams. The training also allows for checking the local arrangement of equipment and possibilities to react to certain emergencies. There are already a few examples of residential in situ simulation in ICUs (see text). *(Photograph by M. Rall.)*

Figure 8-9. In situ mobile crisis resource management (CRM)–focused simulation team training inside an actual operating room. This debriefing room is temporarily set up in an induction room. The use of videos for debriefing (here on a 42-inch flat panel placed over the basin) is highly recommended. Training inside a hospital often includes training actual teams and training a large proportion of employees with the same setup. These mass training sessions seem to have a much greater impact and longer-lasting effects of the lessons learned, including CRM behaviors (see text on subthreshold training). *(Photograph by team TuPASS [Center for Patient Safety and Simulation, University Hospital, Tübingen, Germany], who performed at a full team training of the anesthesia department at Steinenberg Medical Center, Reutlingen, Germany.)*

In other words, the simulator comes to the participants. Mobile simulation can be conducted as in situ simulation in an actual site of a remote client institution, by setting up for simulation in conference rooms or hotel meeting rooms, or by having a simulation facility built into a truck or bus. The built-in mobile facility saves time in setup and takedown. It also is possible to conduct simulated field exercises by setting up the simulator outside (e.g., in a parking lot or athletic field).

ADVANTAGES AND DISADVANTAGES OF DIFFERENT APPROACHES

The advantages and disadvantages of different approaches are summarized in Table 8-1. Sites that lack a dedicated simulation center have no practical alternative either to perform in situ simulation or to be a client for mobile simulation. Simulation in the dedicated center facilitates scheduled training and the use of complex audiovisual gear. Simulators can be preset, tested, and ready to go. Briefing and debriefing facilities are immediately at hand. In a dedicated center, it is common to use inexpensive discarded, flawed, or outdated clinical equipment and supplies. The major disadvantage to a dedicated center is that regardless of how well equipped it is, it can never replicate the equipment, layout, and clinical processes of actual clinical workplaces. In addition, participants know that

they are in a simulation center, and this knowledge may alter their demeanor and reduce the impact of training.

In situ simulation seems ideal in that it probes and challenges personnel and systems as they actually exist, thus unmasking real issues of patient care. It is available, in principle, to all sites, even those without a dedicated center, and it is conducive to short courses and unannounced mock event drills. In situ simulation has disadvantages, however. It is difficult to organize, schedule, and control. The clinical area planned for simulation may not be vacant or may be needed on short notice. The simulations can be distracting to real patient care surrounding them, staff members engaged in the simulation are prone to being pulled into clinical duty, and training sessions may be constantly interrupted. Most clinical supplies must be taken from the stocks of the work unit to prevent mixups with outdated simulation supplies, thereby adding expense. The audiovisual gear that can be deployed in a real clinical site has major limitations. A permanent in situ facility may provide the best of both worlds. Such an arrangement offers unique opportunities, such as the ability to replay immediately difficult cases in the simulator next door, the possibility to use low workload times for spur-of-the-moment simulation sessions, and the ability to conduct long-term simulations (team members responsible for a simulated ICU patient over days or weeks). The major drawback to this approach is that addressing diverse clinical domains requires such a site in every domain, and this could be extremely costly.

TEAM TRAINING, SINGLE DISCIPLINE, AND CREWS

Each discipline in health care can be considered a crew containing one or more individuals. Several crews may work together closely as a team. The operating room team consists of an anesthesia crew, a surgery crew, and a nursing crew (and crews of technicians and support personnel).

Further complementarity exists regarding the homogeneity of the target population in simulations. When the simulation is intended to go beyond specific medical and technical skills for individuals (as in CRM-oriented simulations) and to involve nontechnical skills and teamwork, we distinguish between single-discipline approaches (training crews to work in teams) and true combined team (multidisciplinary) training.

The importance of teamwork and team training is widely accepted,[29-34] although team training is still not widely implemented. The prerequisites for effective teamwork (e.g., team leadership, mutual performance monitoring, backup behavior, adaptability and team orientation,[34] and the concept of team cognition) are discussed in Chapter 7.

SINGLE DISCIPLINE

Training for single-discipline crews (e.g., anesthesiologists) involves curricula in which all participants are from a single discipline, and other crew members' roles are played either by instructors and confederates or by other simulation participants. This approach allows tailoring simulations to challenge skills, knowledge, and situations specific to the discipline, including material that may be of little relevance to other crews and in the context of a wide variety of clinical situations (e.g., cardiac, orthopedic, or general surgery; labor and delivery; intensive care). Single-discipline training can emphasize generic skills of dynamic decision making, resource management, leadership, and teamwork applicable to any challenging clinical situation. In the single-discipline approach, scenarios can be designed that present specific types of personalities and behaviors by other crew or team members, rather than relying on the ad hoc behavior of real personnel from those disciplines. Even without actual personnel from other disciplines, training crews to work in teams also provides a degree of cross-discipline understanding by allowing participants to discuss other team members' views of the same situation.

For dedicated center simulations, single-discipline sessions are simpler logistically because only one discipline needs to be present, rather than scheduling someone from each of the disciplines. In addition, simulations can be applied to some disciplines even in domains where credible simulators for the work of each team member are not yet available. The single-discipline approach may be of particular relevance for trainees who, when finished with their training, will go on to work in many different settings and with many different kinds of personnel. It also may be of greatest value for individuals who do not work in fixed crews or teams and who must acquire generic teamwork skills that can be used with all co-workers.

COMBINED TEAM TRAINING

The complementary approach is to conduct *combined team training,* in which all participants of the team, from crews of several different disciplines (e.g., surgeons, nurses, anesthesiologists), undergo training together. Combined team training allows for more natural team interactions and reinforces understanding across disciplines. Successful examples of such undertakings have been reported in many fields, including obstetrics (combining obstetrics, anesthesia, nursing, and neonatology and pediatrics) and intensive care (combining physicians from multiple disciplines with nursing, respiratory therapy, and pharmacy).[31,35-48]

Combined team training may be most effective when a specific group of individuals is to work together clinically as a dedicated team. In dedicated simulation centers, combined team training can be difficult to schedule, and it may require instructors from several of the disciplines to conduct the debriefings. Combined team simulations may be easiest to organize when they are conducted as unannounced mock events that activate the actual bedside team (e.g., ward or unit team, rapid response team, or code team). In such situations, the real combined team is mobilized as they would be in real life.

DEBRIEFING FOR SIMULATION TRAINING

Debriefing refers to a special time and format for talking about an episode of action in the past; it is the counterpoint to a briefing, which occurs before an action or task.

The term originally came from the military, for after-action reviews of real missions and simulations. In medicine, the debriefing concept was introduced to simulation training by Gaba and colleagues as part of the whole concept of CRM-based simulation training for anesthesia teams.[17,49] This section focuses on debriefings in the context of simulation team training.

DEBRIEFING—HEART AND SOUL OF SIMULATION TRAININGS

In aviation and health care simulations, debriefing after a simulation team training session is a key element—perhaps the most important element—of simulation training.[45] Debriefing offers an unparalleled opportunity to reflect and discuss openly and understand other team member's intentions, thoughts, and problems. Much of the learning occurs in this self-reflective episode. Eventually, these routines will be applied to clinical medicine (e.g., surgical team timeout).

NEW WAY OF TEACHING

Debriefing, as described in aviation and introduced and refined for medicine by Gaba and others,[46,50] requires a complete understanding by instructors of their role in promoting learning (see Chapter 9).[51] The philosophy of teaching and learning in a debriefing of a CRM-based simulation course differs from the traditional clinical teaching style (Table 8-2). The instructor's role is to *facilitate* the learning process, by *directing the participants* to the most interesting and important areas for consideration and *stimulating discussion* among participants to *find the underlying issues* and to seek solutions for future events of similar type. *Facilitation* is a new way of teaching and often must be learned by instructors, even though they have many years of traditional teaching experience. The use of video for debriefing can advance the self-reflective component of debriefings, but it requires additional expertise to integrate it successfully with self-reflection.[52-57] Generally, faculty members intending to be primary debriefers need special training and practice in this teaching method (see the later section on instructor qualification).[52,56-64] Several simulation centers conduct instructor training that emphasizes debriefing skills, and debriefing is a frequent topic of workshops at large simulation conferences.

TECHNIQUE OF DEBRIEFING

Although debriefing styles and philosophies differ at centers around the world, a common ground is shared by most centers: debriefing should *stimulate self-reflection,* and it should analyze *how* something happened and what the *underlying concepts* for doing so were, rather than merely finding out *what* happened. Usually the debriefing session lasts at least as long as the scenario itself.

Detailed discussions about the different techniques appear in the literature.[45,46,51,65-68] To prepare a good debriefing, the instructor is challenged during the scenario with performing several tasks in the control room, such as listening to trainees, talking to the instructor team, controlling the simulator, and making notes for the debriefing. Figure 8-10 illustrates the different levels of attendance.

Debriefings by nature have different phases, as shown in Table 8-3. The phases are not meant to be followed in this time sequence and order. Often two or more phases are covered for one problem of the scenario—especially clinical problems are covered while discussing how and

TABLE 8-2 **TRADITIONAL TEACHING VERSUS FACILITATION IN SIMULATION TRAINING COURSES**

Traditional Teaching: "Teacher"	Debriefing Facilitation: "Instructor/Facilitator"
Focus on theoretical knowledge	Focus on human factors and CRM aspects
Focus on what	Focus on why and deeper analysis of why it did (not) work
Teacher is the best (expert)	Instructor just moderates, uses knowledge of participants
Teacher tells participants what to do	Instructor helps participants to find what they could have done and what would be the best way
Teacher knows what is important for participants	Instructor helps to self-reflect and gain realistic self-awareness and consciousness
	Instructor guides toward interesting areas
Talks most	Stimulates discussion among participants
Domain expert	CRM expert
No teaching training	Extensive instructor training
No video	Use of video of own and others' scenarios
Teacher knows what has been learned (or not)	Instructor may not be aware of all aspects that participants take home

CRM, Crisis resource management.

Figure 8-10. The multiple levels of work for crisis resource management (CRM)–based instructors in the control room. The reflections in the one-way mirror of the control room make the multiple levels of activity transparent. The team of instructors has to control the simulation as such, but team members also make notes for the CRM-based debriefing. The scenario inside and the audio streams (telephone call) must be monitored. In addition, the instructors must deal with simulation team role players and instructor trainees inside the control room. These complex tasks need some training and good team organization on the part of the simulation center team. *(Photograph by B. Schaedle, at a PaedSim training at University Hospital, Tübingen, Germany.)*

TABLE 8-3 **PHASES OF DEBRIEFINGS: ISSUES RELEVANT TO CRISIS RESOURCE MANAGEMENT–BASED SIMULATION DEBRIEFING**

Phase of Debriefing	Explanation
Ending the scenario	When possible, the scenario should not be stopped too early. Participants should be allowed to realize the natural end of the scenario. Ideally, it should not be terminated when participants are in the thick of it.
Scenario-to-debriefing transition	Most sites use "hot" debriefing, in which participants enter the debriefing room immediately from the simulation room. This allows the instructor to hear and see participants' direct reactions. Another option is to give the participants a few minutes to discuss the scenario itself while the instructor is planning the debriefing.
Emotional venting	All participants who were actively involved are given the opportunity to say how they *felt* during the scenario. This vents pent-up feelings and may be a time to deal with anomalies in the scenario (e.g., simulator malfunction).
Descriptive phase	Participants describe what happened (or portions of the video are replayed). Different points of view (e.g., "hot seat" versus first responder versus surgeon confederate) are shared.
Self-identification of issues	It can be useful, before anyone else, including the instructor, is allowed to critique the scenario, to allow active participants to say whether they themselves detected any errors or actions that they would do differently. It can be painful and rude to critique participants about something they are aware of themselves.
Discussion of clinical content	Any major issues of clinical treatment and related crisis resource management points should be covered. A debriefing should not end without discussing and clarifying any significant clinical errors and ensuring that participants understand the correct management.
Analysis	Debriefings should provide considerable analysis of *why* things happened vis-à-vis the intentions of all parties, as well as alternatives and their pros and cons.
Opportunities for systems improvement	Based on the analyses, participants can be asked to suggest how the system can be changed to improve handling of similar situations in the future.
Transfer to the "real world"	Participants can discuss how lessons from the scenario or debriefing can be applied in the real clinical world. They should discuss barriers to improvement and ways to overcome them.
Providing a "take-home message" from the scenario and debriefing	A summary of the key points of the debriefing, either by the instructor or the participants themselves, can be useful.
Terminating the debriefing	Debriefings are rich in content and could extend beyond the time available. Marking the end of the debriefing can be a useful transition to preparing for the next scenario or to the end-of-day activities.

when they happened (analysis). Then another problem is analyzed and discussed in terms of different phases. Nevertheless, at the end of a good debriefing, all phases should have been covered according to their respective importance. No debriefing style is associated with a proven better learning outcome, and there may never be definitive data on the techniques because of the nature of the topic—reflective practice of high-level cognition.

USE OF VIDEO FOR DEBRIEFINGS

Although the value is not proved, segments of video recordings to support and deepen debriefing as a learning and self-awareness experience are frequently used.[57,69] Anesthesia does not allow for much self-reflection and feedback during routine clinical work. Experienced colleagues typically work alone, and there is often little feedback from other anesthesiologists or from other operating room personnel. This situation is changing, however, with the use of automatic anesthetic records and information technology (see Chapters 1, 4, 5, and 6).

The lack of feedback leaves a large theoretical gap between the way individuals think they perform and how they act in reality. Video sequences can correct this gap and provide an awareness of how participants have really acted. In addition, one's own video recordings can be compared with the recordings of other participants (either their own course coparticipants or trigger videos meant to stimulate discussion). "Live transmission" of scenarios to participants not actively involved in the scenario also is useful. When this technique is used, the observers can be given special tasks (e.g., look for CRM key points 10 and 11 in Box 8-4). A study in Tübingen, Germany evaluated the use of so-called collaboration scripts in the passive phase of watching others perform.

The video should be used in the service of the debriefing, rather than the other way around. We believe that if the discussion is active and on target, it is useless to interrupt it just to show a video. Video may have a greater impact during participants' first simulation experiences. Here they are sometimes struck by what can be revealed on seeing themselves and others work. As they gain more experience with simulation, and when debriefers are experienced, participants may not need exposure to the video to hone in on key issues to discuss.

CLINICAL APPLICATION OF DEBRIEFING METHOD

The application of the previously described debriefing techniques to the discussion of real-world clinical critical

incidents seems very promising. Applying the debriefing technique learned in the simulator after a critical incident in short debriefing circles of the involved clinical team has proved quite valuable.[41,50,70,71-73]

SCENARIO DESIGN

The design of scenarios for interactive simulation team trainings is demanding and typically differs from preparing training exercises for traditional curricula, such as megacode trainings in advanced life support. Full simulation scenarios are complex enough that their design is usually an iterative process by which the scenarios are continually improved through experience.

This section can give only an overview of the important aspects of scenario design for realistic simulation team training. The reader is referred to detailed published examples of scenarios in *Simulation in Healthcare,*[74] as well to more detailed literature about the principles of scenario design.[3,75] The topic also is covered extensively in most of the instructor training curricula that are offered at sites around the world. International and regional simulation meetings (International Meeting on Simulation in Healthcare [IMSH] of the Society for Simulation in Healthcare [SSH], Society in Europe for Simulation Applied to Medicine [SESAM]) often provide workshops on scenario design, and the user groups of the major simulator manufacturers also have workshops on the topic (see the later section on simulation societies).

GOAL ORIENTED

Scenarios usually are designed to achieve learning objectives or other goals, such as a formal needs analysis of the relevant target group for training concerning clinical and technical skills or nontechnical CRM skills, or both (see Chapter 7). Alternatively, simulation-savvy clinician educators may intuitively know what kinds of scenarios are likely to be valuable for their participant populations, or they may have learned about good examples in their instructor training or in the literature. The cases are not as important as the nature of the underlying challenges that they pose to participants. *Train the causes, not the cases.*

Scenarios should be relevant to the trainees. This relevance is more important than realism and depends on many factors, including the trainees' backgrounds and experience and the method of conducting the scenario and related parts of the simulation course (e.g., familiarization, case briefing, role players).

CONSTRAINTS AND LIMITATIONS

It is easy to suggest a scenario on paper but more difficult to translate it into an effective scenario for actual use. Limitations and constraints must be considered, including features and limitations of the simulators available, personnel resources at hand, the props or external systems that would be needed to engage participants, and the time available for the proposed scenario. In our experience, most scenarios are first generated with an idea that may be small or undeveloped. The idea is fleshed out by discussion and on paper in an iterative fashion, with limitations addressed either by creative redesign of the proposed situation or by minor technical modifications using the simulator software or simulation environment. The new scenario usually is tested out first by instructors and simulationists (the technical staff members who operate the simulators and prepare the environment). It can be pilot tested with a volunteer group of participants from the target population. The first one or two sessions typically will reveal many problems and flaws in the original scenario layout. After a scenario has been designed and tested, it is advisable to add comments and suggestions for improvement continuously after each training session.

SCENARIO TEMPLATES

Many centers have developed templates for the design of their scenarios. Figure 8-11 is an example of a summary sheet of the template used by M. Rall and P. Dieckmann and taught during their instructor courses. The full version of it is available online (www.inpass.de/download/scenarioscript.html). Other scenario templates are popular, including the Duke University template (simcenter.duke.edu/SimTemplate1203.doc). The peer-reviewed journal *Simulation in Healthcare* publishes "Simulation Case Reports," which contain detailed scenario descriptions. Some professional societies have created scenario repositories for members; the American Society of Anesthesiologists (ASA) Simulation Committee has a repository for scenarios to be shared among its ASA-endorsed simulation programs.

INSTRUCTOR QUALIFICATION

Teaching with simulation covers a diverse spectrum of applications. In some cases, it is similar to teaching at the bedside, only the patient is a simulator, in which case the skills needed are nearly identical to those used in ordinary clinical supervision and teaching. Special implications exist for instructing in courses that involve complex realistic scenarios, with multiple personnel in crews and teams, using video-facilitated debriefings in small groups, and with a focus on human factors and CRM principles and countermeasures. In such courses, the skills needed to be a successful instructor go considerably beyond those typically used by teaching clinicians. Quality of the instructors is *the* essential element for any simulation course: "The key is the program, not the hardware."[10] Ensuring instructor competence in using simulation and in debriefing facilitation skills is very important.

Advanced simulation course formats generally closely reflect Kolb's circle of adult experiential learning: (1) self-experience (participate in the scenario) or vicarious experience (observe scenario live), (2) reflect on experience (debriefing), (3) abstract conceptualization (debriefing, relate to theoretical material), and (4) active experimentation (future scenarios and use of skills in real cases)[76] (Fig. 8-12).

Scenario Script Developed by P. Dieckmann & M. Rall, Germany		
Quick reference: Scenario name		
Major problem	Medicine	CRM
Learning goal	Medicine	CRM
Narrative description		
Staffing	Simulator team	Participants
Case briefing	All participants	"Hot seats" only
Simulator setup Mannequin preparation		
Room setup		
Simulator operation

Props needed		

Figure 8-11. A scenario design template. The figure shows the summary page of a scenario design template, which has more space and details in the full version. The template also includes a script to explain the different fields and their best use. The template is a regular part of the instructor training courses. It can be obtained in a more detailed version from www.inpass.de/download/scenarioscript.html. *(scenario script template by P. Dieckmann and M. Rall.)*

TASKS OF INSTRUCTORS

The tasks of a simulation instructor differ from the tasks of a classic medical educator or a trainer for part-task or skills training. The most prominent differences are the following:

- Need to brief the course participants about an unfamiliar environment
- Creation of relevant, plausible scenarios to reach the intended learning goals
- Theatrical aspects of enacting complex realistic scenarios
- Need for simultaneous control of the simulator, the simulation personnel (instructors, actors, and confederates), and learning objectives during multiperson complex scenarios with built-in problems and challenges and an uncertain flow pathway of action by participants
- Need to provide debriefing and feedback after the scenario, often assisted by replay of video recordings, primarily using a facilitation style in small groups and handling group dynamics and individual sensitivities
- Concentration largely on CRM nontechnical skills of decision making, team management, interpersonal relationships, communication, and professionalism

INSTRUCTOR TRAINING

For such complex instructor skills, formal training seems warranted. David Gaba pioneered instructor training for CRM-oriented simulation courses in a consortium of the Veterans Affairs (VA)–Stanford Simulation Center (Palo Alto, CA) with the Boston Center for Medical Simulation and the University of Toronto Sunnybrooke Simulation Center. This consortium spread the ideas and format of CRM simulation instructor training around the world. Marcus Rall has been running instructor courses in cooperation with Peter Dieckmann for more than 1000 international participants. Many institutions offer different instructor courses nationally and internationally (ranging

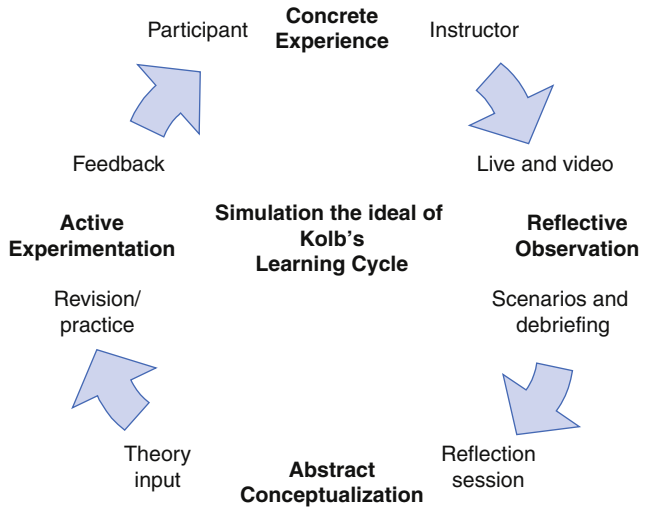

Figure 8-12. Simulation team training with live video transmission as an ideal representation of Kolb's learning circle. During the scenario, trainees have a hands-on experience. This is actively reflected in the debriefing. The live video to the nonactive group in the current scenario allows useful reflective observation. During the debriefing, all trainees have a phase of conceptualization, in which the instructor uses generalizations of factors and root causes to show how behavior developed as it did in the scenario (deep learning). During the feedback in the debriefing, but also in the next active scenarios, participants have opportunities to apply and experiment with the newly learned input. (*Modified from Kolb DA:* Experiential learning: experience as the source of learning and development. *Englewood Cliffs, NJ, 1984, Prentice-Hall.*)

BOX 8-2 ***Learning Objectives for Crisis Resource Management–Oriented Simulation Instructor Courses***

Understand how it feels to be a participant in a simulation scenario and to be debriefed in a group while seeing oneself on video.

Understand the interdependent influence of the different course phases (see Fig. 8-2), and apply this knowledge to a simulation course.

Reflect on the changing instructional styles that can be applicable to simulation courses (instruction—facilitation).

Understand basic concepts of human factors, systems theory, and organizational safety.

Be able to detect, explain, and discuss crisis resource management key points in the debriefing of scenarios.

Use recorded video of scenarios well, and select the most relevant portions for replay and discussion.

Be able to facilitate a debriefing in a nonjudgmental atmosphere with appropriate boundaries.

Understand how to manage the individual sensitivities and group dynamics of participants during debriefing.

Be able to focus debriefing on the analysis of what happened, why things happened the way they did, and how to apply these lessons to real patient care.

Modified from the learning objectives of former instructor courses by Gaba, Rall, and Dieckmann.

from 2 to 6 days in length, depending on the course and its scope); the reader is referred to the simulation societies for information about such courses (SSH, SESAM). The process and impact of instructor training are being evaluated, much as the process of simulation training itself is being assessed. Some early evidence is emerging that such courses have value. In addition, shorter introductory courses on instructor skills are offered every year at the international health care simulation meetings (e.g., SSH's IMSH conference or the SESAM annual meeting), and many workshops at the meetings cover topics such as debriefing, instructor training, and CRM training.

Box 8-2 presents an example of learning objectives for an instructor training course. For experiences and effects of the instructor course by Dieckmann and Rall, a poster presented at the IMSH 2006 with a short description of the InFacT course and results from a response-shift bias analysis can be downloaded from the following website: www.inpass.de/download/infactposter.html. The most difficult task for traditional medical teachers is to learn to stop instructing and start facilitating—guiding participants toward a deep learning experience.

CERTIFICATION OF INSTRUCTORS

The original simulation instructors were self-taught in these skills, and the programs or centers that they founded were pioneers in this field (see also the later sections on pitfalls of performance assessment and the use of simulation for high-stakes evaluation). Now, simulation has become widespread. How can programs of different levels of maturity, experience, and quality be differentiated? Several systems of program approval have emerged, some of them of particular interest to anesthesia professionals. The ASA in 2008 began a process to endorse anesthesia simulation programs (the ASA chose not to use the term accredit) (see also Chapter 1). Centers were originally endorsed for their ability to deliver high-quality continuing medical education (CME) to ASA members. After reaching agreement with the American Board of Anesthesiology (ABA) in 2010, this ASA Simulation Education Network (SEN) rapidly transformed into a group of programs capable of conducting the semistandardized Maintenance of Certification in Anesthesia (MOCA) Simulation Course, a component of Part IV of the ABA MOCA process. As of May, 2013, the ASA had endorsed 36 programs, each of which was reviewed and approved by the ASA Committee on Simulation Education (now considered a Simulation Education Editorial Board) after completion of a detailed application documenting the capability and experience of their simulation instructors, leadership, facilities, and procedures (for ASA members, see http://www.asahq.org/For-Members/Education-and-Events/Simulation-Education.aspx). The American College of Surgeons (ACS) has an accreditation program for Surgical Education Institutes, of which simulation in various forms is an important component. Many anesthesia simulation programs are partners in their institution's ACS accreditation package. The SSH offers a more comprehensive set of accreditations. Most anesthesia simulation programs, even those in the ASA SEN, have chosen not to obtain SSH accreditation and have relied instead on the anesthesia-focused endorsement.

Should instructors receive documented formal training and certification? The SSH offers a Certification for

Healthcare Simulation Educator (CHSE). It is largely oriented to those relatively new to simulation, to document their experience, skills, and knowledge (a written test is given). However, most anesthesia simulation personnel have not and are not planning to obtain SSH CHSE certification. The ASA SEN endorsement process examines the simulation background of instructors, as well as the process by which each site trains and approves new instructors for their program.

It is likely that the skills and certification needed (if any) for an instructor will vary greatly with the particular course or curriculum being taught. Competence in conducting a video-based CRM debriefing would not be needed, and would not help, to teach specific manual procedures (e.g., airway management or central venous cannulation) using part-task trainers. Instructor certification, whether internal to a program or external, could ultimately be connected to the specific types of courses each individual is capable of conducting. A tiered instructor certification system also would likely provide for advancement from novice instructor to grand master as experience and special training are acquired.

CLASSIFICATION OF PATIENT SIMULATORS

No accepted classification scheme has been devised for the use of patient simulators in anesthesia. Any classification involves some overlapping and gray areas.[47] Cumin and Merry published a review about available simulators.[77] The following classification and definitions are used in this chapter. In addition to simulators, computer-assisted instruction programs and computer-based training devices are available. Although training devices may replicate certain portions of the clinical domain, they do not attempt to replicate the bulk of the work environment. Some individuals consider the screen-only microsimulator (also known as a screen-based simulator) to be a training device and not a simulator. Computer-assisted instruction programs and training devices are not reviewed in this chapter. This chapter addresses patient simulators in anesthesia that present the overall patient as would be seen by anesthesiologists, intensivists, or others. Devices related purely to emergency medicine, surgical or procedural simulators that present only the technical work of surgery or invasive manipulations (e.g., bronchoscopy, intravenous access), and partial-task screen-based simulators (e.g., Gas Man, Med Man Simulations, Inc, Boston) are not discussed here.

In this chapter, a *patient simulator* is a system that presents a patient and a clinical work environment of immediate relevance to anesthesiologists (e.g., operating room, postanesthesia care unit, ICU) in one of the following ways:

1. In actual physical reality, defined as a mannequin-based simulator (former and still commonly used synonyms are full-scale simulator, hands-on simulator, realistic simulator, high-fidelity simulator). These simulators can be subdivided in terms of the way that vital signs monitoring is accomplished (interfacing to real clinical monitoring devices or using its own virtual replica of a monitor screen) and in terms of the primary control logic of the simulator (by individual controls and scripts or by using physiologic and pharmacologic modeling).
2. On a computer screen only, defined as a screen-only or screen-based simulator (some anesthesiologists prefer the term microsimulator).
3. Using virtual reality, defined as a virtual reality simulator. In such a device, parts or all of the patient and environment are presented to the user by three-dimensional representations with or without "touch" to create a more immersive experience. A screen-only simulator could be viewed as a very limited virtual reality simulator.

COMPONENTS OF A PATIENT SIMULATOR

A patient simulator system contains several components (Fig. 8-13).[47] A set of outputs makes up a representation of the patient, the clinical environment, and diagnostic and therapeutic equipment. For screen-only simulators, this representation is generated graphically on the computer screen. For mannequin-based simulators, the representation is generated by using a patient mannequin, in addition to either actual clinical equipment or virtual replicas of monitor screens, placed (typically) in a recreated actual clinical setting. The mannequin and, where appropriate, the clinical equipment are stimulated or actuated by interface hardware. Mannequin-based simulators often use physical stimulation of clinical equipment in addition to electronic stimulation. The mannequin can actually be ventilated with any desired mixture of inspired gases. Carbon dioxide and other gases can be introduced physically by the simulator into the mannequin's lungs to provide the desired elements of gas exchange. A real respiratory gas analyzer can be used to measure the inspired and expired gases. The currently available features of full-scale, mannequin-based patient simulators are presented in Table 8-4.

Any simulator must have control logic by which changes in the simulated patient's condition can be generated, controlled, and sent to the appropriate output of the representation. Originally, the control logic was embedded in the software as a fixed sequence of events, or it consisted largely of continuous input from the instructor working from a script. Some current simulators use upgraded types of manual control logic that allow scripting of combinations of changes in control input. Other current simulators incorporate a more sophisticated technique using mathematic difference equations that model a patient's physiology and pharmacology to provide the bulk of the control logic. These models can be tailored to represent different patients with different pathophysiologic abnormalities.

Not all states or changes in a patient can be modeled by differential equations. Ventricular fibrillation is a totally different state of heart rhythm that does not evolve continuously from normal rhythms. No model can predict exactly when a patient will have a myocardial infarction or when an ischemic heart will begin to fibrillate. A model can predict only factors that increase the likelihood of such events. Most simulators incorporate

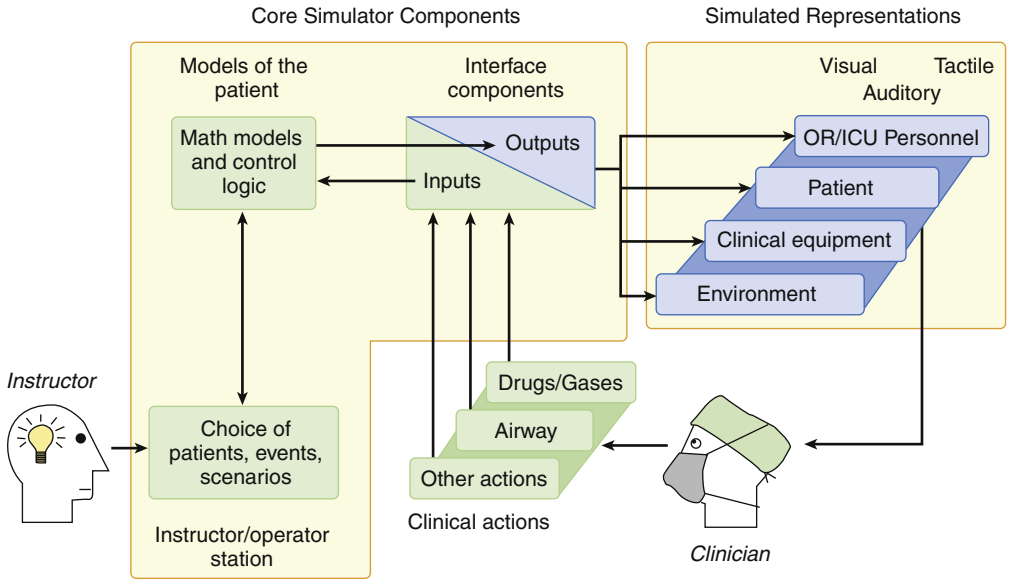

Figure 8-13. Schematic diagram of the generic architecture of patient simulator systems. The simulator generates a representation of the patient and the work environment with appropriate interface hardware, display technologies, or both. The representation is perceived by the anesthesiologist, whose actions are input to the simulator through physical actions or input devices. The behavior of the simulated scenario is manipulated by the instructor or operator through a workstation that allows selection of different patients, abnormal events, and other features of the simulated patient. The control may be manual, script based, or model based with manual adaptation to reach optimal learning outcomes. ICU, intensive care unit; OR, operating room. *(Diagram by D.M. Gaba.)*

TABLE 8-4 **FUNCTIONALITY OF CURRENT MANNEQUIN-BASED SIMULATOR SYSTEMS***

Clinical Area	Features and Functions	Remarks
Airway	Appropriate pharyngeal and glottic anatomy	The airway often provides an acceptable seal for ETT; the seal for supraglottic airway devices can be variable, but it generally does allow positive pressure ventilation.
	Placement of facemask, ETT, LMA, LT, Combitube	
	Laryngospasm, tongue and airway swelling, cervical immobility, jaw closure, breakable teeth	
	Cricothyrotomy	The facemask seal is often difficult, as is placement of the ETT.
	Transtracheal jet ventilation	
	Bronchial anatomy (to the lobar bronchus level)	Cricotomy of modest anatomic realism; the tissue does not feel like real skin and lacks a subcutaneous fat layer; no bleeding occurs; however, the simulation does allow going through the physical steps of inserting a subglottic surgical airway.
Head	Eyelid movement, pupil dilation, and reaction to light or medications	
	Patient voice and sounds such as coughing and vomiting (through built-in loudspeaker)	The live voice is preferred to the prerecorded audio clips because of higher flexibility in scenarios.
	Palpable carotid pulses	
	Cyanosis represented by blue light at the edge of the mouth	The blue light is a cue that the patient is cyanotic, but it does not physically replicate the appearance of cyanosis.
	Tearing, sweating	
Chest	Physiologic and pathophysiologic heart and breath sounds	Breath and heart sounds through loudspeakers; sounds contain artifacts and mechanical noise. Often sound level depends on position of stethoscope relative to loudspeaker.
	Spontaneous breathing with chest wall movement	
	Bronchospasm	
	Adjustable pulmonary compliance	
	Adjustable airway resistance	
	Pneumothorax	
	Needle thoracotomy and chest tube placement	As for cricothyrotomy the anatomy is not very realistic, but the mannequin may allow performance of these procedures.
	Defibrillation, transthoracic pacing ECG	
	Chest compressions	

Continued on following page

TABLE 8-4 **FUNCTIONALITY OF CURRENT MANNEQUIN-BASED SIMULATOR SYSTEMS (Continued)**

Clinical Area	Features and Functions	Remarks
Extremities	Palpable pulses (dependent on arterial pressure)	
	Cuff blood pressure by auscultation, palpation, or oscillometry	
	Modules for fractures and wound modules	
	Intravenous line placement	
	Thumb twitch in response to peripheral nerve stimulation	
	Arm movement	Most current simulators do not provide even limited robotic movement of limbs.
	Representations of tonic-clonic seizure activity	These representations are cues that lack anatomic reality.
Monitoring (waveforms or numeric readouts)	ECG (including abnormalities in morphology and rhythm)	Most simulators provide a simulated virtual vital signs display; some can interface to actual clinical monitors.
	SpO_2	
	Invasive blood pressure	
	CVP, PAP, PCWP	
	Cardiac output	
	Temperature	
	CO_2 (may be actual CO_2 exhalation)	
	Anesthetic gases (may have actual uptake and distribution of agents)	
	Cardiopulmonary bypass	Some simulators include(d) a virtual cardiopulmonary bypass machine.
Automation and sensors	Chest compressions	
	Ventilation rate and volume	
	Defibrillation and pacing (including energy measurement)	
	Gas analyzer (inspired O_2, anesthetics)	
	Drug recognition (drug identification and amount)	

CVP, Central venous pressure; *ECG,* electrocardiogram; *ETT,* endotracheal tube; *LMA,* laryngeal mask airway; *LT,* larynx tube; *PAP,* positive airway pressure; *PCWP,* pulmonary capillary wedge pressure; *SpO_2,* saturation of peripheral oxygen.
*The features listed are each present in some existing simulators, but not all features are present on any single device. Sets of features depend on the device and model.

other modeling techniques in addition to the basic physiologic and pharmacologic mathematic equations, including finite-state models, instructor initiation of abnormal events, and manual modulation of modeled parameters. In finite-state models, different underlying clinical states are defined, each of which has appropriate entry conditions and transition conditions to other states. When an entry or transition condition is met, a new state becomes active and may directly trigger new observable phenomena (e.g., ventricular fibrillation) or may alter constants in the mathematic models that then evolve in time.[78-80]

The control logic of most simulators is manipulated through an instructor or operator's station that allows the instructor to create specific patients, select and implement abnormal events and faults, and monitor the progress of the simulation session. The system may have a remote-controlled, handheld instructor or operator's station in addition to the main instructor or operator's station. The instructor or operator's station typically provides logs of physiologic changes and the anesthesiologist's response, and it may provide graphics to support the analysis of a simulation run. Some screen-based simulators provide advice and tutorials linked to the management of simulated events. With mannequin-based simulators, especially for applications in which complete work environments are recreated, it is common to obtain detailed records of the simulation and the actions taken from video and audio recordings of the personnel working in the replicated clinical environment.

Modern simulators still do not provide many of the desired features listed in Box 8-3. Many different simulator systems are available. No single system is the best choice for all uses, so the decision about the type of simulator required must be based on the objectives and needs of the application. In our experience, the success of a simulator program is not determined primarily by the type of the simulator used, but mostly by the enthusiasm, skill, and creativity of instructors, as well as the time and effort devoted to preparing and performing credible simulation scenarios.[27]

Audio Announcements Are Very Powerful Simulation Tools

In general, a good way to feed information to participants about various phenomena that cannot be simulated physically is to announce the missing signs and symptoms by loudspeaker from the control room to the scenario room. Such information is transmitted at the semantic level of reality and is usually incorporated by participants into their mental model of the simulation (although occasional misunderstandings or mismatches occur between what is observed physically and the information announced by loudspeaker).

BOX 8-3 ***Desirable Features of Future Mannequin-Based Simulator Systems****

Advanced skin signs such as
- Change in skin color to cyanotic or pale
- Improved diaphoresis
- Change in skin temperature (e.g., as a result of shock or fever)
- Rash, hives, or generalized edema

Regurgitation, vomiting, airway bleeding or secretions
Physical coughing (currently only sounds are simulated)
Realistic convulsions
Purposeful movements of extremities
Improved or possible support for spinal, epidural, or other regional anesthesia procedures
Improved EEG signals (e.g., for BIS, AEP, PSI)
Improved intracranial pressure
Support for physical central venous and arterial cannulation
Improved fetal and maternal cardiotocogram

AEP, Auditory evoked potential; *BIS,* bispectral index; *EEG,* electroencephalographic; *PSI,* patient state index.

* This list contains features that are not currently incorporated. Some features may be under development and could be available after publication of this book. In addition, some features are currently available as third-party or homemade add-ons.

VIRTUAL REALITY SIMULATORS

Virtual reality refers to a set of techniques in which one interacts with a synthetic (virtual) environment that exists solely in the computer.[81] In the typical conception of virtual reality, representation of the synthetic environment is fed directly to the eyes (three-dimensional head-mounted displays), the ears, and possibly the hands and limbs (special instrumented gloves and sensors). The actions of the user in the environment are translated directly from typical physical activities, not through manipulating a special pointing device. Realization of this ideal is a continuum involving compromises in these input-output modalities. At one end of the continuum, which we call a *complete virtual reality simulation,* the participant is immersed in a virtual world that fully replicates at least three sensory inputs—full three-dimensional vision, hearing, and touch (the last is more technically known as a haptic-kinesthetic system)[81]—and allows complete physical interaction with the world. The "holodeck" of *Star Trek* would be an example.

At the other extreme of the continuum is a screen-based simulator that generates a limited virtual setting, with its output restricted to a screen display, and provides interaction with the virtual world only through a pointing device. Screen-based simulators provide an interface to the human sensory system that is very far from physical reality, whereas a complete virtual reality simulation may be, in its most advanced form, nearly indistinguishable from the real world. A partial virtual reality simulator would replicate fewer senses (or less complete replication, such as a three-dimensional visual representation on a two-dimensional screen) or could restrict physical interaction with the world, or both. Finally, one can imagine hybrids of realistic simulators and virtual reality simulators (sometimes called mixed reality) in which the virtual reality representation is overlaid onto a real physical environment.

Some surgical and procedural part-task trainers and simulators, such as those used for laparoscopic, endoscopic, or endovascular procedures, could be considered virtual reality because the real procedure is performed only using a video display that can be recreated by the simulator. A comprehensive virtual reality patient simulator would be very complicated, however, because it requires the following:

Complete computer model of the patient, the environment, and the function of every object in the environment that could be used (e.g., monitoring devices, carts)
Means of tracking visual, audio, and touch fields of the user to determine what is to be displayed and to identify what physical actions are being performed
Appropriate display hardware for every sensory modality and appropriate input hardware for each action pathway (e.g., touch, speech)
Hardware to compute all the models, to conduct the tracking, and to produce all the output to the display hardware in real time

Immersive virtual reality is a rapidly developing field. It has stimulated intense interest in numerous domains, particularly space flight, the military, and entertainment. Although the potential of this approach is very exciting, virtual reality is still under development. Prototype virtual reality patient simulators in anesthesia or intensive care have been discussed informally, but as of this writing, no published experience with any meaningful immersive virtual reality patient simulation system exists.

A related type of simulation is the virtual environment or virtual world. According to Wikipedia, a virtual world is a computer-based simulated environment intended for its users to inhabit and interact through avatars (users' graphic [often perspective three-dimensional] representation of their selves). Such systems typically allow multiple participants to control their own avatars (including speech) simultaneously over a network and to interact verbally and by virtual physical actions within a commonly perceived virtual environment. This technology currently portrays the virtual world as perspective three-dimensional images on a computer screen with sound. Virtual worlds have been commonly used for games (the popular World of Warcraft game has 9 million monthly subscribers), whereas other virtual worlds encompass online communities (e.g., Second Life, in which the primary activity is socializing, although commerce and education take place).

In a medical virtual world, the patient may be an automated avatar controlled by the computer, or the patient may be an avatar inhabited by a human participant (an unusual case of an actor playing a standardized patient). Virtual worlds are starting to be used in health care, especially for acute care settings such as the ICU, the emergency department, or field resuscitation.

Although virtual reality simulators have many theoretical advantages over screen-based and mannequin-based simulators (e.g., more overall realism in some cases, instantaneous reset of the environment), these advantages are currently offset by the immaturity of the field. Despite considerable hype about virtual reality, such systems are now either very limited in

capability or very expensive, and in most cases, they are both limited and expensive. A true virtual reality *immersion* experience in a patient care setting comparable to that obtainable with a mannequin-based simulator is not yet on the horizon. Nonetheless, it is likely that virtual reality techniques eventually will eclipse other types of simulators. In the 1990s, Gaba predicted that this would occur by 2020, but the rate of development of immersive virtual reality has been slower than expected.[82,83]

DEVELOPMENT OF PATIENT SIMULATORS

The descriptions given in the following sections are very brief, and the introduction of new or upgraded features in all the simulation systems continues steadily. For up-to-date information about any of the current systems, the reader is advised to contact the manufacturers or developers directly.

The history of the development of patient simulators—particularly the mannequin-based simulators that are in wide use—has been well covered in several review articles and book chapters.[5,84-86] The history is of some relevance to anesthesiology because of the dominant role played by anesthesiologists in the early development of mannequin-based simulation. Anesthesiologists continue to play a major role in this field today, far out of proportion to their numbers relative to other medical domains.

In the late 1960s, a mannequin-based simulator—Sim One—was produced by an aerospace company working with anesthesiologists at the University of Southern California. For that era, it was a technologic marvel and was years ahead of its time.[87] The Sim One project drifted into oblivion, however, largely because the medical professions were not ready to understand the applicability of simulation to key issues of training, research, and assessment, especially regarding the importance of human factors.

Several patient simulators were developed and introduced in the middle to late 1980s. Each was an independent development, and none had any direct connection with the Sim One project. Several factors led to these advances. Most prominent was the new availability of powerful (comparable to advanced minicomputers of a decade earlier) personal computers (PCs) at a relatively cheap price. The popularity of various simulators for PCs (e.g., flight simulators, driving simulators) showed that simulation of complex systems was possible with a PC, and a screen-based simulator could give users some degree of feel that they had been in the environment. On the applications side, the public and the anesthesia profession had become more aware of the utility of simulation-based training for military and commercial aviation, space flight, automobile driving, shipping, military command and control, and the operation of nuclear power plants. Media coverage of the space program and corrective responses to the 1979 Three Mile Island nuclear power plant accident in Pennsylvania highlighted the role of simulators. Another pivotal factor was growing interest in anesthesiology in studying the anesthesiologist's performance and the human factors and ergonomics of the anesthesia work environment (see Chapter 7).[88-91]

SCREEN-BASED SIMULATORS (MICROSIMULATORS)

Beginning in the mid-1980s, several screen-based simulators were developed by anesthesiologists. These included part-task trainers that simulated isolated aspects of anesthesia, such as the uptake and distribution of anesthetic gases in the body given different physiologic and physical chemistry situations (the well-known Gas Man simulator has excelled in this role). Other overall-task screen-based simulators represented nearly all aspects of the patient and clinical environment. Originally, the control logic was based heavily on mathematic models of physiology and pharmacology; some of the screen-based simulators have converted to control largely from scripts and finite-state models. Originally, the patient was represented by drawings or animations, but increasingly in these systems the representation of the patient is by photographs or videos. Vital signs appear on virtual monitors that may mimic real clinical devices. Actions are selected typically using a graphic user interface, pointing and clicking on menus and buttons, and using sliders and numeric entry boxes to allow control of most kinds of interventions that clinicians use on a regular basis.

EXPERIENCE WITH PATIENT SIMULATORS IN ANESTHESIA

Several companies now offer mannequin-based patient simulators with a wide range of capabilities (the term *fidelity* is reserved for the apparent veracity of the simulation; the simulator device has a set of features or capabilities) and with different user interfaces and control logics. Most simulators in use today (coming from several vendors) are considered medium-capability devices. They do approximately 70% as much as a top-of-the-line simulator, but at approximately 15% of the cost of the most expensive simulators. This value proposition has been persuasive to most customers, although for certain applications the high-end simulators still may be required.

The new patient simulators have been in use in anesthesia since the 1990s, and considerable collective experience with the devices already has been achieved. This section and subsequent sections cover the use of simulators for education, training, evaluation, and research (the last especially in decision making and human factors). The results of simulator studies with regard to human performance and patient safety are discussed primarily in Chapter 7.

SIMULATION FOR EDUCATION AND TRAINING OF HEALTH CARE PERSONNEL

The various available patient simulators offer an unparalleled opportunity for students to experience physiologic and pathophysiologic reactions in a realistic manner. Different objectives are possible for teaching sessions. A study by Morgan and Cleave-Hogg concluded that "the simulator environment is somehow unique and allows different behaviors to be assessed."[92] The objectives of *education* are to provide conceptual understanding and an introduction to skills, whereas the objective of *training* is to

implement specific skills and behaviors applicable directly to real-world surroundings. Consistency in objectives is important for evaluating education and training; if we are teaching conceptual understanding, but assessing specific skills, we may obtain misleading results.[93]

A Best Evidence Medical Education (BEME, www.bemecollaboration.org) review by Issenberg and colleagues concluded that high-fidelity medical simulations are educationally effective, but only if the right conditions are met, as follows[24]:

- Educational feedback is provided.
- Repetitive practice is used or is allowed.
- Simulation is integrated sensibly into the standard curriculum.
- The range of task difficulty can be adapted to the level of the learner.

SIMULATION FOR EDUCATION AND TRAINING OF MEDICAL AND OTHER HEALTH PROFESSION STUDENTS

The structured review about simulation effects on simulation-based medical education by Issenberg and colleagues showed the following: (1) the methodologic quality of educational research is often weak; and (2) in the high-quality studies that were evaluated, the effect between hours of simulator practice and learning outcomes equaled a dose-response relationship.[24] Studies by Coates and associates[94] and Gordon and co-workers[95] showed that simulator education for medical students on patient management skills related to dyspnea was superior to problem-based learning.

Various curricula exist,[68,93,96-106] including the following:

- Educational sessions and demonstrations on basic cardiopulmonary physiology or pharmacology; in some institutions, these sessions replace animal laboratory exercises.[107]
- Introduction to integrated management (i.e., interweaving of diagnosis and treatment) of critically ill patients; this training is offered to immediate preclinical medical students as part of their preparation for clinical medicine courses.
- Anesthesia practicum for clinical students during anesthesia or intensive care clerkships.
- Problem-solving skills training; simulation has been tested as a means of educating and training students in the appropriate response to specific critical events. Morgan and Cleave-Hogg tested simulation versus instructor-facilitated viewing of a videotape for this purpose and found no difference between the two.[108] The generalizability of this finding has been questioned, however.[93]
- Adaptation of curricula originally aimed at experienced trainees or practicing clinicians to students; interest is increasing in providing early exposure to medical students, and possibly students of nursing or allied health professions, to interdisciplinary team aspects of medical practice. The aim is to inculcate concepts of teamwork and communication at the earliest stages of education and training as a vehicle to implement long-term culture change in the health care system.

A stimulating critical overview of medical education in general was written by Hodges and was provocatively titled "Medical Education and the maintenance of *Incompetence*" (emphasis added).[109] The article points out that any type of education runs a risk of creating or maintaining *incompetence* in certain areas, especially areas that are ignored by the actual educational program. Objective structured clinical examination–style methods in particular are criticized because students may learn to pass the objective structured clinical examination but still have even gross incompetence in important aspects of real patient care that are not covered by the objective structured clinical examination rating scale. Simulation offers the promise of targeting more thorough integration of different kinds of skills into a better representation of the realities of clinical care. Nonetheless, we recommend that all simulation instructors be especially cognizant of the risks that Hodges articulates.

ANESTHESIA CRISIS RESOURCE MANAGEMENT

In 1989, based on the cognitive process model presented in Chapter 7 and the research results of Cooper and coworkers,[88,110] Howard and associates[111] and Gaba[89,90] of the VA-Stanford group identified gaps in the training of anesthesiologists regarding several critical aspects of decision making and crisis management that were not systematically taught during standard residency or postgraduate education. These gaps were (1) inadequate learning of precompiled plans for dealing with perioperative events; (2) inadequate skills of metacognition and allocation of attention; and (3) inadequate skill in resource management behavior, including leadership, communication, workload management, monitoring, and cross checking of all available information. Historically, it had been assumed that anesthesiologists would acquire these plans and skills by osmosis, solely by experience and by observing role models who had these qualities. As indicated in a previous section, the aviation field had learned that such skills were not acquired unless specifically taught, and CRM training was created to address these issues for flight crews. The VA-Stanford group modeled their ACRM training after CRM,[111] and this approach has been highly influential. ACRM-like curricula are taught at simulation centers around the world, not only in anesthesia, but also in many other domains of health care, including ICU, emergency medicine, labor and delivery, trauma, and field responders.* Figure 8-14 shows a typical ACRM team training scenario.

To target the identified gaps in training, approximately 40% of the emphasis of ACRM is on the medical and technical management of specific high-risk perioperative situations, but at least 60% of the emphasis is on generic principles of crisis management that apply to nearly every complex patient care situation. The key teaching points of ACRM are shown in Box 8-4. These points are emphasized during the ACRM simulation course, and their occurrence or omission is highlighted during the video-assisted debriefing sessions (see more on CRM in Chapter 7).

*References 17, 34, 37, 39, 41, 42, 68, 84, 112-129.

Figure 8-14. Anesthesia crisis resource management team training scenario. A full operating room team (enacted surgeons and nurses) is performing a complicated endoscopic surgical procedure (replayed on screen). The anesthesia team consisting of the trainee ("hot seat") and the nurse must solve complex problems. Video cameras (ceiling), microphones, and loudspeakers provide the necessary connectivity and debriefing tools. *(Photogtaph taken by M. Rall at the Center for Patient Safety and Simulation, University Hospital, Tübingen, Germany.)*

BOX 8-4 ***Key Points in Anesthesia Crisis Resource Management****

1. Know the environment.
2. Anticipate and plan.
3. Call for help early.
4. Exercise leadership and followership with assertiveness.
5. Distribute the workload (10 seconds for 10 minutes).
6. Mobilize all available resources.
7. Communicate effectively.
8. Use all available information.
9. Prevent and manage fixation errors.
10. Cross check and double check (never assume anything).
11. Use cognitive aids.
12. Reevaluate repeatedly (apply the 10 seconds for 10 minutes concept).
13. Use good teamwork.
14. Allocate attention wisely.
15. Set priorities dynamically.

* Detailed explanation of crisis resource management key points is given in Chapter 7.

A working group of the original ACRM centers (VA-Stanford, Boston CMS, Toronto Sunnybrooke) promulgated a set of criteria to be met by a curriculum to be called either "ACRM" or "ACRM-like." Box 8-5 presents an excerpt of the criteria. The full set of criteria is available at http://med.stanford.edu/VAsimulator/acrm/.

These criteria delineate that special training is needed for instructors in ACRM-like curricula. Experience suggests that the most difficult aspect of ACRM instructing is debriefing, and new instructors require a significant period of experience, preferably under supervision by more senior instructors, before being ready to be fully independent instructors. Several groups working separately or collectively have developed comprehensive training programs on simulation instruction, including substantial modules on debriefing and scenario design.

BOX 8-5 ***Characteristics of Anesthesia Crisis Resource Management–Like Simulator Training***

Objectives

Learn generic principles of complex problem solving, decision making, resource management, and teamwork behavior.

Improve participants' medical and technical, cognitive, and social skills in the recognition and treatment of realistic, complex medical situations.

Enhance capacity for reflection, self-discovery, and teamwork and for building a personalized tool kit of attitudes, behaviors, and skills.

Aim

Prevent, ameliorate, and resolve critical incidents.

Setting Characteristics

A realistic simulation environment replicates a relevant work setting (or an actual patient care setting with in situ simulation).

Personnel will represent those persons found in the typical work environment of the participant, including nurses, surgeons, and technicians.

The bulk of the training course consists of realistic simulations followed by detailed debriefings.

Primary participants can request and receive help from other participants.

Participants may rotate among various roles during different scenarios to gain fresh perspectives.

Simulation scenarios may be supplemented by additional modalities, including activities such as assigned readings, didactic presentations, analysis of videotapes, role playing, or group discussions.

Training involves significant time (>4 hours, typically ≥8 hours) and is conducted with a small group of participants.

Content Characteristics

Scenarios require participants to engage in appropriate professional interactions.

At least 50% of the emphasis of the course is on crisis resource management behavior (nontechnical skills), rather than medical or technical issues (nontechnical skills are discussed in Chapter 7).

Observation only is not equivalent to actual participation in the course.

Faculty Characteristics

Training is intense and entails a high level of involvement of faculty with the participants and a low participant-to-faculty ratio.

Faculty members, especially those leading debriefing, have special training or experience in conducting crisis resource management–oriented training.

Debriefing Characteristics

Debriefings are performed with the whole group of participants together and use (as appropriate) audio-video recordings of the simulation sessions.

Debriefings emphasize constructive critique and analysis in which the participants are given the greatest opportunity possible to speak and to critique and to learn from each other (debriefing facilitation).

ACRM-like curricula use several teaching modalities to achieve these goals, including the following:

- A comprehensive textbook on anesthesia crisis management: *Crisis Management in Anesthesiology*. This book includes didactic material on ACRM principles and a comprehensive catalog of critical incidents in

TABLE 8-5 **EVALUATION OF ANESTHESIA CRISIS RESOURCE MANAGEMENT COURSE IN HARVARD ANESTHESIA SIMULATION TRAINING**

		Attending Staff (n = 30)		Residents and Fellows (n = 34)	
Rating	Scale	Evaluation of Simulator Environment (%)	Value of ACRM Course (%)	Evaluation of Simulator Environment (%)	Value of ACRM Course (%)
Less favorable	1	13	3	9	1
	2	10	3	6	2
	3	15	15	11	4
	4	10	25	28	28
More favorable	5	33	54	46	75

ACRM, Anesthesia crisis resource management.

anesthesia that provides guidelines for preventing, recognizing, and managing 83 perioperative situations in a uniform format. The catalog section of the text is intended to provide study material to increase anesthesiologists' stock of precompiled response plans to common and uncommon situations. This textbook has been translated into Japanese and German.

- A brief presentation reviewing the principles of CRM and patient safety.
- Analysis of a videotape of an aviation accident.
- Small group exercises analyzing a videotape of an actual patient care mishap or analyzing written or video presentations about difficult cases.
- Several hours of complex multifaceted realistic simulations in which training participants rotate through different roles, including primary anesthesiologist, first responder (called cold, with no knowledge of the situation), and scrub nurse. Other personnel play the roles of surgeons, nurses, and technicians as in a real operating room. Each situation is followed by a detailed debriefing with video feedback (see the earlier discussion of debriefing).

Several publications have detailed the response of participants with varying levels of experience to ACRM training.[111,125] Participants have been extremely positive about their experience in the ACRM course, and most believe that it contributes to their safe practice of anesthesia. Table 8-5 shows the results of one of the earliest studies on that topic. At VA-Stanford, ACRM has been extended to a multilevel course conducted over several years (i.e., ACRM 1, 2, 3). As the course levels progress, the scenarios become more complex and involve subspecialties of anesthesia. In addition, additional teaching modules cover other important aspects of organizational safety, such as systems thinking in morbidity and mortality conference settings or peer review settings, follow-up response to severe adverse perioperative events, and disclosure to the patient or family of bad news after an adverse event.

ACRM courses and ACRM-like variants are now offered worldwide and are often mandatory for trainees (and in some cases for experienced personnel). In Denmark, ACRM-like training courses are a legal requirement for nurse anesthetists (3-day course) and for first-year (2-day course) and third-year residents (4-day course), in addition to some other simulator training courses (e.g., difficult airway). Further plans are being made to require simulation training for ICU and recovery room nurses and ICU residents.[130-132] Salas and colleagues published an excellent critical overview about prerequisites for effective CRM training.[32]

SIMULATION FOR TRAINING OF ANESTHESIA RESIDENTS

Simulation is now a widely used technique in the training of anesthesia residents (see also Chapter 9). It is used in various ways—for technical training on particular procedures or patient care protocols (especially for airway management), for supplementing didactic instruction about anesthesia equipment, and for training on issues of decision making and nontechnical skills as outlined earlier concerning ACRM. Nearly every anesthesia residency program in the United States offers some cogent simulation training experiences, although the scope, frequency, and target content vary.

Other disciplines and other countries may not have adequate simulation training coverage during residency, as evidenced by a study by Hayes and colleagues.[133] This study examined the perception of Canadian internal medicine residents to be qualified for their service on the cardiac arrest team: 49% felt inadequately trained, 50% believed that the provided advanced life support course did not prepare them enough to lead the arrest team, and almost none received postevent debriefing or feedback.[133]

SPECIAL CONSIDERATIONS IN PEDIATRIC SIMULATION

A sizable body of international experience with simulation in pediatric settings now exists (see Chapter 93).[41,59,127,134,135-140] A study by Overly and co-workers that assessed airway management skills in pediatric residents identified many areas of concern about residents' abilities.[141] The authors concluded that high-fidelity simulation can be used to assess residents' airway management, and that the training program was effective to teach these skills.

Many centers use pediatric simulators predominantly for training of the management of critical incidents and medical emergencies. These simulations target trainees and specialists in anesthesia and pediatric critical care medicine. Because of the frequent organizational and

Figure 8-15. Pediatric full team simulation training. The primary trainees (anesthesia) must solve problems with the infant simulator while urologic surgical team members perform the procedure. *(Photograph provided by C. Eich.)*

Figure 8-16. Neonatal crisis resource management and resuscitation training at a neonatal emergency workplace. All treatment steps must be performed in the simulation to show the need to coordinate and delegate. The experienced instructor (on the right side of the infant) is taking part as a team member, whereas another instructor team is in the control room, to preside over simulation control and debriefing videos. *(Photograph taken at Stanford Simulation Center, Stanford University, Palo Alto, Calif.)*

BOX 8-6 ***Unique Aspects of Simulation in Pediatric Anesthesia***

- Huge discrepancy between high degree of required clinical proficiency and an often limited level of expertise
- Strong demand for training on medical-technical aspects of management—recommendation to participate in a pediatric advanced life support course before simulation team training course
- Need to familiarize with parental presence during pediatric anesthetic care by combination of simulation and role play
- Requirement by the small patient of an even better organization of the work environment and task responsibilities (in situ training)
- High-impact multidisciplinary team training, including crisis resource management
- High level of interest in assessment and certification of trainees and subspecialists for work in pediatric anesthesia

clinical overlap among personnel engaged in pediatric anesthesia, critical care, and emergency medicine, multispecialty personnel (physician crews from different specialties), and multidisciplinary personnel (crews from different professional disciplines), team training can be particularly helpful to prevent failures of cooperation at treatment interfaces (Figs. 8-15 and 8-16). A review by Eppich and colleagues on team training in pediatric acute care settings underlined the impact and effectiveness of team training for pediatric teams.[34] The American Academy of Pediatrics specifically recommends teamwork and communication training for all health care professionals in pediatric emergency settings, and the American Heart Association has included a team concept video and eight elements of team dynamics in its training programs.[142-144]

In contrast to adult medicine, the demand in pediatrics for simulation has been largely to address particular points of medical knowledge and technical skill, perhaps because many medical staff have little experience with pediatric care, especially for cases involving neonates and infants (Box 8-6).[145] Many simulation courses in pediatric anesthesia or intensive care need extensive involvement by experienced pediatric clinicians. More senior clinical personnel who work regularly in pediatric settings may be comfortable with their pediatric clinical skills, but they may be more interested in the generic nontechnical skills that are equally applicable to pediatric and adult care.[142]

A positive correlation exists between the difficulty of pediatric scenarios and the participants' own perception of the learning effect.[145] Scenarios that participants rarely encounter in their clinical practice (e.g., an infant in circulatory shock secondary to extensive thermal injury) on the one hand are thought to be threatening, but on the other hand are considered to be particularly beneficial in terms of training effect. A commonplace but interesting aspect inherent in pediatric simulation is the incorporation of role play by family members. Although family members may be present in adult medicine, their presence in pediatrics is nearly ubiquitous.[146] This presence can put further strain and stress on the provider, thus making it particularly useful to add family role players (either trained actors or instructors or even the participants themselves) to pediatric simulation scenarios.[134]

CONTINUING MEDICAL EDUCATION

Most simulation centers offer CME for experienced practitioners, and nearly all aspects of simulation training for residents (except novice training) can be expanded for this purpose. Several studies have shown that experienced anesthesiologists also have deficiencies in the management of critical patient situations and make severe errors comparable to those of anesthesia residents.[80,132,147-151] A study by Jacobsen and associates in Denmark,[152] involving 42 specialist anesthesiologists, showed major deficiencies in the diagnosis and treatment of anaphylactic shock and in application of the ACRM principles when a score adopted from Gaba and Howard was used.[85,153] Because crisis situations are rare during routine clinical work, these results are not unexpected. In addition, experience in terms of years on the job and hierarchy probably do not correspond to expertise and excellence. Crisis management training with simulators should be started early in education and training and applied on a recurring basis during practice.

An aspect of CME training in the United States is that it is regulated separately by each state, and it is nearly uniformly based only on the number of hours spent in the activity. Reading a short article and answering a handful of questions can generate 1 hour of credit, as can sitting through a lecture. Simulation training is generally much more interactive and much more intensive than other activities. In Australia and Germany, CME requirements are expressed in terms of points to be accrued. Simulation training counts for a large number of points per hour spent, commensurate with its intensity, which may make simulation-based CME financially competitive relative to simpler methods.

The ASA has established a standing Simulation Editorial Board. The ASA offers an endorsement (analogous to but different from an accreditation) of simulation programs that can show their capability to offer excellent CME curricula to ASA members. The Committee began reviewing applicants for endorsement in 2008.

At the Harvard University hospitals, the captive insurer, Harvard Risk Management Foundation, has taken unprecedented steps to link simulation-based CME training to discounts for medical malpractice premium rates for experienced clinicians in anesthesia and in obstetrics (J. Cooper, personal communication, 2005). This forward-thinking program is now being adopted by other malpractice carriers. In some jurisdictions, risk managers have chosen to invest directly in simulation activities at their institution, rather than to use the premium discount approach.

USE OF PATIENT SIMULATION FOR TRAINING HEALTH CARE PERSONNEL OUTSIDE ANESTHESIA

Anesthesiology remains a driving force in the use of simulation in health care, but simulation has spread to nearly every discipline and domain. It has proved particularly applicable to other areas that share the cognitive profile of anesthesiology—dynamic decision making (played out over seconds, minutes, and hours), with complex teams, wielding highly lethal interventions. ACRM-like training has been performed in settings that include, but are not limited to, intensive care,[129,154] emergency medicine and emergency field responders,[155-160] trauma medicine and surgery, neonatology (neonatal resuscitation and neonatal ICU), labor and delivery (see Fig. 8-16),[161,162] cardiac arrest and rapid response teams,[163-165] and radiology. Simulation is such a diverse technique that it is equally applicable—using different modalities of simulation—to nearly all domains. Knudson and colleagues found a significant improvement in overall and teamwork scores in surgical residents taking care of critically injured simulated trauma patients if the residents had undergone CRM-like simulation training.[35]

Figure 8-17. Simulation-based training center for military medics. The room is equipped with 10 SimMan training stations. During training sessions, one instructor team is sitting at each foot of each mannequin. Teaching is provided on scene during the sessions.

The military and the U.S. Department of Homeland Security also have been heavy users of simulation in health care; simulation has been applied to the initial training of new field medics and to the recurrent training of experienced clinicians and clinical teams.[166] Figure 8-17 shows a room with 10 simulators in a training center for military medics that has more than 100 simulator mannequins altogether. In 2013, a first instructor course for North Atlantic Treaty Organization (NATO) Special Operations Forces (SOF) was held at NATO headquarters in Brussels to bring together medical experts from the U.S. SOF, the NATO SOF, and some civilian instructor experts (including M. Rall). By now several such instructor courses have followed.

Simulation is now used more frequently in training for the management of chemical, biologic, or nuclear threats from accidents, weapons of mass destruction, or terrorism. One group in Tübingen, Germany, used their simulator to test the constraints of treating patients in full chemical protection gear (publication of the results is in preparation) to optimize the strategies of the German Ministry of Internal Affairs for dealing with terror attacks or chemical plant disasters (Figs. 8-18 and 8-19) (see Chapter 83). Several investigators have performed multidisciplinary studies with combined simulation modalities (script-based simulators, model-based mannequin simulators, and simulated acted patients) to teach the management of victims of an attack with weapons of mass destruction and terrorism.[74,75] The demand for such training is substantial in nations engaged in active

Figure 8-18. Realistic patient simulation as a test bed for studying the performance of medical rescue teams in full chemical protection gear. Teams wore normal uniforms or full protection suits while performing basic resuscitation actions (e.g., placement of intravenous lines, drawing up drugs, intubation). *(Photograph taken by M. Rall at the Center for Patient Safety and Simulation, Tübingen, Germany.)*

Figure 8-19. In rescue situations with full protective gear, communication within the team and with the patient is difficult. *(Photograph taken by M. Rall from a video screen at the Center for Patient Safety and Simulation, Tübingen, Germany.)*

military conflicts or with an ongoing need to prepare for war or terrorist attacks (e.g., the United States and Israel).

USE OF PATIENT SIMULATION FOR RESEARCH

Research in simulation falls into two categories: (1) research *about* simulation—testing or improving the techniques, technologies, and pedagogy of simulation; and (2) research that uses simulation as a tool to study other things, such as human performance, clinical cognition, or clinical care processes (see Chapter 7). Box 8-7 provides a sampling of these second types of questions. As a research tool, simulation offers some unique features, and it can be thought of as a complementary window on the clinical world relative to other modalities. One can study clinical work by using prospective observation of real cases. This has the benefit of being prospective, but by nature, more cases in most domains would be unremarkable, and one would mostly observe the routine and banal. For

BOX 8-7 *Research Issues That Can Be Addressed by Using Simulation*

Cognitive Science of Dynamic Decision Making (See Chapter 7)

What is the interaction of precompiled procedural knowledge versus deep medical knowledge and abstract reasoning?

How does supervisory control of observation relate to vigilance, data overload, and visual scanning patterns?

What is the information content of watching the surgical field?

How are optimal action planning and scheduling implemented?

How does reevaluation fail and result in fixation errors?

Human-Machine Interactions

What is the distraction penalty for false alarms?

Do integrated monitors and displays have an advantage over multiple stand-alone devices and displays?

How easy to use are the controls and displays of existing anesthesia equipment in standard case situations and in crisis situations?

Teaching Anesthesia in the Operating Room (See also Chapters 4 and 9)

How much teaching can be accomplished in the operating room without sacrificing the anesthesia crew's vigilance?

How well can faculty members detect and categorize the performance of anesthesia trainees?

What teaching styles are best integrated with case management in the operating room?

Issues of Teamwork

How does an anesthesia crew (attending anesthesiologist plus resident or certified registered nurse anesthetist) interact during case and crisis management?

How is workload distributed among individuals?

How do crew members communicate with each other, and how do they communicate with other members of the operating room team?

Effects of Performance-Shaping Factors on Anesthesiologist Performance

How do sleep deprivation, fatigue, aging, and the carryover effects of over-the-counter medications, coffee, or alcohol affect the performance of anesthesiologists?

Intelligent Decision Support

Can smart alarm systems or artificial intelligence provide correct and clinically meaningful decision support in the operating room or intensive care unit?

Development of New Devices and Applications: Research Regarding Techniques of Simulation

How well do simulators resemble the operating room and provoke the same actions as used in the operating room (ecologic validity of simulators)?

How much does debriefing add to learning from simulation? Are specific techniques of debriefing (e.g., use of video, participant-centered discussion) of significant utility?

How does the setting of simulation scenarios influence aspects of perceived reality, and how does it influence transfer into the real world?

Does simulation training lead to better clinical practice and improved clinical outcomes?

TABLE 8-6 **TRANSLATIONAL RESEARCH LEVELS OF SIMULATION-BASED TRAINING**

Level	Description of Study Methodology (Typically in a With/Without Simulation Training Intervention Study Design)	Comments or Examples
0	No measurement of learner performance	Questionnaire of reaction to simulation or change in knowledge
1	Performance measured during simulation only	Can they do better in a simulation?
2	Performance measured during actual clinical care	Can they do better in clinical practice
3	Measurement of improvement in patient outcome	Do patients actually fare better?
3′ (cost effectiveness)	Measurement of the cost of the intervention and the outcome and monetary benefit	Does the intervention yield a net saving of money (with/without also improving outcome)?
4	Measurement of dissemination of the intervention to sites beyond trial sites	Can the intervention be spread elsewhere successfully?
5	Measurement of the adoption of the intervention in regular practice	Can the intervention be widely adopted?
6	Measurement of population health outcome	Will it make an impact on the patient population as a whole?

some purposes, this study would be more than sufficient. Another source of information is in case reports of challenging cases, whether the challenges were expected or unexpected. These also are real cases, and they are out of the ordinary, but the data obtained from such retrospective reports are usually scant and biased.

Simulation provides an alternative view of clinical work that can be prospective and about challenging cases, albeit simulated cases. The simulation centers around the world probably have the largest experience by far of observing anesthesiologists managing (simulated) malignant hyperthermia. It is difficult to imagine how else one could gather systematic data about how clinicians work while managing this uncommon, life-threatening situation.

An important milestone for simulation-based research of both types was the initial publication by the Society for Simulation in Healthcare in 2007 of their peer-reviewed journal, *Simulation in Healthcare* (David Gaba is the founding editor-in-chief of the journal). In addition, for research that is linked tightly to a specific clinical domain, the traditional medical specialty journals have become more welcoming to articles about simulation or that use simulation as an experimental technique.

Cooperation between simulation directors or instructors and psychologists, human factors engineers, or educators has proved useful in research and training. Such collaborations have helped delineate the theoretical foundations of simulation-based experiential learning, improve the understanding of debriefing, and research on work psychology and human performance in health care.[†] Many institutions have integrated psychologists or educators, or both, into their simulation center staff.[120] Ways to make such collaborations fruitful and rewarding also have been described.

APPLYING THE TRANSLATIONAL RESEARCH PARADIGM TO SIMULATION

The concepts of a continuum of research from fundamental science through clinical trials to widespread use in patient care and of potential translational blocks were articulated by Sung and colleagues in 2003.[169] From this publication emerged various nomenclatures for the different levels of the research continuum in terms of increasing level of translation. William McGaghie, PhD, then at Northwestern University, first adapted the T levels of translational research to the arenas of medical education and simulation in health care, comprising T1, T2, T3, and T3′ (Table 8-6).[170-172]

Gaba then adapted additional levels mentioned in other sources,[173] including the website of the U.S. National Cancer Institute (http://www.cancer.gov/researchandfunding/trwg/TRWG-definition-and-TR-continuum), and added levels of T0, T4, T5, and T6 (see Table 8-6). Researchers in simulation are now encouraged to use this terminology in describing and comparing their research protocols and results. At this point, most studies of simulation-based learning are at level T0 or T1. A few studies have been at T2 and only a handful at T3 or T3′. Levels T4 and T5 can be considered implementation science, but few studies of implementation have been performed. The field is encouraged to move toward higher levels of translational research whenever possible. However, doing so will be very difficult, especially in going to the T3 level. Many applications of simulation in anesthesiology especially focus on preparing anesthesia professionals to prevent and manage uncommon but serious adverse events more effectively. The rarity of such events and the many confounding variables that affect patient outcome will make intervention studies very difficult to perform.[174] These studies would perforce need to be large, long, and complicated. To date, almost all studies have been too short and too unsystematic, with weak interventions and without adequate control of confounding variables. Unlike many types of clinical trials, which are funded by the pharmaceutical industry, which is willing to invest heavily even in complex trials because of the high direct payoff when a blockbuster drug is found, simulation interventions have no equivalent funding sources. Obtaining level 1A evidence (multiple randomized controlled trials) of simulation's impact on patient outcome may well take studies of thousands to hundreds of thousands of patients, cared for by hundreds or thousands of clinicians, with simulation

[†]References 18, 19, 25, 26, 47, 167, 168.

interventions that are powerful, comprehensive, sustained, and also linked to performance assessment (and remediation) of individual clinicians. As yet, no agency or commercial firm is willing to fund these kinds of large, long, and complex studies.[174]

USE OF PATIENT SIMULATION IN SUPPORT OF BIOMEDICAL INDUSTRIES

Various simulation activities have been undertaken by the pharmaceutical or medical equipment industries. Numerous centers (perhaps the University of Florida at Gainesville was the first) offer training to executives and sales representatives of equipment and pharmaceutical manufacturers. The simulator allows these individuals to gain some understanding of the clinician's task demands during patient care and the situations in which their company's drugs or devices could be useful. At the Boston Center for Medical Simulation, this course is dubbed "Anesthesia for Amateurs." Other industrial uses include training personnel in the use of novel pharmaceuticals. Simulators have been featured in a multifaceted approach to launch the opioid remifentanil. Simulators were used to train the manufacturer's representatives and clinicians in safe use of the drug, and it was possible to train anesthesiologists in the application of remifentanil with the simulator before remifentanil was approved by the U.S. Food and Drug Administration (W.B. Murray, personal communication, 1998.) Besides offering important educational benefits, industrial activities are an important source of income for simulation centers to help defray the costs of training students and residents.

Simulators have been used to conduct research on human factors issues in the development of new monitoring and therapeutic devices. The simulator also provides a unique test bed and demonstration modality for preprocurement evaluation of the usability of medical devices from different manufacturers. In our own hospitals (Stanford University, Palo Alto, Calif., and Tübingen, Germany), simulators enabled us to conduct evaluations of prototype monitoring systems that were not yet approved for clinical use and could not be evaluated in a preprocurement clinical trial.

OTHER USES OF SIMULATORS

Other unique applications of simulators have surfaced. Some centers use simulators for conducting outreach programs with high school or college students interested in health care. Simulators have been used to help produce educational videos on various patient safety issues. Holding a "legislator day" in a simulator center to familiarize legislators with the demands of dynamic patient care has been suggested.

Simulators have been used as adjuncts in medicolegal proceedings.[175] Current patient simulators cannot predict the exact physiologic behavior of a specific patient, but they can be used to illustrate typical perioperative situations and the role of different monitors and therapeutic actions and to provide context for the patient management questions of the litigation.

EFFECTIVENESS OF SIMULATION TRAINING

Flanagan and associates provided a thorough review of the literature to date on the efficacy of simulation-based training for learning and assessment.[176] The investigators identified more than 3500 articles, of which 458 were included in the review. The conclusion was that "simulation makes a valuable contribution to learning for students, trainees and clinicians. It enables learning of both routine and non-routine procedures and management of patients."[176] They further concluded that simulation is widely used in teaching and learning, is increasingly used for formative and low-stakes assessments, and is rarely used (but under growing consideration for) high-stakes summative assessment. These investigators also observed that the range of simulation modalities used for these activities varies widely.[176] Similar to the BEME review by Issenberg and colleagues,[24] Flanagan and associates found that many studies lacked a robust design, and that the level of outcome effectiveness as measured with a modified Kirkpatrick scale rarely exceeded 3 out of 6, with most at the level of 2 or lower.

The most important question concerning simulator-based training in anesthesia is its cost effectiveness. This complicated question has two independent components. The first component pertains to the impact and benefit of the training on the performance abilities of participants, and the second is the cost to achieve that impact. In principle, simulation has many advantages as a training tool, as follows[177]:

- No risk is posed to a patient.
- Exercises in routine procedures can be repeated intensively, whereas situations and events involving uncommon but serious problems can be presented at will.
- Participants can learn to use actual complex devices (with a hands-on simulator).
- The same situation can be presented independently to multiple subjects for evaluating individual or group performance.
- Errors can be allowed to occur that in a clinical setting would require immediate intervention by a supervisor.
- The simulation can be frozen to allow discussion of the situation and its management, and it can be restarted or begun anew to show alternative strategies or techniques.
- Recording, replay, and critique of performance are facilitated because patient safety or confidentiality is not an issue.

The fidelity required of the simulator and the choice between screen-only and realistic simulators depend on the intended goals of the training and the relevant target population. A spectrum of computer-based training is possible. Computer-assisted instruction programs and part-task trainers can be used to teach basic concepts and technical material, such as the uptake and distribution

of inhaled anesthetics or the pharmacokinetics of intravenous drugs. These uses are appropriate for students, novices, advanced residents, and experienced practitioners. Screen-only simulators are inexpensive and easy to use. They allow the presentation of and practice with the concepts and procedures involved in managing normal and abnormal case situations. They also are useful for numerous user populations. Realistic simulators can be used to capture the full complexity of the real task domain, including human-machine interactions and the complications of working with multiple personnel. They are most appropriately used for residents and experienced practitioners. Regardless of the device used, the simulator is only a teaching tool that must be coupled with an effective curriculum for its use.[24]

The evaluations conducted suggest that simulator-based training is a powerful technique that novice and experienced anesthesiologists believe to be highly beneficial and that participants and instructors alike believe may improve clinical performance. As the developers of Sim One 7 pointed out, when simulation provides an opportunity to teach material that cannot be taught in another way, as for the systematic instruction of anesthesiologists in handling severe critical events such as cardiac arrest, anaphylaxis, or malignant hyperthermia, there is nothing with which to compare the simulator. Assessing whether the actual outcome of patients can be affected by this or any other training modality would be extremely difficult and expensive. Individuals investigating simulator-based training do not believe that definitive outcome studies of this type are logistically feasible.[178] Determining the impact of a given type of simulator training on the intermediate variables of performance and ability is feasible, but it would not be easy. The Leiden group provided data supporting the contention that simulation training improves performance in handling a malignant hyperthermia situation. The potential exists, however, for substantial bias when attempting to measure the impact of simulator training by using performance in the simulator as a criterion. The control procedures used by the Leiden group alleviate this bias, but they cannot eliminate it.[179]

Perhaps of even greater importance, no methodology is currently accepted for measuring the clinical performance of anesthesiologists either in the simulator or in actual practice.[180] Ironically, the simulator itself provides a tool for presenting the same calibrated situation to multiple anesthesiologists and may be a crucial tool in developing such performance measures. Many groups around the world are trying to refine performance measurement tools,[123,162,181-200] but no gold standard measurement is yet available to assess a simulation's effectiveness (see the later section on evaluation of performance).[180]

HOW SIMULATION CAN BE MORE EFFECTIVE

Health care has not yet scratched the surface of assessing the impact of simulation-based training. Most simulation is currently targeted at students and trainees (i.e., residents), although programs targeting experienced personnel are growing. The assessment of the impact of simulation to date can be seen using the following analogy to drug development and testing. Suppose we wished to test whether a purported antihypertensive drug actually succeeded in reducing blood pressure in patients and, more importantly, whether it reduced the occurrence of adverse cardiovascular events, such as myocardial infarction and stroke. Imagine then that we proceeded as follows: Administer a relatively small dose of this drug only a few times per year. Acknowledge variable compliance in taking even these few doses of drug. Immerse all subjects in an environment full of stress and other factors predisposing to cardiovascular events. Use only a few patients, and follow them for a very short time.

Using this methodology, would anyone wonder if no significant effect was found even for a drug otherwise known to be effective? Simulation in health care has so far been tested in this way: very small, short-term studies of infrequent (often short) simulation sessions, whose lessons are not fully reinforced in real clinical environments full of production pressure and stress. In truth, the question is not, Does one run through a simulation course make a practitioner better? To follow the lead of other industries of intrinsic hazard, such as commercial aviation or nuclear power production, the real question is, What is the impact on health care as an industry adopting a comprehensive integrated strategy of intensive simulation-based training and continued performance assessment of clinical personnel, over a long period of time? This is the approach in aviation, in which no matter how senior and how experienced pilots are, they still undergo training and assessment in simulation every year, for the entirety of their careers.

Even so, industries such as aviation do not have anything resembling level 1A evidence for the benefits of simulation, even though such studies could be grafted onto the existing structure of yearly training and testing. It is unlikely that aviation would ever attempt randomized trials. For one thing, as the saying goes, pilots are the first ones at the scene of the accident. It seems unlikely that pilots would forgo simulation training and assessment when their own lives are on the line. For another thing, the public has come to expect a regulatory safety floor imposed by the government to ensure the competence of pilots. The regulator is unlikely to forgo its requirement for mandatory training and testing of pilots. If such requirements continue, there may be only two options: conduct these exercises in real airplanes, with the attendant costs (e.g., fuel) and risks; or conduct them using simulation. With health care heading in that direction,[36,37,41,44,201-205] we may be able to assess the impact of more effective simulation programs, although we may lose a control group that has never experienced simulation.

AVOIDING SUBTHRESHOLD TRAINING EFFECTS

To date, simulation training has largely been employed in small doses given intermittently, not sustained over the long term, and ignoring many personnel who are crucial in the chain of patient care. When conducted this way, simulation training may not achieve a critical mass and may produce a subthreshold effect. It seems likely that a long-term cumulative effect would be achieved only

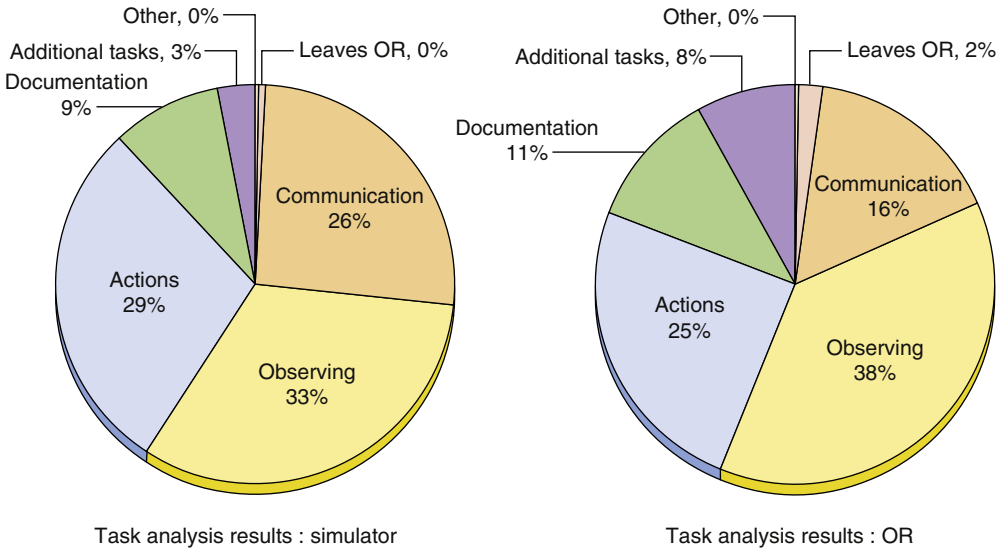

Figure 8-20. Validity of simulator systems versus the operating room (OR). The same anesthesiologists were observed in the OR and in the simulator environment with full enactment of the OR personnel, surgical team, and anesthesia nurse. Even though the two settings have some interesting differences, the overall ecologic validity of the simulator is good. *(Courtesy of T. Manser, ETH Zurich, and University Hospital, Tübingen, Germany.)*

with a long-term comprehensive program of training and performance assessment.

Perhaps it is worth the inherent logistical difficulties and costs to undertake bulk training (>75% of personnel trained in a short time, rather than starting a program of training a few individuals a month and achieving a high penetration rate only in months or years). Where the training is about teamwork and behavioral issues (CRM focused), this may be especially important, so that the lessons taught in the simulator are continuously reinforced by experiences in real patient care. The hope is that creating a critical mass of adherents to CRM principles through simulation would create self-sustaining reinforcement of safety-oriented behaviors that continues with only occasional refresher sessions of simulation.

An analogy for that effect would be the starting of a fire with wood logs: If you take away the match too early, you do not light the fire, and all you get is a black mark on the wood, but if you keep the match on the wood long enough (similar to activation energy), the fire starts to burn and spread to all logs without any more input—similar to what we would like to see with CRM team behaviors.

ECOLOGIC VALIDITY OF SIMULATORS COMPARED WITH THE OPERATING ROOM

The question whether full-scale simulators are an ecologically valid representation of the operating room (i.e., to what extent "the environment experienced by the subjects in a scientific investigation has the properties it is supposed or assumed to have by the experimenter"[206]) was investigated by an interdisciplinary research group in Tübingen, Germany and Zurich[167] (see also Chapter 4). If the actions in the simulator resemble the actions in real operating room environments (*behavioral validity*), it is much more likely that the results of research conducted in a simulator setting or lessons learned in the simulator environment will be transferable to the context of actual patient care. The group developed an improved task analysis method that allows the recording of overlapping activities (41 actions from 5 categories—monitoring, actions, communication, documentation, and other) to analyze and describe the performance of anesthesia.[207]

This method is described in more detail in Chapter 7. Each of the six anesthesiologists participating in the study was observed during two clinical cases and during three comparable simulator cases (one routine and two involving critical incidents). Analysis of the study showed good comparability of the different action categories (Fig. 8-20). The interpretation of the group was that overall comparability between the operating room and the simulator setting is good, thereby indicating high ecologic validity for simulators in anesthesia. The results of the study also showed few, but distinct variations in the task structure of operating room and simulator cases. These variations were mostly the result of organizational factors (e.g., fewer additional tasks required in the simulator). These studies provide objective confirmation of the favorable subjective impressions of realistic simulation scenarios by anesthesiologists of varying levels of experience.[148,149,187,189,208-210]

Some differences between simulation and real patient care are inherent to simulation. Subjects realize that they are in a simulator and are likely to be hypervigilant (e.g., many participants neglect documentation in the simulator while waiting for a disaster to happen). In addition, some organizational factors are usually different in the simulator from the real operating room (e.g., reflected in fewer additional tasks in the simulator compared with the real operating room in the study of Manser and Rall). Careful and creative scenario design and introductory briefings may mitigate the hypervigilance and organizational effects.[45,211]

EVALUATION OF CLINICAL PERFORMANCE DURING SIMULATION SCENARIOS

The introduction of patient simulators allowed the study of human performance when responding to critical events (see Chapter 7). Techniques are needed to assess anesthesiologists' performance.[212] Performance can be divided

into two components: medical or technical performance, which is the appropriateness and thoroughness of the medical and technical response to the critical event; and behavioural or nontechnical[213] performance, which is the appropriate use of sound crisis management behaviors (e.g., leadership, communication, distribution of workload).[214,215] (See Chapter 7 on CRM.) Assessment of medical and technical responses has resulted in technical scores suggested by different authors.[179,180,188,189,216-219]

Simulation offers some benefits in assessing medical or technical performance. Because the nature and cause of the critical incident are known, one can construct in advance a list of appropriate technical activities. Relative weighting of the importance of the different activities can be applied to reflect the fact that different activities, even if appropriate, differ in their importance. This weighting can be done either in advance of data collection, or post hoc (but in an appropriately blinded fashion). For example, when assessing medical or technical performance in managing malignant hyperthermia, termination of the trigger agent and administration of intravenous dantrolene would be highly important, indeed essential, items. Cooling measures, hyperventilation, and bicarbonate therapy would be among many appropriate (but less critical) responses. One also can predict in advance specific technical errors. For example, for malignant hyperthermia management, these could include diluting dantrolene with the wrong diluent or an insufficient quantity of diluent. These errors are known to plague clinicians unfamiliar with therapy for malignant hyperthermia.

Can the clinical outcome of the simulator's mathematic physiology model (if present) predict how a real patient would have fared under the clinician's care? Even when mathematic models are used, they are insufficient to predict what would happen to any actual patient after complex sequences of therapy and more subtle patient care judgments. The models have not proven to be robust enough for such purposes and have shown a lack of reproducible outcomes even when the same patient in the simulation is given identical perturbations and treatments at exactly the same times.

In situations of extremely poor (or good) performance, the model's predicted outcome may properly indicate failure or success of performance. For example, a subject who shows totally erroneous decision making (e.g., failure to defibrillate a simulated patient with ventricular fibrillation) unmistakably allows a patient's state to deteriorate quickly. However, the converse may not be true. Perfect decision making in resuscitation of a real patient cannot guarantee that electric countershock would successfully restore a normal cardiac rhythm. We suggest that even with model-driven simulators, the clinical outcome of the simulated patient is at best one datum that can be used to assess the performance of the anesthesia professional on a simulation scenario. For the foreseeable future, any credible performance measurement technique must involve many subjective and semiobjective judgments by clinical experts. Many empiric studies have attempted to use simulation for different forms of performance assessment in various domains and disciplines.‡

PITFALLS OF PERFORMANCE ASSESSMENT

Previous trials, experience in other industries, and theoretical analysis suggest that simulation offers substantial opportunities to facilitate performance assessment. The following issues must be resolved, however, to make performance assessment a robust capacity:

Technical versus nontechnical (CRM) skills. As indicated in previous sections, it is feasible (if difficult) to assess a technical response to specific events and generic nontechnical behaviors (CRM). For which kinds of assessments is it appropriate to measure only technical performance, only nontechnical performance, or some combination of the two?

Number of scenarios. How many different scenarios are needed to achieve robust performance assessment of individuals in all relevant aspects (technical and nontechnical) of patient care? The literature suggests that having a larger number of scenarios is more effective in improving the reliability of ratings than is having a larger number of raters.[247-249]

Rating individuals versus rating crews or teams. Anesthesiologists work as individuals and in crews and teams with other anesthesiologists and with surgeons, nurses, technicians, and others. Should the performance of individuals working alone be assessed? Should anesthesiologists be able to call for and use help in solving problems? If so, can one still rate the individual when working with a team?

Performance fluctuation. How can performance that fluctuates substantially over time be aggregated into a single rating? This issue was recognized by Gaba and colleagues as a major apparent source of interrater disagreement.[215] It is not addressed by the Anaesthetists' Non-Technical Skills (ANTS) system.[190,250] Which techniques would best address this issue, especially as applied to scenarios that represent the actual complexity of clinical practice?

Criterion thresholds. What level of performance should be set as criterion thresholds for different purposes? Can benchmarks of performance be established by truly expert clinicians (recognizing that years of experience and hierarchic rank are not surrogates for expertise or skill)? Similarly, how does the rating system deal with single actions or behaviors that were lethal or harmful in the presence of otherwise good performance? If used for formative assessment, a rating system should indicate the successes of the examinee and the failures. If used for summative or high-stakes assessment, however, it may be critical to ensure that the examinee who risks harming a simulated patient cannot outscore another examinee whose overall performance is less strong but who at least did not endanger the patient. Not performing chest compressions in a cardiac arrest situation would be such criterion for exclusion.

Appropriate statistical analysis of validity, interrater reliability, and reproducibility of these assessments. Various statistical tests and approaches have been used to evaluate these characteristics. The data on performance show various levels of interrater variance and high interindividual (and interteam) variability.[149,179,187-189,208,215,251] As detailed by Gaba and colleagues,[215] some interrater reliability statistics are more stringent than others, especially in terms of the nature of the "by chance" benchmark. No

firm consensus has been reached regarding which tests are most appropriate to answer key questions about simulation-based performance assessment. Some of the rating systems (including ANTS) have used less stringent tests of interrater reliability. Generalizability theory offers a set of statistical techniques to sort out the impact of scenario, subject, rater, number of scenarios, and other facets on such assessments.[252,253] This technique also specifies how comparisons can be made against reference performance levels or as relative comparisons between subjects without a fixed benchmark.

Although simulation should enable performance assessment, a robust set of performance measures of anesthesiologists' skill would be difficult to develop,[254] even if the simulator is used as a tool to present standardized patient scenarios.[255]

Klemola and Norros published a newer way of looking at performance that involves anesthesiologists' habit of actions.[256] These authors distinguished between "reactive habits" (conservative, self-contained, reluctant to construct subjective evaluations) and "interpretative habits" (creative, interactive, continuous integrative reasoning). This article showed that many issues must be considered when discussing the best method of education and evaluation. Additional issues include defining and assessing professional competence. A more consultant-based method was introduced by Greaves and Grant,[257] who compiled an inventory of characteristics of the anesthesiologist's practice. Epstein and Hundert provided a review.[258]

USE OF SIMULATORS FOR THE EVALUATION AND TESTING OF ANESTHESIA PROFESSIONALS

The use of simulation as a tool for performance assessment has presumed advantages: scenarios are known, errors can be allowed to occur and play out, and intensive recording and archiving of performance is possible; all these features provide a window on performance that is otherwise unattainable.[259] Scoring or certifying competence by using the simulator is more problematic than using the simulator as a teaching tool, however. Anesthesiologists have long discussed the possibility of using the simulator as a tool for examinations, either for graduation from a residency or for ABA certification. In Israel, a simulation examination has become part of the board certification process.[260]

Despite these difficulties, the use of anesthesia simulators to assist in evaluating performance is likely to increase in the future.[§]

Even though simulation is currently used for some high-stakes examinations, the challenges remain the same:

It requires independent evaluation of the simulation scenarios and assessment of the predictive power of the subjective judgments made by experts scoring the examinee.

One obstacle is the lack of any well-accepted standard for performance evaluation.

Another difficulty with using simulation for board certification testing is that the operating room equipment would rarely be the same as that used by the candidate, and the operating room staff's operational protocols could differ from the protocols familiar to the candidate. In the training situation, these difficulties can be overlooked as part of the global suspension of disbelief needed to maximize the benefits of simulator training. In the test situation, these differences potentially could skew the results. This issue could be addressed by allowing candidates preparing to take their examination to undergo sufficient practice sessions to familiarize themselves fully with the standard simulation environment used for the test.

Another situation of simulation-based performance assessment would be for the evaluation of trainees or experienced clinicians who have been placed on probation or for whom dismissal from their position is already a distinct possibility. For these clinicians, the burden of proof is on them to show their skills. Simulation could offer a more controlled environment for these clinicians to do so. The same could be true for practitioners who wish to return to clinical work after a hiatus.

The existing systems of performance evaluation, which use a haphazard composite of subjective judgment of clinical competency in clinical work along with written and oral examinations, has itself never been validated. Many experts believe that the written examination does not correlate well with clinical ability, and the degree to which the oral examination process tests actual clinical skill is unknown. Simulation could offer candidates the opportunity to show their clinical abilities in a controlled clinical domain; appropriate scenarios can also probe language skills and the ability to act as an effective consultant to other clinicians.[263-265]

In the United States, the ABA has been monitoring the progress of simulation for training and performance assessment. The ABA now requires attendance at a simulation training course at an ASA-endorsed simulation program in the 10-year cycle of MOCA for ABA diplomates[266] (Box 8-8). The course must be at least 6 hours in length, must provide every attendee a chance to be the primary anesthesiologist for a scenario, and must cover cases of hemodynamic instability, hypoxemia, and issues of teamwork and communication, and include postscenario debriefing. However, except for the formative assessment intrinsic to debriefing, the MOCA simulation course does not involve any performance assessment of participants and is specifically not an examination. The ABA announced in late 2012 that it will transition by 2017 to a new format for the Part 2 Examination, named the APPLIED Examination, to include an Objective Standardized Clinical Examination (OSCE) component along with the traditional structured oral examination component. An eight-member OSCE Development Advisory Panel has been selected, and it contains many individuals with extensive experience in simulation. The OSCEs may use part-task trainers, actors playing standardized patients or other role players, and other elements within the broad scope of simulation. It appears that the OSCEs will not use full-blown mannequin-based simulations.

BOX 8-8 ***Simulation as a Required Element of Part IV of the U.S. Maintenance of Certification in Anesthesia Program by the American Board of Anesthesiology (See Also Chapter 1)***

The simulation course must be held at a site endorsed by the American Society of Anesthesiologists (ASA), with a curriculum meeting minimum standards set by the ASA. Although not specifying anesthesia crisis resource management (ACRM) directly, the standards for the U.S. Maintenance of Certification in Anesthesia (MOCA) simulation are clearly derived from the ACRM simulation courses that have become common around the world:

- A minimum of 6 hours of total course instruction
- Active participation in realistic (mannequin-based) simulation scenarios
- Postscenario instructor-facilitated peer debriefing
- Management of difficult patient-care scenarios, including at least scenarios involving the following: (1) hemodynamic instability; and (2) hypoxemia of any cause, including management of the difficult airway
- An emphasis on teamwork and communication
- All participants have at least one opportunity to be the primary anesthesiologist in charge (i.e., the "hot seat")
- The instructor–to–student ratio must be no greater than 1:5 (i.e., at least one instructor per five participants)

The first 2 years' experience with the MOCA simulation course showed that participants consistently found the experience to be realistic, relevant, and likely to result in practice change.[266,274] During or after the course, participants must declare what changes they intend to make to their practice. They are queried electronically by the ASA 30 to 90 days after the course to determine whether they made those changes and/or what barriers they encountered in trying to do so. These data are analyzed by the ASA Simulation Editorial Board to attempt to determine the likely impact of MOCA simulation on clinical care by American Board of Anesthesiology diplomates.

Thus, reasonable arguments can be made that the field of performance assessment has advanced sufficiently to allow consideration of simulation-based examinations, including full mannequin-based simulations, even for high-stakes purposes, especially considering the limitations of the current systems of written and oral examination.[263] Nonetheless, simulation-based performance assessment remains a controversial topic for discussion in the simulation and clinical anesthesiology communities. The anesthesia professions should be careful about how they may introduce simulation-based performance evaluation.[267] The controversy should not divert attention from the most common application of simulation, which is to improve clinical performance through training individuals and team to prevent and manage adverse clinical events.

CHARACTERISTICS OF SIMULATION CENTERS

Although one can install a simulator in a laboratory or conference room, or conduct only in situ simulation, many institutions have chosen to construct complete simulation centers. Figures 8-21 and 8-22 show floor plans of medium-sized centers (two to four simulation rooms) for mannequin-based simulation. Typically, these centers provide a separate control room to allow complex simulations to be presented without an instructor intruding on the simulated case. The center also provides a debriefing room where videotapes of the simulation session can be reviewed. Some centers have elaborate computer-controlled audio-video systems allowing the recording of multiple views with real-time annotation rapid search to annotated portions of the recording. Figure 8-23 shows the simulator control room with advanced audio-video equipment at Rall's Center for Patient Safety and Simulation (TuPASS) in Tübingen, Germany.

Universities and hospitals or hospital networks are increasingly constructing very large multidisciplinary and multimodal simulation facilities. Often, these facilities combine all the types of simulation and immersive learning in one large unit, including actors playing standardized patients (usually in clinic settings), mannequin-based simulation, part-task and surgical and procedural trainers, wet and dry work (e.g., plaster casting or procedures on food products), and different forms of virtual reality. Sometimes these also incorporate facilities for dissection of cadavers or the use of anesthetized animals. Having all forms of simulation together also fosters hybrid techniques, as when an actor playing a standardized patient is combined with a part-task trainer, or when a surgical simulator is combined with a mannequin-based patient simulator. Large multidisciplinary facilities may have anesthesiologists in leadership positions. Figure 8-24 shows the floor plan of the center for immersive learning at Stanford University.

The cost structure of a simulation center is a complex issue (see the next section). The cost varies greatly depending on the scope of the facility and its programs, the nature of the target populations, and the extent of use by the different possible stakeholder groups. How the costs are allocated to different elements of an institution or consortium is equally complicated and depends highly on local conditions. No one formula for success exists. In some models, the center is wholly responsible for its own costs but is completely free to generate and retain revenue. At the other extreme is a model whereby the host institution bears all costs of operating a central core facility, but it also collects any and all revenues and may even tax components of the institution (e.g., departments) to offset the costs. Perhaps most common are mixed models in which the central authority bears the costs of initial construction and outfitting (often funded by philanthropy) and some portion of the ongoing infrastructure (simulation operations personnel, capital refurbishment, utilities), and each user (e.g., department) is responsible for providing instructors and paying for the marginal costs of any specific course or application. To date, few, if any, centers truly generate a profit, but many sites have successfully garnered external funds to offset some of the costs of training their own key target populations.

Figure 8-21. Multiroom simulation center at the Veterans Affairs–Palo Alto Health Care System and Stanford University (Palo Alto, Calif.). Two control rooms and two audiovisually interconnected lecture rooms provide the opportunity to run three patient simulators at the same time. *ER,* Emergency room; *ICU,* intensive care unit; *OR,* operating room.

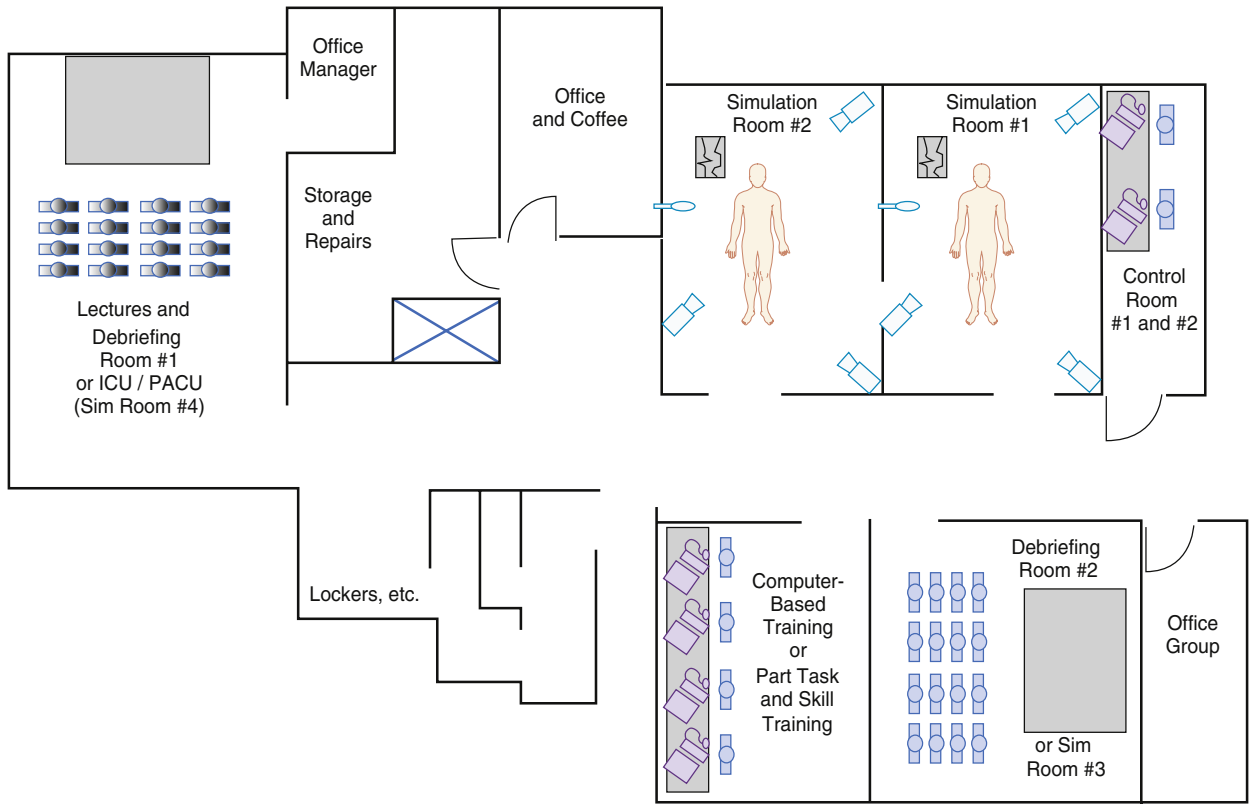

Figure 8-22. An intermediate-sized simulation center with four simulation rooms (Sim Room), a computer-based training room, and several multipurpose rooms, equipped with audio-video patch panels to adjust the room use flexibly to the needs of different training activities (e.g., the large seminar room also can be used as a large intensive care unit [ICU] or postanesthesia care unit [PACG]). *(Photograph by E. Stricker from the Center for Patient Safety and Simulation [TuPASS], Tübingen, Germany.)*

Figure 8-23. Simulator control room. On the left side is the simulator workstation for control of the simulator system itself. In the middle is the audio control desk with integrated control of the simulated patient voice and several wireless headset channels and the remote mixer. On the right are flat screens for selection and control of the multiple views of the video cameras. For anesthesia crisis resource management courses, a multiquad-split view, including the vital sign monitor, is digitally recorded on a hard disk and used for playback. Marks allow jumping to interesting scenes without fast forward or rewind delay. *(Photograph taken by M. Rall in the control room of the Center for Patient Safety and Simulation [TuPASS], Tübingen, Germany.)*

COSTS

What are the costs of simulator-based training? These costs depend on many of the same factors that determine the curriculum, as follows:

Types of training involved, ranging from technology in-service to training in basic anesthesia skills, critical incident management, or CRM
Target populations for the training, whether equipment technicians, medical students, novice residents, experienced residents, nurse anesthetists, teaching faculty, or private practitioners
Organizational and financial characteristics of the institution

The hardware and software costs of the screen-only simulators are quite low (a few hundred dollars), whereas the equivalent cost of a complete hands-on simulator is higher. The prices of commercial simulators range from approximately $25,000 for intermediate-capability simulators to more than $150,000, depending on features; one should contact the manufacturers for detailed information. Cumin and Merry reported on available simulators.[77] This cost does not include the necessary clinical equipment (which might run as high as $150,000) and space.[268] Even these large expenditures do not dominate in the cost equation, however, because the capital equipment can be amortized over a relatively long useful life, with appropriate provisions for service and upgrades.

The dominant cost is likely to be the salaries of expert instructors and trainees. An expert must oversee the curriculum, but the type of training and the target population determine the amount of expert instruction required. A single faculty member can review the summaries of exercises performed by residents on a screen-based simulator in a few hours per resident per year. Nonphysician instructors may be suitable for some task training or for drill and practice sessions. A single instructor can use the simulator to show pulmonary or cardiovascular physiology to a whole class of medical students. For training novice residents in basic anesthesia skills, it may be possible to have senior residents or fellows conduct the sessions at a low marginal cost. For training experienced residents and practitioners in complex material, such as the handling of critical events, no substitute for expert instructors is likely to exist. The cost of expert instruction depends on the organizational arrangements of the institution. In a teaching institution where faculty members all have at least some time allocated for teaching or scholarly activities, some faculty may choose to fulfill this requirement in simulation-based teaching or scholarship. When further staffing is needed, payment for clinical release time may be needed.

Another organizational factor that affects cost has to do with making trainees available for what can be complex, exhausting, and lengthy training sessions. Removing residents from revenue-producing work for training purposes is expensive. If simulator training could allow residents or other anesthesiologists to work more safely and efficiently, the benefit would outweigh the cost. Some residency programs provide protected time for education of residents (e.g., one half day per week). In such cases, residents should be available for educational activities, but faculty time may be even more scarce. Many anesthesia programs have used simulation training as a recruiting tool for residency candidates, although some experts believe that with the high proportion of programs that already have simulation activities (the scope and quality of which are difficult for applicants to judge), the competitive value of simulation has disappeared. Programs that lack such facilities and activities would be the exception and would likely be seen negatively by applicants.

Signs indicate that simulation team training may also improve job satisfaction and effectiveness of routine care, as well as contributing to reduced illness leave and job fluctuations.[269]

Without question, simulation-based training is more costly than exhorting learners to read or putting them in a room with a lecturer. Simulation-based training allows a host of issues to be addressed that cannot be easily tackled in other ways. It is our belief—one that has been borne out by programs "voting with their feet" since the 1990s—that if simulator-based training is deemed to be desirable, innovative changes in organization will evolve to allow it to occur.

PROLIFERATION OF SIMULATION CENTERS

Currently, despite the lack of definitive cost-effectiveness data, training with realistic simulators is under way in many sites around the world,[270] and many of these sites choose to conduct high-end crisis management and

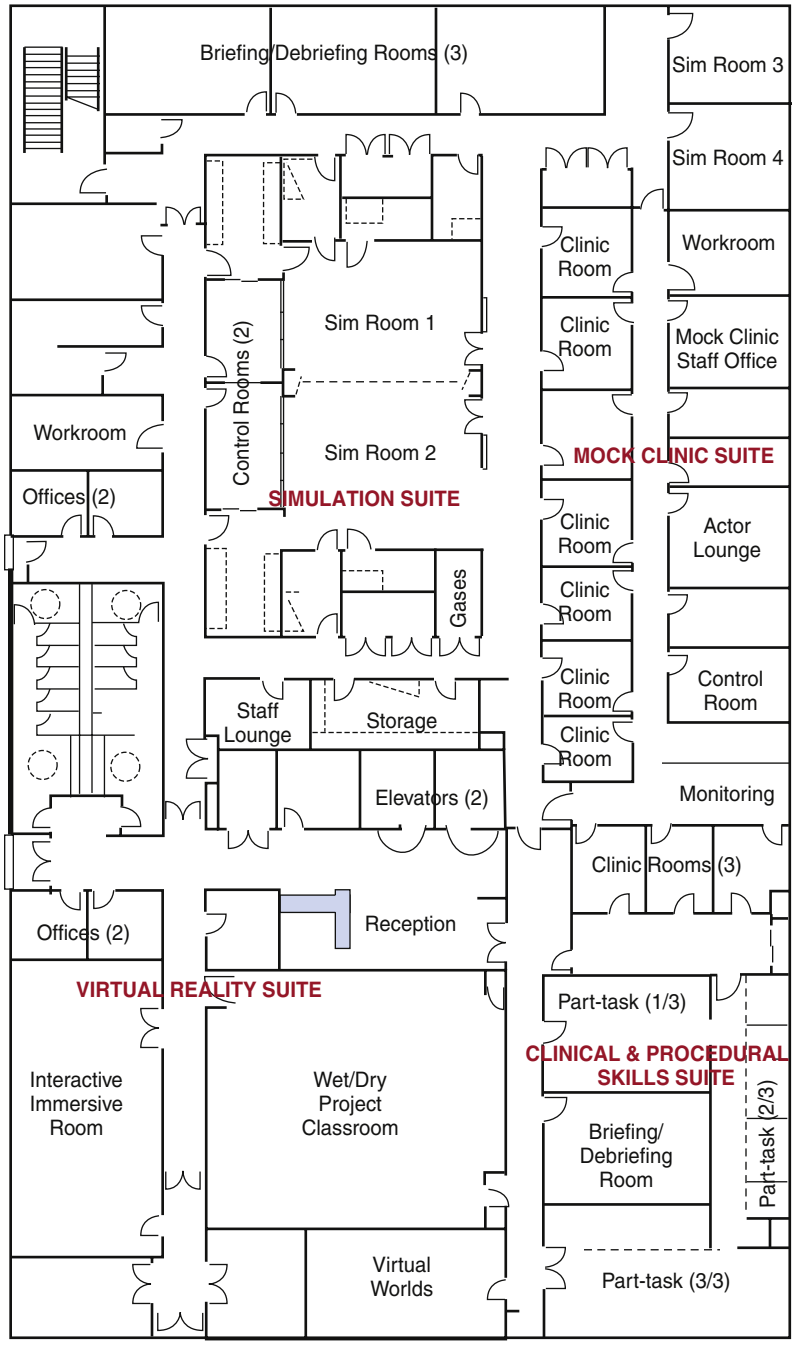

Figure 8-24. Floor plan of a large interdisciplinary simulation center for multiple domains (anesthesia, surgery, students) with several multipurpose simulation rooms (Sim Room) and skills laboratories. *(Photograph taken by D. M. Gaba at the Center for Immersive and Simulation-based Learning at Stanford Medical School, Palo Alto, Calif.)*

critical incident training sessions. Some useful websites of simulation centers and other resources are listed at the end of the chapter (Appendix 8-1). These programs have already voted with their feet on the issue of cost versus benefit. With so many centers exploring the realities of simulation training, we can expect to see additional data on efficacy and cost within the next few years. A definitive study is in principle possible, but it would require a very large number of subjects evaluated by multiple raters and would be complex and costly.

Still other factors complicate assessment of the effectiveness of simulator-based training. Studying the impact of a single session of a course that uses a new technology and a new approach to training may underestimate the course's impact when it is used on a regular and repetitive basis. It is widely believed in commercial aviation that CRM training must begin with the initial training of pilots and must be continued throughout their career. Social psychologists Helmreich and Foushee, two of the main architects of CRM training, wrote: "Data indicate that even intensive initial CRM training constitutes only

an awareness phase and introduction to the concepts, and that continuing reinforcement is essential to produce long-term changes in human factors practice." Similarly, United Airlines states in its CRM manual: "Command/Leadership/Resource management [United's terminology for CRM] cannot be a one-shot approach. It has to be a coordinated long range program. It must therefore be an integral part of the entire training effort: new hire training, transition and upgrade programs, and recurrent training."[271]

Finally, the principles and procedures taught in training must be reinforced within the operational environment. Simulator-based safety training can be totally negated if production pressures or latent failures in the workplace make it impossible to implement its teachings effectively.

It is still too early to make definitive statements about either the benefits or the costs of simulator-based training in anesthesia. To some extent, a catch-22 is involved. One cannot attempt to determine the true cost effectiveness until simulation is widespread enough for complex and expensive studies to be undertaken and until more experience has been gained on the different organizational aspects of providing the training. Many institutions are likely to shy away from taking the risk until the cost effectiveness is proven.

SIMULATION SOCIETIES: SOCIETY FOR SIMULATION IN HEALTH CARE AND SOCIETY IN EUROPE FOR SIMULATION APPLIED TO MEDICINE

One measure of the evolving maturity of simulation in health care consists of the formation and growth of professional societies focused on this topic. Although anesthesiology was the medical field that initiated work on the fully interactive mannequin-based simulator and that dominated the early developments in the field, simulation is a broad strategy that has now been widely adopted by many different disciplines and domains in health care. For the most part, simulation professional societies have sprung up as explicitly multidisciplinary organizations. Major leadership roles in these societies have been played by anesthesiologists and engineers associated with anesthesiology, however.

The largest simulation organization is the Society for Simulation in Healthcare (SSH; www.ssih.org), which was founded in 2004 as the outgrowth of the group that had operated the International Meeting on Medical Simulation for several years as a satellite to the annual meeting of the Society for Technology in Anesthesia. Under the new auspices of SSH, the meeting was transformed into the International Meeting on Simulation in Healthcare (IMSH), encompassing all health care disciplines and domains, not just medicine. Regular scientific congresses on simulation had been under way since the mid-1990s (the Rochester Conferences on Simulation in Anesthesia). Although they originally had approximately 100 attendees, Society in Europe for Simulation Applied to Medicine (SESAM) meetings have now approximately 400 attendees. The IMSH meeting in 2014 had nearly 3000 attendees. This number places it in the category of a medium-sized scientific meeting; to put this in the context of anesthesiology, it would rank as the third largest scientific meeting in the United States, falling below only the ASA meeting and the New York Postgraduate Assembly in Anesthesiology (PGA) conference, but ranking ahead of the International Anesthesia Research Society (IARS) annual meeting.

Another sign of the mainstream nature of simulation is that the SSH has published a quarterly peer-reviewed journal, *Simulation in Healthcare,* since 2006. This journal was approved for indexing by PubMed in 2008. It is an official publication of many international professional societies of simulation in health care, including SESAM (www.sesam.ws), the Australian Society for Simulation in Healthcare, and the Association of Standardized Patient Educators. The organizations have become affiliates of the SSH.

Another sign of maturity is the emergence of a trade organization for simulation in health care dedicated to educating and influencing policy makers, primarily concerning federal legislation and health policy. The Advanced Initiatives in Medical Simulation (AIMS) is a 501c6 organization that is allowed to lobby the U.S. government. What was previously seemingly the province of a few technologically minded anesthesiologists has blossomed into a substantial industry and profession with all the trappings of organizations, meetings, journals, and even lobbyists.

FUTURE OF PATIENT SIMULATION IN ANESTHESIA

The future is now—we are it.[272]

Although nearly 3 decades of consistent development have passed, the field of simulation in health care is still relatively new.[5,17,273] Thousands of simulators are in use around the world, many targeting anesthesiology and critical care, but the fraction of clinicians in these fields who have undergone a meaningful simulation experience is still small.

Simulators have become more sophisticated, and users now can choose from many different models offered by multiple manufacturers. Improvements in simulators depend on the demand for the devices and on the tradeoff between fidelity and cost. Many otherwise desirable improvements may be too costly for their expected impact. Technologic advances are likely to be targeted at portability and reliability, rather than at supporting increasingly esoteric feature sets. Many users have opted for simpler and cheaper simulators that use direct control, modest scripts, and finite state machines to control the changing state of the simulated patient, rather than complex mathematic models. This is partly because the production and use of robust mathematic models have been more difficult than anticipated.

In contrast to aeronautical engineers, physicians do not design and build the systems that they wish to model.

The fundamental differential equations of fluid mechanics and aerodynamics are firmly established, allowing supercomputers to provide technically meaningful simulations as replacements for many wind tunnel tests. There are still wind tunnel tests, however, and test flights of actual prototype aircraft. Sophisticated instrumentation can be built into test structures to define their behavior accurately. Physicians will never have this type of knowledge about the human body. The advantages and disadvantages of the various types of control logic for different applications are still being sorted out.

Interest has been growing in purely virtual reality simulations, often of a type similar to massive online games or to the popular Second Life system. Participating with others in the same virtual world, linked by the Internet, is appealing for many purposes. Such simulations are only as good as the "engines" that drive the underlying patients that may be found there, and the quality of the data provided and interventions and choices supported for implementation in these settings. Virtual reality proponents imagine a virtual reality so realistic that it rivals, or is indistinguishable from, the real world. This would approach the *Star Trek* holodeck. Although we once predicted that such systems could be in place by 2020, the development of such high-veracity virtual reality has not proceeded as quickly as previously imagined, and it is unclear whether full virtual reality of this nature will be available in the next decade.

Patient simulation has now become a regular part of initial and recurrent training of most anesthesia professionals and many other clinicians in the United States, Australia, and the United Kingdom and some other European countries. With patient simulation, the human error–based CRM concept was introduced to medicine as ACRM training, which revolutionized traditional methods and content of teaching and learning. The anesthesia community can be proud of its pioneering role in developing patient simulation technology and simulation-based training curricula, and anesthesiologists and others working with them continue to play dominant leadership roles in many settings of simulation, even those devoted to fields outside anesthesia.

If it can be shown that fully integrated simulation team training with a significant focus on human factors and CRM improves patient safety and acute care quality, and if this type of training is also shown to increase employee satisfaction and effectiveness of routine work, then we may expect a substantial increase in simulation team training as a de facto mandatory feature of clinical work because no one could afford not to use simulation in this way. Whether unequivocal data to this effect can be acquired or not remains to be seen.

Chapter 9

Teaching Anesthesia

MANUEL PARDO, Jr. • RANDALL M. SCHELL

Key Points

- Clinician educators are challenged with having to provide meaningful educational experiences for residents and students in an increasingly complex health care environment, under pressure to be clinically efficient and yet to ensure high quality and safe patient care.
- Additional challenges in anesthesia education include the need to integrate increasingly complex knowledge, to provide adequate clinical experiences (in the face of reduced trainee hours), to ensure acquisition of broad skills, to assess learners in a fair and comprehensive manner, and to ensure patient safety.
- To develop competence in any aspect of clinical care, learners must have a deep foundation of factual knowledge, understand facts and ideas in the context of a conceptual framework, and organize their knowledge to facilitate retrieval and application.
- Competency-based medical education is an approach that incorporates trainee outcomes in the design, implementation, assessment, and evaluation of medical education.
- Competency-based education principles can be combined with a model of skill acquisition to develop a framework for performance assessment. The Dreyfus model describes five stages of development ranging from novice to master.
- The educator in anesthesiology may encounter a wide variety of learners, including anesthesia residents and fellows, medical students, student registered nurse anesthetists, anesthesiologist assistants, and anesthesiologists in continuing medical education courses. In addition to training anesthesia providers, the educator in anesthesiology must also be able to provide appropriate experiences for other trainees in specialties such as otolaryngology, head and neck surgery, plastic and reconstructive surgery, orthopedic surgery, oral-maxillofacial surgery, and emergency medicine.
- Residency programs in the United States are accredited by the Accreditation Council for Graduate Medical Education (ACGME). In addition, the ACGME offers accreditation for anesthesia fellowships in critical care medicine, pain medicine, pediatric anesthesiology, adult cardiothoracic anesthesiology, and obstetric anesthesiology.
- The ACGME established a framework for "milestones" of competency development and advocated for implementation of common evaluation tools in each discipline to document resident achievement of the milestones.
- Resident duty hours have been the focus of much discussion and considerable debate in graduate medical education for several decades. The ACGME recently added additional restrictions on duty hours.
- The ACGME requirements also address new standards for supervision, teamwork, transitions of care, fitness for duty, alertness management, and fatigue mitigation that affect the educational environment.
- Good clinical teaching is multifactorial with emphasis on the noncognitive aspects of teaching (e.g., developing positive relationships with students, creating a supportive learning environment, communication skills, and enthusiasm) more so than the cognitive aspects (e.g., clinical knowledge and reasoning).
- Experienced clinical teachers make use of "teaching scripts" to guide many of their teaching interactions. A teaching script includes three to five teaching points with supporting material, an overview of common errors made by learners, and effective ways to create a framework for understanding.

Key Points—cont'd

- The amount of self-study by residents correlates with scores on anesthesia resident in-training examinations (ITEs). ITE scores predict subsequent performance on certifying examinations.
- Advances in education technology provide new models to deliver content (e-Learning, podcasts), teach and assess (simulations), provide collaborative learning environments (wikis), and increase classroom interactivity (audience response systems).
- Although delivery of anesthesia is the primary responsibility of anesthesiologists, education, responsibility, and leadership in the entire perioperative environment is important. In addition, anesthesiologists frequently have the responsibility for critical care medicine and both inpatient and outpatient pain medicine.
- Advances in the education of anesthesia providers are occurring all over the world (see Chapter 2). While this chapter emphasizes American educational principles, anesthesia educational approaches and systems are extensively being improved in accordance with the increasing complexity of anesthesiology and its responsibilities.

BACKGROUND AND HISTORY OF ANESTHESIA EDUCATION (ALSO SEE CHAPTER 1)

Education in the medical specialty of anesthesiology began after the initial public demonstration of ether as a method to reduce pain during a surgical procedure. Based on that introduction to the use of volatile anesthetics, in 1850, John Collins Warren, a general surgeon at the Massachusetts General Hospital, delivered an address to the American Medical Association on the progress of surgery, including practical advice on how to administer ether safely.[1] He outlined nine steps, many of which remain critical elements in the safe administration of anesthesia today. His steps included recommendations regarding the need for the patient to be fasting, supine positioning, monitoring of pulse and respirations, evaluating the level of muscle relaxation as a sign of anesthetic depth, and avoiding cautery when administering ether anesthesia because of the risk of fire. These principles provided the foundation upon which to begin to train physicians in the practice of anesthesiology. Despite the acknowledgement of the need for training regarding anesthesia administration and safety, formal training programs in anesthesiology did not become the norm until the twentieth century. Initially, implementation of anesthesia care was provided by medical students, interns, and ward nurses, none of whom had any formal or informal training or experience in anesthesia. Although some of the steps described by Warren were addressed, the "art and science" of anesthesia practice were undervalued. In fact, at institutions such as the Mayo Clinic in Rochester, Minnesota, surgeons William and Charles Mayo believed that nurses were better suited to provide anesthesia since "the intern was naturally more interested in what the surgeon was doing."[2]

The first formal anesthesia training program was developed by Ralph Waters at the University of Wisconsin in the late 1920s.[3] The program included didactic elements such as case conferences, Grand Rounds, and literature reviews, for the most part based on models from other specialties. Anesthesia residents, who spent 3 years in training, were responsible for patient care, research, and teaching of medical students and interns. Many of the graduates of the training program at the University of Wisconsin went on to become chairs of other academic departments, disseminating Water's model for academic anesthesiology in the United States, Canada, and the United Kingdom.[4] Although anesthesiology was recognized as a critical skill in caring for surgical patients, anesthesiology was considered a subordinate medical specialty to surgery. Few departments of anesthesiology existed in any U.S. medical schools, and the majority of anesthesia training programs were apprenticeships managed as a division of the Department of Surgery.

Certification in anesthesiology followed a similar course to the formal educational programs. The American Board of Anesthesiology (ABA) was established in 1938, initially as a subordinate board to the American Board of Surgery. The transition to a separately recognized medical specialty followed shortly thereafter with the ABA becoming an independent board in 1939. The ABA helped define the training and clinical experience required to practice anesthesiology by specifying that anesthesiologists had to complete at least 3 years of postgraduate training, have some experience in clinical practice, and pass a series of examinations (written, oral, and practical) to achieve diplomate status.[5] Despite the ABA definition of a curriculum and continuum to achieve board certification, for many of the early years, most residencies were more apprenticeships than formal educational programs.

Medical education and health care delivery have been transformed since the days of the first training program and the founding of the ABA. This chapter addresses the principles of education in anesthesiology during formal residency and fellowship programs and throughout one's career, with an emphasis on both learning and teaching

the principles and practices of anesthesia. Although these principles and practices are relevant to almost any anesthesia practice, the chapter uses specific examples that for the most part reflect the approach to training in the United States. See Chapter 2 for international perspectives on anesthesia training.

CHALLENGES IN MEDICAL EDUCATION

Education and training in anesthesiology and all other medical specialties has evolved considerably since the administration of the first ether anesthetic. Because of the many changes in patient population, surgical and other approaches to managing clinical problems and the major advances in anesthesia care, the concept that clinical experience alone is adequate to prepare the anesthesia provider, is not sufficient. The concept of an apprenticeship in anesthesiology—or the notion that one can isolate oneself behind the "ether screen" disinterested in what a surgeon or other physician is doing—is not an acceptable model of care or training. Anesthesiology has a sound scientific foundation and as a result has fostered development of new technologies and approaches to clinical care within and beyond the operating room that allow patients with complex underlying comorbidities to safely undergo procedures that were previously not possible. While our understanding of the principles and practice of anesthesia evolved with exponential increases in medical knowledge, these other advances in medical technology and changes in health care delivery have created opportunities and challenges related to anesthesia training. For example, whereas medical education continues to be focused on hospitalized patients, particularly those undergoing procedures in an operating room, an increasing amount of patient care has shifted to settings less familiar to the anesthesiologist, including the outpatient setting. Anesthesia practice is no longer restricted to the surgical suite. At the same time, the clinical instructors are under pressure to generate additional income from patient care activities and to improve efficiency of care. Health care systems focus on financial viability and must respond to external pressures to demonstrate quality of care. Accrediting agencies such as The Joint Commission and Centers for Medicare & Medicaid Services provide increasing scrutiny of many aspects of clinical care. Against this backdrop, the Carnegie Foundation for the Advancement of Teaching issued a report calling for reform of medical school and residency, 100 years after their influential Flexner Report of 1910.[6] They identified four goals for medical education:

1. Standardization and individualization: standardizing learning outcomes through assessment of competencies, while also individualizing the learning process
2. Integration: connecting formal knowledge to clinical experience; integrating basic, clinical, and social sciences; incorporating interprofessional and teamwork education into the curriculum
3. Habits of inquiry and improvement: preparing learners to develop expertise, engaging learners in challenging problems including quality improvement and patient safety
4. Formation of professional identity: offering feedback and assessment of professionalism, promoting relationships with supportive faculty who encourage high standards, creating collaborative learning environments committed to excellence and improvement

The challenges in anesthesia education reflect these larger issues (Box 9-1).[7]

LEARNING PRINCIPLES AND LEARNING STYLES

A basic understanding of the science of learning can provide context for teachers as they try to meet these challenges. Over the last 40 years, research on learning, cognitive psychology, social psychology, and anthropology has resulted in an evolving understanding of the scientific basis of learning. The National Academy of Sciences prepared a monograph synthesizing this literature.[8] The key findings, which are relevant to learners of all levels in all disciplines, include the following learning principles:

1. Learners bring preconceptions about how the world works. If their initial understanding is not engaged, they might fail to understand the material that is presented.
2. To develop competence in a topic, learners must have a deep foundation of factual knowledge, understand facts and ideas in the context of a conceptual framework, and organize their knowledge to facilitate retrieval and application.
3. Metacognition refers to the learner's ability to monitor the state of their knowledge of a particular topic. A metacognitive approach to instruction can help learners take control of their learning by defining goals and monitoring progress toward achieving them.

BOX 9-1 *Challenges in Anesthesia Education*

Quantity of Knowledge

- Exponential growth in knowledge—impossible to master the anesthesia literature

Adequate Patient Care Experiences

- Duty hour restrictions affect amount and continuity of patient care
- Health system emphasis on efficiency can exert pressure to minimize trainee involvement
- Appropriate use of education technology (e.g., computer, Internet, simulation) or other means to supplement direct patient care experiences

Learner Assessment

- Competency-based education expected by accreditation bodies
- New assessment methods (e.g., milestones) require faculty training to obtain meaningful measurements

Patient Safety in Era of Cost Containment

- Providing adequate supervision of trainees
- Promoting learner autonomy and preparedness for independent practice

Adapted from Bould MD, Naik VN, Hamstra SJ: Review article: new directions in medical education related to anesthesiology and perioperative medicine, Can J Anaesth *59:136-150, 2012.*

Key aspects of the learning environment are displayed in Figure 9-1. Examples of strategies in the application of these learning principles in anesthesia teaching are shown in Table 9-1.

A *learning style* refers to the complex way that an individual prefers to acquire and process information. The VARK learning style uses the learner's preferred sensory mode of receiving information.[9] The *visual learner* is said to process new information best when it is visually presented, such as with tables, graphs, and diagrams. The *auditory learner* processes new information best by listening, explaining ideas to others, or engaging in group discussions. The *read/write learner* prefers to use textbooks, handouts, and note taking when receiving new information. The *kinesthetic learner* processes new information best when it can be touched or manipulated, such as with concrete, multisensory experiences. This learner responds well to laboratory demonstrations and experiments, and they will likely enjoy participating in simulation activities.

There is no evidence that matching teaching style to the learning style of an individual improves learning outcomes in medical education. The rationale for teachers to understand learning styles is to be cognizant of instructional methods that correspond to the varied learning styles in a group of learners. In addition, knowledge of a particular student's preferred learning style can help a teacher explain a difficult or challenging topic.

ANESTHESIA LEARNERS

Although anesthesia education is generally defined in terms of the training of anesthesiologists through formal residency programs, the learner may be at any of a number of levels of experience and training. In some cases, the learners are from other specialties or professions for which anesthesia training and care are critical elements. With the continuing advances in the science and practice of anesthesiology, the need for continuing education by practicing anesthesiologists, as well as the need for retraining, has taken on greater importance. As a result, the anesthesia educator will encounter a wide variety of learners, including anesthesia residents and fellows, medical students, student registered nurse anesthetists, and anesthesiologist assistants (AAs). In addition, the training programs of specialties such as otolaryngology, head and neck surgery, plastic and reconstructive surgery, orthopedic surgery, and oral-maxillofacial surgery require anesthesia rotation experiences. Practicing anesthesiologists also require continuing medical education and ongoing documentation of clinical competence. As a result, the educator must understand the background, experience, and goals of each learner and develop a curriculum to address their needs.

It is a challenge to address the educational needs of such a diverse group of trainees. One approach is to consider the learner's professional practice after formal training is concluded, and the specific anesthesiology knowledge that will be most relevant. In addition, the educator should determine the current state of the learner's knowledge about anesthesiology in order to design the appropriate learning experience. For example,

TABLE 9-1 APPLYING LEARNING PRINCIPLES IN ANESTHESIA TEACHING: EXAMPLES

Learning Principle	Teaching Strategies
Teachers must determine learners' preexisting understanding	Use open-ended questions In lecture setting, use pretest or audience response system as first step In case discussion, allow learners to share prior experience after case stem is first introduced
Teachers must know common conceptual barriers (misconceptions) and effective strategies for teaching	Use a variety of teaching materials (e.g., textbooks, web pages, simulations, videos, podcasts) Use a variety of teaching methods (e.g., demonstrations, discussions) rather than just one (e.g., lecture)
Learning environment should be knowledge centered	Emphasize practical application of knowledge (e.g., if studying basic science topic, find clinical application) Draw links from what is being learned to examples in practice that learner wants to become competent at.
Learning environment should be assessment centered	To review a topic, use practice questions instead of simply restudying topic For residents who will take American Board of Anesthesiology board examinations, show how topic being discussed was covered on previous examinations (e.g., examinations keywords)

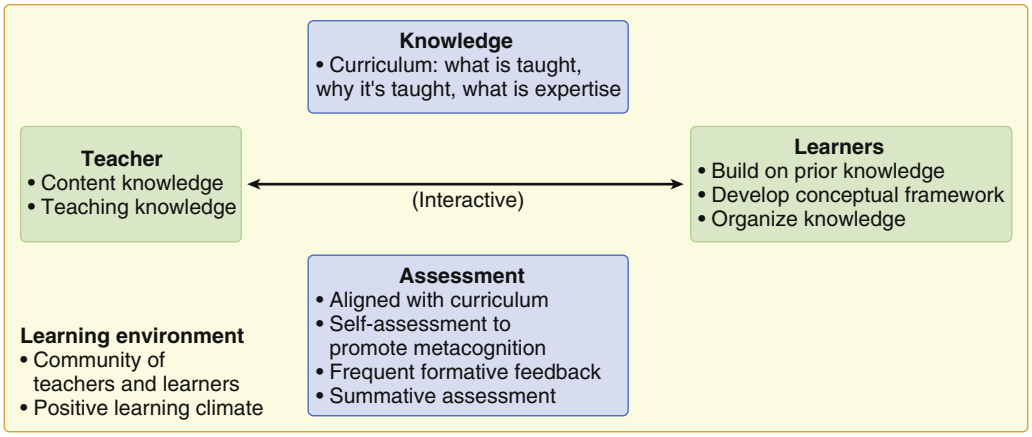

Figure 9-1. Key aspects of the learning environment.

an otolaryngology–head and neck surgery resident may participate in a 1-month anesthesiology rotation as an intern. Appropriate goals of the experience may include preoperative evaluation, airway assessment, and prediction of difficult mask ventilation and tracheal intubation. Topics such as regional anesthesia or epidural anesthesia are likely to be less relevant to this group of learners.

Continuing education and the training of nonanesthesiologists in some aspects of anesthesia care are important, but the primary focus of this chapter is on the training of medical students and anesthesia residents and fellows in the United States. For these trainees, the elements of an anesthesia curriculum include formal and informal didactics, appropriate clinical assignments, and other learning activities. The curriculum is generally conducted over a defined time span, which can vary from 1 to 2 weeks for a medical student rotation to 3 to 5 years for anesthesia residents and fellows. The specific educational goals, clinical exposure, and didactic sessions vary considerably for each level of training.

MEDICAL STUDENTS

The foundation of an anesthesiologist's medical knowledge and clinical skills is established during medical school. Therefore, anesthesia educators must be aware of the medical student curriculum and how clinical skills are being taught. Table 9-2 displays the number of medical students, full-time faculty members, and anesthesiology faculty members in the United States. Anesthesiologists represent a small percentage of medical school faculty members, but should be involved in medical school curriculum committees to understand the school's curriculum management process and potentially influence the curriculum to incorporate anesthesia experiences. Although many medical schools do not mandate an anesthesia clerkship for its students, there are several advantages to a required ("core") clerkship in anesthesia.[10] While providing exposure to the practice of anesthesia may seem the most obvious, a focus on topics of relevance to all medical students may be more appealing to medical school curriculum planners. Topics within the expertise of the anesthesiologist include applied cardiovascular and pulmonary physiology, clinical pharmacology, pain management, preoperative evaluation, care of the critically ill patient, and basic and advanced cardiac life support. In addition, anesthesiologists are capable of teaching basic procedural skills such as airway management and vascular access placement. Besides providing teaching content, anesthesiologists can influence medical student attitudes toward anesthesia. Finally, although many factors affect specialty choice, students who choose anesthesiology careers are more likely to have taken an anesthesiology clerkship.[11]

The traditional clerkship model is a one-discipline experience, typically inpatient-focused during the latter half of the undergraduate medical curriculum. A traditional anesthesia clerkship would include clinical assignments focusing on intraoperative patient care plus didactic sessions covering predetermined topics. An example of the structure of a 2-week anesthesia clerkship is shown in Table 9-3. A new model for the structure of the core clinical clerkship year is the longitudinal, integrated clerkship.[12] The term *longitudinal* refers to the 6- to 12-month period that students spend in a multidisciplinary setting. The organizing principle of this model is continuity. The integration of disciplines takes place via an integrated schedule of discipline-based experiences or by having the student see the variety of patients seen by a primary care physician.[12] This approach allows a student to appreciate a patient's perspective of the health care system, and it provides the opportunity to care for the patient through an entire illness episode even if different

TABLE 9-2 NUMBER OF MEDICAL STUDENTS AND FULL-TIME FACULTY (TOTAL AND ANESTHESIOLOGY-SPECIFIC) IN U.S. MEDICAL SCHOOLS

Academic Year	Number of Medical Students	Total Number of Full-Time Faculty	Number (% of Total Faculty) of Full-Time Anesthesiology Faculty
1990	65,081	72,320	3393 (4.7)
1995	67,030	90,016	4535 (5)
2000	66,500	102,446	4979 (4.9)
2005	68,280	119,025	5471 (4.6)
2010	75,394	133,452	6469 (4.8%)

Data from Rowley B, et al: Graduate medical education in the United States, JAMA *264:822-832, 1990; Graduate medical education,* JAMA *274: 755-762, 1995; Graduate medical education,* JAMA *284:1159-1172, 2000; Graduate medical education,* JAMA *294:1129-1143, 2005; Brotherton SE, Etzel SI: Graduate medical education 2006-2007,* JAMA *298:1081-1096, 2007; Brotherton SE, Etzel SI: Graduate medical education 2010-2011,* JAMA *306:1015-1030, 2011; and The Association of American Medical Colleges. TABLE 9-3 SAMPLE SCHEDULE FOR 2-WEEK MEDICAL STUDENT ANESTHESIA CLERKSHIP

	Monday	Tuesday	Wednesday	Thursday	Friday
Week 1	Orientation Airway workshop Sedation lecture	Clinical assignment	Preoperative assessment lecture Clinical assignment	Clinical assignment	Clinical assignment
Week 2	Simulation/crisis management session Clinical assignment	Case conference Clinical assignment	Grand rounds conference Clinical assignment Acute pain lecture Mechanical ventilation lecture	Clinical assignment	Clinical assignment Reflections session

Learning activities:

- Clinical assignment—clinical teaching by faculty and residents
- Interactive workshops—airway management, simulation/crisis management, reflections
- Lectures—sedation, preoperative assessment, acute pain, mechanical ventilation
- Case-based conferences—case conference, grand rounds

specialty care is needed. An example of how to integrate the discipline of anesthesia into a longitudinal integrated clerkship is shown in Box 9-2. One obvious disadvantage is the time lag between anesthesia clinical experiences, but the continuity of the faculty preceptor allows a focus on the learning goals not yet achieved by the student. Many factors influence the rate of adoption of longitudinal clerkship models, including financial implications and the need for faculty time and training.

GENERATIONAL DIFFERENCES IN LEARNERS

The focus on learner-centered educational environments has implications for teachers and learners. Teachers should be aware that the new generation of learners has been taught with different approaches to meeting learning objectives using more interactive teaching approaches and technology. Teachers are undoubtedly aware that there are generational differences in today's learners. In medical schools, most students are members of one of two generational cohorts: Generation X (born between 1965 and 1980) and Millennial (born between 1981 and 1999). One medical school surveyed more than 800 graduates who matriculated between 1989 to 1994 and 2001 to 2004.[13] The survey tool was the 16 Personality Factor Questionnaire, which measures 16 independent dimensions of personality. Millennial students scored significantly higher than Generation X students on factors such as rule-consciousness, emotional stability, sensitivity, and perfectionism. Generation X students scored higher than Millennial students on self-reliance. It is unclear how (or whether) medical schools, residency, and fellowship programs should adapt to the new generation of learners. Educators have questioned whether changing personalities should lead to changes in the teaching of medical professionalism, advising and mentoring programs, and faculty development.[13]

Teachers should be aware of generational changes in their learners, but learners should be aware of the expectations for excellence of their teachers. At the resident level, there are several features that have characterized excellence (Box 9-3).[14] Another framework is to consider the seven core tasks that may be required of a teacher (Table 9-4), and to determine the corresponding task required of the learner (Table 9-5).[15]

BOX 9-2 *Example of Longitudinal Anesthesia Clerkship Experience*

- Time period of clerkship: 1 year
- Time assigned to anesthesiology: 6 days
- Didactic sessions: six lectures, simulation workshop
- Continuity of anesthesia preceptor: one preceptor for all 6 days
- Required patient care experiences and learning goals
  - Orthopedic surgery patient: exposure to regional anesthesia, laryngeal mask placement
  - General surgery patient: basic anesthesia drug pharmacology, airway management, approach to postoperative pain
  - Major spine surgery patient: monitoring, approach to transfusion
  - Gastric bypass patient: approach to difficult airway management, postoperative pain, and patient safety

RESIDENT AND FELLOW EDUCATION

ROLE OF THE ABA, ACGME, SCHOOL, AND DEPARTMENT

The educational curriculum and core competencies in anesthesia residencies are defined by the Accreditation Council for Graduate Medical Education (ACGME) and the ABA. The residency programs in the United States

BOX 9-3 *Select Features That Characterize Excellence Among Resident Learners*

1. Great fund of knowledge and the ability to apply that knowledge to patient care
2. Skill in performing essential tasks of daily practice
3. Curiosity and love of learning; seeking to understand "how" and "why"
4. Approach to errors: making the most of their own mistakes and those of others, and use to improve their practice
5. Conscientiousness: effective and efficient use of time; enjoy doing a good job for patients and colleagues
6. High degree of personal initiative; doing what is required and then going beyond
7. Reliability: when asked to do something, they can be relied upon to see that it gets done
8. Affable: tend to be liked by most because they treat people fairly and respectfully and have a genuine interest in the well-being of others
9. Character: honest, unselfish, understanding of others, trustworthy

TABLE 9-4 **REQUIRED TEACHING TASKS AND DESCRIPTIONS**

Task	Description
Teach in clinical setting	Teach appropriate knowledge, skills, attitudes
Teach large and small groups	Prepare and deliver lecture; choose and manage appropriate small group format
Facilitate and manage learning	Assist trainee in achieving learning goals; advise and mentor for career goals
Plan learning	Manage the curriculum development process, from needs assessment to implementation
Develop and work with learning resources	Create instructional materials, including handouts and multimedia resources; use appropriate technology including Internet-based and clinical simulation
Assess trainees	Use appropriate assessment tools for learning setting and assessment goal
Evaluate courses and undertake research in education	Use appropriate methods to evaluate courses, teachers, and resource materials; encourage research in medical education

Adapted from Hesketh EA, Bagnall G, Buckley EG, et al: A framework for developing excellence as a clinical educator, Med Educ *35:555-564, 2001.*

are accredited by the ACGME. In addition, the ACGME offers accreditation for the following anesthesia fellowships: critical care medicine, pain medicine, pediatric anesthesiology, adult cardiothoracic anesthesiology, and obstetric anesthesiology. The number of anesthesiology core residency and ACGME subspecialty trainees is shown in Tables 9-6 and 9-7. The ACGME sets forth common program requirements that address issues relevant to all graduate medical education training programs, including institutional responsibilities, program personnel and resources, resident appointments, educational program, evaluation, resident duty hours in the learning and working environment, and program innovations.[16]

While the ACGME accredits residency programs, the ABA provides certification to individual anesthesiologists. Anesthesia residents are offered an annual in-training examination (ITE). After conclusion of residency training, an eligible resident takes the ABA Part 1 (written) and Part 2 (oral) examination. In 2012, the ABA divided the Part 1 examination into two parts. The Basic Examination (written, multiple choice), focusing on basic science and basic clinical aspects of anesthetic practice, is taken at the start of CA-2 year, and an Advanced Examination (written, multiple choice), focusing on clinical aspects of anesthetic practice and emphasizing subspecialty-based practice and advanced clinical issues, is taken after completion of residency.[17] The Applied (oral) Examination is currently scheduled to begin in 2016. It will be taken after successful completion of the Basic and Advanced Examinations, and it will include an objective structured clinical examination (OSCE) component. The ABA publishes a content outline that is used to determine subject matter for the ITE, as well as for the Basic and Advanced Examinations that are part of the certification process (Appendix 9-1). It is a common practice for training programs to address many of these topics in the didactic elements of the curriculum. The ABA also grants certification in anesthesiology subspecialties including critical care medicine,

TABLE 9-5 TEACHING TASKS AND LEARNER ROLES

Teaching Task	Learner Role	Learner Description
Teach in clinical setting	Clinical learner	Be a "cognitive apprentice." Observe and apply thinking processes used by clinicians. Apply skills learned; discover and reflect on new concepts.
Teach large and small groups	Information receiver	Ensure understanding, relate to prior knowledge (e.g., use textbooks or other resources). Teaching peers may help solidify understanding. Ask questions: "Why is this subject being presented?" and "What do I know about this subject?" Note problems of understanding and ask questions.
Facilitate and manage learning	Teaching facilitator, mentee	Should not be an "empty box" passively receiving information. Should act as teacher's facilitator, listening but ready to react. Intention to learn should be clear. Help lead teacher to the point most important for progress. As mentee, learner should give teacher urge and motivation to continue working with interest and enthusiasm. Do this by being present, curious, and involved.
Plan learning	Curriculum co-planner, active participator	Learner should understand demanding nature of medical curriculum, should make effort to keep up with pace of instruction, and alert teacher if pace is too rapid or slow. Learner should participate actively in curriculum.
Develop and work with learning resources	Resource consumer	Use ("consume") learning resources, including those offered by teacher and external resources. Main challenge is often what not to consume, given proliferation of information available on the Internet.
Assess trainees	Teacher's assessor	Should strive for valid, reliable, fair, and congruent way to assess whether teacher delivers course or instruction effectively. Also need to assess teacher's professional interactions.
Evaluate courses and undertake research in education	Curriculum evaluator	Provide feedback on courses and curriculum to enable teacher to adapt or modify curriculum to meet learner needs.

pain medicine, hospice and palliative medicine, sleep medicine, and pediatric anesthesiology. The number of certificates issued is published by the American Board of Medical Specialties (ABMS), of which the ABA is 1 of 24 medical specialty member boards[18] (Table 9-8).

Although the ABA and ACGME provide content and program requirements, this alone does not ensure that anesthesiologists are trained to meet the current and future needs of our specialty. Both organizations have approved innovative approaches to training residents, including integrating core residency and fellowship programs and combining core residency and research training to foster academic careers.

The roles of the department and school involve providing a variety of resources for training programs. Department faculty members are the primary teachers and evaluators for residents. Department chairs must ensure that an appropriate amount of nonclinical time is allocated to meet the administrative and teaching needs of faculty. Resident (and ACGME fellow) salaries are largely funded by Medicare, although there is a cap on the total number of positions funded. If Medicare funding decreases and hospitals do not provide financial support, then departments have to fund positions or decrease the number of residents. The institution (department, school, or teaching hospital) must also provide adequate space and equipment for the education program, including classrooms, study areas, office space, and on-call facilities.

RESIDENT EDUCATION

Over the past few years, medical education has been refocused on documentation of specific competencies as a measure of proficiency and a guide to advancing from one level of training to another. This concept of deconstructing the abilities of a professional into parts, called *competencies*, was first described over 60 years ago as a way to focus on the outcome of an education program. In medical education, competency-based approaches gained prominence

when they were adopted as a framework for evaluation in the United States, Canada, and Scotland—and now in many other countries. *Competency-based medical education* refers to an "outcomes-based approach to the design, implementation, assessment, and evaluation of medical education programs, using an organizing framework of competencies."[19] A *competency* refers to an observable ability of a health professional (e.g., knowledge, skills, attitudes) that can be measured and assessed. The term *competent* refers to "possessing the required abilities in all domains in a certain context at a defined stage of medical education or practice."[19] To have value as a tool for documenting capabilities, a competency must be able to be observed, measured, and assessed, rather than simply described.

The main principles of competency-based medical education (CBME) include the following[19]:

1. Focus on outcomes: This includes ensuring that every graduate is prepared for practice and that they are competent in all domains of their intended practice.
2. Emphasis on abilities: Curriculum is organized around competencies or abilities rather than long lists of knowledge objectives.
3. De-emphasis on time-based training: CBME can shift focus to the abilities actually acquired during training rather than time spent in training.
4. Promotion of greater learner centeredness: CBME encourages learners to take responsibility for their progress through training by mapping out a transparent pathway from predefined milestone to milestone on the path to becoming competent, and beyond.

The terms *competence* and *competency* can be confusing when one considers the spectrum of performance of a given practitioner.[20] To simplify the terminology, a *competency* can be considered a skill, and *competence* can be considered a point on the spectrum of performance. For example, nasogastric tube insertion is a patient care competency. An intern may be competent (has the ability) to insert the nasogastric tube (the competency), but may not be an expert at the procedure. Thus, although ensuring that practitioners are competent may be a goal of CBME, teachers (and learners) should also be concerned with developing higher (i.e., more skillful) levels of performance. In addition, one may be competent at one point in time, but not maintain competence, or can be competent to perform a task in one setting but not another. One might also be competent under ideal circumstances without pressure or stress, but not maintain the same level of competence in urgent or emergent situations.

ACGME CORE COMPETENCIES

In 1999, the ACGME began its Outcome Project to change the focus of residency accreditation from the structure and process of training to the outcomes of training—that is, competency-based medical education.[21] In the first phase of the Outcome Project, programs defined objectives to demonstrate learning in the competencies. In phase 2, programs integrated competencies into their curriculum and assessment. In phase 3, programs were to use resident performance data as a means for program improvement. In phase 4, the ACGME intends to focus on identifying benchmark programs. The deconstruction of the work of a physician to six core competencies (patient care, medical knowledge, professionalism, interpersonal and communication skills, systems-based practice, and practice-based learning and improvement) occurred after considering 84 potential physician competencies in 13 categories.[22] Since then, the six core competencies have also been adopted by medical schools, certifying boards (including the American Board of Anesthesiology), continuing medical education programs, the American Osteopathic Association, and The Joint Commission. The ACGME competencies are incorporated in the common program requirements for all specialties. The specific language used is contained in Appendix 9-2. Two of the competencies (Systems-Based Practice and Practice-Based Learning and Improvement) can be difficult to understand based on their name alone, especially for individuals who have not used those terms in other settings. Examples of how the work of an anesthesiologist can be described by competencies are provided in Table 9-9. Specialty-specific Residency Review Committees (RRCs) determine the program requirements for both residencies and fellowships. The specialty program requirements must incorporate all aspects of the ACGME core program requirements. Key structural elements of the Anesthesiology Program Requirements are listed in Box 9-4.

The widespread adoption of the competency model was accompanied by a proliferation of assessment tools to assess resident achievement of the competencies. In 2000, the ACGME, in conjunction with the ABMS, published a Toolbox of Assessment Methods that listed 13 assessment tools: 360-degree evaluation, chart stimulated recall oral examination, checklist evaluation, global rating, objective structured clinical examination, case/procedure logs, patient surveys, portfolios, medical record review, simulations, standardized oral examinations, standardized patient examination, and written examination.[16] A review of four evaluation tools (global ratings, 360-degree evaluations, direct observation, and portfolios) sought to determine

Anesthesia Event	Relevant ACGME Competencies
Evaluate patient in preoperative clinic	Patient Care, Interpersonal and Communication Skills
Determine dose of intravenous anesthetic	Medical Knowledge
Place internal jugular central venous line	Patient Care
Interact with operating room and PACU nurses	Professionalism, Interpersonal, and Communication Skills
Patient with nerve injury—refer to quality improvement/patient safety committee	Systems-Based Practice
Patient with central line infection—compare prevention strategy with medical literature	Practice-Based Learning and Improvement

ACGME, Accreditation Council for Graduate Medical Education; *PACU,* postanesthetic care unit.

whether the six general competencies can be measured independently of one another in a reliable and valid manner.[23] The studies did not find a method to assess the competencies as independent constructs, with the exception of medical knowledge. Instead, the available assessment tools related to several different competencies. For example, one large study examined global evaluations from more than 1300 residents in 92 specialties.[24] Whereas the global evaluations asked faculty to rate residents on items in all six competencies, analysis of the ratings found that two independent factors could explain most of the variance in the evaluations. The two factors were described as "medical knowledge, patient care and systems-based care" and "interpersonal communication skills and professionalism." Although it is not clear that current evaluation tools can discriminate between individual competencies, it is possible that they can discriminate among different levels of performance within a single competency or a subset of one.[25]

ASSESSMENT AND MILESTONES

The principles of competency-based education can be combined with a model of skill acquisition to develop a richer framework for performance assessment. One such framework, the Dreyfus model, arose from a U.S. Air Force–sponsored research study examining the skill acquisition of pilots.[26] It described five stages of development ranging from novice to master. In health care, the model has been adapted to describe both physician and nursing skills acquisition.[20,27] The principles of the Dreyfus model are highlighted in Table 9-10. For individuals to progress to the expert stage, they need supervision, training, and opportunities for deliberate professional practice.[20,28]

Another framework of clinical skills assessment is known as Miller's Pyramid. Miller, a widely respected medical education researcher, acknowledged that "no single assessment method can provide all the data required for judgment of anything so complex as the delivery of professional services by a successful physician."[29] He suggested a framework within which assessment could occur (Table 9-11) and noted "the inescapable truth that examinations drive the educational system." Miller's Pyramid has served as a useful tool for considering the progression of learners and the types of assessment needed to judge performance. There are several criticisms of the model.[20,28] First, the original description of "knows how" was labeled "competence" and "shows how" was labeled "performance." These terms are misleading when viewed in the context of competency-based medical education and the Dreyfus model of performance assessment. Second, the behavior of a learner in a workplace-based assessment, such as direct observation, may be influenced by their knowledge of being observed and may not necessarily reflect their actual behavior. Third, the model implies that a learner's inability to "show how" (e.g., intubate a mannequin airway) should translate to an inability to "do" in an actual patient; however, this might reflect a lack of fidelity in the mannequin rather than a

BOX 9-4 ***Key Structural Elements in Anesthesiology Program Requirements***

- Duration of training: 12 months of clinical base year, 36 months of clinical anesthesia (CA-1, CA-2, and CA-3 years)
- Required rotation experiences:
  - Two months of obstetric anesthesia
  - Two months of pediatric anesthesia
  - Two months of neuroanesthesia
  - Two months of cardiothoracic anesthesia
  - Four months of critical care medicine
  - Three months of pain medicine (may include 1 month of acute perioperative pain, 1 month of chronic pain, and 1 month of regional analgesia)
  - One month preoperative evaluation clinic
  - Two weeks postanesthesia care unit

From ACGME Program Requirements for Graduate Medical Education in Anesthesiology. <http://www.acgme.org/acgmeweb/Portals/0/PFAssets/ProgramRequirements/040_anesthesiology_f07012011.pdf>. (Accessed 14.03.13.)

TABLE 9-10 PRINCIPLES OF DREYFUS MODEL OF SKILL DEVELOPMENT IN PHYSICIANS

Level of Performance	Description and Attributes of Performance
Novice	Rules and protocols guide performance Uses analytical reasoning to solve problems Minimal ability to filter and prioritize information Unable to manage complexity
Advanced Beginner	Is able to sort through rules and information to determine relevance based on past experience Uses both analytic reasoning and pattern recognition to solve problems Able to achieve partial resolution of complex tasks
Competent	More expansive experience leads to more frequent use of pattern recognition to solve problems May need analytic reasoning for complex or uncommon problems Task seen as one construct (i.e., able to see big picture) Seeks out and applies advice from experts and uses it effectively Reliesy on deliberate planning and experience and less on intuition
Proficient	Breadth of experience allows extensive use of pattern recognition; clinical problem solving seems intuitive Routinely meets acceptable clinical standards Comfortable with evolving situations, can extrapolate from known to unknown situation May need to fall back on analytic reasoning for certain problems
Expert	Performance based on experience and intuition Achieves excellent performance Is open to notice the unexpected Can discriminate features not fitting recognizable patterns In complex situations, moves easily between analytic and intuitive solutions

Adapted from Carraccio CL, Benson BJ, Nixon LJ, Derstine PL: From the educational bench to the clinical bedside: translating the Dreyfus developmental model to the learning of clinical skills, Acad Med *83:761-767, 2008; and Khan K, Ramachandran S: Conceptual framework for performance assessment: competency, competence and performance in the context of assessments in healthcare—deciphering the terminology,* Med Teach *34:920-928, 2012.*

lack of learner skill. Finally, another implication is that if a learner does a skill appropriately and successfully, that level of skill has been attained and can be applied to all practice settings. However, it is clear that performance is highly dependent on context.[28] For example, the ability to place a central venous catheter before elective surgery might not translate to successful performance of the same procedure on a semiconscious injured patient in the emergency department.

TABLE 9-11 MILLER'S PYRAMID FRAMEWORK FOR CLINICAL ASSESSMENT

Level of Pyramid (Highest to Lowest)	Description	Possible Assessment Approach
Does	What learner does in clinical practice	Direct observation, workplace evaluations
Shows how	Learner shows how (i.e., performs)	Simulations, objective structured clinical examination, standardized patient
Knows how	Learner must know how to use knowledge accumulated	Case presentations, essays
Knows	Learner knows what is required to carry out professional function	Cognitive examination

Adapted from van der Vleuten CP, Schuwirth LW, Scheele F, et al: The assessment of professional competence: building blocks for theory development, Best Pract Res Clin Obstet Gynaecol *24:703-719, 2010; and Miller GE: The assessment of clinical skills/competence/performance,* Acad Med *65:S63-67, 1990.*

To advance the core competencies approach, the ACGME adopted the Dreyfus model of skill acquisition to create a framework for milestones of competency development and advocated for implementation of common evaluation tools in each discipline to document resident achievement of the milestones.[30] Programs will use milestones in the resident evaluation and feedback process, and the ACGME will use milestones as part of the accreditation of the residency program. An example of a patient care milestone for various levels of anesthesia residents is shown in Table 9-12.

CURRICULUM DEVELOPMENT

The curriculum for anesthesia residency training is composed of clinical assignments (clinical rotations) that include general and subspecialty rotations. Each rotation should have specific goals and learning objectives, as well as teaching and assessment methods and educational resources. A sample set of goals and objectives for a rotation is provided in Appendix 9-3. As a resident advances through training, the rotations should become progressively more challenging. The resident should also assume progressive responsibility for patient care and be appropriately supervised during the entire training period.

To ensure that the anesthesia resident has a satisfactory breadth of clinical experiences, the program requirements provide a list of minimum numbers of key patient care encounters that should be achieved by the end of training (Box 9-5). Throughout the training period, the resident should gain experience caring for patients with complex comorbid illnesses undergoing complicated surgical procedures. By the end of training, it is expected that the resident will exhibit sound clinical judgment in a variety of clinical circumstances and can function in a leadership role on the

TABLE 9-12 EXAMPLE OF ANESTHESIA RESIDENT MILESTONES: PATIENT CARE COMPETENCY—ANESTHETIC CHOICE AND CONDUCT

Level 1 (end CBY)	Level 2 (Before Subspecialty Rotations)	Level 3 (Completed Subspecialty Rotations)	Level 4 (Ready to Graduate)	Level 5 (After Beginning Independent Practice)
Formulates patient care plans that include consideration of underlying clinical conditions, past medical history, and patient, medical, or surgical risk factors	Formulates anesthetic plans for patients undergoing routine procedures that include consideration of underlying clinical conditions; past medical history; patient, anesthetic, and surgical risk factors; and patient choice	Formulates anesthetic plans for patients undergoing common subspecialty procedures that include consideration of medical, anesthetic, and surgical risk factors and that take into consideration a patient's anesthetic preference	Formulates and tailors anesthetic plans that include consideration of medical, anesthetic, and surgical risk factors and patient preference for patients with complex medical issues undergoing complex procedures with conditional independence	Independently formulates anesthetic plans that include consideration of medical, anesthetic, and surgical risk factors, as well as patient preference, for complex patients and procedures
Adapts to new settings for delivery of patient care	Conducts routine anesthetics, including management of commonly encountered physiologic alterations associated with anesthetic care, with indirect supervision Adapts to new settings for delivery of anesthetic care	Conducts subspecialty anesthetics with indirect supervision, but may require direct supervision for more complex procedures and patients	Conducts complex anesthetics with conditional independence; may supervise others in the management of complex clinical problems	Conducts complex anesthetic management independently

CBY, Clinical Base Year.

care team. The didactic and clinical teaching in a residency program is designed to address subject matter listed in the ABA content outline. In addition, the ACGME program requirements stipulate a few topics that must be in the residency curriculum, including recognizing fatigue and sleep deprivation, alertness management and fatigue mitigation processes, practice management, geriatric patient care, and management of the ambulatory surgery patient.

Anesthesia residents in the United States are offered an annual in-training examination (ITE) by the ABA. Independent study, including assigned reading, has traditionally been used as the main method of preparation. One study assessed the relationship between the amount of independent reading by residents in one program, and their ITE scores.[31] The average weekly self-study time was 8 ± 3.6 hours (range, 1 to 20 hours). Linear regression revealed a positive correlation between hours of self-study and ITE-scaled score (correlation coefficient 0.64; $p < 0.0001$). The correlation seems intuitively obvious, but this relationship had not been confirmed in anesthesiology training. Another expectation is that ITE performance will predict performance on the ABA Part 1 (written, multiple choice) examination. This expectation was confirmed in a 2010 study revealing that the ITE score in clinical anesthesia year 1 (CA-1) was a significant predictor of both Part 1 and Part 2 (oral) examination performance.[32] There are multiple other factors involved in ITE performance, including prior performance on national examinations, program didactics, and study habits of trainees.

WORK HOURS AND IMPLICATIONS FOR ANESTHESIA TRAINING

The duty hours of residents have been a subject of considerable debate in graduate medical education for several decades. For many years, a resident might remain on duty in the hospital overnight ("take call") every other night. On the day after call, the resident could remain in the hospital until the evening to provide patient care. In a given week, a resident might spend over 120 hours on duty. This culture of dedication to patient care had advantages, but there was no doubt that limitations of performance accompanied sleep deprivation. A 1971 study showed that sleep-deprived interns (mean of 1.8 hours sleep) were twice as likely to fail to recognize cardiac arrhythmias on an electrocardiogram than a rested intern with 7 hours of sleep.[33] The 1984 death of college student Libby Zion brought resident duty hours to the national spotlight.[34] Zion was admitted to New York Hospital with fever, tremors, and disorientation. She was given intravenous hydration and meperidine, which likely caused a drug reaction with an antidepressant drug she was taking, phenelzine. She developed extreme fever and died of cardiac arrest. A Manhattan grand jury investigation criticized the 36-hour duty periods worked by the residents, and inadequate supervision by attending physicians.[35] The New York Health Commissioner formed a committee that became known as the Bell Commission, which recommended an 80-hour per week limit on resident duty hours, a maximum of 24 consecutive hours on duty, and the requirement for senior physicians to be present in the hospital. These recommendations were incorporated into the New York State Health Code in 1989.

The ACGME also formed task forces and provided position statements on duty hours. In 1992, the ACGME mandated that all programs require one 24-hour period per week without patient care responsibilities, with assignment to call duty limited to every third night. While the 1992 ACGME rules did not specify hourly limits on resident duty hours, many individual specialty RRCs imposed such limits, including internal medicine, dermatology, ophthalmology, and emergency medicine. Most of these RRCs chose 80 hours as the weekly limit, with emergency medicine setting a limit of 72 hours. There was additional pressure for change. In 2001, a petition requested that the Occupational Safety and Health Administration (OSHA) regulate duty hours of residents because of its potential role as a workplace health hazard. Also in 2001, the U.S. Congress considered legislation to limit resident work hours. In 2003, the ACGME set a maximum limit of 80 hours per week on the duty hours of all residents in all specialties. They also set a maximum of 24 hours of continuous duty, plus 6 hours for continuity and transfer of care. While one intent of duty-hour regulations was to improve patient safety, it was not clear that overall patient safety had improved. This was not unexpected given the many factors that affect patient outcomes and the complexity of the modern health care system. The U.S. Congress requested that the Institute of Medicine, the health arm of the National Academy of Sciences, study the relationship between resident duty hours and patient safety. In 2008, the Institute of Medicine released a report titled "Resident Duty Hours: Enhancing Sleep, Supervision, and Safety." The report "asserts that revisions to medical residents' workloads and duty hours are necessary to better protect patients against fatigue-related errors and to enhance the learning environment for doctors in training. The report recommends that residency programs provide regular opportunities for sleep each day and each week during resident training."[36] In 2011, the ACGME revised its common program requirements to include additional restrictions on duty hours, the most notable being a reduction of continuous duty for interns to a maximum of 16

BOX 9-5 ***Minimum Clinical Experience for Anesthesia Resident***

1. 40 patients undergoing vaginal delivery
2. 20 patients undergoing cesarean section
3. 20 patients undergoing cardiac surgery
4. 20 patients undergoing open or endovascular procedures on major blood vessels
5. 20 patients undergoing noncardiac intrathoracic surgery
6. 20 patients undergoing intracerebral procedures
7. 20 patients undergoing procedures for complex, life-threatening injuries
8. 40 patients undergoing surgical procedures in whom epidural anesthetics are used
9. 40 patients undergoing surgical procedures with spinal anesthetics
10. 40 patients undergoing surgical procedures in whom peripheral nerve blocks are used

BOX 9-6 *ACGME Duty Hour Regulations*

Maximum Hours of Work per Week

- Duty hours must be limited to 80 hours per week, inclusive of all in-house call activities and all moonlighting.*

Duty Periods

- Residents must be scheduled for a minimum of 1 day free of duty every week.*
- Duty periods of PGY-1 residents must not exceed 16 hours.
- Duty periods of PGY-2 residents and above may be scheduled to a maximum of 24 hours of continuous duty in the hospital.
- It is essential for patient safety and resident education that effective transitions in care occur. Residents may be allowed to remain on-site to accomplish these tasks; however, this period must be no longer than an additional 4 hours.
- In unusual circumstances, residents, on their own initiative, can remain beyond their scheduled period of duty to continue to provide care to a single patient.
- PGY-1 residents should have 10 hours, and must have 8 hours, free of duty between scheduled duty periods. PGY-1 residents are not permitted to moonlight.
- Intermediate-level residents should have 10 hours free of duty, and must have 8 hours between scheduled duty periods. They must have at least 14 hours free of duty after 24 hours of in-house duty.
- PGY-2 residents and above must be scheduled for in-house call no more frequently than every third night.*
- Residents must not be scheduled for more than 6 consecutive nights of night float.

From ACGME Common Program Requirements. Effective July 1, 2011. <http://www.acgme.org/acgmeweb/Portals/0/dh_dutyhoursCommonPR07012007.pdf>. (Accessed 14-03-2013.)

†Program director responses: 549 (75% response rate).

hours. A summary of current duty hour regulations is listed in Box 9-6. The ACGME also addressed other aspects of patient safety, including new standards for supervision, teamwork, transitions of care, fitness for duty, alertness management, and fatigue mitigation.[37]

In 2011, the ACGME defined three different levels of supervision that apply during training: direct, indirect, and oversight.[16] With direct supervision, the supervising physician is physically present with both resident and patient. There are two types of indirect supervision. Under "indirect with direct supervision immediately available," the supervising physician is physically present at the patient care site and can immediately provide direct supervision. Under "indirect with direct supervision available," the supervising physician is not physically present at the patient care site, but is immediately available by telephone, and is available to provide direct supervision. With oversight supervision, the supervising physician is available to provide review and feedback after patient care has been delivered.

Since the implementation of the ACGME 2011 duty hour regulations, residents and residency program directors have been surveyed to determine their perceptions of the changes. (Table 9-13).[38,39] Of note, the majority of residents and program directors surveyed believed that patient safety and availability of supervision were unchanged. Perceived quality of life for interns was improved, though quality of life for senior residents was believed to be worse. In addition, preparation for more senior resident roles was perceived to be worse. Other notable survey results included a marked increase in the frequency of handoffs in care, increased assumption of junior resident work by senior residents, and a marked increase in the use of physician extender (nurse practitioner or physician assistant) coverage.[38,39] While these perceptions relate to the initial experience with the new regulations, it is clear that additional work will be needed to determine their effect on the achievement of milestones and readiness for independent practice, which is the ultimate goal of a residency program.

ANESTHESIA FELLOWSHIP TRAINING

As the specialty of anesthesiology has advanced, a number of subspecialties have developed over the past 25 to 30 years that focus on the care of selected patient populations and on the scientific underpinnings of these subsets of the medical specialty of anesthesiology. Many of the subspecialty fellowships are accredited by ACGME, including critical care medicine, pain medicine, pediatric anesthesiology, adult cardiothoracic anesthesiology, and obstetric anesthesiology. The accreditation process requires formal educational curriculum and compliance with the many rules and regulations expected of the core residency program (competencies, milestones, duty hour restrictions). Subspecialties for which the ABA has developed special qualifications with formal examination have a content outline describing the educational requirements. For accredited subspecialties for which there is no formal qualifying examination, the curriculum is defined by each subspecialty, although there is no formal oversight of each educational program. As a result, the teachers have a great deal of flexibility in

defining the content outline. More importantly, many subspecialties are not accredited by ACGME and have no oversight of the trainees by the ABA. For example, neuroanesthesia training programs are not accredited by ACGME, nor do they have formalized didactic or clinical curricula to guide each program and the faculty. As a result, the faculty has a great deal of leeway in defining the clinical experiences and didactic and other educational initiatives, as well as a great deal of responsibility to ensure that the training is evidence-based and comprehensive.

The implication for teaching anesthesia fellows in non-ACGME–accredited programs such as neuroanesthesia is that each individual program must define their own curriculum, clinical experiences, mentorship, and scholarly activity requirements. The lack of accepted standards and an oversight system can lead to significant variability in experiences among fellows in one program and among fellows in different programs. Another important issue for unaccredited fellowships is the service-versus-education balance. A fellow could spend a significant amount of time in junior attending roles that are not in their designated subspecialty area, thereby diluting their educational experience.

ANESTHESIA TEACHING METHODS

Although physicians are expected to mentor colleagues and educate trainees and their patients, few have formal training in teaching methodologies. At the same time, there is an implicit expectation that each physician is a teacher. In fact, the word *doctor* derives from the Latin word *docere,* which means "to teach." For formal educational programs, the lack of education for physicians in teaching and evaluation methodologies is now recognized as a deficiency. In academic health systems in particular, there is increasing acknowledgment of the need for faculty development in anesthesia education.[40] In the last decade, many medical schools have transformed their curriculum, incorporating new approaches such as problem-based learning, computer-based instruction, standardized patients, and simulation training.[41] Similarly, residency and fellowship programs have adapted to new ACGME accreditation requirements. In order to describe the skills needed for excellence as a teacher, one must first define the types of teaching roles encountered in contemporary medical education. One framework describes seven core tasks that may be required of a teacher (Table 9-4).[42] The following section addresses two of the most common anesthesia teaching situations: clinical teaching and classroom teaching of large and small groups.

CLINICAL TEACHING

Learning from the clinical care of patients is the essence of medical education. There are many challenges to teaching in the clinical environment, including other demands for faculty time and attention, the potentially rapid pace of clinical care with associated production pressure, and teaching different levels of learners at the same time. The clinical teacher must provide supervision of clinical care while serving as a professional role model and creating opportunities for the trainee to learn.[43] The question "What makes a good clinical teacher in medicine?" was the subject of a systematic literature review.[44] Good clinical teaching is clearly multifactorial, but analysis of the most commonly reported themes revealed that noncognitive aspects of teaching such as developing positive relationships with students, creating a supportive learning environment, communication skills, and enthusiasm were emphasized more than cognitive aspects such as medical or clinical knowledge, clinical or technical skills, and clinical reasoning.

One model for clinical teaching that has been disseminated and validated is the Stanford Faculty Development Program.[45,46] This model uses seven categories to describe important aspects of clinical teaching.

1. Establish a positive learning climate; this involves the tone of the teaching setting, including learner comfort, enthusiasm of teacher, and mutual respect.
2. Control the teaching session; this includes the teacher's ability to focus and pace the encounter.
3. Communicate goals; this refers to establishment of expectations, which can include knowledge, skills, and attitudes of the learner.
4. Promote understanding and retention; this refers to teaching methods used to enhance the learner's initial understanding and remember it.
5. Establish evaluation techniques to assess a learner's achievement of goals; this can be used to assess ongoing progress or for a final assessment.
6. Provide feedback; this describes how the teacher provides learners with information about their performance for them to improve.
7. Promote self-directed learning; this stresses the importance of acquiring skills to continue learning beyond the teaching session itself.

These skills can be developed in workshop settings and in collaboration with faculty development "peer-coaching" programs.

Another model of clinical teaching that was initially developed in the ambulatory medicine setting is the One-Minute Preceptor.[47] This model describes five sequential steps that can be used to structure clinical encounters that last several minutes.

1. Get a commitment. Ask the learner to articulate their opinion on the patient's diagnosis or an aspect of management. At this point, teachers should not share their opinion.
2. Probe for supporting evidence. Encourage the learner to share their rationale for the commitment they made.
3. Teach general rules. Teachers can help learners understand how the learning from this patient can be applied to other patients.
4. Reinforce what was done well. Positive feedback should be as specific as possible, based on behaviors observed.
5. Correct mistakes. While some teachers avoid giving corrective feedback, this is essential for competent care of patients.

This model can be adapted to many anesthesia clinical settings. Two examples of One-Minute Preceptor teaching sessions are shown in Table 9-14.

TABLE 9-14 EXAMPLES OF ONE-MINUTE PRECEPTOR TEACHING MODEL IN THE ANESTHESIA CLINICAL SETTING

Scenario	Step	Actions	Dialogue With Learner
You are working with a medical student on an anesthesia rotation. A healthy patient is receiving general anesthesia for ventral hernia repair. After skin incision, the heart rate increases.	1	Get a commitment	Why do you think the heart rate is increasing?
	2	Probe for supporting evidence	Why do you think the elevated heart rate is from inadequate anesthesia?
	3	Teach general rules	Discuss how to approach acute elevations in heart rate during general anesthesia.
	4	Reinforce what was done well	You nicely incorporated other vital signs such as blood pressure and respirations into your assessment.
	5	Correct mistakes	In the future, you should not give β-blocker without first ensuring adequate depth of anesthesia.
You are working with a new resident in the ICU. A patient with hypotension requires arterial line placement for monitoring.	1	Get a commitment	Where and how would you place an arterial line in in this patient?
	2	Probe for supporting evidence	Why do you think a guide wire would facilitate line placement in this patient?
	3	Teach general rules	Discuss clinical pearls for arterial line placement.
	4	Reinforce what was done well	The needle angle into the skin was optimal for use of a guide wire.
	5	Correct mistakes	If the guide wire becomes bent, a new one should be used.

ICU, Intensive care unit.

BOX 9-7 ***Strategies for Effective Questions and Explanations in Teaching***

Asking Questions

- Consider whether to use closed, open or clarifying questions. Closed questions can evoke simple recall but can be useful to establish basic facts. Open questions are more likely to promote deeper thinking unless question is overly broad.
- Allow adequate time for learner to respond. Avoid the temptation to speak too soon.
- Resist the urge to answer the learner's question right away. Use a counter question instead.
- Follow a poor answer with another question.
- Consider statements to reduce confrontation, such as "This is sometimes difficult to understand."

Giving Explanations

- Check understanding before, during, and after your explanation. Pay attention to nonverbal cues as well.
- Provide information in easily understood units ("bite-sized chunks").
- Put an explanation in a broader context if appropriate.
- Summarize periodically, or ask the learner to summarize to gauge understanding.
- Reiterate the take-home messages, or ask the learner to do so.

Adapted from Spencer J: Learning and teaching in the clinical environment, BMJ *326:591-594, 2003.*

Experienced clinical teachers make use of "teaching scripts" to guide many of their teaching interactions.[43,48] A teaching script includes three to five teaching points with supporting material, an appreciation of common errors made by learners on that particular topic, and effective ways to create a framework for learners to build on. The use of the One-Minute Preceptor Model can be considered as a way to develop a teaching script. A teacher's communication skills are crucially important, including active listening, sensitivity to verbal and nonverbal cues, asking questions, and giving explanations. Practical tips for asking questions and giving effective explanations are provided in Box 9-7.[49]

Another aspect of clinical teaching is procedural skills teaching. For many generations of physicians, the primary teaching method was captured by the phrase "see one, do one, teach one." This is no longer appropriate in a health care system focused on maximizing patient safety and improving efficiency. In the motor skills and surgical literature, a three-stage theory of motor skill acquisition is widely accepted.[50,51]

In the *cognitive stage*, the learner must understand the task from an intellectual perspective, and then plan distinct steps to accomplish it. The teacher must be able to break down the steps, explain, and demonstrate them.

In the *integrative stage*, the learner's goal is to comprehend and perform the appropriate motor activities. At this stage, the learner still thinks about each step, but the execution is more fluid, with fewer interruptions. Practice with formative feedback is critically important at this stage so that the learner knows whether the steps are correctly performed, and if not, how to adjust accordingly.

In the *autonomous stage*, the learner performs the task smoothly, with speed, efficiency, and precision. At this stage, routine execution of the task is accomplished with little cognitive input, allowing the learner to focus on other aspects of the procedure. An approach to procedural skills learning is depicted in Figure 9-2.[52,53] The first step is to ensure that the learner has the appropriate motivation and background knowledge for performing the task, and that the environment is conducive to learning. For example, it might not be appropriate for a new anesthesia resident to insert their first internal jugular central line in an obese patient who is coagulopathic and receiving mechanical ventilation. Second, the teacher "shows the learner how" to appropriately perform the task. The learner should view a demonstration or video of the entire procedure on a real patient performed by an expert. The teacher then describes the steps of the procedure while explaining each step carefully; this can involve simulations or low-fidelity models. In the next step, which can be considered "guided discovery," the teacher provides appropriate guidance as the learner performs the task

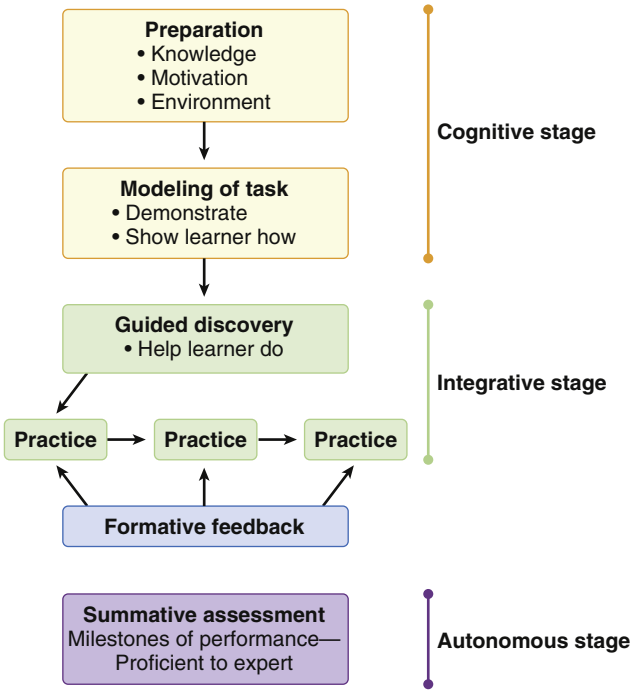

Figure 9-2. Approach to teaching procedural skills.

("helps learner do"). The learner is then allowed supervised opportunities to practice the skill while being provided timely and frequent feedback. Summative assessment of performance occurs after adequate opportunities for practice. Depending on the summative assessment, the level of supervision for subsequent procedures of the same type may be reduced. As part of the spectrum of expertise development, the learner may eventually be expected to teach the procedure to others. If a skill or task is considered complex, one should consider dividing it up into simpler component parts, practicing in isolation, and then progressively combining the parts of the total skill until the learner is able to perform the entire complex task. For example, when teaching a resident to perform a basic transesophageal echocardiography (TEE) examination, one might divide the task as follows: (1) learning to place the TEE probe in a simulator or patient, (2) manipulating the probe in a TEE task trainer, (3) studying the basic TEE views to understand the expected anatomic features of each view, (4) obtaining the TEE views in a task trainer, and finally (5) performing the entire basic TEE examination in a patient under direct supervision.

Medical schools and residency programs (and hopefully individual teachers) desire excellence in clinical teaching. The same learning principles apply to teachers who seek improvement in their teaching skills, including the important role of assessment.[8] One large study in an academic anesthesia department examined 5 years of resident teaching evaluations, and addressed whether evaluation and feedback to anesthesiology faculty teachers from anesthesiology resident learners improved clinical teaching scores. Anesthesia residents' numerical evaluation scores (quantitative summary report) and all narrative comments were provided to each clinical teacher. The average teaching score for the entire faculty rose over time and the increase in teaching scores was attributed to improved teaching. This study suggested that clinical teachers are able to improve their clinical teaching by using feedback from resident learners.[54]

CLASSROOM TEACHING

Classroom teaching of large and small groups is another important teaching skill. Many of the clinical teaching principles of the Stanford Faculty Development model can be applied to this settings as well. However, the lecture format is less conducive to the evaluation of a learner's achievement of goals, and it is not likely to elicit many opportunities for feedback to learners. Some relevant principles for teaching in this setting include:

1. Learn and use the information as soon as possible. For example, a lecture on the management of sepsis should occur during a rotation in critical care as opposed to an ambulatory surgery rotation
2. Activate prior knowledge. Use analogies and examples that connect to students' existing knowledge. Make sure that new information can be situated meaningfully in the context of what learners already know.
3. Make it relevant. Describe how the information presented is relevant to their future performance. Tailor instruction to the type of learner (e.g., medical student, anesthesia resident). Case presentations can be a particularly powerful method.
4. Use multiple modes of explanation. Be prepared to use different approaches to present information, such as words, images, figures, pictures, cases, or problems.
5. Less may be more. The length of a teaching session does not necessarily correlate with the quantity of learning. For example, the *segmenting principle* of multimedia learning states that people learn better when a continuous or large lesson is broken down into smaller, learner-paced segments.[55]

The traditional approach to large classroom teaching consists of a teacher-provided lecture followed by assigned homework that builds on the lecture. An approach called the *inverted* or *flipped classroom model* shifts this dynamic. The foundational learning is done by the student before class. Preparation can consist of required readings or online videos followed by a brief test to reinforce the expectation of preparedness. Classroom time is used for interactive exercises such as audience response system questions and feedback, small group activities, or case discussions. This approach has been studied in a large college physics class, in which the flipped classroom students had higher attendance, more engagement in class, and higher scores on a knowledge examination.[56] In the health sciences, two pharmacy schools have reported positive results in transforming large group courses using the flipped classroom model, including improved grades and favorable student perceptions of the new teaching approach.[57,58]

FACULTY DEVELOPMENT FOR TEACHING

At many institutions, faculty development programs have been designed to improve the teaching abilities of

faculty. One review examined the outcomes of more than 50 different faculty development programs using the Kirkpatrick evaluation model, which describes four levels of impact: learner reaction, learning (change in attitude, knowledge, or skill), behavior change, and results (at the learner level or the organization itself).[59] The program types included seminar series, workshops, and longitudinal programs. The instructional methods used included lectures, small group discussions, role playing, simulations, and video reviews of performance. The following beneficial effects were observed: improvements in teaching behavior, gains in teaching knowledge and skill, and a positive change in attitudes towards teaching and faculty development itself.[60] According to Kirkpatrick, there are four conditions needed to promote behavior change in an individual: desire for change, knowledge of what to do, a supportive work environment, and rewards for changing.[59] While faculty development efforts can help address the first two conditions, the latter two conditions will need support from the community of teachers and learners.

NEW MODELS OF TEACHING

Changes in clinical practice have affected resident education and resulted in the need for new teaching models. The use of technology in patient care (e.g., ultrasound-guided regional anesthesia and vascular access, echocardiography) required instructors to incorporate these tools in their clinical and classroom teaching efforts. Other educational needs are more difficult to address. For example, residents care for many patients undergoing endovascular approaches to vascular surgery. In many programs, however, residents have limited experience with complex procedures such as open aortic vascular surgery. Improvements in patient safety in anesthesia have led to a decrease in crises that are managed by residents. To ensure that anesthesiologists are skilled in the management of rare events and less commonly encountered procedures, residency programs must incorporate alternative methods to prepare residents for practice. Simulation is one such method. Teachers should also be aware of other advances in education technology that present new ways to deliver content, teach and assess, provide collaborative learning environments, and increase classroom interactivity. These methods, which include e-Learning, wikis, podcasts, and audience response systems, have been used increasingly in the teaching of elementary school, high school, college, and medical students. In the future, teachers will be faced with learners who have considerable experience with these approaches. The use of new education technology does not guarantee that the learning process will be more effective. However, teachers and learners should understand how these new teaching models work because there are some features that can facilitate the principles of learning discussed here.

SIMULATION (SEE ALSO CHAPTER 8)

Simulation is a technique to recreate reality in an interactive manner for training or other purposes. There are numerous dimensions to the use of simulation in medical education, including the purpose of the simulation (e.g., training, assessment, research), spectrum of technology (e.g., verbal role play, standardized patient actor, part-task trainer, virtual reality trainer, computer screen-based simulator, mannequin-based patient simulator), site of simulation (e.g., home office, skills laboratory, dedicated simulation center, actual work place—aka in situ), and spectrum of feedback accompanying simulation (e.g., none, automatic critique by simulator, real-time instructor critique, video-based post hoc debriefing).[61] For medical student anesthesia learners, simulation (in the form of part-task trainers) can be used for teaching procedures such as peripheral intravenous catheter placement, mask ventilation, direct laryngoscopy, and tracheal intubation. A mannequin patient simulator can be used to teach intraoperative critical event management (e.g., hypoxemia, hypotension) in novice anesthesia residents.[62] A preliminary evaluation of a virtual reality–based spinal anesthesia simulator described its use as part of an integrated training program, including a cognitive examination, as well as simulator and clinical testing.[63] Simulation can also be used for teaching crisis resource management and teamwork training in anesthesia and other health care settings.[64] Several types of assessment can be performed using simulation, including procedural skills,[65] acute care skills,[66] and nontechnical skills such as communication, teamwork, and situational awareness.[67]

In 2011, the Anesthesiology Residency Review Committee added a new requirement that all U.S. residents. must participate in at least one simulated clinical experience per year. A 2010-2011 survey of U.S. academic anesthesiologists showed that residents in their departments participated in approximately two to three simulation sessions per year (R. Schell, M. Pardo, R. Gaiser, unpublished data). A 2008 survey of all Canadian anesthesia residents revealed that they participated in an average (median) of two simulation training sessions per year.[68] Many residents (81%) experienced anxiety during the simulation exercises; reasons included not knowing the scenario they were about to manage, performing in front of fellow residents and faculty, and limited prior experience with simulation. Despite their anxiety, the Canadian residents expressed desire for more simulation sessions per year and increased participation in multidisciplinary scenarios.

In comparison with no intervention, technology-enhanced simulation training in health professions education is consistently associated with large effects for outcomes of knowledge, skills, and behaviors.[69] However, there is little evidence that simulation improves patient care outcomes. A question that needs answering is: What is the validity and reliability of simulation for procedural clinical and behavioral competency evaluation? In other words, will performance on a given assessment predict future performance in actual practice?

Simulation can provide the opportunity for deliberate practice (i.e., practice undertaken over an extended period to attain excellence), but most anesthesia training programs are not currently structured to provide extensive and frequent simulation training. The use of simulation for team training is also underutilized, in spite of the widespread acceptance of the importance of teamwork (see Chapter 7).

E-LEARNING

e-Learning is also called web-based learning, online learning, distributive learning, computer-assisted instruction, or Internet-based learning. Advantages include widespread access, ability to self-pace learning, and delivery of a consistent curriculum. However, an e-learning module must adhere to proper instructional design principles.[70,71] When properly designed, e-learning is an approach that is flexible, engaging, learner-centered, and interactive. A meta-analysis suggested that e-learning has equivalent time and learning efficiency compared with traditional instruction.[72]

WIKIS

Wikis are collaborative websites that can be edited by groups of individuals (e.g., Wikipedia). A wiki can serve as a central repository for educational content such as slideshow presentations, lecture handouts, lecture podcasts, and journal articles. Wikis can become a tool for collaboration, actively involving learners in their own construction of knowledge, and can provide an opportunity for learners to function as teachers as they provide educational content for others. Potential drawbacks include the open access nature of wikis, which can result in inaccurate information being added by a user. OpenAnesthesia.org, a wiki sponsored by the International Anesthesia Research Society, is an online toolkit intended for anesthesia resident learners.[73]

PODCASTS

Podcasts are repositories of audio or video materials that can be downloaded to portable media players, adding the potential for mobile learning. Podcasts are widely used in medical schools to allow learners to review lectures presented in the classroom. Although lectures are recorded in real time, they can be played back at twice the normal speed to allow for more efficient review of the material.

AUDIENCE RESPONSE SYSTEMS

An audience-response system (ARS) is a classroom technology that allows learners to respond to questions in a slide presentation via small, hand-held remote keypads ("clickers"). Educational uses for the ARS include the following: (1) assess student preparation, (2) provide formative feedback to teacher about the state of learners' understanding, (3) enhance interaction and student attention, (4) use quizzes or tests, and (5) make the lecture more fun for the presenter.[74] Students generally have positive reactions to use of ARS in the classroom, for reasons that include the anonymity of responses, reinforcement of learning, and an ability to compare one's answers to others. A recent systematic review of audience response systems on learning outcomes in health professionals provides some evidence to suggest the effectiveness of ARS in improving learning outcomes, especially when interactive learning sessions with ARS are compared with noninteractive sessions.[75]

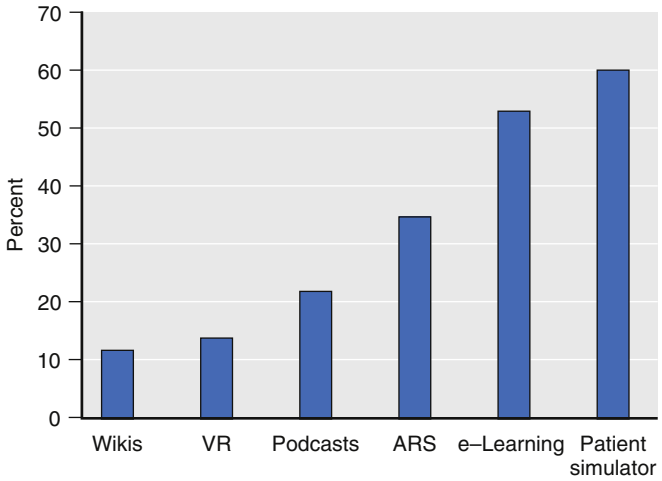

Figure 9-3. Use of technology in anesthesiology education. Responses of the members of the Association of University Anesthesiologists (n = 346) in 2011 to the question, "Which of the following does your department currently utilize?" (R. Schell, M. Pardo, R. Gaiser; unpublished data). *ARS,* Audience-response system; *VR,* virtual reality.

USE AND ACCEPTANCE OF TECHNOLOGY IN ANESTHESIA EDUCATION

In 2011, members of the Association of University Anesthesiologists (AUA) responded to a survey about technology and the self-reported use of technology in anesthesia resident education. (R. Schell, M. Pardo, R. Gaiser, unpublished data) When respondents were asked to rate their feelings about the use of technology in general, most reported that they enjoyed using and learning about new technologies. The data demonstrating which of the technologies their departments used is shown in Figure 9-3. Patient simulation and e-learning modules were used by the majority of respondents, whereas wikis and virtual reality were used the least. The AUA respondents to the survey almost unanimously believed that technology in education will increase in the future. However, perceived reasons for the increased use of technology included "newer generation of learners expect it" and "competition for applicants to programs." Few believed that technology was increasing because it "could replace aspects of clinical training" or "improve outcomes."

THE FUTURE OF ANESTHESIA EDUCATION

Over the past decade, the number of anesthesiology residency positions has increased, and the medical student applicant pool has become stronger academically. However, several factors have the potential to change the desirability of an anesthesiology career, including the changing health care environment, different career expectations, and the ongoing debate about the role of nonphysician providers in health care. Training programs will have to prepare graduates for their roles in clinical practice. Clinical experiences should be broadly based, yet may need to be supplemented using simulation or other teaching methods. Already, a significant proportion of residency training occurs outside the operating room setting. It is likely

that other out-of-operating-room clinical activities will be more important to the anesthesiologist of the future. Evaluation tools such as milestones will be useful to guide residents during training, and perhaps throughout an entire career. Residents will need continued exposure to the quality improvement process, including the use of root-cause analysis and other approaches to evaluate patient care quality and outcomes critically. As health care systems become more complex, residents will need knowledge of how patient care outcomes can be influenced by using and applying evidence-based practices. The challenges of meeting the health care needs of the future must be done in the face of increased public accountability—for patient safety, health care quality, oversight of training programs, and individual practitioners.

APPENDIX 9-1 *Abridged List of Subjects in American Board of Anesthesiology Content Outline*

Basic Sciences

- Anatomy
- Physics, monitoring, and anesthesia delivery devices
- Mathematics
- Pharmacology

Clinical Sciences: Anesthesia Procedures, Methods, and Techniques

- Evaluation of the patient and preoperative preparation
- Regional anesthesia
- General anesthesia
- Monitored anesthesia care and sedation
- Intravenous fluid therapy during anesthesia: water, electrolyte, glucose requirements and disposition, crystalloid versus colloid
- Complications (etiology, prevention, treatment)
- Postoperative period
- Special techniques

Organ-Based Basic and Clinical Sciences

- Central and peripheral nervous systems
- Respiratory system
- Cardiovascular system
- Gastrointestinal and hepatic systems
- Renal and urinary systems
- Electrolyte balance
- Hematologic system
- Endocrine and metabolic systems
- Neuromuscular diseases and disorders

Clinical Subspecialties

- Painful disease states
- Pediatric anesthesia
- Obstetric anesthesia
- Otorhinolaryngology (ear, nose, and throat) anesthesia: airway endoscopy, microlaryngeal surgery, laser surgery, hazards, complications (e.g., airway fires)
- Anesthesia for plastic surgery and liposuction
- Anesthesia for laparoscopic surgery, cholecystectomy, gynecologic surgery, gastric stapling, hiatal hernia repair, anesthetic management, complications
- Ophthalmologic anesthesia, retrobulbar and peribulbar blocks, open eye injuries
- Orthopedic anesthesia, tourniquet management, complications, regional versus general anesthesia
- Trauma anesthesia
- Anesthesia for ambulatory surgery
- Geriatric anesthesia/aging
- Critical care

Special Problems or Issues in Anesthesiology

- Electroconvulsive therapy
- Organ donors: pathophysiology and clinical management
- Radiologic procedures, computed tomography, magnetic resonance imaging and anesthetic implications and management, anesthesia in locations outside the operating room
- Physician impairment or disability: substance abuse, fatigue, aging, visual and auditory impairment, Americans with Disabilities Act
- Ethics, practice management, and medicolegal issues

From American Board of Anesthesiology: Content Outline, Basic/Advanced. Revised January 2014. <http://www.theaba.org/pdf/Basic-and-Advanced-Content Outline.pdf>. (Accessed 19.04.4.)

APPENDIX 9-2 *ACGME Competencies in Residency Program Requirements*

The program must integrate the following Accreditation Council for Graduate Medical Education (ACGME) competencies into the curriculum

Patient Care

Residents must be able to provide patient care that is compassionate, appropriate, and effective for the treatment of health problems and the promotion of health.

Medical Knowledge

Residents must demonstrate knowledge of established and evolving biomedical, clinical, epidemiologic, and social-behavioral sciences, as well as the application of this knowledge to patient care.

Practice-Based Learning and Improvement

Residents must demonstrate the ability to investigate and evaluate their care of patients, to appraise and assimilate scientific evidence, and to improve patient care continuously based on constant self-evaluation and life-long learning. Residents are expected to develop skills and habits to be able to meet the following goals:

- Identify strengths, deficiencies, and limits in one's knowledge and expertise
- Set learning and improvement goals
- Identify and perform appropriate learning activities
- Systematically analyze practice using quality improvement methods, and implement changes with the goal of practice improvement
- Incorporate formative evaluation feedback into daily practice
- Locate, appraise, and assimilate evidence from scientific studies related to their patients' health problems
- Use information technology to optimize learning
- Participate in the education of patients, families, students, residents, and other health care professionals.

Interpersonal and Communication Skills

Residents must demonstrate interpersonal and communication skills that result in the effective exchange of information and collaboration with patients, their families, and health professionals. Residents are expected to:

- Communicate effectively with patients, families, and the public, as appropriate, across a broad range of socioeconomic and cultural backgrounds
- Communicate effectively with physicians, other health care professionals, and health-related agencies
- Work effectively as a member or leader of a health care team or other professional group
- Act in a consultative role to other physicians and health professionals
- Maintain comprehensive, timely, and legible medical records, if applicable

Professionalism

Residents must demonstrate a commitment to performing professional responsibilities and adhering to ethical principles. Residents are expected to demonstrate:

- Compassion, integrity, and respect for others
- Responsiveness to patient needs that supersedes self-interest
- Respect for patient privacy and autonomy
- Accountability to patients, society, and the profession

APPENDIX 9-2 *ACGME Competencies in Residency Program Requirements*—cont'd

- Sensitivity and responsiveness to a diverse patient population, including but not limited to diversity in gender, age, culture, race, religion, disabilities, and sexual orientation

Systems-Based Practice

Residents must demonstrate an awareness of and responsiveness to the larger context and system of health care, as well as the ability to call effectively on other resources in the system to provide optimal health care. Residents are expected to:

- Work effectively in various health care delivery settings and systems relevant to their clinical specialty
- Coordinate patient care within the health care system relevant to their clinical specialty
- Incorporate considerations of cost awareness, risk-benefit analysis in patient and population-based care as appropriate
- Advocate for quality patient care and optimal patient care systems
- Work in interdisciplinary teams to enhance patient safety and improve patient care quality
- Participate in identifying system errors and implementing potential systems solutions

From ACGME Common Program Requirements. Effective July 1, 2011. <http://www.acgme.org/acgmeweb/Portals/0/dh_dutyhoursCommonPR07012007.pdf>. (Accessed 14.03.13.)

APPENDIX 9-3 *Sample Rotation Goals and Objectives (Abridged)*

Description of Rotation

The first month rotation is the introduction to clinical anesthesia. It provides an overview exposure to the delivery of operative anesthesia. Through the arc of providing comprehensive anesthetic care, residents are exposed to preoperative patients on the wards and in the preoperative holding area, intraoperative patients in the procedure suites, and immediate postoperative patients in the postanesthetic care unit (PACU). This comprehensive exposure, coupled with daily lectures and educational conferences, allows the residents to achieve the following competency-based goals and objectives.

Patient Care

Goal

Residents must be able to provide patient care that is compassionate, appropriate, and effective for the treatment of health problems and the promotion of health.

Objectives

For each patient preoperatively:

- Demonstrate comprehensive exam of the airway.
- Assign an American Society of Anesthesiologists (ASA) risk class.
- Formulate an anesthetic plan (including appropriate premedication).
- Prepare, start, and secure an intravenous (IV) catheter.

For each patient intraoperatively:

- Prepare the operating room for anesthetic care, including a machine check, suction, preparation of appropriate drugs, and preparation of appropriate airway management tools.
- Demonstrate preoxygenation and mask ventilation.
- Demonstrate endotracheal intubation, including endotracheal intubation for the patient with a "full stomach."
- Formulate changes in anesthetic management, based on interpretation of data from monitors.
- Maintain amnesia and analgesia through selection of appropriate anesthetic options.
- Plan and demonstrate a plan for safe emergence, including reversal of neuromuscular blockade and extubation.

For each patient postoperatively:

- Transport the patient to the recovery room (PACU) or intensive care unit (ICU)

Medical Knowledge

Goal

Residents must demonstrate knowledge of established and evolving biomedical, clinical, epidemiologic, and social-behavioral sciences, as well as the application of this knowledge to patient care. In this first month of clinical anesthesia year 1 (CA-1), the following objectives are designed to be covered at the introductory level, and will be followed in more detail in subsequent rotations throughout the residency.

Objectives

- Describe basic structure of an anesthesia machine, including vaporizers.
- Describe anesthetic preoperative evaluation.
- Review basic airway anatomy and pulmonary physiology.
- Review basic cardiovascular physiology.
- Review basics of monitors encountered in the operating room: pulse oximetry, capnography, circuit pressure, flow monitors, gas mixture monitors, oscillometric blood pressure cuffs, electrocardiograph, temperature, arterial line, central venous pressure.
- Formulate a plan for IV fluid administration and electrolyte maintenance.
- Review the basic pharmacology of inhaled anesthetics, induction agents, narcotics, local anesthetics, ephedrine, phenylephrine, neuromuscular blockers, and reversal agents.
- Explain how to use a twitch monitor for muscle relaxation.
- Review the ASA difficult airway algorithm and use of the airway management devices included in it.

Practice-Based Learning and Improvement

Goal

Residents must demonstrate the ability to investigate and evaluate their care of patients, to appraise and assimilate scientific evidence, and to improve patient care continuously based on constant self-evaluation and life-long learning. Residents are expected to develop skills and habits to be able to incorporate formative evaluation feedback into daily practice.

Objectives

Discuss positive and negative outcomes of anesthetic care choices by following selected patients (chosen by discussion with one-on-one attending supervisor) postoperatively until discharge.

Systems-Based Practice

Goal

Residents must demonstrate an awareness of and responsiveness to the larger context and system of health care, as well as the ability to call effectively on other resources in the system to provide optimal health care. Residents are expected to work in interdisciplinary teams to enhance patient safety and improve patient care quality.

Objectives

- Coordinate patient care with other health care professionals and trainees from surgical teams and perioperative nursing teams

Continued

APPENDIX 9-3 *Sample Rotation Goals and Objectives (Abridged)*—cont'd

- Participate in the performance of the procedural "time out" before every procedure undertaken
- Keep dirty and clean equipment and medications separate.

Professionalism

Goal

Residents must demonstrate a commitment to performing professional responsibilities and adhering to ethical principles. Residents are expected to demonstrate compassion, integrity, and respect for others.

Objectives

- Complete all anesthetic records, with all required information, for care delivered.
- Demonstrate signing out and accounting for controlled substances.
- Be punctual in care delivery.

Interpersonal and Communication Skills

Goal

Residents must demonstrate interpersonal and communication skills that result in the effective exchange of information and teaming with patients, their families, and professional associates. Residents are expected to communicate effectively with patients and families across a broad range of socioeconomic and cultural backgrounds.

Objectives

- Present comprehensively the findings of preoperative history and physical examination for each patient to be anesthetized.
- Coordinate operating room readiness with surgical, nursing, and technical support staff members.
- Perform appropriate sign-out of care to other residents at end of shift or at breaks.
- Summarize information appropriately to be able to give report to recovery room nurse or ICU care team at end of anesthetic care.

Teaching Methods

Teaching methods will include the following:

- Clinical teaching: one-on-one attending supervision (direct supervision) for entire rotation
- Departmental conferences: daily resident lectures broadly covering the scope of anesthetic care, including drugs, monitors, fluids, and physiology; weekly morbidity and mortality conferences; weekly patient-care conferences; and weekly educational seminars on care-related topics
- Patient simulator: realistic scenarios allowing residents to apply the skills they are learning by working through challenging scenarios independently and as part of resident teams
- Anatomic models: residents practicing airway device use and vascular cannulation
- Role modeling: working daily one-on-one with attending physicians to portray the professional skills and behaviors that residents attain over time

Assessment Method

Assessment methods will include the following:

- Global assessment at end of rotation by faculty preceptors
- Case log review
- Cognitive examinations: Anesthesia Knowledge Tests (AKT-0, AKT-1)

Educational Resources

Educational resources the residents should use on this rotation include the following:

- *Basics of Anesthesia*, ed 6. Philadelphia, 2011, Churchill Livingstone
- Multiple handouts provided over the month during the lecture series

Chapter 10

Ethical Aspects of Anesthesia Care

GAIL A. VAN NORMAN • STANLEY H. ROSENBAUM

Key Points

Ethical Theory

- Deontologic ("rules-based") ethical theory and utilitarian (outcome-based) theory clash in clinical scenarios in which the interests of individual patients are pitted against the interests of larger populations.
- In the United States, the predominant medical ethical principle is that of respect for the patient's autonomy.

Informed Consent

- Informed consent is legally mandated and based on the principle that competent and autonomous individuals can both make choices about their medical care and refuse medical treatments including lifesaving care.
- Physicians have ethical obligations to promote the patient's autonomy.
- Competence to make medical decisions is present if the patient can understand information relevant to the decision, understand consequences of the decision, and express a decision regarding the medical advice being given to them.
- Physicians are obligated to disclose alternatives to medical therapies and the common and serious risks of the proposed therapy.
- In general, competent adult patients can refuse blood transfusions, but rights of children and pregnant women to refuse therapy are less clear.
- Minor patients have varying degrees of decision-making capacity, and they may have legal rights to make certain decisions. Pediatric patients should be involved to the degree that they can be in medical decision making, particularly with regard to elective therapy.

Ethics of Preoperative Testing

- Medical testing should follow the ethical principles of beneficence and nonmaleficence and should be based on sound algorithms whenever possible.
- Medical tests with special social significance, such as pregnancy and human immunodeficiency virus testing, should be undertaken only with the patient's informed consent and should not be undertaken without sound evidence that they are necessary and beneficial.

Ethics of Anesthesia Involving Pregnant Women

- In general, the rights of pregnant women are weighed against the rights of fetuses in a decremental fashion as the fetus approaches and surpasses viable age.
- Women do not lose their rights to bodily integrity and informed consent when they become pregnant, and neither fetal "rights" nor state interests supersede a pregnant woman's right as medical decision maker. A mother's refusal of care can rarely be overridden and generally only when (1) the fetus *will* suffer irrevocable harm without the treatment, (2) the treatment is *clearly indicated* and likely to be effective, and (3) the risk to the woman is low.
- Laboring women are capable of giving informed consent, and the validity of "Ulysses directives" at the time of labor is ethically arguable.

Coercion and Restraint

- Use of restraints is antithetical to promotion of autonomy, and anesthesiologists have both ethical and legal obligations to determine whether such extreme intervention is warranted.

Key Points—cont'd

- Coercing or using physical or chemical means to force competent patients to undergo treatment they are refusing is both unethical and illegal.
- Use of restraints in children is questionable in elective medical care; when treatment must proceed, ethical care should prioritize the patient's safety and dignity.

Truth Telling

- A medical mistake is "a commission or omission with potentially negative consequences for the patient that would have been judged wrong by skilled and knowledgeable peers at the time it occurred, independent of whether there are any negative consequences."
- Respect for patients' autonomy requires that we disclose mistakes that harm patients because in so doing we release patients from misconceptions about their medical past and enhance their ability to share decision making about their medical care.

Advance Directives and Surrogate Decision Making

- An advance directive is a document executed by the patient before incapacity to provide the patient's physicians with guidance in medical decision making when the patient cannot communicate for himself or herself: these directives include, but are not limited to, durable powers of attorney, living wills, transfusion decisions, do-not-attempt-resuscitation (DNAR) directives, and decisions regarding organ donation.
- Surrogate decision makers explicitly act in "substituted judgment" to provide what the patient would have wanted and are not being asked merely for their own preferences. Surrogate decision makers at best only approximate the patient's decisions.
- Some medical decisions may not legally be made by a surrogate decision maker; laws are variable, but such decisions often include those involving electroconvulsive therapy and sterilization.

Do-Not-Attempt-Resuscitation Orders in the Operating Room

- Patients have moral and legal rights to refuse even life-sustaining therapy, and those rights extend to the operating room. DNAR orders should not be automatically suspended in the operating room, but rather they require discussion of risks and benefits, and the goals and decisions of competent patients should generally be honored.
- DNAR orders must never be construed as an excuse to not "care" for the patient. A patient's decision to forgo resuscitation does not imply a wish to avoid other beneficial interventions.

End-of-Life Decision Making

- Arguments that withdrawing or withholding life-sustaining therapy does not violate rules against killing patients are based on ethical differences between killing and letting die and between acts of commission (e.g., lethal injection) and acts of omission (e.g., withdrawal or withholding of ventilator therapy).
- Terminal care requires special knowledge and experience on the part of the physician. It requires expertise in medically supportive therapy, management of problematic symptoms, knowledge about physiologic changes in the dying patient, support and counseling of patients and families, understanding and respect for the patient's autonomy and religious and cultural practices and beliefs, the ability to work within complex health care teams, the ability to communicate well, and empathy.
- Several interventions have special ethical implications—fluid and nutritional management; the administration of sedatives and/or narcotics that have the potential to hasten death; the administration of neuromuscular blocking agents; and deactivating pacemakers, ventricular assist devices, and implanted cardioverter-defibrillators.
- Medical, legal, and religious authorities have all clearly accepted the principle of "double effect," in which an action intended to produce a benefit for the patient produces not only the expected benefit but also potentially significant harm.

Key Points—cont'd

- Neuromuscular blocking agents have no anesthetic, analgesic, or sedative properties, and they have no role in palliative care.
- The use of deactivating cardiac devices at the end of life in response to a competent patient's wishes is ethical, but it should occur only after careful consideration, and with attention to management of distressing symptoms and administration of appropriate comfort measures.

Physician-Assisted Suicide and Euthanasia

- Physician-assisted suicide (PAS) is the provision of medication and/or prescriptions to patients by specific request for the purpose of ending their life.
- Euthanasia involves the administration of medication by someone other than the patient for the express purpose of causing death.
- PAS and euthanasia are legal only in specific parts of the world, but they are generally supported by public opinion polls.
- Concerns about PAS and euthanasia center around the risk that vulnerable populations will be preferentially and disproportionately directed to PAS or euthanasia as an end-of-life management strategy. However, data from regions where PAS or euthanasia is legal suggest that this is not happening.

Organ Transplantation

- Brain death is legally and medically defined as the point at which all cardiorespiratory function irreversibly ceases *or* all function of the whole brain irreversibly stops.
- In donation after cardiac death (DCD), withdrawal of life support occurs with provisions for immediate organ donation after cardiac arrest.
- Controversies around DCD include concerns about when cardiopulmonary death can be declared and whether medications that preserve organ function but may hasten the donor's death can be administered.

Research Ethics—Human Subjects

- Research in human subjects must balance many conflicting interests such as the needs and rights of the research subject; the hypothetic interests of future patients; and the physician's financial, professional, and personal goals.
- The ethical conduct of research in human subjects follows three principles: (1) respect for autonomy, and the obligation to protect subjects with limited autonomy; (2) beneficence, with obligations to minimize risks, maximize benefits, and ensure that the research design is scientifically sound; and (3) justice, the obligation to treat each person with regard to what is morally right and to ensure fair distribution of benefits and burdens.
- Anesthesiologic research often involves the treatment or prevention of unpleasant symptoms, such as pain and nausea, for which effective treatments are well established. Such studies should be restricted to comparison of treatments with known efficacy, not placebo-controlled trials, and "escape" analgesics or antiemetics must be provided on the patient's request.
- If a minor child is "able" to assent, then assent must usually be obtained in addition to the consent of any legal surrogate decision makers. In the United States, federal law requires assent of any minor 7 years old and older to participate in medical research.

Research Ethics—Animal Subjects

- Advances in understanding animal cognition have led most biologists to believe that many, if not all, animals are capable of feeling pleasure, pain, anticipation, and fear, and thus they experience both enjoyment and suffering.
- Allowing animal suffering because of pain, fear, sickness, or poor standards of care is a moral harm that must be avoided, mitigated, and weighed heavily against the benefits it produces.
- Researchers should mind the "Three Rs"—replacement, reduction, and refinement—that is, use animal subjects only when necessary, minimize any suffering incurred in the study, and seek nonanimate replacements for animal subjects.

KEY POINTS—cont'd

Physician Participation in Executions

- U.S. professional organizations for physicians have consistently stated that participation in executions by physicians is unethical.
- Arguments for participation generally cite "beneficence" issues of providing a humane death for prisoners, whereas those against participation cite harms to the profession and erosion of trust in physicians by their agreement to be agents of the state.
- The American Board of Anesthesiologists stated that participation in executions would constitute unprofessional behavior that would result in investigation and possible decertification of anesthesiologists.

Conscientious Objection

- Acceptance of moral objections to certain hotly contended issues such as abortion or PAS may be reasonable, but objections to well-established standards, such as informed consent, are not.
- Moral objections of physicians are also likely to carry more weight if they involve concepts that the physician believes supports him or her as an ethical doctor and not just as an ethical person.

Medicine is a respected profession with codes of behavior and definite rules of conduct. Modern medical practitioners have tremendous power, recognized social import, and powerful financial interactions that touch nearly everyone's lives. In the context of long-held and highly developed rules and practices, this chapter examines the ethical bases of the practices of medicine and the implications for anesthesiologists.

ETHICAL THEORY

VIRTUE ETHICS, UTILITARIANISM, AND DUTY-DRIVEN ETHICS

The classic style of medical practice, called paternalism, is derived from *virtue-based ethics*. In this view, the physician is a genuinely virtuous person, with inherent qualities of competence, sincerity, confidentiality, and altruism, who naturally knows and does what is correct for the patient. The patient, who is not knowledgeable in the art of medicine, should trust the physician to decide what is best. Our society and legal system have changed substantially since paternalism flourished, but some patients and physicians still see this as a desirable component of medicine.

In *utilitarian ethics*, actions are judged right or wrong on the balance of their good and bad consequences. A "right" action produces the most good, based on a perspective that gives equal weight to the interests of all affected parties. Although utilitarian theory is compelling (who would not want to do the most good and minimize evil?), it falls short in defining which benefits are most important. Is it the "good" that all reasonable people want or the "good" defined by the individual patient? What if the only way to maximize "good" is to commit an entirely immoral act? Suppose, for example, the only way to win a war is to torture children systematically? Determinations of "right" or "wrong" based on the outcomes of actions presents other challenges as well. Outcomes of actions often continue to accumulate over time—when on that continuum is it appropriate to determine that an action was right or wrong? The "good" act of saving an individual's life today may be viewed through a different lens when, 20 years from now, that same individual becomes a mass murderer.

Utilitarian theory may be best when applied to analyzing broad-based policies, in decisions regarding rationing of resources, and when attempting to resolve conflicting ethical obligations.

The premise of Kantian-based ethics (also called deontologic—or *duty-based*—theory) is that certain features of actions other than their consequences make those actions right or wrong. Intention is more important than outcome. Furthermore, no person should use another exclusively as a means to an end, because each person *is* the end for which we should act. No person should be used to further the purposes of another person without that other person's autonomous consent. Kantian philosophy would forbid killing one innocent person to save another innocent person, for example.

Deontologic and utilitarian theories are applied to varying degrees in modern medical ethics. Individualism and autonomy are valued highly in Western society, and people tend to turn to Kantian philosophy when ethical questions arise that balance the authority of the physician against the goals and values of individual patients. When broad-based social issues are at stake, such as allocation of scarce medical resources, utilitarian arguments are often used. Some of the toughest ethical questions in medical practice occur when the rights and desires of individual patients are in conflict with social policies. Clashes between deontologic and utilitarian principles are common in the intensive care unit (ICU) (see also Chapters 101 and 102), in managed

care settings, and in the care of poor and older patients whose medical management is funded by the government. In each of these settings, the will of the individual patient may be in conflict with broader principles of minimizing expense, fairly allocating scarce resources, and determining where and how society's health care dollars are best spent.

The political tradition of the United States provides a clear underpinning to individual freedom, hence the translation of the Jeffersonian "life, liberty, and the pursuit of happiness" into the contemporary interest in the physician's beneficence and the patient's autonomy. With the background of this political tradition, contemporary bioethics shifted away from paternalism. At the beginning of the twentieth century, the concept of the autonomy of patients began to emerge.

CLINICAL ETHICS

INFORMED CONSENT AND INFORMED REFUSAL

Legal and moral imperatives for informed consent are based on the ethical principle of respect for patient autonomy. *Autonomy* refers to the ability to choose without controlling interferences by others and without personal limitations that prevent meaningful choices, such as inadequate information or understanding.[1] Individuals have the right to determine what happens to them to the degree that they are capable of doing so. In the United States, this right is rooted in constitutional guarantees of privacy and noninterference. In 1914, the case of *Schloendorff v Society of New York Hospital* established that it was the right of "every human being of adult years and sound mind to determine what shall happen to his own body."[2] In 1957, the term *informed consent* was first used in the case of *Salgo v Trustees of Leland Stanford Hospital*, which established that it is not sufficient for physicians simply to secure consent; physicians have a duty to inform patients about the risks and alternatives to treatment, in addition to the procedures themselves and their consequences.[3]

Respect for the patient's autonomy requires physicians to respect decisions made by competent patients and to *promote* autonomy by removing barriers to competent participation in decisions. Such obstacles range from incomplete or inaccurate information to reversible medical conditions that interfere with a patient's ability to understand the information given to him or her.

Competence or Capacity

Autonomy to make medical decisions cannot exist in the absence of competence. Because *competence* is a legal term, most medical experts prefer the term *capacity* to describe the necessary skills to participate in medical decisions.

Impairments of capacity can be temporary or permanent. Examples include some mental illnesses, dementia, immaturity, anxiety, pain, and medication effects. Older patients, patients suffering from mental impairment, and children are particularly vulnerable to having their participation in medical decisions inappropriately curtailed or even denied because their capacity to participate is frequently underestimated. Hearing loss and expressive aphasia can create the false impression that capacity is impaired. Many children make medical decisions in ways similar to those of adults but may be mistakenly excluded from the decision-making process solely because of their age. Language barriers can present significant challenges to communication.

Capacity is both relative and task specific. Patients may be able to understand and make decisions about medical issues while being unable to care for themselves in other ways.

Both prejudice and paternalism permeate physicians' behavior in the informed consent process. Challenges to a patient's competence rarely occur unless the patient and the physician have a difference of opinion or values. Patients are often referred for competency evaluations because they refuse medical advice, although refusal of treatment is not itself evidence of incompetence.[4] Physicians often disagree with a patient's decisions because they regularly ascribe a lower quality of life to impaired and handicapped patients than do patients themselves. Doctors are mistaken about patients' preferences regarding life-extending therapies in the majority of cases, and they underestimate older patients' desires for life-extending therapies in up to 30% of cases.[5] Moreover, surveys indicate that physicians and other health care workers are likely to *act* on personal prejudices regarding handicapped or impaired patients.[6]

Functional capacity for decision making must be judged separately from the perceived quality of the decision itself. Patients have the right to make "bad" decisions if they are competent and have appropriate information. Otherwise, the physician could merely substitute his or her own judgment for that of the patient, and autonomy in medical decision making would be nonexistent.

How do we recognize competence? When assessing a patient for anesthesia care, the anesthesiologist should focus on the following concerns: (1) Can the patient receive and understand the information relevant to the decision? (2) Can the patient understand potential consequences of the decision, including potential risks and benefits, even if in a very simplified way? (3) Can the patient express a decision and communicate his or her values regarding the medical advice being given?

The anesthesiologist has an ethical duty to treat reversible conditions that interfere with medical decision making. Elective surgery may have to be postponed until expert consultation for a determination of mental capacity or treatment of reversible conditions can occur. When surgery is urgent or a patient is impaired by an irreversible condition, the anesthesiologist may have to rely on a surrogate decision maker or proceed with the best determination of the patient's interests in mind.

Disclosure

The informed consent process requires honest disclosure of medical information to the patient. U.S. courts currently rely on two standards of disclosure: the reasonable person standard and the subjective standard. A third, professional standard, in which the physician is obligated to disclose only what other physicians of the same specialty

would disclose, was subject to abuse and manipulation and is essentially no longer recognized. In the *reasonable person standard,* the physician must disclose any information that a theoretically reasonable person would want to know. This standard does not require an exhaustive recitation of facts, and it acknowledges that not all information related to the procedure is integral to making a decision about whether to undergo that procedure. The *subjective standard* recognizes that some patients may have special needs for specific information, and when that need is obvious or has been brought to the attention of the physician, the information must be disclosed. A concert violinist may have a specific need to know about the potential for nerve damage from an axillary block, for example. In general, legal and ethical standards now require that the physician (1) accurately discuss the therapy and its potential alternative—including no therapy—and (2) disclose the common risks (because they are more likely to happen) and the serious risks (because the consequences are severe).

The doctrine of *therapeutic privilege* is sometimes cited to avoid discussing risks, the reasoning being that the stress of discussing risks can psychologically or physically harm the patient. Studies of patients' stress during the informed consent process *do not* support this concept.[7] Therapeutic privilege is probably invoked in many cases because the physician is uncomfortable with disclosure or wants to curtail discussion. Although it is ethical to forgo or curtail risk discussions at the patient's request, it is generally not ethical for the physician to decide to do so unilaterally.

The physician-patient relationship is inherently unequal because of the physician's knowledge and authority and the patient's dependence on the physician for care. Physicians have ethical obligations to avoid exploiting their influence for the purpose of accomplishing their own ends. Although offering a rational basis for a medical choice is acceptable, it is generally unethical to coerce or manipulate patients into decisions by presenting real or implied threats or by omitting or misrepresenting key information.

Legal Implications of Informed Consent

The informed consent process does not prevent legal liability when adverse events occur. Flawed informed consent processes have been cited, however, as evidence of a lack of quality of care by the physician. The American Society of Anesthesiologists (ASA) closed-claims database reveals that informed consent is cited in approximately 1% of cases, and cases with inadequate informed consent documentation are associated with larger monetary awards.[8] Studies repeatedly show that the risk of filing a malpractice claim is directly related to the patient's perception of his or her relationship with the physician.[9] The informed consent process provides one of the few opportunities anesthesiologists have to establish that relationship, however brief, and the medicolegal importance of that process should not be underestimated.

Informed Refusal

Informed consent is meaningless if the patient cannot also refuse medical therapy because the consent process is then merely an exercise in the patient's acquiescence to the physician's will. Examples of informed refusals in anesthesiology include the following: requests to withdraw or withhold life-supporting care in the ICU; do-not-attempt-resuscitation (DNAR) orders in the operating room; cases in which the patient has objections to certain forms of therapy, such as the Jehovah's Witness who refuses blood transfusions; and cases in which a patient refuses preoperative testing, such as human immunodeficiency virus (HIV) or pregnancy testing.

Informed refusal has concerns and requirements similar to those of informed consent. When patients refuse medical care or insist on what the physician believes is suboptimal care, disclosure of the risks and benefits becomes even more important because these decisions may veer from options that are already widely accepted and for which the risks are believed to be lowest. It is easier to justify agreeing to unusual preferences of a well-informed patient than to subject a poorly informed patient to unorthodox care.

Despite full information, patients may sometimes request or demand care that is unreasonable, either because it will adversely affect the performance of a surgical procedure or because it would be associated with unreasonably high risks. When a patient demands a technique that is inappropriate or outside of the realm of reasonable practice, the anesthesiologist is under no ethical obligation to provide that care. No physician can be compelled by a patient to practice negligently.

Special Issues in Informed Consent and Informed Refusal

The Jehovah's Witness Patient. The classic example of a patient who refuses therapy in anesthesia practice is that of Jehovah's Witnesses, many of whom believe that accepting a blood transfusion violates a Biblical injunction. The Jehovah's Witness doctrine has been subject to change over time, with resulting inconsistencies in religious practice with regard to which, if any, blood components may be acceptable. Individuals interpret religious doctrines in light of their own spiritual contexts, and not all believers hold to the same tenets with identical fervor. Church doctrines, like medical practices, evolve over time, and practices that are acceptable at one time may not be years later. Anesthesiologists and surgeons have cited individual and doctrinal inconsistencies as justification for ignoring the wishes of Jehovah's Witness patients, but to do so is no more logical than assuming that every hypertensive patient needs or will respond well to identical treatment or that optimal treatments will not evolve over time.[10] Moreover, *any* patient has the right to refuse blood transfusion therapy, regardless of whether this desire is founded in religious preference. Such refusals have become more common in patients who are not Jehovah's Witnesses because blood transfusion therapy was connected to cases of acquired immunodeficiency syndrome (AIDS) in the 1980s, and patients began questioning the value and necessity of transfusion therapy in light of its risks (see also Chapter 61).

Because of the differing beliefs regarding which, if any, blood replacement therapies are acceptable, the anesthesiologist must have a thorough and detailed preoperative

discussion of possible therapies with the Jehovah's Witness patient, and the conclusions should be documented in the patient's chart. An anesthesiologist who cannot comply with an adult patient's desire to forgo transfusion has an ethical obligation to find an alternative caregiver whenever possible.[11]

The courts strongly support the rights of adult patients to refuse blood products for themselves but have been inconsistent and have interfered in cases of some pregnant patients. Transfusion of pediatric Jehovah's Witness patients by court order is common. However, this may become ethically and legally less acceptable as alternative bloodless therapies to maintain oxygen-carrying capacity evolve, as the Jehovah's Witness church further defines its doctrines with regard to children, and as the capacity of children to consent to or to refuse therapy is better understood.

The Pediatric Patient and Other Patients With Impaired Competence. The ethical practice of medicine weighs heavily toward adherence to the respect for autonomy in patients who are competent to make medical decisions (see Chapter 93) or who have executed advance directives when they were competent to do so. Medical care of individuals who have never been autonomous relies on principles such as respect for human dignity, beneficence, avoidance of harm, and adherence to the principle of justice.

Children are examples of persons who may or may not yet be autonomous (see also Chapter 92). Laws in each state define the age at which children become *legally* competent to make medical decisions (usually 18 years of age), but many younger children have the mental and emotional capacity to make medical decisions. Forcing such individuals to undergo treatments they do not want is unethical and could be illegal as well.

Decision-making capacity in children is variable. Most 2-year-old children are clearly not able to make medical decisions. However, the range of capability in children as young as 7 or 8 years old is wide, and studies suggest that the average 14-year-old adolescent makes medical decisions in ways similar to adults. In one study, children 6 through 9 years of age who were invited to participate in influenza vaccine research asked pertinent questions about individual risks and benefits and whether their community and other children would benefit.[12]

Most states recognize "emancipated minor" status, in which a court determines that a minor can legally make medical decisions for himself or herself. Legal exceptions to the age of consent are recognized in most states when treatment is believed to be in the minor's best interest and when a requirement for parental consent would interfere with the child's ability to receive medical help. The law recognizes that, tragically, some conditions for which a minor seeks therapy may even be the result of parental abuse, and seeking parental permission for treatment may actually further endanger the minor. Thus, minors are allowed in many states to consent for treatment for substance abuse, sexually transmitted disease, mental illness, and medical care affecting pregnancy, including abortion. When a minor has decision-making capacity but is not "emancipated," a judge may declare the child to be a "mature minor," with decision-making rights.

Ideally, individuals of any age should be involved in medical decisions to the degree that their capacity allows. A minor who possesses capacity to make decisions should not be coerced or restrained under most circumstances.[13] Determining whether a minor has such capacity may require formal consultation and assessment. The term *assent* rather than consent is used to refer to agreement with treatment from children who do not fall into legal categories awarding them adult rights. The American Academy of Pediatrics has stated that physicians who care for children "should give serious consideration to each patient's developing capacities for participating in decision-making, including rationality and autonomy."[14]

When children dissent from medical care, persistent refusals may be ethically binding, particularly in the case of participation in research. Medical personnel should respect the wishes of a patient who withholds assent and should try to gain a better understanding of the patient's situation or deal with his or her fears. "A patient's reluctance or refusal to assent should also carry considerable weight when the proposed intervention is not essential to his or her welfare and/or can be deferred without substantial risk."[14]

Ethical Challenges of Preoperative Testing

The ethical implications of medical tests, such as genetic testing, have been widely discussed in the literature, but the ethical implications of more routine testing have been largely overlooked by professional societies (see also Chapter 38). The performance of diagnostic tests does have ethical dimensions, however. We generally undertake such tests precisely because we intend to help the patient (beneficence) or to use the information to minimize other risks (nonmaleficence). However, medical tests may also carry implications for the patient's autonomy, privacy, and even social justice.

Routine Preoperative Testing Protocols. Preoperative testing may help identify unrecognized or disguised conditions that could adversely affect anesthetic risk. All medical tests carry risks, however. False-positive and false-negative results may either label patients as having a condition they do not have or inappropriately assure patients that they do not have a condition that they in fact do. Erroneous results may lead either to further testing or to inappropriate and unnecessary therapy associated with further complications. Errors can also cause patients to be deprived of important therapy they would otherwise receive. Tests sometimes have accompanying physical complications, and they are certainly always associated with economic costs. Systematic overtesting increases the costs of health care for entire populations, thus unnecessarily burdening an already costly system and diverting badly needed funds to unnecessary enterprise. Medical tests may involve problems of conflicts of interest, if the physician determining the need for testing has an economic relationship with the entity that will carry out the tests. In addition, not all medical tests are ethically equivalent. Certain tests, such as pregnancy testing and HIV testing, may have complex social consequences and may lead to specific, avoidable harms.

Modern medicine is a science that incorporates theories that are expected to be consistent and generalizable. Although all data are deeply theory laden, the practice of evidence-based medicine (EBM) is founded in the concept that conscientious, judicious, and explicit use of the best available medical evidence should be integrated with clinical experience derived from systematic research in making decisions about the medical care of individual patients. In general, nonsystematic clinical experience, anecdote, and untested theory are not sufficient grounds for clinical decision making.

The practice of EBM also focuses on patients' autonomy through informed consent and recognitions of patients' values and goals. EBM and medical ethics share common principles and goals: both are aimed at maximizing benefits and minimizing risks, as well as at involving the patient in shared decision making.[15]

The use of EBM to guide clinical testing and therapy is supported by analysis of traditional therapies that were never subjected to rigorous testing but that, on examination, were shown to be not only unhelpful to patients but also possibly harmful. A Cochrane review, for example, suggested that administration of human albumin, a mainstay of therapy for treatment of shock, may be associated with increased mortality.[16] Another Cochrane review demonstrated that although mammography screening will prolong the life of 1 in 2000 women over a 10-year period, it will lead to the false diagnosis of cancer and the institution of cancer treatment in 10 women during that same period; these findings raise serious questions about the benefits and risks of routine mammography.[17] With regard to hydroxethyl starch administration, the decision to administer this colloid was complicated by a leader in the field (Boldt) who provided "fake" data (see Chapter 61). Using systematic evaluation of medical diagnostic testing to develop principles of preoperative testing not only serves the ethical principles of beneficence and nonmaleficence but also permits us to provide patients with accurate and up-to-date information on the potential benefits of tests to aid their understanding and input in their medical care—thus honoring the principle of respect for the patient's autonomy.

Conversely, EBM presents potentially significant ethical concerns. In relying on traditional medical experimentation, EBM may not sufficiently take into account the role of social and cultural factors (e.g., poverty, ethnicity, spirituality, and gender) that may have considerable influence on health and instead may rely too heavily on a narrowly drawn biomedical model of the patient's experience of health and disease. In the words of Rogers, "those with the greatest burden of ill health are disenfranchised, as there is little research that is relevant to them, there is poor access to treatments, and attention is diverted from activities that might have a much greater impact on their health."[18]

Despite the potential limitations of EBM, it nevertheless seems reasonable to believe that in trying to maximize beneficence and minimize nonmaleficence, EBM provides at least an improvement in the search for a rational, cost-effective approach to medical testing over simply adopting "traditional" therapies or protocols without evidence that they will contribute to accomplishing those goals. Applying medical tests inappropriately can cause very real harm to patients. Simply stated, if medical care is not valid, then it is not ethical.

Evidence that routine tests or traditional patterns of preoperative testing enhance perioperative outcomes is often scant. Large population studies of many routine preoperative tests, such as coagulation screening,[19] chest radiography,[20] and electrocardiography,[21] have, on the contrary, suggested that these tests increase costs without necessarily positively affecting outcomes and can even lead to detrimental outcomes (see also Chapter 38). The ASA Task Force for Preanesthesia Evaluation acknowledged that most routine testing is not necessary.[22] When evidence-based algorithms for preoperative testing are available, they should be used to guide clinical decision making.

Routine Preoperative Pregnancy and HIV Testing. Social risks of preoperative testing may not be as obvious to the physician as medical risks, but they can be the source of significant harm (see also Chapter 77). Examples of tests that can produce social harm and are of limited preoperative utility are HIV and pregnancy tests. Both tests have serious ethical consideration; have limited, if any, beneficial impact in the setting of surgery; may have serious social and economic consequences for the patient beyond the operating room; and require the patient's informed consent.

HIV tests are usually ordered for the purpose of singling out patients for whom extra universal precautions could be taken to reduce transmission in the operating room. Most surgeons and anesthesiologists believe that compulsory HIV testing would reduce their risk of exposure, and many believe that this testing is the physician's prerogative and can be done without the patient's consent.[23]

However, HIV testing does not necessarily yield safer anesthetic management and is more costly than diligent application of universal precautions.[24] In low-prevalence populations, testing is more likely to give false-positive results that wrongly reassure operating room workers that a patient is not infected. This may paradoxically increase the risk of HIV transmission if relaxation in vigilance is the result.

HIV tests can result in loss of employment or insurance coverage, or both. Seropositive women often experience marital breakup, abandonment, verbal abuse, and physical violence if their status is disclosed.[25,26] The threat of compulsory HIV testing almost certainly would prevent some patients from seeking needed surgical care.[23]

Routine preoperative pregnancy testing has ethical ramifications analogous to those of HIV testing. Despite pervasive beliefs to the contrary, large, well-designed population studies did not demonstrate that anesthetic agents lead to early fetal loss or increased fetal malformation.[27-30] Studies have also shown that even adolescent girls generally accurately report the possibility of pregnancy when asked privately.[31] Legal ramifications of not routinely testing for pregnancy preoperatively have been virtually nonexistent, and fewer than one third of practices in the United States require this testing.[32] A positive pregnancy test may have extremely negative consequences if a vulnerable patient is in a social situation in

which pregnancy is not accepted. Abandonment, negative family interactions, and violence to the patient or her fetus, or both, may all occur. Adolescent pregnancies are sometimes the result of child abuse or rape, and referral of adolescents who are pregnant to child protective services should be considered.[32] In many states, it is illegal to disclose or even insinuate a child's pregnancy status to her parents regardless of her age. Therefore, the anesthesiologist who discovers an adolescent patient's pregnancy has few comfortable or legal options.

Many patients may choose not to undergo an elective surgical procedure if they know they are pregnant. However, *coercing* a female patient to have a test against her wishes and that she may find insulting explicitly violates the principle of the patient's autonomy. The physician's self-interest is not a sufficient justification for disregarding a patient's autonomy or violating a patient's privacy. The ASA Task Force on Preoperative Testing and the ASA Committee on Ethics jointly recommended that anesthesiologists offer the *choice* of preoperative pregnancy testing to any female patient who may desire it, explain the potential risks and benefits, and obtain informed consent for the test.[22]

Ethics of Anesthesia Involving Pregnant Women

Maternal-Fetal Conflicts. In general, the rights of pregnant women to refuse therapy, even if it will be detrimental to their fetuses, are protected under right-to-privacy provisions in the U.S. Constitution (see also Chapter 77). Those rights are weighed against potential harms to the fetus in a decremental fashion as the fetus approaches and surpasses viable age. When the fetus is of nonviable age, the mother's rights prevail. Court decisions have consistently upheld the rights of pregnant women to have abortions, to not be subjected to drug testing, and to forgo transfusions early in pregnancy. Attempts to charge women with child abuse, child endangerment, drug trafficking, murder, and attempted murder for activities deemed dangerous to their fetuses have almost uniformly failed.[33] In general, women do not lose their rights to bodily integrity and informed consent when they become pregnant, and neither fetal "rights" nor state interests supersede a pregnant woman's right as medical decision maker.

The American Academy of Pediatrics Committee on Ethics outlined conditions that in their view are necessary to override a mother's refusal of care: (1) the fetus *will* suffer irrevocable harm without the treatment, (2) the treatment is *clearly indicated* and likely to be effective, and (3) the risk to the woman is low.[34] The American College of Obstetricians and Gynecologists condemned the use of coercion in pregnant women and advocated counseling the patient carefully about risks, as well as consultation with an ethics committee.[35]

Informed Consent in Laboring Women. The validity of informed consent for epidural anesthesia in laboring women is a topic of concern to anesthesiologists, who periodically raise the question whether laboring women are able to consider and weigh the risks of labor analgesia sufficiently while they are in pain. Although ideal conditions for informed consent are often lacking during labor, it is important to realize that the ideal is seldom achieved even in surgical patients; therefore, it is crucial to distinguish between conditions that are not *ideal* from conditions that are not *adequate*.

Competence to give consent requires the ability to assimilate information, debate the risks and benefits, and communicate a decision. Despite frequently voiced concerns by anesthesiologists about informed consent during labor, most studies show that laboring women have the same capacity to give informed consent as the general surgical population,[36,37] are able to recall details of the consent process long after labor is finished, and indicate that labor did not alter their decision making.[38] Some investigators even argue that it is only after the patient can assess the severity of pain and consequences of proceeding without analgesia that she can be fully informed.[37]

An ethical conflict can arise in the case of so-called Ulysses directives in which, before labor, a woman executes an advance directive that refuses epidural analgesia and instructs doctors to ignore her pleas for epidural anesthesia at the time of labor should she change her mind. Although some experts suggest that ignoring the Ulysses directive disrespects a woman's long-term preferences, others argue that "information and valid experience are critical prerequisites for autonomous decision making" and that only the current wish (to receive an epidural) is ethically relevant.[36] Such cases appear to have no clear and unequivocal ethical ground on which to proceed, and circumstances must guide the physician. However, if an anesthesia practice decides to disregard Ulysses directives routinely, this should obviously be disclosed to patients in advance of labor whenever possible.

The Uncooperative Patient—Coercion and Restraint

The use of physical restraint to control medical research subjects was first directly addressed in the Nuremberg Code following the Doctors' Trial in 1947 to 1949 and is a continuing subject of intense scrutiny.[39] For anesthesiologists, chemical restraints often replace physical ones, but the ethical issues are the same. Anesthesiologists are often asked by medical colleagues to chemically restrain uncooperative patients. Use of restraints is antithetical to promotion of autonomy, and anesthesiologists have both ethical and legal obligations to determine whether such extreme intervention is warranted. Coercing or using physical or chemical means to force a competent patient to undergo treatment that he or she is refusing is both unethical and illegal. Refusal of medical care and angry behavior are not proof of incompetence, intoxication, or inability to make medical decisions.[40]

When faced with the uncooperative adult patient, questions to ask include the following: (1) Is the patient clearly incompetent or merely angry and uncooperative? Does the patient show evidence of neurologic impairment, acute intoxication, or severe mental disability? (2) Is the patient in immediate danger? (3) Does the patient pose a direct threat to staff or other patients? (4) Does a compelling need to treat life-threatening injuries exist? In the absence of any of the foregoing, the use of coercion or physical or chemical restraints is neither ethical nor legal.

Physicians may be forced in some situations to act within a time frame that does not permit lengthy evaluation of a patient's competence or a protracted search for a surrogate decision maker. In such cases, the physician must rely on professional judgment in deciding how to care for the uncooperative patient who either cannot speak for himself or herself or who appears incompetent to refuse care at a time when a decision must be made. The standard applied in such cases would be to do what a "reasonable" person would wish. Coercion or restraint (or both) in such situations is not ideal, but it may be necessary and ethically permissible.

The uncooperative child presents special ethical concerns. When a patient who does not have the capacity to make health care decisions dissents from medical care, the anesthesiologist is ethically required to provide care that is most likely to benefit the patient and prevent harm while preserving the dignity and safety of the patient. Although violation of respect for autonomy is technically not possible in a patient who does not have autonomy, violations of principles of beneficence, nonmaleficence, and respect for dignity certainly are. Indiscriminate use of physical or chemical restraints is not without physical risk, and the fear and anger provoked by such tactics can lead to future aversion of medical care and mistrust of health care providers. The American Academy of Pediatrics Committee on Child Abuse and Neglect stated that restraint should not be used in pediatric care "unless it is necessary for proper diagnosis and treatment in a sick child, as in the case of a child with a high fever and potential ear infection, or in emergency situations."[41]

Behavioral control in the uncooperative child or incompetent adult should focus on alternatives to physical restraint, such as offering choices on how to go to sleep and use of fantasy or hypnotic suggestion. Despite many possible social, economic, and scheduling pressures to the contrary, delaying or rescheduling a surgical procedure in a hysterical patient is better than using coercion or force. Delaying elective surgery may reduce stress, allow adequate premedication, and promote safer induction conditions. If medical care is urgent, or if delay is unlikely to result in better conditions for the patient, then the anesthesiologist should proceed in a manner designed to preserve the patient's dignity and safety.

TRUTH TELLING—DISCLOSURE OF ERRORS AND APOLOGY

Nonmaleficence has been a foundational principle for the medical profession since the time of Hippocrates, and this principle draws no distinction between deliberate and unintended harms (see also Chapter 11). Medical care is fraught with uncertainty, risk, and error. Harms resulting from unexpected complications, accidents, systems issues, and medical mistakes are to be gently avoided with equal diligence whenever possible.

Wu and colleagues defined a medical mistake as "a commission or omission with potentially negative consequences for the patient that would have been judged wrong by skilled and knowledgeable peers at the time it occurred, independent of whether there are any negative consequences."[42] Medical errors occur in 3% to 5% of all hospitalizations.[43] More than 40% appear to be preventable, and more than 15% result in patients' deaths.[44] In 1999, the release of the Institute of Medicine's report *To Err Is Human* focused public and political attention on the terrible fallout of medical errors in the United States.[45]

Studies showed that 76% of physicians admitted to a medical error that they did not disclose to the patient,[46] and 22% of physicians indicated that they would not disclose an error that caused a patient's death.[47] Reasons cited for a physician's reluctance to disclose errors included personal shame, fear of loss of prestige in the physician's cohort, fear of direct reprisal, lack of experience in disclosing uncomfortable information, fear of causing further harm (emotional or psychological) to the patient and family, and fear of litigation.[48] In many cases, legal advice to physicians has discouraged disclosure and apology in the belief that these tactics decrease medicolegal liability.

Obfuscating the root cause of a patient's complication when it is caused by a medical error is not difficult in the physician-patient relationship because the physician has unique expertise and is the recipient of unique trust. Furthermore, a minimum standard of disclosure simply does not exist. The Code of Ethics of the American Medical Association (AMA) states that patients have a right to be free of misconceptions about their medical condition and that physicians have ethical obligations to "inform the patient of all the facts necessary to ensure understanding of what has occurred."[49] However, the AMA Code of Ethics addresses only "harms" and not "errors," thus implying no duty to disclose medical errors that do not lead to harm. Although some experts state that physicians may have a lesser obligation to disclose harmless errors and/or "near misses," it is nevertheless arguable that they should consider doing so. The physician has little to lose, and such disclosures may enhance discussion of medical care with the patient and result in a strengthened doctor-patient relationship. Legalistically, some experts consider full disclosure of medical errors to be an extension of the legal principle underlying informed consent: "Clearly, if the patient is entitled to know the risks of a procedure and what could go wrong prior to giving their consent, it follows that they would be entitled to know if something has in fact gone wrong, regardless of whether it was unanticipated."[50]

Respect for patients' autonomy requires that we disclose mistakes that harm patients because in so doing we release patients from misconceptions about their medical past and enhance their ability to share decision making about their medical care.

Both deontologic ethics and consequentialist (utilitarian) ethics support ethical obligations of beneficence and nonmaleficence and require physicians to report errors to patients. The patient can then seek and receive timely treatment of adverse effects of the error. Disclosure prevents mistaken attribution by the patient of adverse consequences to noncontributory causes. Disclosure is usually necessary for informed consent for treatments to address complications of the error. Disclosure may enhance patients' trust in physicians. Moreover, disclosure may facilitate a patient's obtaining just and fair

compensation for economic consequences of the injury, such as lost work and pay.

The concern that disclosure of errors to patients will increase litigation or decrease patients' trust, either in the doctor involved or in doctors in general, has not been borne out. Studies have suggested that full disclosure of a medical error reduces the likelihood that patients will change doctors, improves patients' satisfaction, increases trust in the physician, and leads to a more positive emotional response.[51] Studies also have demonstrated that patients take legal action because they want more honesty from their physicians and assurances that the physician has learned from the mistake and that future patients therefore are less likely to suffer.[52]

Physicians may benefit from a sense of relief after disclosure and, in many cases, the forgiveness of the patient. Disclosure helps physicians learn and improve their practice. Failures to report errors, learn from errors, and communicate errors and their potential solutions within a health care system are major causes of medical errors themselves. One could argue that a physician who does not disclose a preventable error, such that it is repeated, bears responsibility for harm not only to his or her own patient but also to all future patients in whom the error could have been prevented had it been disclosed.

Harms that can arise from disclosure are generally visited on the physician: disclosure is stressful, litigation may result, malpractice premiums may rise, and future employment may be adversely affected. However, in the doctor-patient relationship, ethical frameworks hold that benefits and harms to the patient should hold greater weight than benefits and harms to the physician.

Do we have an ethical duty to disclose the errors of others? Legally, some North American courts have held that we do not,[50] and social norms about "tattling" on others are powerful deterrents to such disclosures. The reporting physician may hesitate because of a lack of definitive information, potential accusations of interfering in the doctor-patient relationship of another, worry that professional interactions such as patient referrals and performance evaluations may be affected, and fear of libel suits. When a physician observes a medical error committed by another physician, the options include nondisclosure, recommendations to the involved physician to disclose the error, disclosure of the error to a third party such as a risk-management group, or direct disclosure to the patient. Although no strict legal guidelines are in place, ethical principles favor actions that lead the patient to have a full understanding of what has occurred during the course of his or her medical care.

Apology (as opposed to disclosure) remains a controversial aspect of communication following medical errors, largely because of a well-founded fear, at least in the past, that it could be used as an admission of negligence in subsequent litigation. Yet apology appears in many cases to decrease the risk of subsequent litigation, and lack of apology is a commonly cited reason among malpractice plaintiffs for their legal action.[53] Spurred on by a desire to reduce litigation, many states have enacted "apology laws" that prohibit use of various types of apologies in court against physician defendants in malpractice cases. The impact of these laws and the impact of apologies on the incidence and outcomes of malpractice litigation remain unclear, although significant numbers of patients who have sued physicians have indicated that an apology would have prevented them from doing so.

ADVANCE DIRECTIVES AND SURROGATE DECISION MAKERS

Critical decisions regarding medical care often arise when patients are too ill to formulate or express decisions regarding medical interventions (see also Chapter 11). *Advance directives* were developed after several legal decisions affirmed that patients can refuse even lifesaving medical care and that clear and convincing evidence of the patient's wishes is needed to allow surrogate decision makers to request withdrawal of life-sustaining therapies.[54] An advance directive is a document executed by the patient before incapacity to provide the patient's physicians with guidance in medical decision making when the patient cannot communicate for himself or herself. Such directives include the following: living wills, which detail the therapies a patient would accept or refuse in the case of terminal incapacity; DNAR orders; and any other information regarding medical care decisions.

A surrogate decision maker may be someone whom the patient has appointed to make health care decisions for him or her (a durable power of attorney [durable POA]) or an individual with other legally recognized authority by virtue of his or her relationship with the patient.

A durable POA for health care decisions may be given by the patient to a specific person he or she designates to make health care decisions for the patient if he or she becomes incapacitated. The authority vested in a POA supersedes most other decision makers, including family members, except a court-appointed guardian.

When the patient has not designated a durable POA, doctors rely on family members to make decisions for the patient. Many states have a legally defined hierarchy of decision makers. Usually, the spouse or legally recognized domestic partner is considered the first-line surrogate decision maker. Commonly, the surrogate hierarchy after the spouse is children, if all are in agreement, then parents, if both are in agreement, and then siblings, if all are in agreement. When a patient has no advance directives and either a surrogate decision maker is not available or family members cannot agree, the courts may appoint a guardian ad litem to represent the patient in medical decision making.

Surrogate decision makers explicitly act in "substituted judgment" to provide what the patient would have wanted and theoretically are not asked merely for their own preferences. However, surrogate decision makers at best only approximate the patient's decisions because their interpretation is subject to their own biases, values, and psychological agendas. Incompetent patients can be emotionally and financially burdensome, and decision makers may have conflicts of interest that distort their beliefs and testimony about what the patient would have wanted.

Studies demonstrate that patients and their proxies only infrequently discuss issues and values involving life-sustaining technologies. Discrepancies between

patients and proxies are often significant in the assessment of patients' emotional health and satisfaction. Neither physicians nor proxies can always accurately predict the patient's preferences for life-sustaining therapies.[55-57] Nevertheless, with all the imperfections, proxy decision making may be the only option if a patient has not left specific directives.

Medical Decisions That Cannot Be Made by a Surrogate Decision Maker

Some medical treatments have intense cultural connotations, may involve limitation on private freedoms such as reproduction, or may have historically been subject to abuse. Decisions regarding these interventions *cannot* be made by a surrogate decision maker (even if one is available) and require a court review. Examples of such treatments in many states include sterilization and electroshock therapy.

The anesthesiologist should review the patient's record before taking the patient to the operating room and ascertain (1) whether the patient has advance directives, (2) who the patient's surrogate decision makers are, (3) whether the procedure is legally allowed with consent from a surrogate decision maker, and (4) in special cases, whether an appropriate court order has been obtained.

Special Issues With Advance Directives—Do-Not-Attempt-Resuscitation Orders in the Operating Room

Up to 60% of anesthesiologists wrongfully believe that DNAR orders are automatically suspended during anesthesia and surgery. The ASA,[11] the American College of Surgeons,[58] the Association of Operating Room Nurses,[59] and The Joint Commission[60] all published practice guidelines requiring reconsideration, not abandonment, of the DNAR orders in the perioperative period.

The DNAR order is, in essence, documentation of the patient's wishes to avoid the medical interventions associated with resuscitation. Because the causes and outcomes expected with a cardiac arrest in the operating room are different from what may happen elsewhere and prognosis is more favorable, it is very important to reassess the patient's desires when surgery is anticipated.

The ASA issued guidelines for management of the patient with DNAR orders and other directives limiting medical care.[11] Although the patient's primary care physician may have introduced the idea of DNAR orders to the patient or the surrogate decision maker, it is specifically the anesthesiologist's duty to discuss the risks and benefits of resuscitation in the setting of anesthesia and surgery before undertaking the patient's care. The anesthesiologist should include in this discussion the following steps: (1) determine the patient's goals regarding surgery and resuscitation; (2) establish exactly what is meant by "resuscitation," in contrast to routine anesthetic care; (3) educate the patient about the risks and benefits of resuscitation in the operating room setting; and (4) document the agreements reached with the patient about which interventions commonly associated with resuscitation are acceptable to him or her. Such interventions could include, but are not limited to, intubation, administration of vasoactive drugs, administration of direct current (DC) countershock, and institution of chest compressions. Many patients who express reluctance about resuscitation during surgery are fearful of burdensome outcomes, such as permanent neurologic impairment. Education and discussion may reassure these patients about the favorable outcomes of resuscitation in the operating room and can establish ground rules for discontinuing interventions postoperatively if they do not lead to a chance of meaningful recovery.

Surgery depends on the cooperation of many caregivers with differing expertise, each of whom has independent ethical obligations to the patient. Therefore, resuscitation agreements must be discussed with other members of the operating room team. This communication prevents crucial disagreements from occurring during a critical event when treatment decisions must be made quickly. It also allows "conscientious objectors" to withdraw from the health care team.

Advance directives are legally and ethically binding. Despite clear, consistent, and forceful legal decisions, many physicians still resist imperatives to respect patients' wishes regarding resuscitative care, life-sustaining therapies, or both. Anesthesiologists have ignored DNAR directives under the false assumption that the legal authority of advance directives and living wills is not binding in the operating room or that the physician has discretion in deciding when to follow or ignore such directives. In response, courts have awarded significant monetary damages for the costs of continued health care and punitive damages for the pain, suffering, and mental anguish of the patients' survivors when DNAR instructions are ignored.[61]

Finally, DNAR orders must never be construed as an excuse to not "care" for the patient. A patient's decision to forgo resuscitation does not imply a wish to avoid other beneficial interventions. Placement of a pulmonary artery catheter, for example, may help ensure optimal management of a frail patient who has a DNAR order by enabling the anesthesiologist to avoid situations in which the patient's DNAR status becomes pivotal.

END-OF-LIFE DECISION MAKING

A 1996 review by the AMA showed that the following end-of-life issues were of foremost importance to patients: control over the timing and location of death; management of symptoms such as pain, dyspnea, anxiety, and depression; financial management of medical care; and maintenance of therapeutic options, including physician-assisted suicide (PAS).[62]

Withdrawal or Withholding of Medical Therapies—*Curing* versus *Caring*

More than 80% of deaths in the United States occur in health care facilities, and most deaths in ICUs occur after an explicit decision to withdraw or withhold treatments.[63] Patients and doctors alike recognize that aggressive medical therapy may not be desired or even appropriate in the presence of advancing disease. Continued therapy may not be warranted or desired when quality of life is extremely poor, even if the patient is not suffering from terminal disease.

Before the midtwentieth century, the concept of beneficence in the eyes of physicians was strongly tied to preventing death. Ethical distinctions between acts of omission ("letting die") and acts of commission ("killing") were and remain confusing at best. Worse, physicians faced threats of criminal punishment if a patient's death resulted from withdrawal of medical treatments. In 1976, the case of Karen Ann Quinlan established that patients have a right to forgo invasive treatments, even if lifesaving, and that surrogate decision makers could ask for withdrawal of lifesaving therapies if the surrogates could show that the patient would not have wanted them.[64] The right to forgo lifesaving treatments was later extended in the cases of Claire Convoy and Nancy Cruzan to include *any* treatment if the patient refused it or if clear and convincing evidence indicated that the patient would have refused therapy if he or she could not speak for himself or herself.[54] These decisions were revisited and reconfirmed in the tragic case of Theresa Schiavo in 2005.[65]

Arguments that withdrawing or withholding life-sustaining therapy does not violate rules against killing patients are based on ethical differences between killing and letting die and between acts of commission (e.g., lethal injection) and acts of omission (e.g., withdrawal or withholding of ventilator therapy).[66] Because such distinctions are confusing to both physicians and patients, a *principle of proportionality* is often applied when withholding or withdrawing treatments.[67] In this principle, treatment is indicated to the extent that it is likely to present more benefits than burdens to the patient based on the patient's perception of such medical, social, and psychological benefits and burdens. Of course, competent patients still always have the right to refuse therapy, even if lifesaving and otherwise indicated.

Two common settings in which anesthesiologists may be involved in withdrawing or withholding life-sustaining interventions are the ICU and the operating room before organ donation after cardiac death (DCD). In both cases, the issues and principles of withdrawing or withholding treatments are the same.

Withdrawal of life-sustaining interventions heralds the final phase of end-of-life care, and it is a socially critical phase in the life of the patient and family. Terminal care requires special knowledge and experience on the part of the physician. It requires expertise in medically supportive therapy, management of problematic symptoms, knowledge about physiologic changes in the dying patient, support and counseling of patients and families, understanding and respect for the patient's autonomy and religious and cultural practices and beliefs, the ability to work within complex health care teams, the ability to communicate well, and empathy.[68] Anyone intimately involved in care of the dying patient should also be intimately familiar with ethical and legal standards.

Withdrawal of life-sustaining care begins with an assessment of the individual patient's physiology, level of dependence on therapy, degree of consciousness, preferences regarding sedation and analgesia, and preferences regarding privacy and level of involvement of family and other loved ones. All the patient's treatment orders should be reviewed to meet the new treatment goals. Treatments promoting the patient's comfort should generally be continued, whereas those directed only at physiologic maintenance may all be withdrawn. Family members and others attending the patient at the end of life should be educated about physical and mental changes they can expect to see as treatments are scaled back, including the possibility that death will not occur imminently once support is withdrawn.[69]

Several interventions have ethical implications and deserve special consideration—fluid and nutritional management; the administration of sedatives and narcotics that have the potential to hasten death; the administration of neuromuscular blocking drugs; and deactivation of pacemakers, ventricular assist devices, and implantable cardioverter-defibrillators.

The issue of fluid and nutritional support is controversial. Burdens associated with continuation of fluid and nutritional support include prolongation of the dying process and complications and suffering from placement and maintenance of intravenous or enteral access (or both). However, feeding and hydration may have important connotations for family members and members of the health care team by allowing a sense of nurturing and mitigating feelings that they are "abandoning" the patient.[70]

Pain, dyspnea, and depression are all common symptoms that cause suffering in the dying patient. Alleviating pain and dyspnea carries the risk of hastening death. Medical, legal, and religious authorities have all clearly accepted the principle of "double effect," in which an action intended to produce a benefit for the patient produces not only the expected benefit but also the potential for significant harm. It is entirely ethical and legal to administer high doses of pain medication and sedatives for the intended effect of relieving suffering, even if the treatment has the side effect of hastening death. However, to administer any medication with the explicit intention of hastening death is euthanasia and not medical therapy.[70]

Neuromuscular blocking drugs have no anesthetic, analgesic, or sedative properties and have no role in palliative care. Such drugs should not be initiated if withdrawal of ventilatory support is anticipated. When withdrawal of ventilator support is anticipated in a patient already receiving such drugs, they should be withheld in all but extraordinary cases. Paralyzing the patient to comfort *the family* so that they see no disturbing movements or respirations as the patient dies is not justifiable. Even worse, it can mask symptoms and signs of distress and can thus prevent relief of suffering during the dying process[69] (see also Chapter 101).

Pacemakers, implantable cardioverter-defibrillators, and ventricular assist devices are increasingly used in both long-term medical therapy and intensive care (see also Chapters 48 and 101). When a patient who has a cardiac device requests withdrawal of life-sustaining interventions, questions sometimes arise about whether it is ethical to deactivate such devices.

Some experts have said that that these devices must be treated differently from other medical interventions because by virtue of implantation they have become a "biofixture," or literally a part of the patients

themselves.[71] Such arguments are difficult to sustain when we consider that many people undergo implantation of medical devices and subsequent explantation of them when the devices are no longer working or do not serve the patient's purpose. Common examples include artificial joints, intraocular lenses, medication delivery devices, and orthopedic hardware. Furthermore, these devices are never uniquely a part of the patient in the same sense as DNA or their native organs. In fact, the ethical distinction between disabling a pacemaker in a pacer-dependent patient and turning off a ventilator for a ventilator-dependent patient is minimal, if the request comes from a competent patient or the surrogate decision maker. Both actions involve discontinuance of artificial therapies that the patient no longer desires, and both may be followed by rapid death.

As with other end-of-life therapies, discontinuance of such devices should include due consideration of whether the decision is made by a competent patient and with full informed consent. Management of discontinuance of device therapy should always include planning for treatment of distressing symptoms and administration of appropriate comfort measures.

Physician-Assisted Suicide and Euthanasia

PAS involves the provision of medication or prescriptions to patients by specific request for the purpose of ending their life. PAS requires a patient who is both competent and capable of communicating the request. Euthanasia involves the administration of medication by someone other than the patient for the express purpose of causing death, in the belief that this would be best for the patient (but not necessarily at the specific request of the patient). Both practices differ ethically from withdrawing or withholding life-supporting medical treatments. In PAS and euthanasia, the primary intention is to cause death, which secondarily ends suffering. In withdrawal of withholding of life-supporting treatment, the primary intention is to discontinue treatments that are causing suffering with an understanding that death may or probably will result.

Currently, euthanasia is legal only in the Netherlands, Belgium, and Luxembourg. In the United States, euthanasia remains illegal regardless of circumstance, but PAS is legal in the states of Oregon, Washington, Montana, and Vermont and is being considered in other states. Internationally, PAS is legal in the Netherlands, Belgium, Luxembourg, Germany, and Switzerland.[72]

Supporters of PAS argue that the right to privacy and respect for autonomy support a patient's right to determine the time, location, and circumstance of his or her own death. The public consistently rates loss of autonomy and control, inability to pursue previously valued activities, and loss of dignity as the major concerns at the end of life.[73] Adequate control of pain, anxiety, dyspnea and other symptoms at the end of life remain a challenge to the medical profession, thereby fueling the desire for a means to end life when suffering cannot be controlled. Opponents argue that PAS "medicalizes" death, overly idealizes the physician-patient relationship, ignores possible personal and professional conflicts of interest, and leads to erosion of trust between dying patients and their doctors. Although many ethicists acknowledge that individual circumstances may make assisted suicide an ethically permissible action, most express concerns about potential abuse. Vulnerable members of society, such as the poor, old, and handicapped, could be pressed by financial and social factors into a suicide option in preference to palliative care.

An additional argument against PAS or legalized euthanasia is that these approaches could provide solutions to the medical, social, and economic problems common to older and poor patients that are simpler and less expensive than seeking and requiring more difficult, but definitive remedies.

More than 10 years have passed since Oregon legalized PAS and the Netherlands legalized both PAS and euthanasia, and significant data now provide some insights into whether these concerns about PAS and euthanasia are materializing.

More than two thirds of the U.S. population polled favored legalizing PAS, and approximately 58% favored legalization of euthanasia.[74] The percentage of U.S. oncology patients favoring a PAS or euthanasia option in end-of-life care rises to approximately 65%,[75] whereas physicians frequently involved in end-of-life care, such as intensive care specialists, oncologists, and palliative care specialists, are the most uniformly opposed specialists.[76] This finding represents a significant discordance between physicians and their patients.

In Oregon, where PAS has been legalized for the longest period of time in the United States, data show that patients who requested PAS had generally higher economic status and education, more than 96.7% were insured, and 92.5% were enrolled in hospice care. Most were more than 65 years old (65%), and 82% were suffering from cancer. Approximately 20% of patients receiving prescriptions for PAS never used them and ultimately died of their underlying disease—with many surviving significantly longer than predicted. More than 93% of patients enrolled in the Oregon program cited loss of autonomy as a primary reason for pursuing the option.[77,78] Some authors have suggested that the possession of a means to end their lives legally and humanely prevented "preemptive" suicides that could have occurred earlier and thus may have prolonged lives.[79]

Concerns regarding abuses of PAS and euthanasia will undoubtedly continue, but thus far, evidence of systematic abuse is lacking in places where PAS is legalized and regulated. As the population ages and patients desire greater control over end-of-life care and circumstances, debate over PAS and euthanasia in the United States can be expected to grow.

ETHICAL ISSUES IN ORGAN TRANSPLANTATION

Two issues critical to vital organ transplantation that confront anesthesiologists are the concept of brain death and the linkage of withdrawal of life-sustaining therapies with organ retrieval and transplantation after cardiac death (DCD) (see also Chapters 74 to 76).

Brain Death

Before the 1960s, death was defined as the moment when the heartbeat stopped and respirations ceased. Advances in cardiopulmonary resuscitation and mechanical ventilation then made it possible to postpone death, seemingly indefinitely. In 1968, the Ad Hoc Committee of the Harvard Medical School proposed redefining death as the point at which all cardiorespiratory function had irreversibly ceased, *or* all function of the whole brain had irreversibly stopped (brain death).[80] The committee gave two explicit reasons for redefining death. The first was to allow patients to be declared dead and not maintained on machines—thus limiting expense; reallocating medical resources to other, salvageable patients; and allowing the social rituals surrounding death to occur. The second was to allow the donation of vital organs before circulation stopped.

The public has been slow to accept brain death, in part because it requires complete trust in physicians and ignores indicators of death that the public already understands. To nonphysicians, brain-dead donors are superficially indistinguishable in many ways from living persons, and nonphysicians must therefore rely completely on the physician for both accurate and honest information of a loved one's death.

Diagnosing brain death is relatively straightforward. In the United States, it requires demonstration that, in the absence of drugs, paralytic agents, hypothermia, and other reversible conditions that mimic loss of brain function, no cortical or brainstem function is present. The diagnosis is usually made either clinically, by demonstrating that cortical activity and brainstem reflexes are absent, or by radiographic studies demonstrating the complete absence of cerebral blood flow.

Although brain death is a *social* and not a *biologic* definition of death, medical, ethical, theologic, and legal experts generally agree that brain death adequately defines a condition in which a person with ethical and legal rights and moral standing ceases to exist and should no longer be treated as though alive. Expensive medical interventions can be discontinued without legal ramifications, and vital organs can be donated for transplantation if the patient or the surrogate decision maker agrees.

Before assuming care of a brain-dead organ donor, the anesthesiologist is obligated to review the chart for documentation of the declaration of brain death and the criteria on which it was based. If any questions exist about the diagnosis, organ donation should be postponed until the anesthesiologist is satisfied that these concerns are addressed.

Donation After Cardiac Death

DCD occurs when a patient wishes to have life-sustaining medical therapies withdrawn and also wishes to proceed with vital organ donation after death. Controlling the time and place of death so that timing of organ donation can be optimized has obvious medical and ethical advantages. The decision to donate organs is made before death, thereby allowing time for discussion and informed consent. Ischemia time can be minimized. The dual decision to withdraw life-sustaining interventions and donate vital organs after death can create ethical conflicts, however. When a dying patient becomes an imminent organ donor, the risk is that the patient's interests will be minimized or ignored in favor of the organ recipient.

The Institute of Medicine reviewed DCD in 1997[81] and 2000[82] and found serious ethical questions, such as determining how quickly after asystole organ donation can begin and whether medications can ethically be administered to the donor before death that are solely for the purpose of organ preservation.

Ethical, theologic, and legal principles prohibit us from killing one person to benefit another, but the point at which actual death has occurred in DCD donors is unclear. Although expedient donation is the very purpose of DCD, doctors must never sacrifice any living patient in the process or even take significant risks of doing so; the mistrust this would engender among the public could place the entire concept of DCD donation at risk by reducing potential donors and ultimately harming future potential organ recipients.[83-85] Loss of consciousness occurs quickly after asystole, but brain function can continue for some time, and irreversible brain injury may not occur for many minutes. Yet many protocols call for organ retrieval to begin only 2 minutes after circulation has stopped, and in at least one institution, organ donation is allowed to begin within seconds of cardiac arrest.[86] Scientific and philosophic uncertainty exists about when death is complete—this could even lead to accusations that physicians deliberately kill patients to obtain organs for transplantation. Mistakes have occurred in some cases of brain-dead organ donors for which clear clinical criteria exist; DCD organ donation is potentially even more prone to error because no such clinical guidelines are universally accepted.[87]

Donation of vital organs after brain death and DCD are both ethical and legal, but the interests of the dying patient must be absolutely protected until after death has occurred. Anesthesiologists can play a vital role in the organ donation process by helping hospitals develop reasonable and ethical policies for the management of brain-dead donors and DCD donors. Every anesthesiologist should be thoroughly familiar with brain death criteria and should review the process of brain death determination before accepting care of a brain-dead donor. It is inappropriate for anesthesiologists to be involved in organ DCD unless they have expertise in the relevant ethical, legal, and medical issues and are experienced in end-of-life care.

RESEARCH ETHICS

HUMAN SUBJECT RESEARCH

The premise that the physician always puts the best interests of the patient first can be jeopardized when research objectives enter the doctor-patient relationship. Human subjects are asked to put aside their own interests to benefit some future, hypothetic group of patients. In extreme cases, the patient becomes a research "object" who will not benefit personally from the experiment at all. Two examples include experiments in healthy subjects and phase I cancer trials in terminally ill patients in which

the goal is to determine the toxicity of treatment—not remission, palliation, or cure.

Human subject research must balance many conflicting interests, such as the needs and rights of the research subject, the hypothetic interests of future patients, and the physician's financial, professional, and personal goals. Academic or corporate advancement, personal prestige, and financial incentives may be disincentives to researchers who diligently protect patients' interests or who remain objective in designing protocols and analyzing and reporting their findings. Thus, human subject research is more closely regulated, supervised, and controlled than any other medical endeavor.

Regulation of research began after World War II, with the Nuremburg Code and the Helsinki Declaration outlining the ethical obligations of physicians engaged in human research. The United States was slow to awaken to the parallels between the concentration camp experiments and the sometimes gruesome treatment to which they subjected their own subjects in similar trials.[88] In the years that followed the Doctors' Trial at Nuremburg, Fox[89] and Beecher[90] found that researchers were aware of the standards set at Nuremberg but regularly did not comply with them. In 1974, the National Research Act established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, out of which the modern institutional review board was born.[54]

The ethical conduct of human subject research follows three principles: (1) respect for autonomy and the obligation to protect subjects with limited autonomy; (2) beneficence, with obligations to minimize risks, maximize benefits, and ensure that the research design is scientifically sound; and (3) justice, the obligation to treat each person with regard to what is morally right and to ensure fair distribution of benefits and burdens.

In addition to the comprehensive presentation to research subjects of the risks and benefits of procedures or medications to which they will be subjected, disclosure must include the possibility of commercialization of the results, financial interests of the researchers, and any other actual or perceived conflicts of interest on the part of researchers and their institutions and sponsors. Subjects must be free to refuse or end participation at any time without penalty. *Situational coercion,* in which subjects feel that they are not truly free to refuse, should be avoided or mitigated. Examples of situational coercion include prisoners whose terms and experiences of incarceration may be affected by their decision to participate or refuse and hospitalized patients who may believe that their care could be compromised if they do not cooperate with researchers.[88]

Monetary or other inducements to participate in research are probably permissible if they do not undermine the freedom of the subject to refuse under reasonable circumstances. Significant monetary awards may have adverse effects on the autonomy of subjects and may negatively affect the scientific quality of the research. If remuneration is high, for example, subjects could conceal factors that would otherwise disqualify them from participating, thus compromising the research results and exposing themselves to greater risks.

Researchers are obligated to maximize benefits and minimize potential harms, including physical, psychological, social, legal, and financial harms. The research must address a question of sufficient value to justify the level of risk and must follow the approved protocol. Findings must be promptly and accurately reported. The research must be terminated immediately if it is suspected to be harmful to the participants.

Anesthesiology research often involves the treatment or prevention of unpleasant symptoms, such as pain and nausea, for which effective treatments are well established. Such studies should be restricted to comparison of treatments with known efficacy, not placebo-controlled trials, and "escape" analgesics or antiemetics must be provided on the patient's request.[70]

No population group should be unfairly subjected to research without having equal access to its benefits. Finally, the interests of the individual must always prevail over the interests of society.

Children as Research Subjects

Children are particularly vulnerable as research subjects because they may lack the ability to make mature decisions, are subject to the authority of others, may defer to their parents and others in ways that mask underlying dissent, and may have conditions requiring immediate decisions not consistent with informed consent (see also Chapters 92 and 93).[91] Children's rights are frequently undervalued, whereas parental authority may be overvalued. Studies show that even children with decision-making capacity are often excluded from the consent process by both parents and physicians.[92]

If a minor child is "able" to assent, then assent must usually be obtained in addition to the consent of any legal surrogate decision makers. In the United States, federal law requires assent of any minor 7 years old and older to participate in medical research. Particularly for research in which no substantive individual benefit is expected, many ethicists believe that a child's dissent *must always be honored*.[92,93]

ETHICS OF ANIMAL RESEARCH

The animal rights movement in the United States has gained significant momentum since the 1980s, following in the wake of the U.S. civil rights movement and paralleling increasing awareness and concerns about the human impact on the environment and other animal species. In 1959, William Russell and Rex Burch published their sentinel book regarding the ethics of animal research, *The Principles of Humane Experimental Technique*, introducing the concept that humane treatment of animals was not merely an ethical imperative, but absolutely necessary to high-quality research.[94] Federal legislation protecting animal welfare began with the Laboratory Animal Welfare Act of 1966. In 1985, the Health Extension Act and amendments to the Animal Welfare Act required the establishment of Institutional Animal Care and Use Committees (IACUCs), which oversee conditions of laboratory animals; review and approve animal research protocols; educate and train investigators in ethical issues and aspects of animal handling such as

anesthesia, analgesia, and euthanasia; and act as community liaisons.[95]

Some researchers deny that animal experimentation could be subject to any moral reservations and assert that medical advances have been and continue to be completely dependent on continued animal research. Many animal welfare activists insist on the moral equivalence of animal experimentation to that of human experimentation and accuse researchers of being blind to or, even worse, actually unmoved by the suffering of animal subjects. The simplicity of these polarized views does not do justice to the complexity of the issues.

Advances in the understanding of animal cognition led most biologists to believe that many, if not all, animals are capable of feeling pleasure, pain, anticipation, and fear and thus experience both enjoyment and suffering. Many bioethicists accept that the higher animals therefore have sufficient awareness to possess moral standing, although how much moral standing is intensely debated.[96,97] Allowing animal suffering as a result of pain, fear, sickness, or poor standards of care is a moral harm that must be avoided, mitigated, and weighed heavily against the benefits it produces. Ethicists maintain that cruelty to animals is immoral and that animals should be protected from it, not merely because they have moral standing, but because he who is cruel to animals is more likely to be cruel to humans.[98]

Researchers have obligations to provide clean and humane conditions and appropriate veterinary care for animal subjects. Researchers should mind the "Three Rs"—replacement, reduction, and refinement—that is, use animal subjects only when necessary, minimize any suffering incurred in the study, and seek nonanimate replacements for animal subjects.[99] Mediocre or repetitive research using animal subjects should not be allowed. It is the responsibility of the medical and scientific community to continue aggressively to seek and promote alternatives to the use of animal subjects.[98]

PHYSICIAN PARTICIPATION IN EXECUTIONS

U.S. professional organizations for physicians have consistently stated that physicians' participation in executions is unethical, yet many physicians admit that they would agree to be involved. The role of physicians in euthanasia and executions is of particular concern to anesthesiologists, who have been identified as ideal candidates for duties that involve killing because of their particular professional skills. Arguments in favor of physicians' involvement in executions usually cite the principle of beneficence in allowing a humane death.

Historically, however, beneficence arguments have led to "slippery slope" justifications for physicians to be involved in the killing of persons who have never faced an accuser or had a fair hearing—such killings have included persons with physical or mental handicaps and other "social flaws" for the "benefit" of the individual and of society as a whole. Once physicians accept a beneficence argument for participating in executions, it is difficult ethically to draw the line at participating in other state-sponsored activities, such as torture, coercion, and "medical incarceration," because these activities are also usually defended as being beneficial to society.[100]

When physicians agree to participate in an execution, they act as agents of the state while appearing to act on behalf of the "patient." This situation can lead to eventual erosion of public trust and respect. It also at times undoubtedly leads to physicians' participation in the killing of innocent persons.[101]

To avoid intolerable self-condemnation, virtually all executioners undergo "moral disengagement" in which they dehumanize the convicts and devalue their lives, thereby deflecting moral responsibility for the execution away from themselves by blaming juries, judges, governors, and "the law," rather than accept the responsibility they share in ending the prisoner's life.[102] It is difficult to reconcile the medical profession's overt ethical imperatives of valuing human life, respecting individuals, and accepting personal moral responsibility with participation in a process that requires a rejection of these very values.

In 1980, the AMA issued an opinion that physicians' involvement in capital punishment is unethical and defined "participation" broadly as including not only actions that themselves would lead to the death of the condemned but also any activity that assisted, supervised, or contributed to another's being able to do so.[103] However, no direct sanctions of any participating physician were addressed. In 2010, the American Board of Anesthesiology (ABA) became the first organization of physicians not only to condemn participation in capital punishment as unethical but also to state that physicians who were certified by their board and who participated in lethal injection would be subject to disciplinary action that could include revocation of their diplomate status.[104]

MORAL INTEGRITY—CAN THE PHYSICIAN BE A CONSCIENTIOUS OBJECTOR IN MEDICINE?

Anesthesia care of patients can involve ethical controversy, legitimate disagreement, and moral ambiguity. When a physician's personal values run counter to acceptable ethical standards of care, how should the physician resolve such conflicts? Medical professional societies recognize the right to conscientious objection in medical practice. The ASA, the British Medical Association, and the Hastings Center all have issued statements recognizing the physician's right to withdraw from situations in which ethical standards of patient care are in serious conflict with his or her personal values.[105] The ASA specifically recognizes conscientious withdrawal from patient care in the case of patients with DNAR orders or other directives that limit treatment.[11] These rights have limitations, however. Acceptance of moral objections to certain hotly contended issues such as abortion or PAS may be reasonable, but objections to well-established standards, such as informed consent, are not. Moral objections of physicians are also likely to carry more weight if they involve concepts that the physician believes supports him or her as an ethical doctor, and not just as an

ethical person, because these concepts are more likely to be founded in professionally established standards than in personal beliefs.[105]

SUMMARY

Anesthesiologists face many ethical challenges, including promotion of the patient's autonomy, resolution of patient-physician conflicts in medical decision making, ethical obligations in human subject and animal research, and ethical conflicts during end-of-life care in the ICU and during organ donation. Knowledge of the ethical and professional standards in patient care and research is essential in the specialty of anesthesiology, which is more than the mere provision of a technical service on demand. Anesthesiologists may find that accepted values in ethical practice sometimes conflict with personal values and goals. This is a common challenge to all physicians, but ethical decisions cannot be left to the individual physician's values, and adherence to the ethical principles of the medical profession should prevail.

Chapter 11

Legal Aspects of Anesthesia Care in America

DAVID B. WAISEL

Key Points

- The medical malpractice tort system is intended to improve patient care.
- Medical negligence occurs when a physician's failure to meet the standard of care directly leads to a patient's injury.
- A fully informed attorney is the physician's best advocate.
- Physicians having their medical competence publicly questioned may feel guilt, failure, anger, shame, isolation, depression, fatigue, denial, and physical symptoms.
- A detailed, legible anesthesia record strengthens the defense against a malpractice suit.
- More than half the states have laws prohibiting the admission of apology or sympathy as evidence of wrongdoing.
- The goal of informed consent is to maximize the ability of the patient to make substantially autonomous informed decisions.
- Evidence of decision-making capacity (the ability to make a particular decision at a specific time) includes the ability to understand medical problems, proposed treatments, alternatives, options to refuse treatment, and foreseeable consequences of accepting or refusing proposed treatments and the ability to express a preference based on rational, internally consistent reasoning.
- The reasonable person standard of disclosure requires that the extent of the disclosure be based on what a reasonable person would consider material for choosing whether to undergo the proposed intervention.
- Anesthesiologists may refuse to provide care when they ethically or morally disagree with the procedure or if they believe the patient's choice is too inappropriate or likely to result in harm.
- Competent patients have a virtually unlimited right to refuse life-sustaining medical treatment.
- Anesthesiologists are responsible for negligent acts made within the scope of defined duties by trainees and certified registered nurse anesthetists (CRNAs).
- Physicians have been held liable for inadequate pain control.
- In the end, case law does not provide clear guidance. If the information is possibly relevant to decision making, it is prudent to disclose, even if not absolutely legally required.

Statute law, case law, and regulations affect anesthesiologists (Table 11-1).[1-7] Statute law is the body of prescriptive law created by a legislature to achieve a specific purpose. For example, the National Organ Transplant Act is the law that established the Organ Procurement and Transplantation Network and authorized it to maintain a national registry for organ matching. State legislatures subsequently establish state laws governing organ procurement (see also Chapters 74 and 75).

When statute laws need interpretation, when they clash, or when no definitive statute law exists, disagreements may be adjudicated by the judicial system. The aggregate of reported cases, known as case law or common law, is used as the basis for future court decisions. The results of these cases are rarely prescriptive and may lead to a collection of confusing, ambiguous, and even contradictory cases that rest on diverse rulings in different jurisdictions. For example, a widow donated the kidney of her deceased husband to a long-time friend. The transplant surgeon, upon receiving and examining the kidney, declared it unsuitable because of a renal artery aneurysm. The transplant surgeon then asked for the donor's second kidney. By then, the donor's second kidney had been allocated to another patient. The plaintiff

TABLE 11-1 LAWS AND REGULATIONS THAT AFFECT MEDICAL PRACTICE

Law or Regulation	Comments
Patient Protection and Affordable Care Act (PPACA; commonly known as ACA or Obamacare)[1]	The PPACA is a wide-ranging act that will be phased in over several years. It mandates that an individual carry health insurance, establishes standards and requirements for health insurance, launches health insurance exchanges to market policies, increases clinical preventive services, and restructures Medicare reimbursement. It establishes the National Prevention, Health Promotion and Public Health Council to develop a national preventive health strategy and the Patient Centered Outcome Research Institute to perform comparative effectiveness research. The PPACA specifically authorizes funding to advance research and treatment of pain management.
Health Insurance Portability and Accountability Act (HIPAA)[3]	HIPAA's privacy rules protect individually identifiable health information held or transmitted in any form, whether electronic, paper, or oral. This includes a patient's past, present, or future health or condition, provision of health care or payment for the provision of health care, and information that either identifies the individual or for which there is a basis to believe the individual can be identified through common identifiers. Privacy rules apply to health plans, to health care clearinghouses, and to any health provider who transmits health information. HIPPA is a complex law that includes many other provisions, including making insurance portable from one employer to another. The PPACA added requirements and increased the penalties for noncompliance.
Health Information Technology for Economic and Clinical Health Act (HITECH)[2]	The 2009 HITECH was instituted to develop a nationwide health information technology infrastructure that would improve health care quality and care coordination. HITECH established economic incentives tied to "meaningful use" of electronic health records.[104] HITECH also established requirements for federal notification in the event of a breach of privacy for health care information, the effects of which have been seen in high-profile cases over the last few years, usually involving stolen laptop computers. The act also provided for patients to obtain an audit of all disclosures and uses of their electronic records, and it prohibited selling patients' health information. Since 2010, more than 500 breaches have occurred. More than 60% involved theft or loss of information, typically on electronic devices such as laptop computers.[2]
Emergency in Medical Treatment and Active Labor Act (EMTALA)[4,5]	EMTALA governs when a patient may be refused treatment and when an unstable patient may be transferred from one hospital to another. More commonly stated, the purpose of EMTALA is to prohibit "dumping" of emergency patients onto other hospitals. Hospitals must perform a screening medical examination to determine whether an emergency condition exists, must provide stabilizing treatment if an emergency condition does exist, and may transfer the patient to another hospital only under certain conditions, such as the patient requests transfer, the patient is stable and transfer will not worsen the patient's condition, and the receiving hospital has treatment capabilities unavailable at presenting hospital. The receiving hospital must accept the transfer, and physicians must certify that the patient can be safely transferred. EMTALA also requires assigned on-call physicians to respond to emergency situations.
Employment Retirement Income Security Act (ERISA; several amendments to ERISA are relevant to health benefits, including HIPAA)[7]	ERISA established uniform federal standards to protect private employee benefit plans. The U.S. Department of Labor administers and enforces ERISA, and federal courts interpret it. The relevance in medicine is that it regulates health benefit plans. Case law interpretation of ERISA affects how, where, and for what members may sue health maintenance organizations.
Controlled Substance Act (CSA)[6]	This act permits the federal government to regulate manufacture, importation, possession, and distribution of certain drugs to control traffic of controlled substances. This act permits the federal government to determine whether a drug should be a controlled substance and into what drug schedule it should be placed. This act does not control the medical use of these drugs.

sued, claiming that the organ procurement organization misappropriated the donor's second kidney and alleging in part that, under conversion tort, the organ procurement organization interfered with the plaintiff's right of possession of personal property, in this case, the kidney (see also Chapters 74 and 75). On appeal, the court ruled for the defendant, the organ procurement organization, because the plaintiff had no common law right to the second kidney, given that a person cannot have property rights to a dead body.[8]

This chapter uses descriptions of legal cases. Readers should be aware that the medical facts of these cases are based on information presented in possibly incomplete or erroneous court documents.

Regulations arise from administrative authorities tasked with applying the law. For example, the U.S. Department of Health and Human Services develops the regulations that implement the health care insurance requirements stipulated by the Patient Protection and Affordable Care Act (PPACA).[1]

PROFESSIONAL LIABILITY

THE MEDICAL MALPRACTICE TORT SYSTEM

The medical malpractice system is intended to improve patients' safety and compensate patients injured by negligence (see also Chapter 10). To do so, malpractice cases would have to influence the behaviors of individual clinicians and organizations appropriately but not encourage "defensive medicine." Systems would have to encourage the communication needed to improve patient care systems.

The malpractice system does not achieve these goals. Jury trials of medical malpractice suits do not reliably inform physicians, in part because of the inconsistencies in case law and in part because juries tend to correlate liability with severity of harm and not with physicians' negligence. Cases are often appellate decisions that are decided on legal rather than medical grounds. Indeed, malpractice cases increase liability concerns and lead to more expensive and possibly riskier interventions. Nearly all physicians have made clinical decisions to avoid liability, and these "defensive" decisions may contribute up to 25% of health care costs.[9,10] Data regarding the effects of defensive medicine are primarily self-reported, however, and are open to memory and response bias.

Physicians fear a mercurial malpractice system.[11] Fear thwarts honest discussion of clinical events. More than 60% of physicians feel the threat of malpractice litigation in their day-to-day practice, and more than 60% are concerned that they will be involved in a malpractice case over the next 10 years.[10] Although these concerns are significantly out of proportion to the actual risk, heightened sensitivity to malpractice is likely attributable to the tendency to overestimate the likelihood of rare events and to magnify the risks of unfamiliar, devastating, or arbitrary events.[10]

Juries may not be as pro plaintiff as physicians seem to think. Medical experts and juries overwhelmingly agree in assigning liability in cases with weak evidence of negligence.[12] In cases with strong evidence of negligence, experts are far more likely than juries to assign liability to the defendants.[13]

Reform efforts have focused on reducing the costs of the medical liability system (Box 11-1).[14] Caps on noneconomic damages have reduced claim payouts by 20% to 30%.[14,15] For the most part, other reforms have had limited effects on costs. In other health care systems, administrative medical injury compensation systems seem to decrease cost but may increase claims.[11] The Congressional Budget Office has suggested five reforms that will reduce the cost of malpractice insurance by 10% (Box 11-2).[16]

Whether financially centered reforms will minimize some of the harms of the medical malpractice system depends on whether defensive medicine is rooted in financial concerns or more complex motivations.[17,18] Some experts argue that successful reform requires fundamental change, such as safe-harbor legal protection for following clinical guidelines.[15,17] Another possible fundamental change is judicial branch reform, whereby judges are supported by neutral medical experts, are trained in adjudicating medical malpractice, and will "own" the case from beginning to end. This reform is expected to promote speedier resolution through earlier, more frequent, and private meetings.[15] The 2010 PPACA authorized grants for seeking new ways to resolve medical injury disputes.[1]

DISCLOSURE, APOLOGY, AND OFFER

The disclosure, apology, and offer approach may increase frank discussion about medical error, provide fair compensation to patients, decrease costs, and reduce the stress and the harms of the current system (Table 11-2).[19]

BOX 11-1 *Traditional Malpractice Reforms*

Malpractice reforms are designed to encourage parties to settle legitimate claims and deter questionable suits.

Caps on noneconomic damages: They limit the amount of money that can be awarded for noneconomic ("pain and suffering") losses.

Pretrial screening panels: They provide an opinion on whether a claim has sufficient merit to proceed to trial. This opinion may be advisory or binding and is a possible source of evidence.

Certificate of merit: This requires a plaintiff to present an affidavit certifying that a medical expert believes there is a reasonable and meritorious cause for the suit.

Attorney fee limit: This limits the amount of a malpractice award a plaintiff's attorney may take in a contingent-fee arrangement.

Joint-and-several liability reform: This reform limits the financial liability of each defendant to the percentage fault that the jury allocates to that defendant. If the jury determines that a specific party is 20% responsible for the outcome, then that specific party is liable for only 20% of the award, even if other parties cannot pay their share.

Collateral-source offset: This requires that other reimbursements related to the injury must be deducted from the award the defendant must pay.

Periodic payment: Awards may be paid over time rather than in one sum.

Schedule of noneconomic damages: This reform guides financial awards by categorizing the extent of "pain and suffering" by the severity of injury. This compensation schedule may be advisory or binding.

Administrative compensation systems or "health courts": These alternative processes for resolution of malpractice claims often involve specialized judges, decision and damages guidelines, and neutral experts.

BOX 11-2 *Congressional Budget Office Recommendations to Reduce the Cost of Malpractice Insurance by 10%*

1. A cap of $250,000 on awards for noneconomic damages
2. A cap on awards for punitive damages of $500,000 or two times the award for economic damages, whichever is greater
3. Modification of the "collateral source" rule to allow evidence of income from such sources as health and life insurance, workers' compensation, and automobile insurance to be introduced at trials or to require that such income be subtracted from awards decided by juries
4. A statute of limitations—1 year for adults and 3 years for children—from the date of discovery of an injury
5. Replacement of joint-and-several liability with a fair-share rule, under which a defendant in a lawsuit would be liable only for the percentage of the final award that was equal to his or her share of responsibility for the injury

From Elmendorf DW: Letter to Hon. Bruce L. Braley, Dec 29, 2009. <http://www.cbo.gov/ftpdocs/108xx/doc10872/12-29-Tort_Reform-Braley.pdf/> (Accessed 27.09.13.)

This approach rejects the traditional "deny and defend" response of physicians and hospitals that generates an adversarial relationship. It embraces disclosing freely, offering compensation for questionable care, and vigorously defending reasonable care. The University of Michigan

TABLE 11-2 DISCLOSURE, APOLOGY, AND OFFER

Objective	Action of Hospital or Insurer
Increase transparency, reduce adversarial relationships	1. Disclose adverse outcomes of care 2. Build a system to support disclosure 3. Apologize 4. Explain results of investigation and changes to be implemented
Improve patients' safety	1. Implement systems to encourage sufficient clinician candor to address patients' safety 2. Implement systems in a timely manner to avoid recurrence
Avoid lawsuits, reduce liability costs, and improve access to compensation of families and patients	1. Distinguish between injuries from medical negligence and those from disease or as a result of high-risk medical care 2. Offer financial compensation when care was unreasonable without the patient's needing to initiate a lawsuit 3. Defend "vigorously" when care was reasonable

TABLE 11-3 CAUSES OF ACTION MOST RELEVANT TO ANESTHESIOLOGISTS

Type	Description
Medical negligence	Breach of a duty of a standard of care with resulting harm
Wrongful death	A wrongful death is one that occurs earlier than it would have otherwise; if negligence causes death, survivors may sue for damages
Lack of informed consent	Obligation to provide information material to a reasonable person
Abandonment	Obligation to provide continuity of care once physician assumes responsibility for the patient
Vicarious liability	Obligation for reasonable oversight of those persons working for the physician
Loss of chance of recovery or survival	The patient must show that the chance of recovery was likely but for the action of the physician
Battery	Touching a person without their express or implied consent; no need for the plaintiff to prove harm in battery cases
Assault	The attempt to touch another person; no need to prove actual harm

From White C, Rosoff AJ, LeBlang TR: Informed consent to medical and surgical treatment. In Sanbar AA, Firestone MH, Fiscina S, et al, editors: Legal medicine, *ed 7. Philadelphia, 2007, Mosby, pp 337-343.*

Health System, an early adopter of this approach, reported a resultant reduction in number of claims, settlement amounts, and defense costs.[20]

The disclosure, apology, and offer approach has legal, cultural, and logistic barriers. It likely fails in systems of asymmetric risk. For example, in some states, charitable corporations such as hospitals have limited tort liability, which means that in the short run, the practice of offering compensation may increase their costs.[19] To be successful, the disclosure, apology, and offer approach must be practiced by all the hospitals and physicians within a health care system. Otherwise, ill-aligned values and strategies will bring chaos, followed by the death knell.

The current system endorses name-based reporting to various state and national authorities. Because most systems require settlements to be reported, physicians may be tainted even if the injury was unrelated to their actions. To be sure, this concern in part reflects an extremely out-of-proportion view of how malpractice reports affect credentialing or licensing. Addressing these concerns will require both a change in reporting requirements and a willingness of institutions to accept responsibility for system-level events.

Attorneys may impede adoption of the disclosure, apology, and offer approach. Plaintiff attorneys may believe that the tort system best protects the patient's interest. Defense attorneys may be concerned that this approach is not in the individual client's interest.

MEDICAL MALPRACTICE

The most common cause of medical malpractice is medical negligence (Table 11-3). *Negligence* is a breach of a duty that is the proximate cause of a harm.[21] *Medical negligence* occurs when a physician's failure (breach) to meet the standard of care (duty) directly leads (proximate cause) to a patient's injury (harm). Proximate cause should be tightly coupled and requires proof of cause-in-fact and foreseeability. *Cause-in-fact,* often known as the "but for" test, means that without the negligent act, the harm would not have occurred. The classic definition is that the act was indispensable in causing harm. Some jurisdictions have expanded the "but for" rule to include actions that substantially contribute to the harm. Foreseeability suggests that injuries must be of the type that would be anticipated by a reasonable practitioner. For example, an unrecognized esophageal intubation would have been prevented "but for" the anesthesiologist's forgoing end-tidal carbon dioxide monitoring because the reasonable anesthesiologist would foresee that this breach of standard of care could lead to an unrecognized esophageal intubation. A harm must have occurred for which the individual needs to be compensated. Awards may be given for noneconomic losses, for the economic costs of repairing the damage, and for loss of income. *Statute of limitations* defines the amount of time in which a plaintiff can bring an action; it is governed by state law and typically begins upon the occurrence or discovery of the allegedly negligent act or of the harm.

Medical negligence may be adjudged as *criminal medical negligence* if it deviates greatly from the standard of care, whether unknowingly (criminal negligence) or knowingly (criminal recklessness).[22] Criminal medical negligence is rarely prosecuted, but characteristics of these cases include failing to modify care based on past similar experiences, hiding errors, and practicing in a way that appears

to favor financial and personal gains over patient care. For example, an anesthesiologist was prosecuted (but eventually acquitted) for reckless manslaughter when, after more than five documented episodes of falling asleep during anesthesia, he fell asleep during a case in which the child died. He was convicted of criminal medical negligence, although that conviction was eventually overturned because the prosecutors had not brought the criminal medical negligence charge within legal time limits.[23]

THE PROCESS OF BEING SUED

Some lawsuits may begin "informally" by a request from a potential plaintiff's attorney to review records or to discuss a case. An attorney should be consulted before engaging in these actions to ensure that proper procedure is followed. Lawsuits officially begin with a document called a Summons and Complaint, which is a notification to respond to allegations by the plaintiff.

Following initiation of the suit, the process of discovery begins through an exchange of documents and a deposition. The purpose of the deposition is for the other side of a legal action to obtain information or clarification otherwise unavailable, particularly about the reasoning underlying actions.[24] At the deposition, oral testimony is taken under oath, is transcribed, and may be used as evidence in trial. Experts, consultants, clinicians, witnesses to the event, or defendants may be deposed. Some conversations are privileged and may not be discovered by the plaintiff. These include discussions with attorneys, risk management personnel, insurance company representatives, a spouse, personal clinicians (including psychotherapists), and clergy. Conversations with close friends are discoverable.

Before the deposition, the physician should inform the attorney about his or her relationship with the plaintiffs and any problems that may have occurred. The physician should educate the attorney about complex medical components of the case and expected weaknesses. A fully informed attorney is the best advocate.

In addition to the defendant, the defendant's attorney, the plaintiff's attorney, and the court reporter, the plaintiff may also be present at the deposition. After the court reporter administers the oath, the plaintiff's attorney will ask standard questions, including education, licensing, and certification. The defendant's attorney will intercede as appropriate. The same questions may be asked several times over. One goal of a plaintiff's attorney is to develop a casual atmosphere to lower the guard of the defendant before asking the more relevant questions. A defendant is best served by not speculating about factual matters that may be found on the medical records, answering only the questions asked, and asking for clarification if unclear about the meaning of a question.

MALPRACTICE DEFENSE

Physicians having their medical competence publicly questioned may feel guilt, failure, anger, shame, isolation, depression, fatigue, denial, and physical symptoms.[25] If the suit is based on what the physician believes was a medical error, these feelings are intensified. After a medical error or a "near-miss," many physicians demonstrate symptoms similar to posttraumatic stress disorder.[26] Perhaps most damning to future practice is self-doubt to the extent that practice is affected.[27] Lawsuits recrudesce quiescent insecure feelings related to the event. It is important to be forthright about these feelings and to manage them, if for no other reason than to be able to participate fully and positively in the legal defense.

Defendants often rebut the claims that the standard of care was not met and that the alleged failure to meet the standard of care was a proximate cause to harm. To help support these arguments, expert witnesses, medical texts, journal articles, practice guidelines, and anesthesia records are often used.

Expert witnesses explain the relevant science and offer professional opinions about the standard of care and causation.[28] Although courts commonly accept the expertise of most expert witnesses, courts and juries do use qualifications to modulate the weight they give the testimony. An expert witness can support the idea that a different explanation or approach, especially one that other physicians would support, may meet a sufficient standard of care. The obligations of expert witnesses include that "…expert testimony by anesthesiologists should be readily available, objective and unbiased. To limit uninformed and possibly misleading testimony, experts should be qualified for their role and should follow a clear and consistent set of ethical guidelines" (Box 11-3).[29] The American Society of Anesthesiologists (ASA) has an Expert Witness

BOX 11-3 ***Guidelines for Expert Witness Qualifications and Testimony***

Expert Witness Qualifications

1. The physician (expert witness) should have a current, valid, and unrestricted license to practice medicine.
2. The physician should be board certified in anesthesiology or hold an equivalent specialist qualification.
3. The physician should have been actively involved in the clinical practice of anesthesiology at the time of the event and should have relevant clinical experience and knowledge in the clinical practice areas that are the subject of the proceeding.

Expert Witness Ethical Guidelines

1. The physician's review of the medical facts should be truthful, thorough, and impartial. The physician should not exclude any relevant information to create a view favoring either the plaintiff or the defendant.
2. The physician's testimony should reflect scientific evidence and accepted practice standards prevalent at the time of the event in question.
3. The physician should make a clear distinction between medical malpractice and adverse outcomes not necessarily related to negligent practice.
4. The physician should make every effort to assess whether the alleged substandard practice was causally related to the adverse outcome.
5. The physician's fee for expert testimony should relate to the time spent and in no circumstances should be contingent upon outcome of the claim.
6. The physician should be willing to submit such testimony for review.

From American Society of Anesthesiologists: Guidelines for expert witness qualifications and testimony. <https://www.asahq.org/For-Members/Standards-Guidelines-and-Statements.aspx>. *Amended 16.10.13.*

Testimony Review Program,[30,31] through which an ASA member may file a complaint about the expert testimony of another member. The ASA reserves the right to censure, suspend, or expel members who violate these ethical guidelines, with concomitant reporting to the National Practitioner Data Bank.

Practice guidelines are increasingly used as evidence of a standard of care.[32] Although authors of practice guidelines routinely state that guidelines are not intended to set a standard of care, it is highly likely that juries will be strongly influenced by them. Some authors have even proposed that practice guidelines should replace expert opinion.[32]

A detailed anesthesia record often strengthens the defense against a malpractice suit. A goal of documentation should be that uninvolved anesthesiologists should be able to understand interventions, the reasons for interventions, and the outcomes of interventions. Precise documentation and written explanations of thought processes lead to better understanding, which is important because malpractice claims often result from a failure or delay in diagnosing problems. For example, when using a nerve stimulator to administer regional anesthesia, an anesthesiologist may want to document the length and type of needle used, the nerve stimulator type and settings, the number of attempts, the strength and location of muscle contractions, whether paresthesia occurred, and how the paresthesia was managed.[33] Alternatively, consider the effect of documentation on the fairly routine event of decreased urine output. Assume that a patient had no urine output over a certain period in a previously functioning bladder catheter. The anesthesiologist treated the decreased urine output by the intravenous administration of crystalloid. The record would ideally indicate "zero" under urine output and indicate a bolus of fluid under fluid administration. Assume, then, that 30 minutes after the crystalloid administration, the patient still had no urine output. At this point, it would be reasonable for the anesthesiologist to write a note on the anesthesia record that discussed the decreased urine output, the initial interpretation and treatment of the decreased urine output, the results of that treatment, and the current interpretation (including differential diagnoses) and planned treatment of the decreased urine output. The anesthesia record should contain certain information (Box 11-4).[30,31]

Countersuits such as abuse of process, malicious prosecution, and defamation have been consistently rejected by the courts.[34] From a public policy perspective, the courts may be concerned that abuse of process countersuits that may limit the ability for plaintiffs to seek redress.

BOX 11-4 ***Guidelines for Documentation***

I. Preanesthesia evaluation
  a. Patient interview
    i. Patient and procedure identification
    ii. Medical history (medication, allergies, family history of anesthesia problems, pertinent review of systems)
    iii. Anesthetic history
    iv. Nil per os status
  b. Appropriate physical examination (including vital signs, documentation of airway status, and pertinent negatives)
  c. Review of objective diagnostic data (e.g., laboratory, electrocardiogram, radiographs) and medical records.
  d. Assignment of ASA physical status
  e. Medical consultations
  f. Formulation of the anesthetic plan, and discussion of the risks, benefits, and indications
  g. If appropriate, explanations of what may be considered atypical choices of the anesthesiologist or the patient
  h. Documentation of appropriate informed consent
  i. Appropriate premedication and prophylactic antibiotic administrations

II. Intraoperative or procedural anesthesia (time-based record of events)
  a. Immediate review before initiation of anesthetic procedures
    i. Patient reevaluation
    ii. Check of equipment, drugs, and gas supply
  b. Monitoring of the patient vital signs, oxygenation, and ventilation data and the use of any nonroutine monitors
  c. Doses of drugs and agents used, times and routes of administration, and any adverse reactions.
  d. The type and amounts of intravenous fluids used, including blood and blood products, and times of administration
  e. Estimated blood loss and urine output
  f. The technique(s) used and patient position(s).
  g. Intravenous/intravascular lines and airway devices that are inserted including technique for insertion, and location
  h. Unusual or unexpected events during the administration of anesthesia, including explanations of the recognition, treatment, and outcome of the event
  i. The status of the patient at the conclusion of anesthesia

III. Postanesthesia evaluation
  a. Evaluation and documentation by a practitioner who is qualified to administer anesthesia consistent with hospital policies and state licensure
  b. Patient evaluation on admission and discharge from the postanesthesia care unit
  c. A time-based record of vital signs and level of consciousness
  d. A time-based record of drugs administered, their dosage, and route of administration
  e. Type and amounts of intravenous fluids administered, including blood and blood products
  f. Any unusual events including postanesthesia or postprocedural complications
  g. Medical interventions
  h. Postanesthesia visit
    i. Must be completed within 48 hours from when the patient is moved from the designated recovery area
    ii. Must occur for surgery involving general anesthesia, regional anesthesia, or monitored anesthesia care
    iii. Elements of a postanesthesia evaluation
      (1) Respiratory function
      (2) Cardiovascular function
      (3) Mental status
      (4) Temperature
      (5) Pain
      (6) Nausea and vomiting
      (7) Postoperative hydration

Data from American Society of Anesthesiologists: Documentation of anesthesia care. *Amended 16.10.13 and Merchant R, Chartrand D, Dain S, et al: Guidelines to the practice of anesthesia, revised edition 2013.* Can J Anaesth *60:60-84, 2013.*
ASA, American Society of Anesthesiologists.

APOLOGY AND DISCLOSURE BY THE INDIVIDUAL

Although often inappropriately conflated, an apology, an expression of regret or sorrow, is distinct from a disclosure, which is a revelation about what happened. Apologies and disclosures may occur at the same time.

More than half the states have laws prohibiting the admission of apology or sympathy as evidence of wrongdoing.[25,35] Most apology laws permit the sympathetic statement "I am sorry this happened," but they do not protect sympathetic statements that include explanations ("I am sorry I made a mistake."). Fewer states have disclosure laws, which typically require notification of untoward events. Laws that require disclosure and protect sympathetic statements but do not protect explanations can lead to odd discussions, which may be perceived by patients as insincere.[35]

Some recommendations suggest apologizing for the effect on the patient but without admitting fault. Sometimes this approach may make sense, for example, if a previously acceptable antibiotic caused a rash. Not to take responsibility may seem stilted, however, such as when an anesthesiologist errantly administers an antibiotic to a patient who has a clearly documented allergy to that medication. In the name of good relationships with patients, apologies should not be limited to events that may result in a suit. For example, consider a 6-year-old girl who is wildly screaming and thrashing upon entering the operating room. Following a discussion with the father, who is present, a decision is made to hold her down and apply the mask. A follow-up discussion with the family may include not only an apology for the induction ("I am sorry that was so unpleasant for Becky and you.") but also an acknowledgment that the induction did not produce the desired reaction ("That is not our goal for induction. We would like it to be smoother." and "Going without sedation turned out to be a mistake."), as well as a recommendation for the future ("In the future, I would give oral sedation before going to the operating room."). Although this approach technically seems to admit wrongdoing, it is simply acknowledging what happened and educating the family for the future.

Although I believe that it is better to apologize, concerns exist about apologizing. The action for the physician, particularly if the apology is not readily accepted, may be painful. An apology may also embolden an otherwise unsure plaintiff,[36] and it may be construed as admission of error in court.

Whether one should admit fault for something that more likely may be medically negligent is more complicated. Consider, for example, repeated attempts to place an epidural needle in a patient who is anesthetized and has previously undergone back surgery. The anesthesiologist tries repeatedly without success and without incorporating other methods such as fluoroscopy. The patient awakens with a nerve injury consistent with wayward insertion of an epidural needle. Some experts would suggest that although it is acceptable to express sympathy for the pain and discomfort ("I am sorry for your discomfort."), it would be legally harmful to acknowledge fault and a desire to do it differently ("I am sorry about your injury. In retrospect, although I am not sure what happened, I suspect that it was the result of the needle placement. I should have used direct imaging of the back such as fluoroscopy.") Another opinion suggests that the second apology with the disclosure is better because it explains what happened, why it happened, and how it may be prevented in the future. Although this disclosure and apology approach admits culpability, it discloses only information that would be eventually discovered. I would suggest that the potential advantages gained by a genuine apology, delivered properly and under the appropriate circumstances, outweigh the potential harms of admitting culpability.

Full disclosure makes sense. From a wholly practical point of view, the patient will eventually learn what was withheld and will wonder, probably with animosity, why such information was not disclosed. Apology and disclosure for a potentially negligent event should be performed with thoughtful planning and support, and it is best practice to include in the discussion an expert in apology and disclosure. Disclosure may have three components. Upon realization of the problem, the goal is to give as much information as known, but not to speculate about what is not known, particularly about fault. Physicians should clarify the medical implications of the event, any necessary treatment or follow-up, and who will function as a contact for the patient regarding the event. The hospital's apology and disclosure expert often coordinates communication and follow-up. The next step should be to conduct a thorough investigation, with an eye toward minimizing problems in the future. Finally, the patient should be informed about what the investigation found, including the cause of the event and how such events will be prevented in the future.

LEGAL ASPECTS OF INFORMED CONSENT

Until the 1950s, physicians routinely obtained assent, the general agreement of the patient to have a procedure. The 1957 legal case *Salgo v Trustees of Leland Stanford Hospital* codified the modern concept of informed consent.[37] The judge clarified the difference between informed consent and assent by declaring, "A physician violates his duty to his patient and subjects himself to liability if he withholds any facts which are necessary to form [the] basis of an intelligent consent by the patient to a proposed treatment…."[37]

The goal of informed consent is to maximize the ability of the patient to make substantially autonomous informed decisions. The modifier "substantially" is used because it is unreasonable to expect a patient to be fully informed. The more appropriate goal of substantially informed consent acknowledges that consent may be sufficiently autonomous even if not completely informed. Modern informed consent has seven components.

COMPONENTS OF INFORMED CONSENT

Decision-Making Capacity

Decision-making capacity is defined as the ability to make a particular decision at a specific time. Evidence of

decision-making capacity includes the ability to understand medical problems, proposed treatments, alternatives, options to refuse treatment, foreseeable consequences of accepting or refusing proposed treatments and the ability to express a preference based on rational, internally consistent reasoning. Decision-making capacity is distinct from the legal concept of competency. Courts determine competency and often make a global determination of competency, thus declaring that a person is either competent or incompetent for all matters. Adults are presumed to be legally competent unless declared otherwise by a court. In contrast, anesthesiologists are responsible for assessing decision-making capacity and can make this determination only in specific situations.

Anesthesiologists should permit patients to make decisions to the extent of their abilities. For most patients, decision-making capacity is not in question. However, anesthesiologists must actively evaluate the decision-making capacity for patients whose decision-making capacity has been temporarily altered, who do not have legal decision-making authority, or who have preexisting limitations in decision-making capacity. Consider the patient who has received pain medication before giving informed consent. The level of impairment varies depending on the medication, the tolerance of the patient to the medication, and the decision to be made. Indeed, some patients, such as parturients, may have improved decision-making capacity when pain is decreased. To determine whether a patient has decision-making capacity for a specific decision, anesthesiologists need to balance the medication given and its expected effects with the ability of the patient to show evidence of rational reasoning and understanding. When a patient has temporarily lost decision-making capacity, such as when the patient is anesthetized, anesthesiologists should not implement nonemergency care until after the patient regains decision-making capacity and gives consent. However, in emergencies, anesthesiologists should proceed without obtaining informed consent, based on the presumption that patients want life-sustaining treatment unless they have declared otherwise.[38]

Voluntariness

Physicians should perform procedures only on competent patients who participate willingly. Anesthesiologists compromise voluntariness through manipulation and coercion. *Manipulation* involves the deliberate distortion or omission of information in an attempt to induce the patient to accept a treatment, such as downplaying or omitting information to influence a patient to make a specific decision. *Coercion* involves the use of a credible threat to ensure complicity.

Anesthesiologists also hinder voluntariness when they physically restrain or sedate patients who have sufficient decision-making capacity. Competent patients have the legal and moral right to refuse treatment even in life-threatening emergency situations. It is often difficult for physicians to accept that a patient wishes to make what a physician perceives to be a foolish decision. *Shine v Vega* illustrates the complexity of these situations.[39] In 1990, Shine, a competent adult, went to the hospital and received oxygen and an unspecified medication for an asthma attack. Vega, the emergency department attending physician, thought that the patient was very ill and recommended endotracheal intubation. Shine stated her long-standing refusal of endotracheal intubation (confirmed contemporaneously by her sister and father) and continued to receive oxygen by mask. Later, Shine's sister came into her room in the emergency department and noted that Shine was breathing more easily but was arguing with the staff. Shortly thereafter, Shine and her sister attempted to leave but were forcibly detained by a physician and security. Shine was placed in four-point restraints, and Vega, choosing to disregard Shine's objection, intubated the patient's trachea. On appeal, the Massachusetts Supreme Court stated that the competent patient has a right to refuse potentially life-sustaining treatment, even if her decision is considered unwise.

Another issue of voluntariness is when the interests of a woman and her fetus differ (see also Chapter 77). When a woman refuses a recommended diagnostic or therapeutic procedure, such as cesarean delivery for fetal indications, physicians may choose to respect the patient's autonomy and not proceed, to encourage the woman to seek health care elsewhere, or to seek judicial involvement. Before seeking judicial involvement, physicians should consider the social, physical, and psychological harms of violating individual liberty and the fallibility and limitations of medical knowledge. Physicians may want to seek judicial involvement only when they are highly confident that the recommended treatment will substantially reduce harm to the fetus, that the risks to the woman are relatively small, and that no comparably effective less-intrusive option exists.[40] Particularly relevant to anesthesiologists is the American College of Obstetricians and Gynecologists position on forced interventions: "Even the strongest evidence for fetal benefit would not be sufficient ethically to ever override a pregnant woman's decision to forgo fetal treatment."[40]

Disclosure

The goal of disclosure is to provide information relevant to the decision maker and the decision to be made. Skilled disclosure builds trust, helps patients make good decisions, and is a fundamental component of the obligation to respect a patient's autonomy.

Established in 1972, the *reasonable person standard* requires that the extent of the disclosure be based on what a reasonable person would consider material for choosing whether to undergo the proposed intervention.[41,42] Informed consent discussions should routinely include the specific risks and benefits of reasonable anesthetic options and monitoring techniques, as well as the presence and use of a fallback plan.[38] Anesthesiologists may want to inform patients of common but less severe risks, such as postoperative nausea and vomiting, and uncommon risks of more long-term significance, such as brain injury and death. If appropriate, the patient should be informed of the quality of the data, such as whether the information has questionable certainty. Anesthesiologists should also inform the patient whether an individual or an anesthesia care team will be providing anesthesia

services, and, if a team, the names and specific roles of the team members. To maintain good relations, patients should be told about other practical matters, such as the likely sequence of events upon arrival to the surgical unit, who will be with them at the various stages, what to expect for postoperative pain management, and realistic time estimates.

In general, courts have not actively required disclosure of professional experience, personal health matters, and disciplinary history, except when relevant to a patient's decision making.[43]

Lack of disclosure about experience is often not admitted into evidence in part because the experience of a physician is not a risk inherit to the procedure.[44] In case law, however, these matters are decided on the specific merits of the case. Therefore, it may be prudent to inform patients if the individual clinician or "system" is inexperienced in a particular situation. A dentist was found liable when she failed to disclose that she was using equipment novel to her.[45] The court ruled that a reasonable person would desire this information and could expect it to be offered unsolicited. In another case, the court interpreted the hospital environment (decreased staffing on the weekend) and other available opportunities (a nearby hospital with greater experience in a complex surgery) as relevant within the legal definition of disclosure and informed consent.[46]

Courts have at times expanded the duty of disclosure to include personal issues, such as alcohol abuse, prior license suspension, and a directly relevant medical problem.[47] Other courts have considered such data to be in the domain of hospital credentialing and not a relevant part of disclosures.[48] Courts have ruled that doctors do not need to disclose the chance of negligence.[49] Whether a clinician's history of success with a procedure must be disclosed depends on the particular situation.[50]

Exceptions to the obligation to disclose material information include patients who choose not to be informed,[51] emergencies in which a valid informed consent cannot be obtained, and situations of therapeutic privilege. Physicians employ therapeutic privilege when they choose to withhold information because they believe disclosure would cause the patient to become "so ill or emotionally distraught on disclosure as to foreclose a rational decision, or complicate or hinder treatment, or perhaps even pose psychological damage to the patient."[52] Therapeutic privilege has a narrow scope and should be used prudently. Simply because information is undesirable or upsetting to the patient does not mean that such information should be withheld. For example, it may be reasonable to invoke therapeutic privilege when discussing the risk of death with a patient who is acutely having a myocardial infarction; it would not be reasonable to do the same when discussing the risk of death with the parents of an infant.

Recommendation

Anesthesiologists should offer an opinion about which options are preferable and the advantages and disadvantages of each option. By explaining the value judgments and the quality of data supporting their opinions, anesthesiologists allow the patient not only to receive the benefit of their expertise but also to understand the reasons for the recommendations. Patients can then decide for themselves which choices best fit their priorities.

Understanding

Patients need to understand the risks and benefits of the proposed procedures, the recommendations made, and the reasons those recommendations were made. It is difficult to determine whether a patient fully understands the informed consent discussion, and, indeed, many patients may not. Pain and distress do not seem to compromise the ability to recall risks and do not preclude obtaining a legally sufficient informed consent.

Decision

After considering the information and the anesthesiologist's recommendation, the patient chooses an anesthetic technique. Patients vary in their preferences for participation in decision making, and anesthesiologists should be sensitive to these preferences. The desire to participate in the decision-making process may be a function of the individual, extent of illness, gender, age, and level of education. Anesthesiologists should attempt to tailor the extent of the patient's and the physician's decision making to the patient and the situation.[51]

When a patient refuses an anesthesiologist's recommendation or requests a technique that the anesthesiologist believes is inappropriate, the focus of the conversation moves from informed consent to informed refusal. Informed refusal requirements are similar to informed consent requirements in that the patient should be substantially well versed about the risks, benefits, and alternatives before declining. However, although it may be reasonable to permit a patient who agrees with a recommended or acceptable procedure to refuse extensive information (especially if the likelihood of harm is low), it is more difficult to honor a patient's preference to receive limited information when that patient desires a suboptimal approach.[53] The anesthesiologist may wish to provide additional information about the choice to be sure that the patient has all possible information. If, in fact, the patient chooses without sufficient information, the anesthesiologist has not fulfilled the obligation of informed refusal. Of course, a patient still may refuse to hear information. In either case, when a patient chooses a technique that the anesthesiologist believes is inappropriate, anesthesiologists are not obligated to provide care in nonemergency situations.

Autonomous Authorization

The informed consent process concludes with the patient's intentionally authorizing the anesthesiologist to perform a specific procedure. This authorization is the expression of the patient's self-determination and is the basis of informed consent.

DOCUMENTATION OF INFORMED CONSENT

Informed consent for anesthesia may be documented on the surgical consent form, by a handwritten note, or by a separate anesthesia consent form (see also Chapter 38).

The use of a surgical consent form is suboptimal because surgeons cannot capably discuss the risks of anesthesia, and therefore it is unclear what is being documented. Both handwritten notes and anesthesia consent forms may be acceptable. Handwritten notes detail specific discussions with patients. Writing a note for each patient, however, may be impractical and time consuming, and it may miss key aspects of informed consent. Anesthesia consent forms may act as a prompt for anesthesiologists to discuss key aspects of informed consent. Space for handwritten notes on the consent form will permit additional details to be documented. Having the patient sign the handwritten consent or the consent form gives an indication that some form of communication took place. However, because consent forms by themselves do not fulfill the legal requirement of informed consent, an informed consent discussion must still occur.

THEORIES OF SUIT IN INFORMED CONSENT

Negligence relating to the informed consent process may occur if the anesthesiologist provides a disclosure that is insufficient to allow a patient to make an informed decision and an injury subsequently occurs, even if the injury was foreseeable and took place in the absence of a treatment error.[38] To determine whether sufficient information was given, the courts look for materiality and causation. *Materiality* assesses whether the information given met the standard of care. If the disclosure did not meet the standard of care, then it may be considered a breach of duty. *Causation* then assesses whether sharing the omitted information would have caused the patient to choose a different option.[38] Most jurisdictions use the *objective standard,* which bases causation on whether a hypothetic reasonable person would have used the additional information to make a different decision. Some jurisdictions use the *subjective standard,* which is contingent on whether the specific patient involved would have made a different decision. A few jurisdictions combine the two standards by heeding the objective standard while considering factors specific to the patient and situation. Courts also consider how the information was given. The informed consent discussion should occur in a setting conducive to decision making, and it should give the patient a chance to ask questions and consider answers.

The disclosure process is not intended to be armor against medical malpractice liability if an adverse event happens. Informing a patient about a risk does not eliminate liability for its occurrence. *Liability* is based on negligence theory and depends mainly on whether the standard of care was met and whether the failure to meet the standard of care was a proximate cause of injury.

REFUSING TO PROVIDE CARE

Anesthesiologists may refuse to provide care when they ethically or morally disagree with the procedure or situation, such as elective termination of pregnancy. Although physicians have an obligation to provide care altruistically, this requisite does not always oblige physicians to subjugate their morals. Furthermore, society and medicine have a fundamental interest in preserving the moral fabric of individual physicians. Anesthesiologists should perform care that violates their conscience and possibly weakens their moral constitution only in critical, presumably life-or-death, circumstances. More practically, an anesthesiologist who ethically or morally disagrees with a patient's choice will have difficulty in providing the care requested. In a nonemergency situation, such an anesthesiologist should withdraw from patient care. The anesthesiologist may then be obligated to make a reasonable effort to find a competent and willing replacement.

Physicians may also ethically refuse to provide care if they believe the patient's choice is too inappropriate or is likely to result in harm. Determining that an anesthetic choice is inappropriate is difficult and should not be invoked lightly or out of convenience. The patient's choice and the resultant risks must be sufficiently extreme that they, say, elicit a similar response from at least several other anesthesiologists. In addition, anesthesiologists may refuse to provide care if they do not feel qualified to provide the needed care.

LEGAL ASPECTS OF END-OF-LIFE CARE

Acknowledgment of patients' rights to refuse life-sustaining treatment began in the midtwentieth century with the rise of civil liberties, individual rights, and respect for the importance of self-determination (see Chapters 75 and 101). In 1974, the American Medical Association asserted the following: "The purpose of cardiopulmonary resuscitation is the prevention of sudden unexpected death. Cardiopulmonary resuscitation is not indicated in cases of terminal irreversible illness where death is not unexpected."[54] Policies acknowledging the need to permit patients to limit resuscitation during terminal illness were prominently published several years later.

Progression of the rights of the individual to refuse potentially life-sustaining care may be seen through case law. The 1976 case of Karen Ann Quinlan first established the right to refuse potentially life-sustaining care. In *Quinlan,*[55] the courts upheld the legality of disconnecting the ventilator from a patient thought to be ventilator dependent and in a permanent vegetative state.[55] The court based this decision on the general constitutional right to privacy. In addition, the court determined that a surrogate had the right to decline medical treatment for an incompetent patient if the surrogate concluded that the patient would have preferred limited care. Quinlan's father thus discontinued his daughter's mechanical ventilation. Quinlan lived for nearly a decade, sustained by nasogastric feeding.

The right of a competent person to refuse potentially life-sustaining care was established in the 1984 case of *Bartling v Superior Court*.[56] Bartling was a competent adult patient with an incurable disease who for 6 months received medical therapy against his clear wishes. After a pneumothorax from a needle biopsy, Bartling became ventilator dependent. He subsequently received a tracheotomy to facilitate weaning attempts. During this ordeal, Bartling made clear his desire not to receive continued therapy, and at one point he declared: "While I have no wish to die, I find intolerable the living conditions forced

upon me by...."[56] Although Bartling died before his case could be adjudicated, the appellate court issued an opinion based on the constitutional right of privacy that supported the right of a competent patient to refuse medical treatment.

The 1990 case of *Cruzan v Director, Missouri Department of Health* concerned a young woman involved in an automobile accident that left her incapable of expressing a preference.[57] Several years before the accident, Cruzan had expressed to a friend in a somewhat serious conversation a desire not to live in a state of diminished capacity. In seeking to withdraw potentially life-sustaining treatment, the Cruzan family used this conversation as evidence that Cruzan would have wanted therapy stopped. The Supreme Court of Missouri held that Cruzan's informal statements did not meet Missouri's evidentiary standard of "clear and convincing evidence" of a patient's wish to terminate potentially life-sustaining care and thus mandated continuation of treatment. The case was appealed to the U.S. Supreme Court.[58] Unlike *Quinlan* and *Bartling*, the Supreme Court grounded the right of a competent patient to refuse treatment in the liberty interest of the Fourteenth Amendment, which states, "No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty or property...." The decision also upheld the rights of states to determine the standards for the level of certainty required, thus permitting Missouri to use the "clear and convincing evidence" standard.

Competent patients have a virtually unlimited right to refuse potentially life-sustaining medical treatment.[59] For the incompetent patient, three hierarchical levels of judgment direct the decision-making process for end-of-life care. The once-competent patient's previously expressed preferences for end-of-life care should be followed as best as possible. When the patient's declared preferences are not known, *substituted judgment,* which is the use of the surrogate's intimate knowledge of the patient's attitudes and beliefs to determine what the patient would have chosen, may be used to direct care. Although these are two distinct categories, both levels require the surrogate to know the patient sufficiently to choose or interpret the patient's preferences appropriately. These standards put significant burdens on decision makers who may have legitimate doubts about the appropriateness of their decisions. When a surrogate has to make decisions for a patient who has never been competent, such as a young child or a mentally disabled adult, substituted judgment is impossible, and the surrogate must rely on the best interest standard. The *best interest standard* requires the surrogate to make decisions based on the surrogate's view of what is best for the patient.

ADVANCE CARE PLANNING

Advance care planning permits a patient to declare preferences for medical treatment if he or she becomes incapacitated. Advance directives are designed to minimize the likelihood of undesired overtreatment and undertreatment. Partially as a result of *Cruzan*, the Patient Self-Determination Act (PSDA) was introduced in 1991 to increase the use of advance directives.[60] The PSDA requires health care institutions, such as hospitals, nursing homes, and hospice programs, to notify individuals about their rights regarding advance directives. Three types of advance directives are living wills, health care proxies (also known as durable power of attorney for health care decisions), and physician orders for life-sustaining treatment (POLST). Living wills allow patients to declare the extent of desirable interventions, but they may not be able directly to address the subtle differences that characterize clinical situations. The difficulty of applying living wills to clinical situations led some patients to prefer the greater flexibility provided by the health care proxy, in which the surrogate decision maker can consider the specific details when making clinical decisions. Health care proxies permit patients to designate surrogate decision makers (including those who are not family members) to make decisions for them should they become unable to make such decisions for themselves. If the patient does not assign surrogacy, most jurisdictions have a hierarchy for assigning surrogacy, but this approach often excludes domestic partners and other individuals the patient would prefer to be the decision makers.[61]

Surrogacy is not always effective, particularly for patients who do not make their preferences clearly known to the surrogate before losing their decision-making capacity.[62] Given the strengths and weaknesses of each approach, the best option may be preparation of a designated proxy with some written form of preferences, which can then be followed by a POLST when appropriate.

POLST (sometimes known as MOLST or COLST with "medical" or "clinical" replacing "physician" or sometimes with the name of the state as the first word) supplements advance directives by focusing on advance planning for the seriously ill. Similar to other advance directives, POLST forms present options regarding cardiopulmonary resuscitation, medical interventions, and artificial nutrition. Traditional advance directives require frequent reinterpretation and must be reestablished in every treatment venue. In contrast, POLST is a medical order signed by a physician, and it remains in force whether the patient is at home, in the hospital, or at a long-term care facility. POLST is designed to increase the likelihood of compliance with the patient's wishes for life-sustaining treatment. This may be particularly important in areas that require specific authorization to refuse artificial nutrition.[63]

Advance care planning is an ongoing process. Competent patients may obviously modify their previously declared preferences. Demented patients, who previously made an informed choice to limit certain therapy, may express an interest in receiving that therapy.[64] If patients have evidence of decision-making capacity, such as being able to provide internally coherent reasoning, their wishes to receive therapy should be honored. However, the process of resolving this situation in a patient without decision-making capacity and with almost no likelihood of regaining decision-making capacity is more complex. In this situation, it is better to base judgment on therapy from multiple sources, including significant others, the type of documentation, and the best interests standard.

REFUSAL OF CARDIOPULMONARY RESUSCITATION

The right of a patient to reject unwanted therapy in the operating room is well accepted (see also Chapter 108). Before the patient proceeds to the operating room, perioperative do-not-resuscitate orders should be reevaluated in light of the surgical procedures, the anesthetic options, and the patient's overall goals. Anesthesiologists are then prepared to clarify and document the desired resuscitation status in the operating room, often by using the goal-directed approach.[65] The process of obtaining and documenting perioperative refusal of resuscitation should comply with hospital policy and jurisdictional law. Written documentation may include the patient's diagnosis and prognosis, the characteristics of perioperative resuscitation, likely outcomes, and the patient's reasoning. If a surrogate is making the decision, the record should note the surrogate's relationship with the patient and the basis of the surrogate's decision.

Refusal of resuscitation in an emergency situation without time to clarify a patient's wishes is inherently different. The traditional bias of providing treatment in the absence of a clear decision not to treat still holds for the anesthesiologist in the emergency situation. The situation can always be clarified later, and the patient can be withdrawn from the ventilator if it is determined that the patient would have preferred not to receive the interventions. In short, the "inconvenience" of a short period of mechanical ventilation is worth the opportunity to ascertain the patient's desires correctly.

THE DEMAND FOR LIFE-SUSTAINING THERAPIES

Patients or families may demand therapies that clinicians believe are inadvisable because of burden to the patient, cost, or uncertain benefit. When these cases become irreconcilable, the cases may go to court, often not to determine what therapy should be given but to determine who should be the decision maker for a noncompetent person. For example, Helga Wanglie was an 86-year-old patient in a persistent vegetative state who was receiving mechanical ventilation. The medical center believed that further therapy was inadvisable for Mrs. Wanglie and wanted to withdraw mechanical ventilation. When Mr. Wanglie refused the medical center's request to stop mechanical ventilation, the medical center sought appointment of an independent guardian to supplant Mr. Wanglie as her guardian. The Court declared that Mr. Wanglie was best able to be Mrs. Wanglie's surrogate.[66,67]

In the 1995 case of Gilgunn,[68] a jury supported a unilateral refusal of potentially life-sustaining care. Catherine Gilgunn had multiple medical problems and severe brain damage, and she was in a coma. Her daughter Joan, representing the family, requested that everything be done. The Optimum Care Committee of the hospital agreed with the physicians that providing cardiopulmonary resuscitation was not a genuine therapeutic option. The legal division approved the do-not-resuscitate order because they believed that the physicians were acting in the patient's best interest. Gilgunn was disconnected from ventilator support and died a few days later. The jury supported the actions of the physician and hospital to impose a unilateral do-not-resuscitate order. There was no appeal.

Physicians and hospitals have been very successful in defending lawsuits about unilateral refusal of potentially life-sustaining care.[69,70] Nonetheless, unilateral physicians' declarations are insufficiently respectful of patients' autonomy. Evidence indicates that negotiation nearly always resolves these problems without the need to resort to unilateral action. However, being able to resolve differences of opinions about applying treatments with low likelihoods of success is important. Policies for resolution based on a procedural approach, in which the process for resolving conflict is described, are more practical. Good policies are public, reflect the moral values of the community, and include processes for identifying stake holders, for initiating and conducting the policy, for commencing appellate mechanisms, and for determining relevant information.[71]

In a different approach, the Texas Advance Directives Act permits physicians to unilaterally withhold or withdraw treatments they regard as "futile," provided the physicians follow certain guidelines, including obtaining the agreement of the hospital ethics committee.[72] Other states are considering this approach.[73] On the other end of the spectrum, some jurisdictions have passed laws requiring treatment against the clinician's wishes until the patient can be transferred to a willing clinician or hospital or until judicial review.[74,75] Another approach is seen in the Consent and Capacity Board in Ontario, Canada. This is an independent, government-based tribunal for resolution of consent and capacity issues. Although most cases involve involuntary commitment to a psychiatric facility, this board has been involved in cases regarding end-of-life care. Other areas are exploring this approach.

PHYSICIAN-ASSISTED SUICIDE

Physician-assisted suicide is the act by a physician of prescribing lethal quantities of medication for self-administration by the patient (see also Chapter 10). In the United States, courts have held that no constitutional right to physician-assisted suicide exists.[76,77] The courts have followed common ethical opinion in drawing a distinction between the positive right to demand an action (e.g., physician-assisted suicide) and the more powerful negative right to be free of bodily invasion. Although no constitutional right to assisted suicide exists, individual states may choose to legalize or prohibit this act.[78] In 1997, the State of Oregon legalized the Oregon Death With Dignity Act, which permitted terminally ill patients to receive prescriptions in lethal quantities for the purpose of self-administration. This law does not permit any other forms of physician-related aid-in-dying, such as having another person administer the medication. From 1998 through 2011, prescriptions were written for 935 patients, and 596 patients used them. The most common diseases in patients who chose to ingest a lethal dose of medication were malignant neoplasms (81% of patients), amyotrophic lateral sclerosis (7% of patients), and chronic lower respiratory tract diseases (4% of patients).[79] The number of prescriptions written and used annually has

slowly and steadily increased since 1998.[79] The financial and educational status of patients does not seem to play a role in the request for physician-assisted suicide.

OTHER LEGAL ASPECTS OF ANESTHESIOLOGY

CARE OF THE JEHOVAH'S WITNESS

Jehovah's Witnesses interpret Biblical scripture to prohibit taking in blood because it holds the "life force," and anyone who partakes of it shall be "cut off" from eternal life after death.[80] Jehovah's Witnesses have different interpretations about the prohibition of blood transfusions, and anesthesiologists must actively clarify what the patient considers acceptable (see also Chapter 63). Documenting acceptable interventions crystallizes the patient's desires and provides legal documentation for the anesthesiologist. Anesthesiologists must be certain that they are capable of fulfilling the patient's requests; otherwise, they should not agree to provide anesthesia. Indeed, the anesthesiologist and surgeon should provide nonemergency care to the patient only if all parties can agree on the approach to blood management.

Case law strongly supports the right of the adult patient to refuse blood products. One case illustrates a different consideration in the care of Jehovah's Witnesses. Mary Stinemetz, a practicing Jehovah's Witness, refused to have a liver transplant in Kansas because she wanted to go to Nebraska to receive a "bloodless transplant." An appeals court ruled that the state had violated her constitutional right when they denied Medicaid coverage for the out-of-state transplant.[81]

LAW REGARDING PEDIATRIC PATIENTS

For the most part, parents or other surrogate decision makers of children make health care decisions for minors (in general, children <18 years of age) (see also Chapters 92 and 93). However, the participation of children should increase as they grow older, and it depends on both the patient's maturity and the consequences of the decision. Informed assent acknowledges that although most pediatric patients cannot legally consent to medical care, they should share in decision making to the extent that their development permits.

Some minors are permitted to consent for themselves.[82] *Emancipated minors* are patients less than 18 years old who have been given the global right to make their own health care decisions. This status varies by state but is generally awarded to patients who are married, parents, in the military, and economically independent, and it may include patients who are pregnant. The *mature minor doctrine* holds that minors who have decision-making capacity are legally and ethically capable of giving informed consent in specific situations as determined by a court. Although particulars vary, the mature minor doctrine in general requires patients to be at least 14 years old, and it tends to permit decisions of lesser risk. The courts will balance the maturity and decision-making capacity of the minor with the risks associated with honoring the minor's wish. As minors near the age of majority, the likelihood increases that the court will support the right of minors to determine therapy. For example, in a case in 2007 that seemed be on the margin, a judge ruled that a 14-year-old practicing Jehovah's Witness would be permitted to refuse transfusion therapy during treatment for a type of cancer that had a 70% 5-year survival rate. The patient subsequently died.[83]

Even though pediatric patients who are pregnant may be considered emancipated, many states require some form of parental involvement such as parental consent or notification before an elective abortion in an adolescent (see also Chapter 77). If a state requires parental involvement, the ability of the minor to circumvent this regulation by seeking relief from a judge, known as judicial bypass, must be available. Requirements and enforcement of statutes vary from state to state. The need for parental involvement in minors who have abortions is not always legally straightforward, and it may be best to consult with hospital counsel in determining such issues.[84,85]

Parents and medical personnel may disagree about what is in the best interest of the child. Based on the legal doctrine of *parens patriae,* which is the government's obligation to protect the interests of incompetent patients, parents are not permitted to make decisions that represent grossly inappropriate overtreatment or undertreatment.[86,87] One way to decide what is in the best interest of the child is to define what choices fall outside of the range of acceptable decision making. The extent to which one intervenes between a patient and the surrogate's decision depends primarily on how harmful the decision is to the patient. Criteria to make this determination include the amount of harm to the child by the intervention or its absence, the likelihood of success, and the overall risk-to-benefit ratio.[87] Charging a parent with not acting in the child's best interests has significant social, fiscal, and familial ramifications. If, however, after exhausting other options the anesthesiologist believes the parent has chosen unacceptable treatment, the anesthesiologist should report the situation to proper child welfare authorities for possible legal action.

Anesthesiologists caring for a child of a Jehovah's Witness should inform the patient and family that attempts will be made to limit the need for transfusion therapy and to abide by their transfusion preferences, but that in a life-threatening situation the anesthesiologist will seek a court order authorizing the administration of potentially life-sustaining blood. When the likelihood of requiring blood is high or the local judiciary is not that familiar with case law for Jehovah's Witnesses, the anesthesiologist may choose to obtain the court order before the operation. In crisis situations in which no court order exists, anesthesiologists should initiate emergency transfusion therapy before obtaining a court order. As a child becomes older, the courts become less likely to intervene, and they often grant the emerging adolescent more decision-making latitude. In elective procedures that may be safely delayed, the patient and family may also consider postponing the procedure until the child is of sufficient age and maturity to decide about transfusion therapy (see also Chapter 61).

SUPERVISION AND PROFESSIONAL ASSOCIATIONS

Attending physicians may be sued because of residents' actions. The question of what is considered acceptable resident supervision is affected by local policies and national guidelines, but again, in any individual case, a jury often determines the standard of care. Specific guidelines about what trainees are permitted and not permitted to do may provide some protection for the attending physician if the trainee deviates from these guidelines (see also Chapter 9). In addition, residents are being named in lawsuits with increasing frequency. As a general rule, a resident is held to the same standard of care as a practicing attending physician in that specialty.[88]

Under the doctrine of *respondeat superior* and the theory of *vicarious liability,* anesthesiologists are responsible for negligent acts made within the scope of defined duties by certified registered nurse anesthetists (CRNAs).[89] The fundamental issue of vicarious liability is whether the anesthesiologist is controlling the activities of the CRNA. Although the question of vicarious liability may depend on who remunerates the CRNA, this tends to be an ineffective defense because in these situations anesthesiologists tend to have full authority to direct CRNAs medically. The scope of defined duties and the determination whether adequate supervision occurred are affected by societal expectations, medical customs, history, practice, manuals, agreements, actions, expert analysis, and written documentation, but they are ultimately determined by a jury in any individual case. For example, in one case, a CRNA did not promptly summon the anesthesiologist for help in managing fatal postoperative laryngospasm and bronchospasm.[90] The anesthesiologist was found vicariously liable for negligence, in part because of the lack of clear understanding between the professional group and the CRNA about when the anesthesiologist should be called.

Many controlling authorities (e.g., state statutes or hospital bylaws) require physicians to participate in certain aspects of anesthesia care when they supervise CRNAs. It is also the responsibility of the professional association to set forth the expectations in a manner that is consistent with law and regulations. Accepting a standard below the medical community's published standards (e.g., ASA guidelines) risks liability.

Federal regulations for accreditation of hospital and ambulatory surgery facilities require that a CRNA must be supervised by the physician performing the procedure or by an immediately available anesthesiologist.[91,92] State governors may opt out of this supervision requirement if they deem doing so to be in the best interests of their citizens. For the opt-out approach to have practical consequences, however, state laws must also not require supervision. Pending appeals, 17 states have opted out of the federal rule requiring physician supervision. Health care facilities within states that have opted out may still require supervision.

Anesthesiology professional associations may be held libel if they do not ensure that members are competent and that appropriate policies are followed.[93] Many agreements between professional associations and hospitals require service that complies with governmental and professional standards.[93] Obligations of professional associations may extend to letters of reference. For instance, an anesthesiologist was terminated with cause secondary to abuse of meperidine (Demerol).[94] When the anesthesiologist went to a locum tenens company, letters of reference from shareholders of the previous professional association did not mention the abuse or that the anesthesiologist was fired with cause. Subsequent negligent care by this anesthesiologist caused severe brain damage to a patient. The court held the previous professional association liable for part of the financial award.

Professional associations are responsible for addressing impairment of physicians. An *impaired physician* is one who is unable to perform professional or personal responsibilities. Physicians impaired through alcohol and other addictive disorders are considered to have chronic medical illnesses. The Americans with Disability Act, written in 1990 and amended significantly in 2008, forbids discrimination against individuals who are in recovery.[95] Treatment records of impaired physicians are confidential.

LEGAL ISSUES IN PAIN MANAGEMENT

Inadequate pain management is a health problem (see also Chapters 64 and 98). Part of the problem may stem from the tension inherent in unclear regulations, regulatory scrutiny, and criminal investigation and prosecution by state medical boards and drug enforcement agencies.[96,97] For example, the Drug Enforcement Administration's ability to monitor prescriptions for controlled substances electronically gives this agency access to physicians' prescription histories. Physicians are concerned that knowledge of prescribing practices, divorced from patient-specific context, will lead to misunderstandings and possible investigations. Physicians' concern about being investigated may affect the doses, quantities, number of refills, or even type of drug used in the care of patients with chronic pain.[97] The Drug Enforcement Agency suggested that this issue should have no effect and emphasized that only 0.06% of all physicians had investigations initiated, 0.05% of all physicians had actions taken against them, and 0.01% of all physicians were arrested.[98,99] However, 0.06% may be fallaciously low because that percentage is out of all practicing physicians. A more relevant percentage would be based on a population comprising only physicians who prescribe narcotics for pain control and thus are at risk for investigation. Many of the physicians investigated did have actions taken against them.

The *Gonzales v Oregon* decision should comfort physicians because it limits the effects of the Drug Enforcement Agency on physicians.[100] *Gonzales v Oregon* prohibited the U.S. Attorney General from forbidding physicians in Oregon to prescribe schedule 2 drugs for terminally ill patients to use to commit suicide. The point of the case

TABLE 11-4 **DATA BANKS**

Data Bank	Purpose	Information	Who Can Query
National Practitioner Data Bank (NDPB)[105]	"To restrict the ability of incompetent physicians to move from State to State without disclosure or discovery of the physician's previous damaging or incompetent performance"[105]	Medical malpractice payments Adverse actions: licensing, clinical privileges, professional society, Medicare and Medicaid exclusions and U.S. Drug Enforcement Administration actions	Hospitals Health care entities with review process Professional societies State licensing boards Plaintiffs and their attorneys Self-query

Federation of State Medical Boards (FSMB)[107]	"[P]romoting excellence in medical practice, licensure, and regulation as the national resource and voice on behalf of state medical boards in their protection of the public"	Recording of actions by state medical boards against physicians	Medical boards Public

is that the U.S. Congress can set national drug prescribing rules through the Controlled Substances Act (CSA), but Congress cannot affect the ability of states to set medical practice standards. Although several reasons existed, the primary reason was that the CSA does not regulate the practice of medicine. The practice of medicine is regulated by the state.

Physicians have been held liable for inadequate pain control. For example, an 85-year-old man was admitted to a medical center for 5 days in 1998 before his death several days later.[101] He received inadequate pain control during his hospital stay. Although a medical malpractice suit was dismissed and the state medical board did not pursue any action against the physician, the family won a civil suit against the physician under the California's Elder Abuse and Adult Civil Protection Act.

ELECTRONIC MEDIA

Physicians may violate privacy while "blogging" or otherwise discussing clinical practice on various forms of social media. Using electronic media while providing patient care is a distraction and increases liability because the times and extent of electronic media use can be precisely defined. Even if no event occurs during that time, it sets the tone for the quality of care that increases the likelihood of a successful lawsuit. It was reported that in one settled case, a surgeon made numerous personal cell phone calls during an operation that resulted in permanent harm to the patient.[102]

Heightened societal awareness of poorly timed electronic media use (e.g., while driving) has increased patients' concerns about use during patient care. A 2010 survey of perfusionists found that more than 50% had texted or used a cell phone during cardiopulmonary bypass, and more than 20% had accessed email.[103] One of the problems is the routine and unthinking nature with which we consult electronic media. Many institutions are implementing policies defining appropriate use of electronic media, to increase awareness of the problem, clarify expectations, and provide legal protection.

ELECTRONIC RECORDS

The 2009 Health Information Technology for Economic and Clinical Health Act (HITECH)[2] authorized a nationwide technology infrastructure to improve health care quality and care coordination. It established economic incentives tied to "meaningful use" of electronic health records.[104] HITECH also required federal notification for breaches of privacy of health care information. Since 2010, more than 500 breaches have occurred. More than 60% involved theft or loss of information, typically on electronic devices such as laptop computer.[2] To improve transparency, patients may obtain an audit of the use of their electronic records.

DATA BANKS

Federal data banks are designed to improve health care by tracking performance and by flagging suspect health care practitioners and entities (Table 11-4).[105-107] By way of context, from 2001 to 2011, the National Practitioner Data Bank recorded 134,862 malpractice payments and 58,285 adverse actions. Reports of malpractice payments have steadily decreased from nearly 16,000 in 2001 to approximately 8500 in 2011. Adverse actions have remained consistent during this period. Adverse actions include clinical privilege actions and society membership actions.[99] Concerns about adverse actions prompted proposal of a bill "to prohibit health care entities from reporting certain professional review actions against health care professionals before adequate notice and hearing procedures are afforded to such professionals…."[108]

Chapter 12

Anesthesia Business Models

NEAL H. COHEN • LARS I. ERIKSSON

Key Points

- Anesthesia practices have evolved over the past decade, in part due to changes in the roles anesthesiologists play in the management of both inpatients and outpatients and in part due to dramatic changes in the relationship between anesthesia practices, other providers, and health care systems.
- At the same time, models of health care and the clinical scope of practice for anesthesiologists have expanded dramatically. As a result, anesthesia practices have had to respond to the changing health care environment, gain new skills, and tailor their practices to ensure continued success.
- To retain a meaningful role in perioperative care, pain management, and critical care medicine, anesthesia practices must expand their clinical perspective and in doing so document clinical and economic value to patients, health systems, and payers.
- To ensure the long-term future of the practice, anesthesiologists must deliver care that is safe, of high quality, and efficient and provide metrics to document outcomes of care. Public reporting of outcomes associated with all aspects of care is now expected, particularly in the United States.
- Anesthesia business practices also have to be revised to address the changing needs of patients, other providers, and health care systems to maintain a meaningful role in health care delivery.
- Anesthesia practices have adopted a variety of business models to address the needs of the local environment, the relationship between the anesthesiologists and the community, and the roles played by anesthesiologists in perioperative management.
- At the same time, particularly in the United States, consolidation of anesthesia practices through acquisition and other business relationships has created large national and regional practices that contract with health care systems to provide clinical care and practice management services. In some cases, these large groups include other specialists, such as hospitalists, emergency department physicians, and interdisciplinary critical care providers. This multispecialty model allows the groups to coordinate care and offer broad services to hospitals and health systems.
- While there is no single business model that is appropriate for every anesthesia practice, the key components of any model must ensure a collaborative business relationship and financial support from the health systems.
- For academic programs, the traditional business model that relies on clinical income to support the other missions, including education and research is no longer viable. Alternative sources of revenue are required to ensure the scientific underpinnings of the specialty while partnering with the clinical enterprise to optimize patient care.

This chapter provides an overview of the essential business, management, and staffing models utilized in anesthesia practices in a variety of settings, including urban and rural practices and community-based and academic programs. While no single model is appropriate for every practice setting, whatever approach is used must not only address the financial viability of the practice but must also ensure that the anesthesiologists are valued and collaborative partners with other providers and the health system and that they ensure the delivery of safe, high-quality, and efficient care. At the same time, while this discussion identifies some of the current approaches to practice management, it is important to acknowledge the dynamic health care environment, both internationally and in the United States. Anesthesiologists have been leaders in patient safety and quality and have expanded their roles to include preoperative management, extended postoperative care, intensive care medicine, pain medicine, and in some countries sleep medicine and palliative care. In addition, a number of new opportunities have presented themselves as a result of changes in the delivery systems and the role of other providers in perioperative care. Implementing some of these new practice opportunities in perioperative management, such as the perioperative surgical home and other initiatives, will require considerable creativity and flexibility. The traditional business models no longer apply. New approaches to clinical care, staffing, and compensation must be implemented to achieve the goals of both patients and health systems. While some of these new opportunities are briefly discussed in this chapter, they are more comprehensively described in Chapter 3. This discussion will identify some of the critical business practices and ways to optimize the financial performance of anesthesia departments in the changing health care environment. Although the financial support for education and research is beyond the scope of this chapter, the discussion here will identify some ways in which the business models may need to be modified to address the needs of the academic departments and ensure the future scientific foundation for the specialty.

It is essential that each practice build a business model that is financially viable and supports clinical needs within the health care system. At the same time, however, business practices and staffing models must be designed to optimize delivery of high-quality, safe care to the patient populations being served. Each practice must determine the model that most effectively and efficiently ensures the availability of well-trained anesthesia providers to its population. In addition, anesthesia providers across the spectrum of subspecialties, critical care anesthesiologists, and pain medicine physicians are required to support the needs of the health system or facility in which the practice works. The expanding role for anesthesiologists in preoperative management, pain medicine, critical care medicine, and ambulatory care provides new opportunities and requires different approaches to practice management (see Chapter 1).

Some of the business practices described in this chapter apply to every practice setting whereas others are appropriate for select practices, such as in large urban or academic settings, or both. In addition, although this chapter defines some of the current business models, the dynamic health care environment mandates flexibility and entrepreneurship to take advantage of new technologies, such as telemedicine, and to manage the evolving needs of an increasingly complex patient population. Some new opportunities related to the perioperative surgical home (PSH) and other initiatives beyond traditional perioperative management by anesthesiologists will also have an effect on the business models for anesthesia practices. Although these opportunities are discussed briefly in this chapter, they are more comprehensively described in Chapter 3.

PRACTICE MODELS

GENERAL MODELS OF ANESTHESIA PRACTICE

The models of anesthesia practice vary considerably within the United States and throughout the world. This variability is true for practices in all settings, including private practice, military medicine, and government-supported hospitals (e.g., Veterans Administration and city-county hospitals). In those countries with primarily publicly supported health care systems, physicians are often employed by the government directly or through a government-supported health authority, and care is provided within public hospitals, including military institutions. In some countries, there is a parallel private health care system and physicians may work outside the government system, providing care in the private sector, often while also spending the majority of the clinical time in the public sector, "moonlighting" in the private institutions to supplement income. In these parallel structures, the anesthesiologists and other physician practices are salaried within the government system and bill personally for care provided to patients in the private system. For many of these practice options, the business models are relatively straightforward. The government or health authority compensates the anesthesia providers based either on an annual budget or contract or on the basis of some assessment of work units. Compensation for care delivered outside of the public sector is often self-paid on a fee-for-service basis because in many cases there are limited health insurance options for patients receiving care in the private sector. Recently, in many countries, private insurance options have become more common, though the payment for services varies considerably based on the insurance options, costs, and other considerations.

In the rapidly changing health care environment throughout the world, anesthesia practices are evolving and identifying new ways of caring for patients in the operating room and other inpatient and ambulatory settings. While many of these changes are now being implemented within the United States, many of the models of care being evaluated in the United States are based on delivery and financing models used in other countries. The changes in the financing of health care, payment models for anesthesia services, and the expanding role of anesthesia services outside of the traditional operating room environment require new models of practice and

new skills to ensure that the practice is financially viable and that patient care is optimized.

EUROPEAN BUSINESS MODELS

The business models for anesthesia practices in Europe provide interesting examples of the differences in health systems and their impact on anesthesiologists throughout the world. There are various models of practice throughout the continent. These models are largely dependent on the distribution of governmental health care systems or private practices within each country. For example, in France more than 60% of anesthesia services are provided by private practice, whereas in Scandinavia and the United Kingdom more than 90% is provided within governmental health care systems.

In Germany and Sweden, payment for perioperative care is typically based on disease-related groups, that is, a single payment for all in-hospital care costs related to a specific disorder or surgical or diagnostic procedure. This payment includes costs for anesthesia and postoperative care. The disease-related group payment is made to the primary care provider (e.g., gastric surgery department for a bariatric surgery procedure) and is followed by internal cost allocation, which can be made in several ways. As a result, the business models used for internal cost allocation to anesthesia departments varies between countries and can vary within a country.

In Germany, one third of anesthesia departments receive internal cost allocation payments based on a median national anesthesia cost estimation that is related to each specific disease-related group. The remaining two thirds of anesthesia departments in Germany generate their internal reimbursement based on a combined flat rate payment that includes payment for case load and time—that is, a combined formula with a flat rate for preanesthesia and postanesthesia visits, staffing, and maintenance, with additional payment for cases that are complex and that require intraoperative and postoperative time. While each of these payment distribution models is unique to the environment in which they have been implemented, they provide some important lessons, particularly to practices in the United States which are likely to have an increasing proportion of payments for clinical services be bundled.

In the United Kingdom, more than 90% of anesthesia departments are primarily funded through the National Health Service. Each department is provided an annual budget for staffing and maintenance of the department's infrastructure, whereas surgery departments receive additional funds to cover surgical services, including drugs, operating room equipment, and postoperative care. To the extent that the anesthesiologists broaden their clinical role to optimize perioperative management, they may (or may not) be successful in generating additional payment for these expanded services. Similar models are used in other countries that have national health programs, though some countries have a parallel private system with a different, usually a fee-for-service model of payment.

In France, government-based anesthesia services are reimbursed based on cost estimates made jointly by the Ministry of Health and associations of physicians. These estimates are based on a flat rate that pays for basic anesthesia services, with provisions for additional payment for more complex procedures and patients with comorbidities of certain risk factors (e.g., at the extremes of age).

UNITED STATES BUSINESS MODELS

In the rapidly changing health care environment of the United States, anesthesia practices are evolving and identifying new ways of caring for patients in the operating room and other inpatient and ambulatory settings. While many of the changes are being implemented in practices within the United States, many of these models have accounted for lessons learned from business and clinical models in other countries. At the same time, particularly in the United States, changes in the financing of health care and payment models for anesthesia services and the expanding role of anesthesia services outside of the traditional operating room environment require new models of practice and new skills to ensure that the practice is financially viable and that patient care is optimized.

The United States has a wide variety of business models for the practice of anesthesia in both community and academic practices, each developed in large part based on the source(s) of funding, how the funding is distributed, and the requirements that must be met to receive these funds. Academic practices have generally been more integrated with the health system, either through a faculty practice plan (in many cases an independent corporation) or through an employment model. In these models, income from patient care is often the largest source of funding, though many departments also receive funds from research grants and contracts and, in rare cases some financial support for the educational initiatives (payment for residency program direction, course directors, etc.). While these other sources of revenue are critically important to academic departments, much of the funding to support the academic missions has traditionally come from patient care. As clinical demands have increased, academic faculty have less time to pursue research and educational activities, limiting the ability to generate other sources of support. At the same time, the clinical income has not kept pace with the increasing financial pressures on the academic departments, requiring academic practices to identify new business models and new relationships with the health systems to fulfill their academic potential.

Similarly, the business models required to support community practices are also undergoing dramatic changes. The historical practice model for anesthesiology was often a loosely affiliated group of anesthesiologists who shared clinical coverage for patients undergoing anesthesia in a hospital setting, including providing call coverage. The primary roles fulfilled by the anesthesia practice in this "informal" model included scheduling of anesthesia providers. In most other respects, each anesthesiologist was relatively autonomous, although in some cases billing was centralized for all providers either within the group structure or outsourced to a billing company familiar with anesthesia billing requirements. In some of these models of practice, anesthesiologists worked with individual surgeons, rather than as a

coordinated group of providers. Although this approach worked well for the individual anesthesia provider and the surgeon, scheduling and coordination became increasingly complex, particularly when care was provided in more than one facility.

Over the past 2-3 decades, the relationship with hospitals and health systems and the changing health care environment has necessitated that practices become more integrated group practices. While in some cases there remain individual or small group practices providing care in physician offices or ambulatory surgery centers, most practices have evolved and become more sophisticated in the business aspects of anesthesiology in order to compete successfully and to ensure the financial viability of the practice. A number of "group" models of practice have been created; with the current challenges in health care financing and the mandate to document and publicly report clinical outcomes, the practices have had to develop or acquire additional skills to remain successful both clinically and financially. As a result, while in some select situations the "independent" anesthesiologist model is still viable, for the most part group practices that share both clinical responsibilities and business practices now dominate the specialty. The model has evolved to include formally incorporated partnerships and corporations to coordinate anesthesia care, manage the business practices and optimize contractual relationships with payors.

Many other factors have contributed to the changes in and coordination of business practices for anesthesia groups. First, the clinical capabilities and skill sets have expanded considerably, requiring each group to ensure that among the members of the group, the clinical needs of a diverse population can be met. As a result, recruitment and retention of anesthesia providers has taken on greater significance. Second, most health systems prefer to either employ physicians or contract with a single anesthesia group (i.e., rather than individuals) to provide the needed services. In order to be competitive under this model, the group must have sound business capabilities and negotiating skills. Most groups have also expanded the scope of services beyond scheduling, billing and collection to include benefit management (e.g., retirement plans), and malpractice insurance and increasingly other services to support members of the group. At the same time, the consolidation of hospitals into health systems and the need for sophisticated clinical and business systems to support the anesthesia practice have led either to the acquisition of many "hospital-based" anesthesia practices by regional or national anesthesia groups or to their integration into multispecialty practices within a community or region. The pace of acquisition of anesthesia practices into these systems has accelerated over the past 3 to 5 years. According to some estimates, as many as 31 anesthesia and pain practices were acquired mostly by national or regional anesthesia provider groups in the United States in 2013.[1]

While the consolidation is changing the landscape of anesthesia practices, there are other pressures that are having major implications on the future of anesthesiology practices, both within the United States and internationally. Most significant have been the dramatic changes in the clinical practice of anesthesiology and the scope of anesthesia services (see Chapter 1). Because of these changes—a focus on evidence-based clinical practice and the development of clinical guidelines, protocols and practice parameters[2,3] (also see Chapter 6), new drugs, improved monitoring capabilities, and better preoperative assessment and management—a more diverse and in many cases complex patient population is now receiving anesthesia services. The practice of anesthesiology has expanded to include preoperative assessment and preparation of patients with chronic medical problems, acute and chronic pain management, critical care medicine, perioperative care and management services, and other clinical and administrative roles (see Chapter 1). These changes have had a major effect on the business models for anesthesia practices and the scope of services provided by anesthesiologists. The business models and scope of activities required of each practice is determined in large part on the relationship between the practice and the environment within which it provides care. In most cases, however, to maintain a consistent standard of care, to provide ongoing documentation of clinical competence, and to monitor outcomes of care, a group must have a strong management structure and analytic skills to document its value to the health system.

STAFFING MODELS

PHYSICIAN ONLY PRACTICES

In most parts of the world, anesthesiology is provided by physicians with specialty training in anesthesiology and, in some cases subspecialty training. In some locations in the United States, physician anesthesia practices predominate, particularly on the West coast. In this model of care, anesthesiologists provide care in the operating room and, now, commonly in other settings including, but not limited to, ambulatory surgery centers and ever expanding non–operating room environments. In this model, anesthesia is personally provided by the anesthesiologist; preoperative and postoperative care may be provided by the same individual or another member of the same anesthesia group.

As the roles and clinical scope of practice have expanded, anesthesia departments have recruited anesthesiologists with diverse subspecialty skills, not only to improve care within the operating room, but also to provide care in other settings. Many departments now include physicians with subspecialty training in critical care medicine, pain management as well as the other subspecialties of anesthesiology (pediatrics, cardiothoracic anesthesia, obstetric anesthesiology). This expansion in the scope of practice has been successful for the departments, health systems and, most importantly patient care, but it has also complicated scheduling and coordination of services across the continuum of patient care. For example, staffing all subspecialty surgical services can present operating room management challenges (see Chapter 4).

Some anesthesia practices have also incorporated physicians from other specialties to expand the clinical

capabilities and improve coordination of care. For example, some groups include hospitalists with a special interest in perioperative care, internal medicine physicians to improve preoperative management of complex patients, and critical care and pain medicine physicians whose primary training is in a specialty other than anesthesiology.

ANESTHESIA CARE TEAM MODELS OF PRACTICE

In most countries and selected areas of the United States, anesthesia is provided by physicians practicing independently; however, the anesthesia care team model predominates in some parts of the United States, with the practice employing anesthesiologists, CRNAs, and AAs in some states.[3,4]

For groups that use the anesthesia care team model, the relationship between the anesthesiologist and the nonphysician providers varies, although in most cases the CRNAs and AAs are employed by the anesthesia group. All business practices are managed by the group, and the providers are employed by the group. In some cases, the nonphysician providers are employed by the health system, though no matter who employs the nonphysician providers, in all cases the anesthesiology department has responsibility for oversight of all anesthesia services. In states that require supervision of all nonphysician anesthesia providers, when CRNAs and AAs are employed, the anesthesiologist is responsible for the care provided during the entire perioperative or periprocedural period, including the preoperative evaluation, presence for critical portions of each case, and postoperative management. In most cases, based on requirements outlined by the U.S. Centers for Medicare and Medicaid Services, the anesthesiologist may supervise up to four CRNAs at a time.

Nurse Anesthetists

A nurse anesthetist is a nurse who has specialized in the administration of anesthesia. Nurse anesthetists typically complete a 4-year undergraduate degree, have 2 years of clinical work experience (often in an ICU setting) and then a 2-year master's level anesthesia training program. Nurse anesthetists have a certification examination and, after successful completion of the examination become certified nurse anesthetists (CRNAs). Recently, some nurse anesthetist programs have begun to offer a doctorate of nursing practice (DNP) or doctorate of nurse anesthesia practice (DNAP). In many parts of the United States, nurse anesthetists work in the anesthesia care team model under medical direction or medical supervision. As part of the anesthesia care team, a nurse anesthetist may evaluate patients preoperatively and administer anesthesia under the supervision of an anesthesiologist as noted above. In some states, nurses may work independent from physician supervision, in accordance with each state's nurse practice act.[6]

Anesthesia Assistants

Anesthesia assistants (AA) work under the direction of an anesthesiologist as a physician extender in the anesthesia care team model. AAs complete a 4-year bachelor's degree, with a 2-year master's level program, followed by a certification examination. AAs can take preanesthetic health history, perform preoperative physical examinations, establish noninvasive and invasive monitors, administer medications, evaluate and treat life-threatening situations, and execute general and regional anesthetic techniques, as delegated by the anesthesiologist. Currently, AAs are not able to practice independently in any state in which they are licensed.

HEALTH SYSTEM–EMPLOYED PHYSICIAN MODELS

With the increasing consolidation of health systems, hospitals are now more commonly employing physicians directly. In these models, the practices are managed by the health system rather than an independent group or practice plan. Some states do not allow these employment models,[7] but a number of alternative models have developed that effectively result in the physicians becoming employees either directly or through a foundation or other approach that is essentially controlled by the health system. These models are becoming more common in selected parts of the United States, often initially developing on employment relationships for hospital-based physicians, such as anesthesiologists. In these employed or foundation models, the anesthesia providers are salaried. All business aspects of the practice are managed by the health system or foundation, including, but not limited to contracting, billing, coding, and collections.

Employment relationships with physicians are being expanded in a variety of not-for-profit as well as for-profit hospital systems, in an attempt to more effectively create coordinated approaches to clinical management, cost containment, and alignment of incentives. Currently, a majority of hospitals and health systems provide some level of financial support for physician practices in both academic and community environments. More than 80% employ primary care physicians, and more than 60% employ some office-based specialists. Almost one third of the hospitals are pursuing some form of joint venture with segments of their medical staffs, and a number of others are considering this possibility. Initiatives include cardiac services, magnetic resonance imaging, positron emission tomography scans, mammography, sleep laboratory, wound care, women's health, oncology services, and medical office buildings. Surprisingly, only one third of those involved in a joint venture gave it a high rating related to hospital-physician alignment. Hospital chief executive officers admit that negotiating and managing these initiatives is difficult and time consuming.

Despite the challenges associated with these changes in the hospital-physician relationship, the trends are clear. As more physicians become employees of health systems or foundation models, the ability of independent physician practices to compete will diminish. As a result of these pressures to align more closely with the health systems, many anesthesia practices are finding it difficult to address some of the pressures put on them by the health system, payers, and other providers. In response, there has been increasing consolidation of anesthesia practices into regional and national groups with the size

and sophistication to not only manage the clinical practices, but also provide the data needed to effectively negotiate with the health systems and payers and to provide metrics to document clinical outcomes. If this consolidation continues, the survival of individual hospital-based or independent anesthesia practices is in jeopardy.

Company Model

While most employed models compensate anesthesia providers based on either clinical productivity (e.g., work relative value units) or fees collected on behalf of the anesthesia group minus administrative costs, one employment model for anesthesia practice raises considerable concern. The "company model" has gained some support from other physician specialties such as gastroenterologists and other proceduralists.[8] Under the company model, referring physicians, who typically also own the facility where procedures are performed, form a separate "anesthesia company" to share in anesthesia revenue. The intermediary company employs anesthesiologists, collects the professional fees on their behalf, and shares the difference between the collected fees and salary with the corporate shareholders. The fees are generally not based on the costs of managing the anesthesia billing and collections, but rather are described as management fees retained by the corporation. Many questions have been raised by this model of practice, since the arrangements between the physicians who own the facility and the anesthesiologists might violate the federal anti-kickback statutes.

In June 2012, the Office of Inspector General (OIG) for the U.S. Department of Health and Human Services issued Advisory Opinion 12-06 citing the "company model" and "management fee" both posed more than a minimal risk of fraud and abuse.[9] Anesthesiologists being approached with such offers should review the documents with their attorneys to avoid violating anti-kickback laws that could lead to civil penalties and criminal fines.

Academic Practices

In most academic practices, anesthesiologists work within the academic structure, as employees of the school of medicine or the faculty practice plan. With an academic structure, medical centers (i.e., hospitals) may provide funding to the faculty practice plan. In many but not all academic practices, the anesthesia group is a member of the faculty practice, sharing business practices with the other departments represented by the faculty practice plan. The specific business models vary considerably, although in most cases the faculty anesthesiologists are employed by the university, the health system, or the faculty practice. In selected cases, the anesthesia department is an independent corporation or partnership functioning autonomously from other physician groups or the health system. Because of the increasing support required from the health system to ensure availability of anesthesia services across the spectrum of clinical services, these autonomous models are rapidly being replaced by the integrated practice plan. In most academic models, contracting and other business services are provided by the practice plan. Because of the diverse roles and responsibilities of the faculty in academic departments, the financing of the department and compensation of the staff is complex, with various approaches to determining total compensation based on clinical effort as well as other roles and responsibilities (teaching, research, administration). Over the past few years, most academic departments have transitioned to providing base salary with an increasing proportion of overall compensation based on incentives.

The academic practices have multiple missions, which complicates the business models and creates potential and real conflicts between clinical and academic needs. The "triple threat" academic physician who is the outstanding clinician, educator, and researcher is often perceived (particularly by the hospital leadership) to be less efficient and less committed to patient care. In response, many academic departments have recruited faculty with a primary (sole) commitment to clinical care. This change has created a two-tiered system and, in some cases undervalued the teaching and research roles. At the same time, research funding has decreased and many departments are finding it difficult to maintain scholarship while also addressing the increasing clinical demands of the health care system.[10]

Another challenge facing academic departments is the changing role for residents (see Chapter 9). In addition to providing high-quality, efficient, and safe care, the academic departments are responsible for training the next generation of anesthesiologists and for providing broad-based clinical experiences and didactic educational programs. The anesthesia residencies are accredited by the Accreditation Council for Graduate Medical Education. The oversight and accreditation process has become more rigorous and challenging for the academic departments to meet. Residents have restricted work hours to reduce the effects of fatigue on performance. Supervisory expectations have increased, requiring more one-on-one oversight of the resident in the clinical environment. In addition, the implementation of simulation and other models of education have replaced some of the clinical experiences. Because of these changes, the residents are no longer the primary providers of clinical care under faculty supervision; faculty members are providing personal care or supervising other nonphysician providers more commonly in academic environments. The financial and business implications of these changes are significant. Anesthesia departments in the United States now receive significant support from the academic health system in order to remain financially viable.[11,12] Although clinical income has always provided the resources to support the academic programs in the past, the importance of clinically generated income has increased as extramural research funding has decreased. The business practices required to support academic practices are now highly similar to those required to support other large group practices. As a result of these significant challenges for academic departments, the "value" of the academic program to the health system has been questioned. In some cases, entire academic departments have been replaced by large national anesthesia groups to manage the department and deliver care,[13] putting into question how we can ensure the ongoing training of anesthesiologists.

ESSENTIAL BUSINESS PRACTICES

In order to concentrate on delivering anesthesia services, each anesthesia practice has to ensure that the business functions of the practice are being provided appropriately and responsibly. Although each model of practice may have a different business structure to support the practice, the anesthesia providers retain the responsibility for ensuring that the business practices are ethical, fulfill legal and regulatory requirements, and that the quality of care is continuously assessed and refined to remain evidence-based and within the standard for the community. These responsibilities can be delegated, but cannot be abrogated. As a result, whether the anesthesia providers are employed or are members of a professional corporation, they must understand the business practices, provide oversight, and continuously ensure that the practice is well managed. To fulfill these critical responsibilities, the basic business functions of the anesthesia practice should focus on the most effective ways to facilitate high-quality, safe patient care in whatever clinical settings the practice works, optimize the clinical environment, and identify new opportunities to expand or enhance the practice while also ensuring the financial underpinnings of the practice. Achieving these goals requires that the business practices be built on a foundation of collaboration and cooperation with other providers from other specialties, hospitals, health systems, and payers. The business functions should support each of the following requirements of practice.

FOSTER CLINICAL CARE

The business models should be designed to allow anesthesia providers to concentrate their attention on patient care. Most anesthesiologists have little interest in managing their practices, although some members have both the interest and skills to do so. The practice should be designed to take advantage of the skills of each member, allowing those interested in participating in the business functions to do so, while the majority of the group concentrates on delivering high-quality care, assessing outcomes of care, and modifying practices to improve quality and safety.

One of the major challenges facing every practice is the transition from payment for clinical care, primarily the fee-for-service model, to pay for performance. In some cases, rather than paying for documented performance on specific process or outcome measures, payers are not paying if there is evidence of poor outcome (e.g., central line infection, ventilator-associated pneumonia).[14] At the same time, not only are third-party payers reducing payment when complications occur, but hospital subsidies can also be based on specific quality metrics. For the practice to ensure that clinical care is optimal as is often required for payment of clinical services, reliable information about all aspects of the clinical practice must be available. Good data about the practice will allow an organization to identify and promote best practices and improve both the quality and efficiency of care. Data will also facilitate the sharing of information among all the providers, precisely defining opportunities to improve care. To provide the data on outcomes and costs of care, coordination and integration of information is required from the anesthesia record, operating room, and the overall hospital information system. Now, these goals are increasingly dependent on implementation of an integrated electronic medical record (see Chapter 5). Most independent anesthesia practices cannot afford to implement the electronic anesthesia record on their own and, more importantly, cannot easily integrate their data with that of the hospital system without considerable support. As a result, only larger organizations that are working collaboratively with health systems will be in a position to acquire, analyze, and disseminate data to support the quality and efficiency of care provided by the group.

MANAGE THE PRACTICE

Although patient care is the primary purpose for which the anesthesia practice exists, the anesthesia providers will only be successful in providing high-quality, safe care if the business model supports the needs of the practice and its patients. The business model must provide the infrastructure to ensure that systems are in place to foster clinical care in every environment in which the providers practice. The usual business practices, including billing, coding, and collections, must be managed either internally or through contracts with other companies that have the experience to do so cost-effectively.

The group that provides billing and coding services must understand that it is handling sensitive patient information and under The Health Insurance Portability and Accountability Act of 1996 (HIPAA) privacy, security and breach notification rules, it is responsible for protecting the security and confidentiality of health data on the patient's behalf. If an outside vendor is providing these services, the group must have a business associates' agreement documenting the responsibilities of each party, particularly related to HIPAA requirements.

Coding of claims is a challenging task. Specific documentation of all aspects of care provided to the patient is critical; the documentation is the basis on which to code a claim. If the documentation is inadequate, the payment will not reflect the physician's work. In all cases, the claim should be easily determined from the clinical documentation. The claims should be standardized and "clean." There should be no ambiguities in the reason a service was provided (ICD-9/ICD-10 diagnosis code) and what service was provided (Common Procedural Terminology [CPT] code). For most services, clinical face-to-face time is required in the submittal, so the actual time spent with the patient must be clearly reported in the clinical documentation and on the claim.

Whoever provides the coding and billing functions must be aware of the regulatory requirements and the guidelines established by the practice related to ethical billing practices. An outside contractor can do the coding or bill for clinical services, but the ultimate responsibility for correct coding and billing remains with the anesthesiologist who provides the clinical care. The providers must ensure that documentation supports all clinical care and that charges reflect the actual service provided to the patient. For operative anesthesia services billed in the United States, the American Society of Anesthesiologists' *Relative Value Guide* is generally used to determine

the anesthesia unit value; the conversion factor for each payer determines the payment for anesthesia services. For nonprocedure billing, such as critical care and some pain medicine services, most charges are based on evaluation and management codes, which are billed using the resource-based relative value system (RBRVS). For evaluation and management services, the level of service is determined by the care provided to the patient as documented in the medical record. If documentation is inadequate, the charges and collections might not reflect the level of service actually provided to the patient. Each practice should routinely monitor the documentation to ensure that the coding is correct.

The real value of a billing service is not the timely filing of the claim (billing) for service, but in the tenacity of follow-up. While payers seem to be reluctant to pay claims and may even deny them on administrative technicalities, a "clean" claim with persistent follow-up will be paid. The same is true for the patient's contribution or copayment. The patient copayment is often the most difficult to collect and is a differentiator between billing companies.

While correct coding, billing, and collections are critical for the ongoing financial viability of the practice, the business office also facilitates contracting and negotiation with payers and the health systems to ensure that the practice is compensated at a level consistent with the services provided. To do so requires strong financial expertise and an understanding of the current and rapidly changing health care environment, as well as the ability to gather key measures of outcome and performance (e.g., patient satisfaction) to market the practice and to justify contractual negotiations. Without objective data to support the practice claims about quality, safety, and patient satisfaction, the practice is vulnerable and its future relationships with the health system could be compromised by competing practices.

CONTRACTING

One of the critical roles for the practice is to contract with payers independently or jointly with other providers and the health system to provide services to select (covered) groups of patients. Traditionally, fee-for-service contracting models were most common; however, other models of payment have been developed to reduce overall costs of care and, more importantly, to align incentives to optimize care and quality and reduce costs and needless services. In the United States, each state has laws regarding who can contract with providers to deliver health care. Contracting entities typically have direct contact with the providers and provide for the selling or the assigning of physicians or physician panels to other health care entities. The providers are then termed *participating*. Contracting entities can only grant access to a participating physician by a health care contract. Contracting entities offer contracts to providers that are generally either risk-sharing or non–risk-sharing agreements. A non-risk contract to a provider means that the contracting entity bears all the financial risk and pays the provider for the services requested and rendered. A shared-risk contract pays providers for services rendered, but withholds some of the payment depending upon the use of services.

A number of different contracting vehicles are used in health care, including managed care contracts (e.g., health maintenance organizations [HMOs]), physician health organizations (PHOs), preferred provider organizations (PPOs), and other models. Although the various approaches differ and have important implications for anesthesia practices, some general principles differentiate the approaches. The managed care model, which was common about 20 years ago, gave responsibility for managing the care of a population of patients to a primary care provider. Referrals to specialists were determined by the primary care provider, who in most cases was compensated based on a capitated payment methodology. The primary care provider received a monthly payment for managing the care of each patient; specialists were paid using a fee-for-service (or reduced fee for service) payment methodology. The HMO model did not significantly reduce the cost of care nor improve quality. As a result, a number of alternative models have been used to better align the physicians, patients, payers, and health systems. Newer models of care incorporate both risks and incentives into the payment methodology and potentially improve the ability for physicians and hospitals to collaborate on initiatives to improve outcomes, reduce costs, and optimize patient care during hospitalization and through the continuum of care needs.

One area that has the potential to benefit both parties is gainsharing, which has typically referred to an arrangement in which a hospital provides the physicians with a share of any reduction in the hospital's costs attributable in part to the physician's efforts. Gainsharing programs are designed to align the economic incentives of hospitals and physicians to provide cost-effective care and to maintain or improve quality of care and patient satisfaction. In addition, gainsharing programs allow physicians to share in the cost savings through some combination of a percentage payment, hourly or fixed fee, and to play a significant role in the planning process to achieve those savings. From the hospital perspective, gainsharing programs reduce costs through standardization and economic efficiencies of scale. From the physician's perspective, gainsharing programs provide a financial incentive to cooperate with hospitals in the development and planning of programs designed to reduce hospital operating costs without compromising quality of care to patients. Gainsharing programs work to gain physician acceptance and change practices to control costs and increase margins on hospital business.

Recent actions by both the OIG and the Medicare Payment Advisory Commission (MedPAC) seem likely to increase hospital–physician gainsharing agreements. In March 2005, the OIG issued six favorable advisory opinions involving hospital–physician gainsharing programs.[15] MedPAC recommended to the U.S. Congress that the Secretary of Health and Human Services be granted the authority to permit and regulate gainsharing arrangements between hospitals and physicians.

AUDITS

The practice should have documentation of billing policies and procedures and a well-defined compliance plan to support all clinical and business functions. As a routine part of management, the practice should regularly

review the claims management processes, cash flow, and compliance with applicable regulations. Billing audits identify when claims are appropriately coded according to CPT codes, have sufficient documentation to support the claim, and when they adhere to payer payment policies. Claims need to be reviewed regularly for underpayment, overpayment, and billing errors. If irregularities are identified, these require immediate resolution, including notification to the payer and refunds as appropriate. Audit findings are discoverable, and thus all reviews and audits should be managed under the direction of the practice attorney. In general, the findings are privileged communications between the attorney and the practice, although each practice should be aware of all regulatory and legal issues related to billing and compliance reviews and audits.

For government payers, the OIG Compliance Guidance for Individual and Small Group Physician Practices outlines the requirements.[16] It describes a variety of business practices physicians can adopt that, in the agency's view, will help them avoid submitting erroneous claims or engaging in unlawful conduct. The physician guidelines describe seven basic compliance plan elements:

1. Conducting internal monitoring and auditing with periodic audits and implementing compliance and practice standards with written standards and procedures
2. Designating a compliance officer or contact to monitor compliance efforts and enforce practice standards
3. Conducting appropriate training and education on practice standards and procedures
4. Responding appropriately to detected violations with an investigation
5. Developing corrective action and disclosure to appropriate government entities as necessary
6. Developing open lines of communication including staff meetings, bulletins
7. Enforcing disciplinary standards through well-publicized guidelines

Anesthesia practices have some specific guidelines and requirements that must be fulfilled.

LEGAL SERVICES

Anesthesia groups should utilize the expertise of attorneys knowledgeable about each aspect of clinical practice as well as the relationship between the group and other health care entities (see Chapter 11). The legal counsel should be familiar with issues specific to anesthesiology and should understand the specific practice model and relationships. Some of the common issues that benefit from legal assistance include employment agreements; regulatory and compliance issues; physician licensure issues, including reporting to the National Practitioner Data Bank; antitrust issues; restrictive practice covenants; and interactions with industry, particularly related to Physician Financial Transparency Reports (Sunshine Act).[17]

INSURANCE

Anesthesiologists must protect themselves from legal action, whether related to clinical care or other aspects of practice. The anesthesia practice should ensure that both the practice and each provider have appropriate levels of insurance, including, but not limited to professional and general liability insurance. For officers of a practice, the group should provide directors and officers with insurance to cover claims related to wrongful acts of a director or officer. Other insurance coverage, such as disability, worker's compensation, and property and auto insurance are provided by the practice in some circumstances. The practice should seek counsel from insurance professionals to determine the specific needs of the practice.

Each anesthesiologist must have professional liability insurance to cover the full cost of legal defense related to a malpractice suit. In most cases, professional liability coverage is provided by the practice, although in some cases individual providers must purchase their own insurance. There are two types of professional liability (i.e., malpractice) insurance policies in the United States: occurrence-based and claims-made. Occurrence-based policies provide protection against incidents that occur during the *term* of the policy, regardless of when the claim is made. Claims-made policies provide coverage for incidents that occur during the *policy period*.

When terminating a claims-made policy, "tail insurance" can be purchased to provide coverage from incidents that occurred when a claims-made policy was active. Tail insurance is typically a single payment and often costs a multiple (1.5 to 2.5 times) of the annual claims-made policy. On occasion, a physician will change malpractice carriers. When this occurs, "nose insurance" (i.e., for prior acts) can be purchased to function similarly to tail insurance.

The cost of professional liability coverage includes the cost of claims made for pain and suffering and other losses. Some states have adopted tort reform, limiting the payment for pain and suffering. The cost of professional liability insurance in the states that have adopted tort reform is considerably lower than it is in states without any limits for malpractice claims.

RECRUITMENT

One of the key roles for the practice is the recruitment and retention of an appropriately diverse group of providers to meet the clinical needs of the patient population being served by the practice. Practices must have a formal process for recruiting new members. In each case, it should define the goals for the recruitment and the relationship that the new member of the group will have. The group should clarify the business relationship with every new recruit, in addition to whether the new member will be an employee, whether a partnership track is possible, and the terms and conditions for becoming a partner. The recruit should be provided with a contract that defines the relationship, compensation package, and all other terms and conditions. The American Medical Association provides a useful resource describing the basics of a physician employment agreement.[18]

One of the other important aspects of recruitment relates to the clinical needs of the department and the skills and clinical expertise expected of the recruit. Because the practice generally works within one or more health

systems, the recruitment of new surgeons or other physicians may necessitate hiring new anesthesia providers with specialized skills, such as pediatric anesthesiologists, cardiothoracic anesthesiologists, neuroanesthesiologists. Every anesthesiologist certified by the American Board of Anesthesiologists is trained to care for the wide spectrum of patients requiring anesthesia services, but there are selected groups of patients for whom subspecialty training and certification may be required. For example, the needs of pediatric patients are currently undergoing evaluation to define children for whom pediatric certified anesthesiologists should be available and those who can receive care from a board-certified anesthesiologist who has not completed pediatric anesthesia subspecialty training (see Chapter 93). Recently, the American College of Surgeons published recommendations for pediatric surgical care based on the model used to support trauma care (see Chapter 81).[19] The recommendations provide a framework for considering the most appropriate way to provide care to pediatric patients requiring surgery, although they have also raised some concerns about access to anesthesia care for all pediatric surgery patients. The practice leaders and practitioners must be aware of their diverse clinical needs in order to recruit, credential, and retain the appropriate balance of anesthesia providers.

In most cases, the practice should be working collaboratively with the health systems, hospitals, and freestanding facilities to identify opportunities to expand their scope of services. Many anesthesia groups provide critical care, pain management, and other specialty care services to support the needs of the patients served by the health systems in which the group works. The expansion of anesthesia services outside the operating room has also created new opportunities for anesthesiologists to participate in care for a much broader range of patients (see Chapter 90). For example, the care of patients undergoing some diagnostic and therapeutic procedures is improved when an anesthesia provider is caring for and monitoring the patient during the procedure. Some payers have suggested that anesthesia services are not required for some of these procedures and that they simply add unnecessary costs to care; therefore, the practice should be able to document improved outcomes and reduced costs. To do so requires that the practice understand the overall cost structure of the services provided to the patient and that it work collaboratively with the hospital or other facility to document the costs of care and clinical outcomes.

Additional opportunities that should have support from practice leaders include development of new models of care, such as the preoperative management of patients with underlying chronic diseases (e.g., diabetes, chronic obstructive pulmonary disease), PSH, and the provision of postoperative monitoring after discharge using technology to foster communication and coordination of care with the primary care provider. To take advantage of these opportunities, the practice must define the staffing needs and in some cases try to identify new models of care that include anesthesiologists working collaboratively with nonanesthesiologists (e.g., surgical hospitalists) in relationships that can be both clinically and financially successful models.

PARTICIPATION IN HEALTH SYSTEM GOVERNANCE

Anesthesiologists should be active participants in governance of the health system in which they work. The medical staff members provide the professional oversight for medical care in facilities in many states based on legal statute. The most important component of the medical staff is medical peer review, the promotion of the highest quality of medical care, and patient safety. Its secondary function is to determine whether a practitioner's clinical privileges or membership in a professional society will be adversely affected by a physician's competence or professional conduct.

In most cases, the chief of the anesthesia service will serve as member of the medical staff executive committee, unless anesthesia services are not structured as a separate clinical department. Each practice should identify opportunities to participate in both the medical staff structure and the governance and operations committees of the health system. Anesthesiologists can have numerous opportunities to take leadership roles in the oversight of perioperative services, critical care medicine, pharmacy and therapeutics committees, patient safety initiatives, code blue committees, rapid response teams, and other patient safety programs. The more engaged in medical staff and system roles, the greater the likelihood that the anesthesia practice will be highly valued by the organization and will maintain its role in providing the staffing and oversight of all anesthesia care.

NEW FINANCIAL MODELS

Traditional fee-for-service payment has been the most common method of payment for physician services for some time. The fee-for-service methodology provides payment based on the level of service provided to the patient. Unfortunately, this model of payment has been criticized for contributing to the increasing costs of health care, encouraging overuse of clinical services, and fostering the implementation of expensive technologies that do not necessarily improve outcomes. As a result, a number of other payment methodologies have been developed to reduce costs of care and overuse of clinical services and to align the goals for the patient, health system, and providers. Each practice should understand the various payment methodologies and ensure that it has the information about the practice to understand the risks, benefits, and financial implications of each model.

A number of alternative models have been proposed, including a shared savings model of payment, episode of care payments, and bundled payment models for physicians alone or combined physician and health system payments. In some cases, these models are proposed for all levels of service and in some cases to coordinate clinical care for specific patient populations, such as solid organ transplants, selected surgical procedures. Under a shared savings program, the provider receives a share of savings associated with reduced health care spending. This model is essentially a pay-for-performance system. Unfortunately, shared savings rewards the high spenders rather than the high performers and is not sustainable.

Comprehensive care payment is intended to reduce the number of unnecessary episodes of care. It is proposed as a methodology to reduce the cost associated with management of chronic conditions. This model encourages preventive care, and it is intended to reduce the number of procedures, which could have implications for anesthesia services.

Recently, a number of new models of care have been implemented to optimize comprehensive care and overall health outcomes. The Patient-Centered Medical Home model is designed to improve management and coordination of patient care across the continuum with management by a primary care provider in conjunction with other clinical providers (e.g., advance practice nurses, physical therapists, social workers). The outcomes of care associated with the medical home are still unknown, although early data provide interesting information about where this model might be most successful and some of the challenges associated with its implementation.[20,21]

A recently proposed model of care that is gaining momentum is the accountable care organization (ACO). It was first described by Dr. Elliot Fischer and incorporates three core principles: (1) a provider-led organization with a strong primary care base, (2) payments that are linked to quality improvements that lower overall cost, and (3) reliable performance measures that support the quality improvements for a population of patients.[22] In this case, *accountable* refers to the role of both patients and payers to ensure delivery of appropriate, high-quality, and cost-effective care. The ACO model has been promoted as a way to improve care and outcomes under the Affordable Care Act adopted by the U.S. Congress in 2010.[23,24] The proposed goal is to promote clinical excellence and control costs by coordinating the care provided by facilities, physicians, and other providers and providing financial incentives to limit unnecessary expenditures. For anesthesiologists, the ACO model can create some opportunities to extend care through the entire perioperative period both within the hospital and after discharge. In the role as a perioperative physician, the anesthesiologist (or group of anesthesia providers working collaboratively) can direct the entire surgical process—that is, evaluate and optimize the condition of the patient preoperatively, manage the intraoperative course, provide appropriate postsurgical care (including critical care and pain management), and facilitate the transition of care to the primary care physician. In the current health care system, many of these services are either not provided by the anesthesiologist or are provided informally and are often not documented, measured, or directly compensated. If the anesthesia practice is to assume this new role, it will have to document the services provided, their value, and negotiate with the health system for appropriate compensation for the services provided.

Whether the ACO model will succeed remains unknown. Many health care systems are participating in ACOs with variable outcomes. The primary reticence of health care systems and providers to participate in this model is probably related to concerns about whether the organizations are prepared to accept the risks.[25]

More important to anesthesia practices than participation in the ACO model is the current interest in developing the PSH model of care, which provides the opportunity for the anesthesia practice to expand its role in the care of selected patient populations and to assume a greater role in the overall management of the surgical patient. In many respects, it builds on the medical home model of care. In this model, anesthesiologists should be able to improve outcomes and reduce costs. Compensation to the anesthesia group will be based on these achieved goals. This model of care and payment can also serve as the model for distribution of payment for other bundled clinical services. The concept of the PSH and its implications for anesthesia practices is described in more detail in Chapter 3.

Anesthesia business practices continue to evolve in response to changes in the health care environment and advances in clinical practice resulting from improved technology. The dramatic changes in the financing and delivery of clinical care will continue to challenge anesthesia practices, but also create new opportunities to expand the scope of anesthesiology. For example, new practice initiatives such as the PSH will allow anesthesiologists to assume a broader and exciting new role in health care. The challenge is to ensure that business practices advance at the same pace as these new clinical initiatives so that the desired outcomes of improving quality, maintaining safety, and reducing costs are achieved.

Chapter 13

Consciousness, Memory, and Anesthesia

GEORGE A. MASHOUR • KANE O. PRYOR

Acknowledgment: The editors and the publisher would like to thank Drs. Max Kelz, Ted Abel, and Mervyn Maze for contributing a chapter on this topic to the prior edition of this work. It has served as the foundation for the current chapter.

Key Points

- Mechanisms of consciousness and memory, and their interruption by general anesthetics, are important scientific problems that have clinical relevance for the practice of anesthesiology.
- Consciousness is characterized by wakefulness (i.e., state of being arousable) and awareness (i.e., subjective experience).
- Anesthetics act at structures in the brainstem, hypothalamus, and basal forebrain that regulate sleep-wake states, which may account for loss of wakefulness.
- Anesthetics disrupt connectivity and communication across cortical and thalamocortical networks, which may account for loss of awareness.
- Memory can be subdivided into explicit (conscious) and implicit (unconscious) recall; an example of explicit episodic recall is remembering a surgical event.
- Suppression of explicit episodic recall is one of the most potent effects of most general anesthetics.
- Effects on the hippocampus, amygdala and prefrontal cortex—as well as the connectivity of these structures—may account for anesthetic-induced amnesia, even before loss of consciousness.

SCIENTIFIC AND CLINICAL IMPORTANCE

Consciousness and memory are among the most fascinating and complex subjects in all of science. The richness of human consciousness and memory—and the ability to express this richness in language—is a defining characteristic of homo sapiens. These cognitive processes, however, are also notoriously difficult to study. As Thomas Huxley famously noted, "How it is that anything so remarkable as a state of consciousness comes about as a result of irritating nervous tissue, is just as unaccountable as the appearance of the Djin when Aladdin rubbed his lamp."[1] The medical specialty of anesthesiology is in a unique position to shed light on the problems of both consciousness and memory because the drugs used in common anesthetic practice infallibly place the genie of consciousness back in the lamp—and bring it out again almost just as uniformly. Furthermore, at doses significantly smaller than those required for unconsciousness, general anesthetics also cause amnesia. As such, anesthetics are being recognized increasingly as tools to study consciousness and cognition,[2,3] a trend that fulfills the vision of anesthesiologist Henry K. Beecher in the 1940s.[4]

Consciousness and memory also have clinical relevance for the anesthesiologist; together, the experience and explicit episodic recall of surgical events is known as the problem of "intraoperative awareness." This complication occurs in approximately 1 to 2 cases per 1000[5-7] and is associated with a frequent incidence of posttraumatic stress disorder.[8] As such, there is a strong motivation to prevent consciousness and explicit recall, but current technology may not be a significant advance over traditional methods of assessing anesthetic depth such as minimum alveolar concentration[9,10] (see Chapter 50). To advance the field of perioperative brain monitoring, a detailed understanding of the neurobiology of consciousness, memory, and anesthesia is required.[11]

CONSCIOUSNESS

HISTORY AND TERMINOLOGY

For the greater part of the twentieth century, the study of consciousness was not considered a serious scientific pursuit. Yet, the past two decades have seen a dramatic increase in the number of rigorous investigations into consciousness. This was stimulated, in part, by public attention in the 1990s from a number of high-profile scientists such as Nobel Laureates Francis Crick and Gerald Edelman, as well as renowned physicist Roger Penrose. At approximately the same time, the first multidisciplinary conference on consciousness studies was hosted in 1994 at the University of Arizona, and several journals on the

subject were founded (*Journal of Consciousness Studies*, *Consciousness and Cognition*). Although some seminal papers on consciousness and anesthesia were published more than a decade ago,[12] the specialty of anesthesiology has now turned its attention to the science of consciousness. Indeed, it was only in the seventh edition of *Miller's Anesthesia* that consciousness made its formal appearance[13] in the chapter titled, "Sleep, Memory, and Consciousness." Since then there has been an explosion of exciting data on the neurobiology of consciousness and anesthesia.

The field of consciousness studies is complicated by the indiscriminate use of the term *consciousness*. In this discussion of consciousness, *subjective experience* is meant. As has been suggested, consciousness is what we lose when we have dreamless sleep and what we regain again in the morning upon awakening.[3] There are several important definitions and distinctions that should be considered.

1. **Awareness**: Cognitive neuroscientists and philosophers use the term *awareness* to mean only subjective experience. In clinical anesthesiology, the term *awareness* is used (inaccurately) to include both consciousness and explicit episodic memory (the taxonomy of memory will be discussed in the next major section of this chapter).[11]
2. **Wakefulness versus Awareness**: *Wakefulness* refers to the state of being arousable, which can be manifest by sleep-wake cycles and can occur even in pathologic conditions of unconsciousness such as vegetative states. Thus, being awake is dissociable from being aware.[14]
3. **Phenomenal versus Access Consciousness**: Phenomenal consciousness is a subjective experience itself, whereas access consciousness is that which is available to other cognitive processes, such as working memory or verbal report.[15]
4. **External versus Internal Consciousness**: External consciousness is the experience of environmental stimuli (e.g., the sound of an orchestra), whereas internal consciousness is an endogenous experience (e.g., a dream state).[16]
5. **Consciousness versus Responsiveness**: An individual may fully experience a stimulus (e.g., the command "Open your eyes!") but not be able to respond (as when a patient is paralyzed but conscious during surgery).[17,18]
6. **Levels of Consciousness versus Contents of Consciousness**: Levels of consciousness can include alert versus drowsy versus anesthetized, whereas the contents of consciousness refers to the particular phenomenal aspects such as a red rose versus a blue ball.

SYSTEMS-BASED APPROACH

There have been a number of theories proposed to explain the mechanisms of consciousness and general anesthesia. Advances in neuroscience, however, have now enabled us to move beyond speculative frameworks and focus on a systems-based approach to both subjects.[19] The remainder of this section on consciousness will adopt such an approach by discussing (1) brainstem and hypothalamic nuclei regulating the sleep-wake cycle (and therefore arousal states), (2) the role of the thalamus in consciousness and anesthesia, (3) cortical-subcortical connectivity, with a focus on the thalamocortical system, (4) corticocortical communication, and (5) network-level organization.

SUBCORTICAL NUCLEI REGULATING AROUSAL

It was hypothesized in the mid-1990s that anesthetics suppress consciousness by actions at the subcortical nuclei that evolved to control sleep-wake cycles.[20] The past decades have supported the hypothesis that anesthetics interact with a number of these sleep-wake centers,[21] although precise interactions and contributions to the state of general anesthesia have yet to be elucidated. The following is a description of select subcortical nuclei in the brainstem and hypothalamus that mediate sleep-wake cycles and, potentially, some traits of anesthesia. The basic neurochemistry of the sleep-wake cycle is shown in Figure 13-1.

Brainstem

Locus Ceruleus. Norepinephrine is synthesized in the locus ceruleus (LC), which is located in the pons and projects widely throughout the cortex.[22] Like other monoaminergic neuronal populations, LC activity is highest during waking consciousness, decreased during non–rapid eye movement (NREM) sleep, and at its nadir during rapid eye movement (REM) sleep.[23,24] Thus, the LC is associated with cortical arousal only during wakefulness and not with the cortical activation during REM sleep. LC neurons are hyperpolarized by halothane.[25] The role of norepinephrine (generated by the LC) in anesthesia is likely important because barbiturate anesthesia time is increased by antagonizing norepinephrine and reduced by agonizing it.[26,27] Norepinephrine transmission in the basal forebrain may be of particular relevance to anesthetic depth.[28] The LC and the role of norepinephrine in hypnosis are of particular interest because of the alpha-2 agonist dexmedetomidine in clinical care. Microinjection of dexmedetomidine in the LC results in reduced levels of consciousness that can be prevented by coadministration of the alpha-2 antagonist atipamezole.[29] Expression of c-fos, a marker of antecedent cellular metabolism, after exposure to dexmedetomidine mimics NREM sleep in that the LC and tuberomammillary nucleus (TMN) are deactivated, whereas the ventrolateral preoptic nucleus (VLPO) is activated.[30] However, recent data in dopamine-β-hydroxylase knockout mice (which lack the ability to synthesize norepinephrine) demonstrate a hypersensitivity to dexmedetomidine, suggesting alternative mechanisms of action.[31] In addition, administration of ketamine increases c-fos expression in the LC,[32] which appears to contribute to its anesthetic effects.[33]

Laterodorsal/pedunculopontine tegmentum (LDT/PPT). Along with the basal forebrain, the laterodorsal tegmentum (LDT) and pedunculopontine tegmentum (PPT) in the pons are the brain's source of acetylcholine and project throughout the cortex.[34] There are also direct projections to the thalamus with a known role in the generation of slow oscillations and sleep spindles,[35] which together represent a neurophysiologic sign that information transfer to the cortex is likely blocked.[36] As with the noradrenergic LC, activity of the LDT/PPT is high during waking consciousness and decreases during

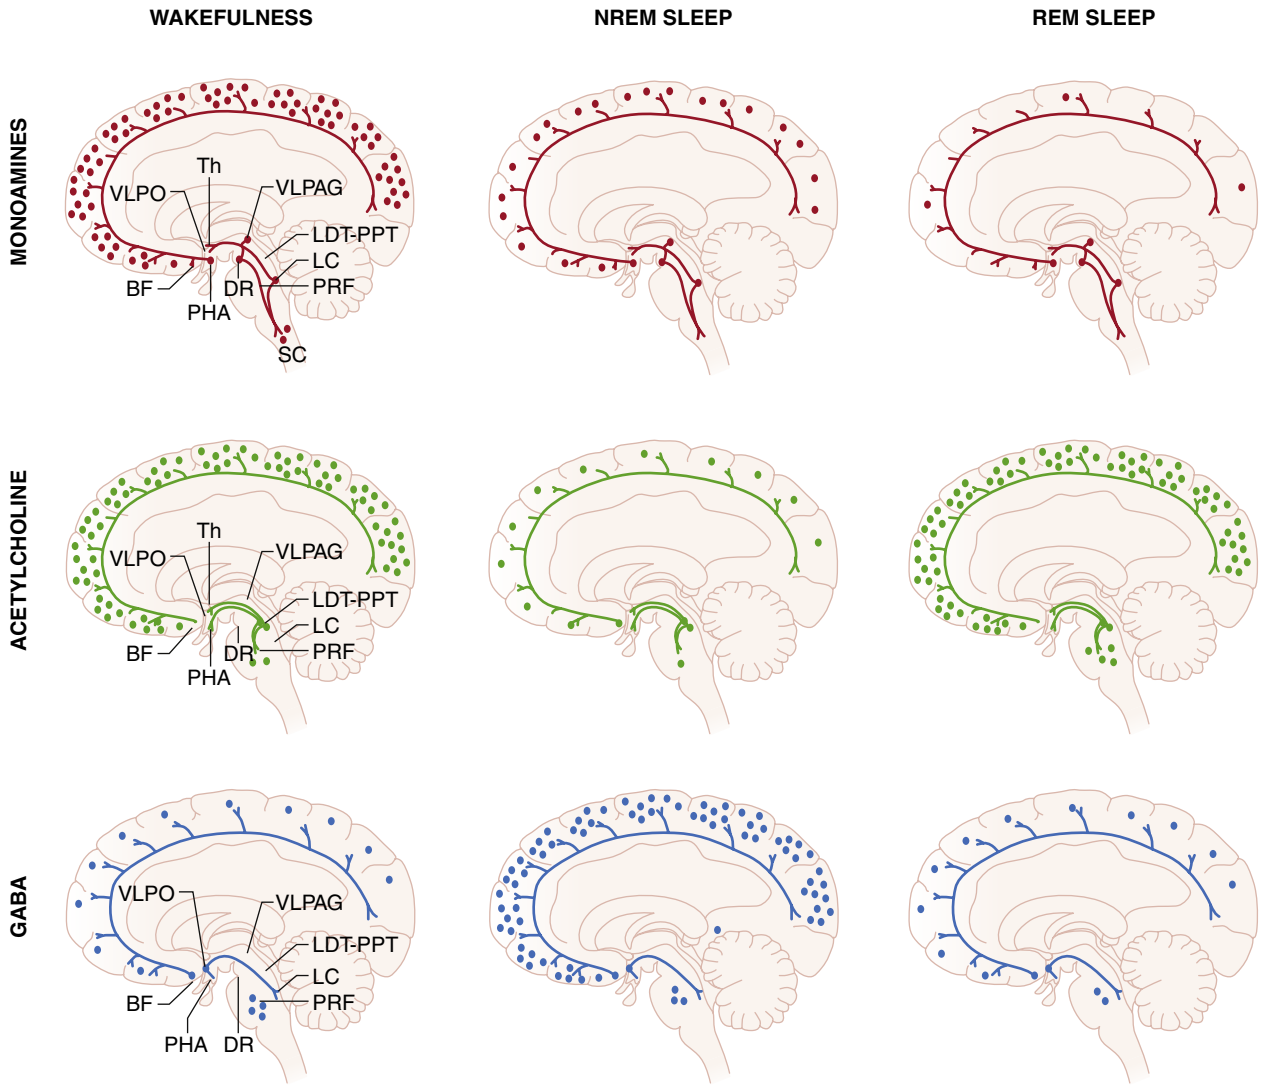

Figure 13-1. Neurochemistry of sleep and wakefulness. State-dependent changes in monoaminergic (*red*), cholinergic (*green*), and γ-aminobutyric acid (GABA)ergic (*blue*) neurotransmitter systems across the sleep-wake cycle. The density of the dots at the schematized nerve terminal reflects the state-dependent increases or decreases of release of the particular neurotransmitter. Monoamines (e.g., norepinephrine) have peak release during wakefulness, with decreases during non–rapid eye movement sleep and a nadir during rapid eye movement (REM) sleep. Cholinergic transmission is associated with cortical activation during waking or REM sleep. Acetylcholine and GABA have an inverse relationship across the sleep-wake cycle. The "shared circuits" of sleep and anesthesia suggests that general anesthetics have their effects through, in part, the sleep and arousal centers identified in the figure. *BF,* Basal forebrain; *DR,* dorsal raphe; *LC,* locus ceruleus; *LDT-PPT,* laterodorsal and pedunculopontine tegmentum; *PHA,* posterior hypothalamic area; *PRF,* pontine reticular formation; *SC,* spinal cord; *Th,* thalamus; *VLPAG,* ventral periaqueductal gray; *VLPO,* ventrolateral preoptic nucleus. *(Reproduced from Baghdoyan H, Lydic R: The neurochemistry of sleep and wakefulness. In Brady S, et al, editors:* Basic neurochemistry, Oxford, UK, *2012, Elsevier.)*

NREM sleep.[22] However, in contrast to the LC and other monoaminergic neurons, the cholinergic LDT/PPT is also active during REM sleep, during which the cortex is aroused. Thus, both states of cortical activation across the sleep-wake cycle are associated with high cholinergic tone. General anesthetics modulate cholinergic projections from the LDT/PPT. Sleep spindles occur during halothane anesthesia and are associated with decreased cholinergic transmission to the medial pontine reticular formation (PRF).[37,38] In addition, synaptic and extrasynaptic γ-aminobutyric acid (GABA) receptors play a role in modulating LDT neurons,[39] which could provide a direct link to molecular mechanisms of numerous general anesthetics.

Pontine Reticular Formation. The PRF is part of the reticular activating system, which plays an important role in cortical arousal. Although GABA is the primary inhibitory neurotransmitter in the brain, the actions of GABA in the PRF are associated with cortical arousal.[40] For example, there is increased time spent in the waking state when the $GABA_A$ receptor agonist muscimol is microinjected in the PRF.[41] When the $GABA_A$ antagonist bicuculline is microinjected, wakefulness is suppressed, but REM sleep (another state of cortical arousal) is triggered. Vanini and colleagues[42] found that decreased levels of GABA in the PRF correlated with isoflurane-induced unconsciousness, muscular hypotonia, and decreased respiratory rate. Since the effects of anesthetics are normally associated with a

potentiation of GABA activity, these findings highlight that a specific neuroanatomic and neurochemical milieu can play a unique and unexpected role in the mechanisms of consciousness and anesthesia. In addition, the mesopontine tegmental anesthesia area is located in the PRF. When pentobarbital is microinjected in this area, a reversible state with anesthetic traits is induced.[43]

Ventral Tegmental Area. Dopaminergic neurons of the ventral tegmental area (VTA) in the midbrain have not classically been considered key mediators of sleep-wake cycles because of relatively less evidence of state-dependent changes compared with other brainstem nuclei. This view has been challenged in sleep neurobiology,[44] and there is a renewed interest in the ability of dopaminergic activity in the reversal of general anesthesia. Studies of the dopamine agonist methylphenidate have revealed an ability to reverse the effects of both isoflurane and propofol[45,46]; preliminary evidence suggests that the VTA is the source of the dopaminergic transmission mediating arousal during exposure to anesthesia and that electrical stimulation of the VTA itself can reverse the state of general anesthesia.[47] Of note, a dopaminergic pathway regulating sleep-wake states has been identified in drosophila.[48]

Hypothalamus

Ventrolateral Preoptic Nucleus. The anterior hypothalamus plays an important role in sleep-wake regulation.[49] The VLPO is a structure in this region that transmits GABA and galanin.[50] Neurons in the VLPO are maximally active during NREM and REM sleep[51,52]; the median preoptic nucleus is also active during sleep. Of note, the activity profile of GABAergic neurons in the VLPO correlates with sleep amount, whereas the activity of GABAergic neurons in median preoptic nucleus correlates with homeostatic sleep pressure or propensity.[53] Importantly, the activity of the VLPO during sleep is correlated with inhibition of other arousal centers in the brainstem and hypothalamus.[51,54] Given its potentially central role as a mediator of sleep, the VLPO is an attractive candidate as a mediator of anesthetic-induced unconsciousness. Nelson and colleagues[55] demonstrated an increase in c-fos expression (a marker of neuronal activity) in the VLPO after systemic administration of propofol or thiopental. Eikermann and associates[56] conducted studies of rats with chronic lesions of the VLPO and found that ablation of VLPO resulted in sleep deprivation (as expected) but increased sensitivity to the effects of isoflurane.[56] This finding would argue against a critical role of the VLPO in the mechanism of anesthesia; however, acute lesions of the VLPO confer resistance to the effects of isoflurane, an effect that appeared to be mediated specifically through the sleep-active neurons in the VLPO.[57] Taken together, these data suggest that the VLPO plays a role in anesthetic-induced unconsciousness (as evidenced by acute lesion data), but the effects of sleep deprivation associated with chronic VLPO lesions could overwhelm this role. Indeed, the effects of both intravenous and inhaled anesthetics are potentiated by sleep deprivation[58,59] and by mechanisms that are likely independent of the VLPO (e.g., adenosine signaling in basal forebrain).

Orexinergic Neurons. Orexinergic neurons are found in the perifornical region of the lateral hypothalamus and provide an important arousal stimulus for the cortex. There are two types of orexin (A and B), which are also referred to as *hypocretins*. These neurons innervate other arousal centers in the brainstem and basal forebrain. Orexinergic neurons fire maximally in the waking state, are suppressed during NREM sleep, and show occasional bursts during phasic REM sleep.[60,61] Dysfunction of the orexinergic system is associated with narcolepsy in both humans and animal models.[62,63] The often dramatic delay of anesthetic emergence in narcoleptic patients[64] has motivated the study of orexin in anesthetic mechanisms. Orexins attenuate the effects of isoflurane,[65] propofol,[66] ketamine,[67] and barbiturates[68] using various measures. Local infusion of orexin in the basal forebrain is associated with electroencephalographic arousal and decreased emergence time in animals anesthetized with sevoflurane[69] and isoflurane.[70] Microinjection of propofol in the perifornical region of the hypothalamus (the locus of orexinergic neurons) is associated with a decrease in cortical acetylcholine, an important mediator of arousal.[71] Importantly, both genetic and pharmacologic studies have demonstrated that orexins do not influence induction, but play an important role in the emergence from sevoflurane and isoflurane anesthesia.[72] This seminal study suggested that there is a distinct neurobiology of induction and emergence, and formed the basis for a theory of "neural inertia" across state transitions.[73] Yet, halothane did not influence orexinergic neurons, and emergence time was not altered in orexin knockout mice.[74] Data from sevoflurane and isoflurane have recently been confirmed for propofol, which reduces c-fos expression in orexinergic neurons in rats. Infusion of orexin in the basal forebrain affects emergence but not induction time.[75]

Tuberomammillary nucleus. The TMN is located in the caudal hypothalamus and is the brain's source of histamine, an arousal-promoting transmitter. TMN activity and histamine levels are highest during wakefulness and lowest during sleep[76]; the TMN is thought to have a relationship of reciprocal inhibition with the sleep-promoting GABAergic neurons of the VLPO.[51,54,77] Histamine release in the anterior hypothalamus is depressed during sleep[78] and halothane anesthesia.[79] Systemic administration of propofol, pentothal, and the GABA agonist muscimol all result in decreased c-fos expression in the TMN, suggesting depressed activity.[55] Microinjection of histamine in the nucleus basalis magnocellularis of the basal forebrain reverses the depressant effects of isoflurane on the electroencephalogram (EEG), an effect likely mediated by H1 histamine receptors.[80] A recent study in which $GABA_A$ receptors were genetically removed demonstrated that histaminergic neurons are resistant to the effects of propofol.[81] However, at the behavioral level, there was no effect of the genetic alteration on loss of righting reflex, a surrogate for anesthetic-induced unconsciousness. Thus, the role of TMN and histaminergic transmission in the mechanism of anesthesia is still unclear.

ROLE OF THE THALAMUS

The thalamus is composed of approximately 50 nuclei and subnuclei that serve either as relays for sensory

input from the periphery ("specific" nuclei) or as multimodal, integrative regions that receive input from the cortex ("nonspecific" nuclei). The thalamus has been of continued and intense interest to those investigating mechanisms of general anesthesia. There are at least three possible roles for the thalamus in the suppression of consciousness by general anesthetics.

Thalamus as Switch

The thalamus has been proposed as an ON/OFF switch for anesthetic state transitions.[12] This theory was generated based on the consistent metabolic depression of the thalamus by a number of inhaled and intravenous anesthetics[82-84] (with the exception of ketamine[85]). The hyperpolarization of the thalamus would shift tonic firing to burst firing that—as with sleep—would prevent afferent sensory stimuli from arousing the cortex. Evidence for the thalamus as an ON switch has been derived primarily from animal experiments, in which stimulation of the centromedian thalamus by either nicotine or antibodies blocking voltage-gated potassium channels could reverse the effects of inhaled anesthetics.[86,87] Although microinjection of large doses of nicotine into the thalamus could precipitate anesthetic emergence, antagonism of nicotinic acetylcholine receptors in the same location did not appear to contribute to anesthetically induced unconsciousness. Central thalamic activation results in behavioral improvement in humans with traumatic brain injury.[88] In addition, activation of the thalamus (along with other subcortical structures) in humans is correlated with recovery from anesthesia, suggesting the involvement of the thalamus in the primitive or "core" consciousness observed at emergence.[89]

Thalamus as Cortical Readout

The studies identifying the depression of the thalamus were derived from neuroimaging modalities such as positron emission tomography (PET) or magnetic resonance imaging, which are both associated with poor temporal resolution. These studies could not distinguish definitively whether deactivation of the thalamus was a cause of anesthetic-induced unconsciousness or the consequence of a deactivated cortex. Nonspecific nuclei of the thalamus have been proposed as a computational blackboard for the cortex.[90] Thus, if the mechanism of anesthetic-induced unconsciousness was achieved primarily by a suppression of cortical computation, a depressed thalamus should be the result. To address this question, Velly and colleagues[91] conducted a neurophysiologic study using scalp electroencephalography (reflecting cortical signals) and subthalamic nuclei electrodes (which were argued to reflect thalamic activity). Induction of anesthesia with either propofol or sevoflurane was associated with cortical rather than subcortical changes, suggesting that the depression of the thalamus identified through neuroimaging studies reflected an effect rather than a cause of anesthetically induced unconsciousness.

Thalamus as Participant

The prior two possibilities treat the thalamus as a passive player in general anesthesia; however, recent theories suggest that it might play an active role. A study using human electroencephalographic data and computational modeling argued that the action of propofol on GABA receptors in the nucleus reticularis generates a hypersynchronous alpha rhythm (8-13 Hz) with the frontal cortex that potentially blocks sensory input.[92] Hypersynchrony of alpha may block the flexible corticocortical communication required for normal consciousness.[93] The potential role of thalamocortical interactions in anesthetic-induced unconsciousness stimulates additional consideration of the thalamus and its connectivity to the cortex.

CORTICAL-SUBCORTICAL CONNECTIVITY

The closely integrated function of the cortex and thalamus (which has been referred to as the *seventh layer* of the cortex) suggests that the two can be treated as a single thalamocortical system. The thalamocortical system undergoes state-dependent changes across the sleep-wake cycle, and it is thought to play a critical role in consciousness. This role is defined by its ability to integrate the activities of functionally diverse cognitive modules, a property that is central to the integrated information theory of consciousness.[94] This theory argues that consciousness is informative (in that it reduces uncertainty by discriminating among multiple possible states) and unified (in that a number of distinct modalities are fused into one experience). Based on neuroimaging data, the connectivity of the thalamocortical system has been investigated during the state of general anesthesia. A reanalysis of early PET studies demonstrating the metabolic depression of the thalamus by halothane and isoflurane revealed a disruption of thalamocortical connectivity during general anesthesia.[95] Recent studies using functional magnetic resonance imaging have refined the role of thalamocortical connectivity in anesthesia. One study identified a propofol-induced disruption of connectivity between the thalamus and lateral frontal-parietal networks, which are thought to be important for external consciousness.[96] Similarly, a study of the specific nuclei (linked to particular sensory modalities) and nonspecific nuclei (linked to integrative functions) found that disrupted connectivity between the nonspecific nuclei and the cortex best accounted for a reduction in the level of consciousness by propofol.[97] Disrupted thalamocortical connectivity has also been identified in animals anesthetized with propofol[98]; impaired functional connectivity of the thalamus and posterior parietal cortex has been found in humans exposed to 1% sevoflurane.[99] However, the finding of impaired thalamocortical connectivity in association with anesthetic-induced unconsciousness has not been universal. A functional magnetic resonance imaging (fMRI) study of propofol revealed more profound functional disconnections between the cortex and putamen, a subcortical structure in the basal ganglia.[100] In contrast, thalamic connectivity was relatively well preserved. The potential role of the striatum (composed of the putamen and caudate) in anesthetic-induced unconsciousness has been demonstrated in a study of rats undergoing isoflurane anesthesia.[101] This study was conducted with fMRI and found that the functional connection between the frontal cortex and the basal ganglia was disrupted during general anesthesia. A functional disconnection of association cortex and subcortical structures has also been shown by fMRI in a study of propofol-induced unconsciousness in humans.[102]

CORTICOCORTICAL CONNECTIVITY AND COMMUNICATION

The last three sections were organized according to a bottom-up approach to consciousness and anesthesia, starting with the brainstem and then moving to the diencephalon and thalamocortical system. Sleep is clearly generated through such bottom-up mechanisms[103]; however, it is not yet clear whether anesthetic-induced unconsciousness is accomplished through a bottom-up or top-down mechanism. If it were the latter, the effects of general anesthetics on the cortex would be of paramount importance. Early studies using PET demonstrated regional depression in cortical areas, including lateral and medial frontal-parietal networks.[104] These networks can mediate external consciousness of the environment (lateral system) and internal consciousness of, for example, dream states (medial system). Disruption of functional connectivity across the cortex during general anesthesia has been demonstrated in a number of different imaging studies using fMRI.[96,99,105-107] However, the cortex is amenable not only to fMRI but also neurophysiological techniques of assessing connectivity, enabling data on anesthetic-induced unconsciousness with improved temporal resolution. EEG can be used to measure functional connectivity (the statistical covariation of the activities of brain regions) and effective connectivity (the presumed causal influence of one brain region on another).[108] There are several key studies to consider that assess corticocortical communication (i.e., exchange of information) after anesthetic-induced unconsciousness.

As with fMRI, there is neurophysiologic evidence of disrupted functional connectivity during a variety of anesthetics. Quantitative EEG analysis of 176 surgical patients anesthetized with volatile anesthetics, propofol, and nitrous oxide suggested that there is a functional uncoupling of interhemispheric and anterior and posterior brain regions.[109] The anesthetic-mediated inhibition of anterior-posterior phase synchrony has also been shown in a rodent model.[110] However, communication between anterior and posterior brain regions may not be completely disrupted by general anesthetics. In rats, Imas and colleagues[111] measured transfer entropy in the γ bandwidth of EEG in response to visual flash stimuli and found that during isoflurane-induced unconsciousness, the anterior-to-posterior communication ("feedback" connectivity) was disrupted, whereas posterior-to-anterior communication ("feedforward" connectivity) was preserved. It was only at levels of surgical anesthesia that communication in both directions was suppressed. Lee and associates[112] studied directed connectivity in human volunteers and found that feedback connectivity from frontal to parietal regions was selectively inhibited by an intravenous bolus dose of propofol. In surgical patients undergoing induction of anesthesia with either propofol or sevoflurane, Ku and coworkers[113] used symbolic transfer entropy to identify a preferential inhibition of frontoparietal feedback connectivity in association with anesthetic-induced unconsciousness (Figure 13-2). Both directions of connectivity were suppressed at the level of surgical anesthesia, and frontoparietal connectivity returned to baseline at recovery. The unique importance of frontoparietal connectivity was demonstrated in a study of recovery from propofol-induced and dexmedetomidine-induced unconsciousness using PET scanning.[89] An investigation of human volunteers using high-density EEG has confirmed the loss of frontal-to-parietal feedback connectivity, and dynamic causal modeling has supported the hypothesis that this is indeed a corticocortical (as opposed to thalamocortical) interaction.[114] Hypersynchronized thalamocortical α rhythms[92] may be a neurophysiological mechanism for the interruption of corticocortical communication.[93] The selective loss of feedback connectivity is of particular interest to the field of consciousness research because feedforward communication can mediate subliminal (i.e., unconscious) sensory processing, whereas feedback connectivity (both within and across modalities) mediates conscious perception.[115] The findings of inhibited feedback connectivity and preserved feedforward connectivity (which is thought to mediate sensory representation) during anesthesia are consistent with results of the previously discussed fMRI studies in which sensory networks are maintained during anesthetic-induced unconsciousness. Preserved feedforward, but inhibited frontal-to-temporal connectivity, occurs in patients in vegetative states, but not in minimally conscious states or normal controls.[116] Other methods of measuring corticocortical communication, such as Granger causality, have yielded different results in terms of the directionality of information transfer.[117]

The inhibition of frontal-parietal communication is likely representative of a more global disruption of cortical communication. A study using high-density EEG and transcranial magnetic stimulation revealed an inhibition of cortical effective connectivity after midazolam-induced unconsciousness.[118] After administration of the benzodiazepine, local cortical activation could be observed at the site of magnetic stimulation, but robust evoked potentials were terminated at less than 100 ms, and cortical communication was limited (Figure 13-3). Of note, this finding is consistent with findings in NREM sleep.[119] The concordant findings could reflect a common neurophysiologic mechanism of disrupted cortical connectivity through slow oscillations, which share a number of characteristics in NREM sleep and general anesthesia.[120] A study of three epilepsy patients who received implants of both cortical grids (for clinical purposes) and a 96-channel microarray (for research purposes) sheds light on this potential mechanism.[121,122] Within 5 seconds of propofol-induced unconsciousness, there was a dramatic increase in the power of slow oscillations. Although single-unit neuronal activity was initially suppressed, it returned to baseline (or above baseline) but was fragmented into highly active and quiescent periods. Neural firing became coupled with the slow oscillation. However, the slow oscillations themselves demonstrated decay in phase coupling with increased distance across the cortex. Thus, neuronal spike activity became fragmented into "on" and "off" periods, which became temporally uncoordinated across the cortex. These neurophysiologic conditions dramatically reduce the probability of meaningful corticocortical communication. Whether the slow oscillation is a cortical or thalamocortical phenomenon is still unclear. Understanding the origin and regulation of the slow oscillation could help clarify whether anesthetic-induced unconsciousness has a top-down or bottom-up mechanism.

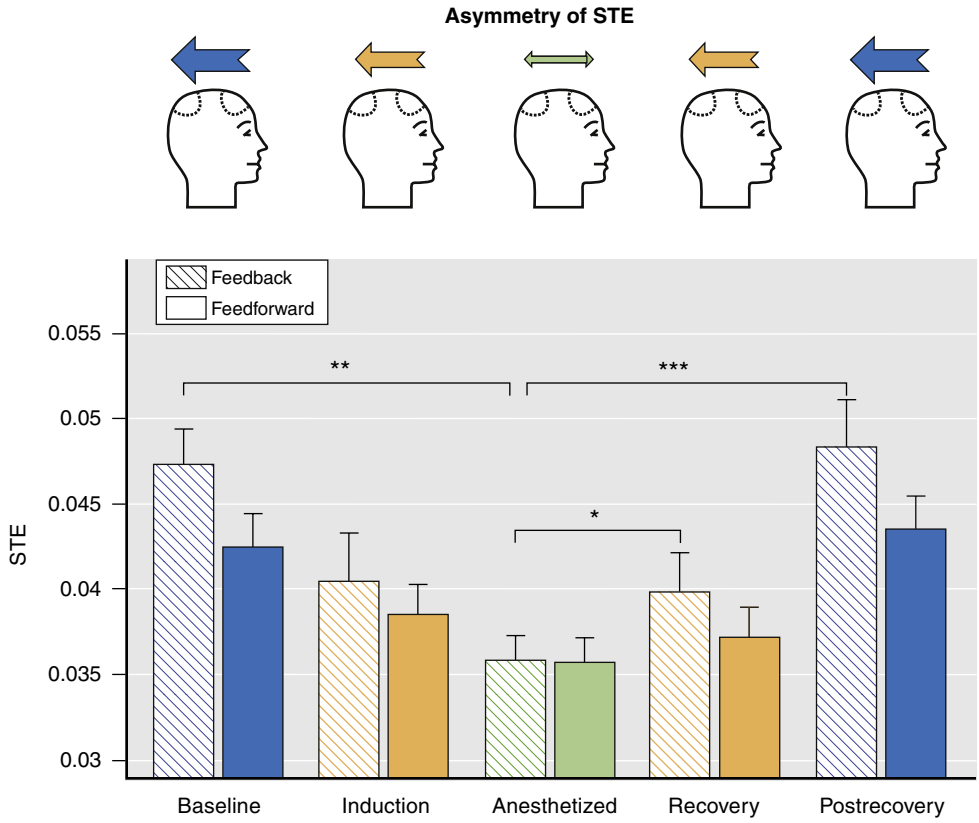

Figure 13-2. Frontoparietal communication during consciousness, anesthesia, and recovery. The lateral frontoparietal system is thought to be important for consciousness and is inhibited during general anesthesia, sleep, and vegetative states. This study of 18 surgical patients induced with propofol or sevoflurane shows state-dependent changes in communication across frontal and parietal regions, as assessed with electroencephalography and a method of measuring directed functional connectivity termed *symbolic transfer entropy* (STE). Feedback connectivity is thought to be particularly important for conscious processing and appears to be preferentially susceptible to the effects of general anesthetics. Of note, feedback connectivity also appears to be selectively suppressed (compared with feedforward connectivity) in vegetative states. *(Reproduced from Ku, et al: Preferential inhibition of frontal-to-parietal feedback connectivity is a neurophysiologic correlate of general anesthesia in surgical patients,* PLoS One *6:e25155, 2011.)*

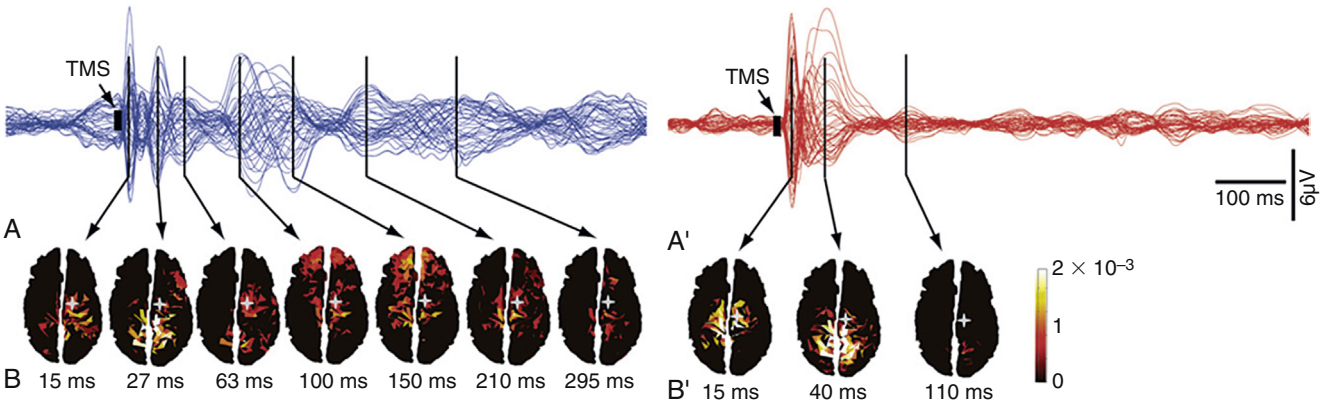

Figure 13-3. Effective connectivity and anesthetic-induced unconsciousness. Effective connectivity is the measure of causal influence among distinct brain regions. In this study, six human volunteers underwent high-density electroencephalography and transcranial magnetic stimulation (TMS) during wakefulness or midazolam-induced unconsciousness. **A** and **A′** show the potentials evoked by TMS during wakefulness **(A)** and after loss of consciousness **(A′). B** and **B′** show the cortical currents (dark red, minimal; white, maximal) in response to TMS during wakefulness **(B)** and after loss of consciousness **(B′).** Note the midazolam-induced reduction in cortical potentials and currents, which terminate at less than 120 ms. Similar findings were obtained in humans during non–rapid eye movement sleep. Importantly, cortical activation can occur during anesthesia (or sleep), but communication and causal influence (i.e., effective connectivity) across the cortex are suppressed. *(Figure reproduced from Ferrarelli, et al: Breakdown in cortical effective connectivity during midazolam-induced loss of consciousness,* Proc Natl Acad Sci U S A *107:2681-2686, 2010.)*

NETWORK-LEVEL ORGANIZATION

It would be reasonable to assume that the widespread effects of general anesthetics on corticocortical and cortical-subcortical connectivity would lead to a complete breakdown of functional network organization in the brain. Surprisingly, this is not the case. The functional architecture associated with the performance of human sensory, motor and cognitive tasks is still present in anesthetized nonhuman primates.[123] Using electrocorticography in humans receiving propofol, Breshears and coworkers[124] demonstrated a number of dynamic neurophysiologic changes that occur against the backdrop of such preserved functional architecture. The brain can reconfigure network structure as a method of adapting to the anesthetized condition while maintaining global organization. Using EEG, Lee and associates[125] demonstrated that humans undergoing induction of anesthesia with propofol maintain scale-free features in dynamic networks despite marked changes in connectivity. The hypothesis of "adaptive reconfiguration" during anesthesia has been supported by a study of humans using fMRI, in which key organizational network properties such as "small worldness" (an organization similar to that of an airport system with large hubs) were maintained despite propofol-induced unconsciousness.[102] In rats, isoflurane is also associated with an organizational shift of networks in which the "community structures" of interacting brain regions are reconfigured, whereas small-world and other network features are maintained.[101] Thus, although critical information processing hubs (e.g., the posterior parietal cortex)[126] can be particularly susceptible to the effects of general anesthetics, it appears that important network features are maintained.

This line of investigation is important for several reasons. First, these studies suggest that key principles of network efficiency and organization are not specific to the conscious state because they persist during general anesthesia. Second, the adaptive reconfiguration of networks to maintain global organizational features may be relevant to the reversibility of the anesthetized state, in contrast to more chronic brain disorders (e.g., Alzheimer dementia, schizophrenia) in which these features are lost. Finally, these types of studies demonstrate the power of general anesthetics to probe the mechanisms of consciousness and the functional organization of the human brain. The next section discusses memory, the thread that links conscious experiences together to form the narrative of "self."

MEMORY

HISTORY AND TERMINOLOGY

Modern understanding of the structure and organization of human memory is deeply informed by the study of amnesia. As early as the seminal writings of Théodule Ribot[127] and Hermann Ebbinghaus[128] in the late nineteenth century, it was appreciated that the meticulous description of memory failure could yield valuable insights into the underlying architecture and mechanism of normal memory function. The culmination of this tradition occurred in 1957, when Brenda Milner of the Montreal Neurological Institute reported the remarkable case of Henry Gustav Molaison (1926-2008),[129] an amnesiac who would be known famously as H.M. and who would represent the single most influential case study in the history of neuroscience. In an experimental procedure intended to treat a refractory seizure disorder, neurosurgeon William Beecher Scoville removed significant portions of the medial temporal lobe (MTL) bilaterally—including the hippocampus, amygdala, and adjacent parahippocampal gyrus. Postoperatively, H.M. developed profound and enduring anterograde amnesia, and he was unable to establish any new memory, irrespective of the sensory modality. He also developed a window of retrograde amnesia and was unable to recall events occurring within the 3 years preceding his surgery. Remarkably, though, most of his associated functions—perceptual processing, language, attention, access to semantic knowledge, and capacity to retain small packages of information in constant rehearsal—remained largely or entirely intact. Before H.M., the prevailing theory—articulated by eminent neuropsychologist Donald Hebb[130]—was that there was no brain region dedicated to memory function. Instead, memory processes were thought to be distributed and integrated into region-specific perceptual and cognitive functions. As a result, for example, the visual attribute of a memory would be wholly served within the striate and extrastriate cortical regions responsible for visual perception. The description of H.M. immediately disproved this model. It became clear that the MTL was a specialized and obligatory structure for the establishment and early preservation of all modalities of conscious memory. The trajectory of memory research was powerfully transformed. Initially, largely independent branches evolved to focus on the structural-functional organization of the MTL (Figure 13-4) and the nature of cellular-level neuroplastic processes—the latter notably marked by the discovery of long-term potentiation (LTP) by Terje Lømo and Timothy Bliss in 1973.[131] Subsequently, systems-level constructs were developed emphasizing the pivotal role of oscillatory phase synchronization in neuronal assemblies and networks subserving memory.[132]

Amnesia is also the term used to describe one of the cardinal properties of general anesthesia. As understood by most anesthesiologists and the layperson, this description is phenomenological; it states that patients do not recall the events that occur to them while under anesthesia. However, this usage confuses a critical mechanistic and semantic distinction. Unlike H.M., who had intact perception and conscious experience of himself and the external environment but could not establish memories, patients in a true state of general anesthesia are unable to process and bind perceptual elements into an integrated conscious experience. From the perspective of cognitive neuroscience, the "amnesia" of general anesthesia does not constitute a problem of memory. It is a problem of consciousness. It simply reflects that a conscious experience cannot be represented and reconstructed by memory processes when it does not exist in the first place. Further confusion is added by the frequent use of the term *awareness*—a synonym for conscious perception—to describe the (usually undesirable) case in which a patient is able to

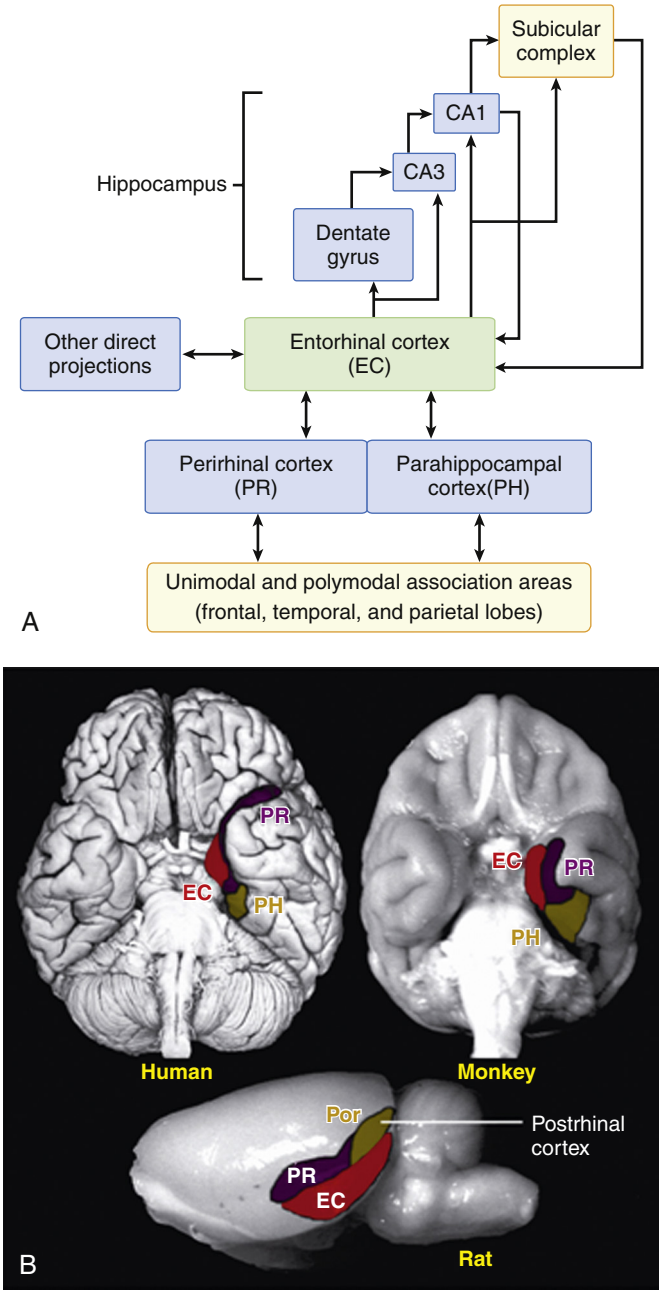

Figure 13-4. Medial temporal lobe memory system. **(A)** Schematic view of the medial temporal lobe memory system for declarative memory, which is composed of the hippocampus and the perirhinal, entorhinal, and parahippocampal cortices. In addition to the connections shown here, there are also weak projections from the perirhinal and parahippocampal cortices to the CA1-subiculum border. **(B)** Ventral view of a human brain (*upper left*), monkey brain (*upper right*), and a lateral view of a rat brain (*lower center*). The major cortical components of the medial temporal lobe are highlighted and outlined. The hippocampus is not visible from the surface, and in the human, lies beneath the cortex of the medial temporal lobe. Its anterior extent lies below the posterior entorhinal (*red*) and perirhinal (*purple*) cortices, and the main body of the hippocampus lies beneath the parahippocampal cortex. In the rat, the parahippocampal cortex is termed *postrhinal cortex*. *EC,* Entorhinal cortex; *PH,* parahippocampal cortex (*dark yellow*); *Por,* postrhinal cortex; *PR,* perirhinal cortex. *(From Squire LR, Wixted JT: The cognitive neuroscience of human memory since H.M.,* Annu Rev Neurosci *34:259-288, 2011.)*

consciously recall events occurring during the administration of an anesthetic. This ignores the fundamental lesson from H.M. that memory is functionally dissociable from consciousness. Awareness is *necessary* for the establishment of memory under anesthesia, but it is not *sufficient*. Conscious recall can occur only if awareness is accompanied by memory processes in the MTL that establish and preserve a representation that can be reconstructed later.

These statements of causality construct a framework for the scientific study of how anesthetic drugs affect memory. First, they establish an axiom: Patients who form memories while under anesthesia must possess a conscious substrate and therefore cannot be truly unconscious. Second, they pose a question: Do anesthetic drugs have direct effects on memory processes dissociable from those on consciousness? That is, are anesthetics true amnestic agents? The affirmative answer to this second question is unambiguous and is encountered in everyday anesthetic practice—in the patient receiving a small dose of propofol or midazolam who engages in a normal conversation that they are later unable to recall, or in the postanesthetic patient who has no memory of a lucid discussion with their surgeon in the recovery room.

Hidden in this everyday clinical experience is an observation of tremendous significance to cognitive neuroscience: anesthetics possess a remarkable ability to create a state of anterograde amnesia that bears a striking resemblance to that experienced by H.M. Although the study of anesthetics on memory is in infancy, its scientific foundation is the profound legacy of H.M.—more than a half century of vigorous multidisciplinary investigation into the MTL and other memory processes and systems. The promise of the research is not only to understand the mechanisms underlying the clinically relevant amnestic effects of anesthetic drugs. The selective memory effects of the drugs provide inducible, reversible, and reproducible pseudo-knockout behavioral models that can be evaluated safely in animals and humans and that are complemented by parallel knowledge of the pharmacology. Therefore, the promise of the research is also to make an important contribution to neuroscience through building on the tradition of understanding memory through the study of amnesia.

ORGANIZATION AND FUNCTION OF NORMAL MEMORY

Multiple Memory Systems

When the term *memory* is used in everyday language, it almost always refers to declarative memory. Declarative memory is the representation of prior events and knowledge that is accessible to consciousness and is manipulable by attention and executive function. It is the form of memory that H.M. was unable to establish and is the form of memory referred to in the context of anesthetic amnesia.

Further important organizational structure exists within declarative memory. The first is the distinction between episodic and semantic memory. *Episodic memory* is the recollection of events with a clear spatiotemporal context (as when recalling autobiographical events with

a distinct sense of personal experience, time, and place), whereas *semantic memory* is the capacity to recall facts and knowledge about the world without spatiotemporal context (as when recalling that Mount Everest is the tallest mountain in the world without any sense of time and place for the acquisition of that knowledge). Episodic and semantic memory are dependent on the MTL and medial diencephalon,[133] but episodic memory is additionally dependent on frontal and parietal structures.[134,135] A second organizational structure is the dual-process distinction between recollection and familiarity. *Recollection* involves remembering specific contextual details about a prior event, whereas *familiarity* represents recognition devoid of associated contextual details (as when one recognizes a face, but cannot remember a context of person, place, or time). Whether this distinction reflects the functional organization of the MTL is not clear. One model proposes that the hippocampus selectively supports recollection, whereas the adjacent perirhinal cortex supports familiarity.[136] An alternate view holds that the functional organization is not based on these psychological constructs, but on the processing of stimulus attributes[137,138]; perirhinal cortex neurons are often constrained to an attribute-specific response, and are sufficient to support familiarity judgments, but hippocampal neurons, which combine multiple attributes of a stimulus, are required for the association of an item and its context.

Early findings from H.M. suggested that other forms of memory are dissociable from declarative memory. H.M. was capable of learning a hand-eye coordination skill over several days, even while possessing no memory of having practiced the task.[139] Similar findings led to an initial distinction between declarative and *procedural* memory, with the latter being dependent on the caudate nucleus. Subsequently, memory-impaired patients were also found to have intact *priming*,[140] which is a nonconscious or *implicit* memory process in which exposure to a stimulus influences the response to a later stimulus—for example, amnesiacs can name pictures 100 ms faster if they have seen them previously, despite having no declarative memory of the exposure.[141] The neuroanatomic correlates of most priming behaviors remain poorly understood but must not rely on the MTL. In the last two decades, a large body of work, principally in rodents, has extensively elucidated the *emotional learning* system, which is experimentally studied using classical (Pavlovian) and variant fear conditioning paradigms: an emotionally neutral conditioned stimulus is paired with an aversive unconditioned stimulus, leading to an involuntary associative response to the conditioned stimulus. This is dependent on convergence in the lateral nucleus of the amygdala[142] and can occur in the absence of conscious perception.[143] With these progressive developments, the initial distinction between declarative and procedural memory eventually shifted to a framework that accommodated multiple memory systems in the brain.[144] Although these systems are distinct, the term *nondeclarative memory* is often used as an umbrella to collectively distinguish them from MTL-dependent declarative memory.

Usually considered separately, *working memory* refers to the capacity to maintain limited amounts of information in mind, which can be manipulated to perform complex cognitive tasks such as reasoning, comprehension, and learning.[145] The concept of working memory evolved from, and has largely replaced, earlier ideas about *short-term memory*, but the terms should not be used interchangeably. Working memory implies both a short-term memory store and the capacity for manipulation. The most influential current model, first proposed by Baddeley and Hitch in 1974,[146] divides working memory into capacity-limited component subsystems: a *phonological loop* that maintains information through vocal or subvocal rehearsal, such as when one holds a telephone number in mind; a *visuospatial sketchpad*, which holds and manipulates spatial, visual, and kinesthetic information; and a *central executive*, which is responsible for regulating selective attention and inhibition. A fourth subsystem, the *episodic buffer*, was recently added to the model[147] and is responsible for temporarily storing multidimensional representations and integration with declarative memory.

H.M. possessed intact working memory, and subsequent investigations continue to reinforce the view that working memory is not supported by the MTL.[148] Rather, working memory appears to be served by a distributed cortical network with a critical executive hub that is situated in the dorsolateral prefrontal cortex and is interconnected with the parietal cortex, thalamus, caudate, and globus pallidus.[149] This functional and structural distinction between working memory and the MTL does not mean that working memory and declarative memory systems do not interact. Working memory depends on declarative memory representations to provide semantic meaning and context. During working memory tasks, cortical perceptual areas associated with representations of declarative memory become activated and show increased synchrony with prefrontal regions.[150] Reciprocally, the establishment of declarative memory is strongly influenced by the nature of processing occurring in working memory, with deeper levels of executive processing resulting in better learning.[151]

Intuitively, one might suspect that the relationship between working memory and declarative memory was sequential—that is, information that is established in declarative (long-term) memory is longitudinally transferred from working (short-term) memory. However, this conclusion may be incorrect based on rare case examples of patients who have a selective short-term memory deficit but intact declarative memory function.[152] The presence of information in working memory and then in declarative memory retain "appears to occur". Understanding is not so definitive to go beyond this. via parallel (albeit interacting) processes and not through sequential transfer.

Long-Term Potentiation, Synaptic Tagging, and the Consolidation Model of Memory

The consolidation hypothesis of memory was first proposed by Müller and Pilzecker in 1900.[153] They noted that memory for new information could be disrupted by learning other information shortly after the initial training. This effect, called *retroactive interference*, is temporally graded such that the susceptibility of the memory is greatest immediately after learning and decreases with time. Müller and Pilzecker proposed that the memory trace must initially exist in a fragile state, but subsequently becomes stable through the process of *consolidation*.

The consolidation hypothesis remains the framework for understanding the temporal course of memory processes and behavior.[154] Consolidation was what H.M. was unable to perform and, as discussed later, consolidation appears to be the critical functional target of amnestic anesthetics.

For a memory trace to be consolidated, it must of course be created. The term used to describe this process is *encoding*. Encoding implies that the networks serving the neural representation of an event do not immediately return to their previous state, and are modified in such a way that potentiates reactivation of that representation. Within the framework of the *synaptic plasticity* and *memory hypothesis,* which states that activity-induced synaptic plasticity is both necessary and sufficient for the information storage underlying memory,[155] encoding therefore implies that some form of synaptic plasticity has been initiated. However, to be viewed correctly as a separate process from consolidation, encoding cannot in itself assure the propagation of a memory trace. Encoding creates the potential for the formation of a long-term memory.

The minimal events that constitute initial synaptic potentiation as it relates to memory, that is, the neural correlates of encoding, are incompletely understood. An immediate functional expression of change in synaptic strength seen in cellular models can occur in the absence of any structural change in dendritic spines.[156] Therefore, the most nascent form of potentiation can be mediated by purely functional changes: a presynaptic increase in glutamate neurotransmitter release, and increased postsynaptic incorporation of α-amino-3-hydroxyl-5-methyl-isoxazole-propionate receptors (AMPARs).

The perpetuation of these initial changes in synaptic strength through structural and functional remodeling represents the neural correlate of memory consolidation. The prevailing cellular model for this is LTP, which describes a durable increase in synaptic transmission efficiency following a stimulation protocol. The initial description reported that high-frequency stimulation of the perforant path (connecting entorhinal cortex to hippocampus) caused a sustained increase in synaptic transmission in the dentate gyrus.[131] It is now recognized that LTP occurs richly throughout the hippocampus (although the synapses between the Schaffer collateral and commissural axons and the apical dendrites of CA1 pyramidal cells are most frequently investigated), as well as in other afferent pathways.[157] In addition, in addition to high-frequency stimulation, which is nonphysiologic, LTP can be induced by stimulation protocols that resemble physiologic activity, the most important of which are bursts in the hippocampal theta (θ) range (4 to 8 Hz).[158] This is of particular relevance to memory, because synchronized hippocampal θ oscillations appear critical to successful memory behaviors.[132]

The breadth and depth of literature on the mechanisms of LTP are far too voluminous to summarize here. Nonetheless, certain principles are essential and relevant to anesthesia studies and can be stated succinctly. The induction of most forms of LTP requires activation of postsynaptic *N*-methyl-D-aspartate (NMDA) receptors, and specific NMDA receptor antagonists block the induction of LTP.[159] On depolarization, Mg^{2+} dissociates from its binding site in the receptor, allowing influx of Ca^{2+}. This rise in intracellular Ca^{2+} is the critical trigger for LTP. Next, downstream activation of calcium-calmodulin-dependent kinase II (CaMKII) is required,[160] which is maintained by autophosphorylation.[161] CaMKII and integrin-driven actin polymerization are necessary for the initial cytoskeletal reconfiguration.[156,162] Activation of several other cell-signaling cascades also contribute to LTP: cyclic adenosine 3′,5′-monophosphate (cAMP)-dependent protein kinase, protein kinase C, tyrosine kinase, phosphatidylinositol 3-kinase (PI 3-K), and mitogen-activated protein kinase (MAPK/ERK). The downstream effects of MAPK/ERK activation are diverse and include as substrates the nuclear proteins *c*-Myc, *c-fos*, and *c-jun*, cytoskeletal proteins Tau and MAP-2, Elk-1, and cAMP response-element binding protein.[163] The terminal expression of LTP is protein synthesis, occurring in both the soma and local dendrites, and resulting in enduring structural changes at the synapse.[164,165] A large number of experiments have demonstrated protein synthesis inhibitors to prevent sustained LTP in vitro and learning in vivo.[166]

LTP thus proceeds in two phases, corresponding to memory phases observed across multiple species. Early LTP (E-LTP) is the phase independent of protein synthesis and can be sustained across an interval of minutes to a short number of hours. Late LTP (L-LTP) is dependent on intracellular signaling and protein synthesis and can be sustained across many days. The MAPK/ERK cascade likely represents the critical transition between the two phases.[157,164] However, LTP in simple systems is incomplete in explaining the time course of human memory, which can endure over years or decades.

A contemporary theory that explains several characteristics of LTP, and conceptually bridges encoding to long-term memory, is the *synaptic tagging* and *capture hypothesis*.[167] In this model, encoding sets a synaptic tag—a temporary change in the structural state of the synapse—that is dependent on CaMKII. This tag establishes the potential for long-term structural changes, but for the cascade to continue the tags must capture plasticity-related proteins (PRPs) synthesized in the soma or dendrites. The tag exists for a limited time window, and in the absence of arrival and capture of PRPs, it will decay and the potential for the transition to long-term structural changes will expire. In contrast, if PRPs are captured a cascade of presynaptic and postsynaptic changes are triggered[168] and lead to the induction of L-LTP. What makes the synaptic tagging model so attractive to systems-based models of memory is that it allows the thousands of dendrites of a single neuron to support memory stabilization processes at various states of evolution because the tagging and PRP capture need not occur as a singular event. In other words, past and future PRP release modulates the fate of the tag. This nondeterminism is consistent with true memory behavior, which in multiple contexts is influenced by events preceding and following encoding.

Reconsolidation

For decades, the understanding of memory consolidation was that it was a unitary process; that is, once protein

transcription occurred and a memory trace was stabilized, it was no longer dynamic and underwent gradual decay. In 2000, Nader and colleagues[169] reported that an old memory for auditory fear conditioning, which would normally not be sensitive to protein inhibitors, can be made newly sensitive if it is retrieved. The implication was that retrieval of a memory renders it transiently plastic, after which it restabilizes. This process is termed *reconsolidation* and has been subsequently demonstrated in multiple settings and species, including in human behavioral paradigms.[170,171] Reconsolidation can be viewed as a modulatory process that mediates strengthening of an existing memory, but it is clear that it also provides a window in which the existing memory is malleable and can be updated with the addition of novel information.[172,173] Both explicit recall and implicit internal reactivations—as likely occur during sleep—elicit reconsolidation events. Reconsolidation shares many of the cellular mechanisms of LTP that are associated with initial consolidation. However, the temporal dynamics differ, and consolidation appears to require several areas that are not required for reconsolidation.[174] Reconsolidation may represent a modulatory phase of an extended consolidation process. Certainly, most pharmacologic agents—including anesthetic drugs—that inhibit consolidation would be rational candidates for similar effects on reconsolidation.

Phase Synchronization

The neurons in assemblies and networks do not function in isolation but undergo oscillatory activation and inhibition. Phase synchronization of these oscillations, which coordinates the excitability of related neurons, is a fundamental neural mechanism. It supports neural communication by creating transient and dynamic associations between different functional brain regions. For example, a significant body of evidence supports the hypothesis that γ-phase (~40 Hz) synchronization binds the regions serving the various attributes of a conscious perception.[175]

Phase synchronization appears to be fundamental to neural plasticity and memory,[132,176] and studies have shown that increased synchrony during encoding is predictive of improved learning and memory.[177-179] γ-Phase synchronization is believed to support Hebbian plasticity in the hippocampus; that is, plasticity that involves the coordinated firing of presynaptic and postsynaptic neurons. The frequency of γ oscillations is optimal to coordinate presynaptic and postsynaptic inputs inside a window of 10 to 30 ms, which is key to the induction of LTP in so-called spike-timing-dependent plasticity.[180] However, γ synchrony cannot fully explain declarative memory, in part because the phase is not time-locked to a stimulus; that is, γ synchrony supports the induction of plasticity in a network serving a memory, but is agnostic to specific content. Here, significant interest has focused on θ-phase (4 to 8 Hz) synchronization, which in contrast to γ undergoes phase reset in response to a stimulus. Many studies have connected θ reset and phase synchrony with LTP and successful declarative learning.[181-184] Furthermore, amygdalo-hippocampal θ synchronization has been identified as critical in fear-based memory.[185-187] θ-Dependent plasticity is non-Hebbian, in that it is determined only by the incoming (presynaptic) conditions. LTP is induced only during the peak of a θ oscillation,[182] and so θ phase reset and synchronization may therefore function to coordinate input from broadly distributed brain regions. A cooperative relationship between θ and γ synchrony exists such that the phase of γ oscillations are coupled to the amplitude (phase-amplitude coupling) or phase (phase-phase coupling) of the slower θ oscillation.

EFFECTS OF ANESTHETIC DRUGS ON DECLARATIVE MEMORY FUNCTION IN HUMAN SUBJECTS

The theoretical number of mechanistic pathways through which an anesthetic drug could cause amnesia is enormous, most of which cannot be directly assessed in human subjects. However, the putative candidates can be dramatically narrowed by appreciating that memory-related processes are constrained to operating within a specific time domain and in a specific neuroanatomic location. A significant emphasis of current research in humans is therefore the drive to define the temporal and neuroanatomic characteristics of anesthetic amnesia precisely, because these characteristics richly inform and dismiss hypotheses regarding underlying mechanisms.

Behavioral Studies of Retrograde Amnesia and Retrograde Facilitation

Although some anecdotal accounts and isolated case reports have led to occasional confusion, in systematic investigations there is no evidence that anesthetic drugs cause retrograde amnesia in humans. Studies in the early 1970s found no retrograde amnesia with the administration of thiopental (6 mg/kg) and methohexital (4 mg/kg).[188] Adult patients have normal memory for visual stimuli presented 4 minutes before administering midazolam (2, 5, and 10 mg[189]). Similarly, memory is normal for word lists learned in the preoperative holding area or operating room immediately before induction,[190] and for pictures viewed immediately before propofol induction.[191] Studies of pediatric patients have shown normal memory for pictures presented immediately before sedation with both midazolam[192] and propofol[193] (see Chapter 93). In controlled laboratory settings using human volunteer subjects, there is no impairment of memory for pictures[194] or words[195,196] presented before target-controlled sedative infusions of propofol (brain concentration [C_{es}], 0.3 to 2.5 μg/mL), midazolam (20 to 35 ng/mL), thiopental (2 to 7 μg/mL), or dexmedetomidine (0.25 to 0.8 ng/mL).

A recent study[197] described an experiment in which volunteer subjects learned a word list and were then immediately administered a steady-state infusion of either propofol (0.9 μg/mL) or placebo for 90 minutes. Memory for the words was tested at several intervals across a time domain spanning from 20 minutes to 24 hours after encoding. In contrast to finding retrograde amnesia, propofol subjects paradoxically retained more material than did placebo subjects. A similar effect is described for midazolam in the psychology literature.[198] This phenomenon is called *retrograde facilitation*. The basis is best appreciated by considering the opposite effect, called *retrograde interference*—the observation that mental exertion, especially that engaging memory processes, inhibits the consolidation of recently formed memories, with the

newest memories being most vulnerable.[199] In mechanistic analogues, it is clear that the induction of new LTP interferes with recently formed LTP and memory performance, even when the tasks are unrelated.[200,201] When the induction of new LTP is blocked by a selective NMDA antagonist such as AP5 or CPP, interference with recently formed LTP does not occur, and memory performance improves[202-204]—that is, the analogue of retrograde facilitation occurs. The most parsimonious explanation for the retrograde facilitation seen with propofol and midazolam is that it similarly blocks the induction of new LTP—albeit likely via a GABAergic pathway—freeing consolidation resources that enhance the survival of recently formed LTP.

The finding of retrograde facilitation and failure to identify retrograde amnesia strongly suggest that the mechanism of anesthetic amnesia is restricted to induction processes in the consolidation cascade. Induction failure will have effects on downstream processes, but it is more difficult to rationalize that downstream elements represent independent targets. To illustrate: if a drug had a direct effect on a process occurring t_c minutes after encoding, the effect would be to block consolidation for an event that occurred t_c minutes in the past, creating a clear retrograde amnesia window. Although current studies do not have the temporal resolution to dismiss the possibility of drugs targeting processes commencing only seconds after the initiation of E-LTP, later stages of the E-LTP time domain, and the time domain covering the transition from E-LTP to L-LTP have certainly been tested. The strongest counterargument to the induction hypothesis has suggested a direct role for downstream protein transcription processes,[205] but the temporal window in which this might occur remains undefined.

Clinically, there is no basis for the use of any anesthetic drug as a retroactive treatment for the prevention of intraoperative awareness with recall. Acute stress and anxiety have complex noradrenergic-mediated effects on memory that can cause anterograde and retrograde amnesia surrounding emotional events,[206,207] and this constitutes a credible explanation for the small percentage of patients who do not recall the immediate preanesthetic period.

Mathematical Modeling of Anesthetic Amnesia

Attempts to model mathematically what happens to memory over time date back to the late nineteenth century, when Ebbinghaus[128] demonstrated that memory decay is characterized by a rapid initial decline, followed by a more gradual loss. Nearly a century later, Wickelgren[208] developed a complex predictive model that is neuroscientifically attractive because its component elements—the coefficients—are hypothesized to index specific memory processes. The most complete version of the *Wickelgren Power Law* is as follows:

$$m_t = \phi\,(1 + \beta t)^{-\psi} e^{-\pi t}$$

where m_t is memory at time t, ϕ reflects the degree of initial learning (and is thus a measure of encoding strength), β is a scaling constant derived from differential equations describing memory trace fragility, ψ describes the core decay characteristics (and thus reflects consolidation processes), and the exponential term $e^{-\pi t}$ expresses decay caused by interference from interpolated material that is similar to the learned items.

A simplified version of the Wickelgren Power Law was applied in a large human volunteer study to characterize the amnestic effects of several intravenous anesthetic drugs.[195] Using reasonable assumptions, the complete equation was reduced to a two-parameter power decay function:

$$m_t = \lambda t^{-\psi}$$

where λ reflects the initial memory strength (the encoding index), and ψ expresses the rate of decay (the consolidation index). A given memory state m_t is thus a function of two variables that can theoretically be modulated independently. The power of the mathematical modeling technique is that it enables characterization in terms of both encoding failure (decreased λ) and consolidation failure (increased ψ). In contrast, measurement of m_t at a single point in time—that is, simply sampling how much has been forgotten after t minutes—captures no such information.

The two-parameter power decay function accurately describes the temporal course of amnesia for subjects receiving propofol (0.45/0.90 μg/mL), midazolam (20/35 ng/mL), dexmedetomidine (0.20/0.40 ng/mL), and thiopental (1.5/3.0 μg/mL); it also characterizes the drugs by demonstrating marked differences in the way they modulate the component elements. Propofol, a moderately selective $GABA_A$ receptor agonist, is an archetypal amnestic drug: it permits robust encoding of material, but the information undergoes accelerated decay because of a failure of consolidation. In contrast, dexmedetomidine—a highly selective α_{2A}-adrenoceptor agonist that causes a widespread decrease in noradrenergic tone throughout cortical and subcortical structures—archetypally conserves consolidation, but leads to memory impairment because of a failure of information to be strongly encoded. Thiopental—less selective than propofol, but which nonetheless shares the $GABA_A$ receptor as its primary target—interestingly behaves similarly to dexmedetomidine, causing marked encoding failure but demonstrating minimal effect on consolidation. The benzodiazepine midazolam, another $GABA_A$ receptor agonist long used clinically for its amnestic potency, behaves like propofol at lower doses—selectively causing consolidation failure while leaving encoding intact—but with increasing dose a significant encoding impairment emerges. The discrepant patterns observed in the three GABAergic drugs demonstrate that nonspecific $GABA_A$ agonism per se is not sufficient to explain the ability of a drug to cause consolidation failure.

Neuroimaging Studies of Cortical Encoding Processes

A small number of functional neuroimaging studies have evaluated the effect of anesthetics on cortical regional activation during memory encoding. An early PET study investigated propofol (0.52/0.83 μg/mL) using a word memory task.[209] In this study, the regions of interest were the left inferior prefrontal cortex (LIPC), associated with successful encoding,[210] and the dorsolateral prefrontal cortex (DLPFC), a region most associated with executive

functioning. LIPC activation was conserved, suggesting that propofol did not block the processes required to support successful encoding. DLPFC activation was decreased. In a subsequent investigation using an auditory depth of processing task, LIPC function was again found to be preserved with propofol (0.9 μg/mL), but was decreased with thiopental (3.0 μg/mL).[211] Although thiopental subjects had inferior LIPC activation at the time of encoding, propofol subjects had a significantly poorer memory performance at 200 minutes. The characterization of the drugs based on functional neuroimaging is thus congruent with that derived from mathematical modeling: thiopental impairs memory because information fails to be encoded, whereas propofol exhibits a clear amnestic potency that is unrelated to its effect on encoding processes.

An earlier PET study of midazolam (74/129 ng/mL) using an oddball detection paradigm reported a dose-dependent decrease in activation in Brodmann areas 9, 10, and 46, which overlap regions of both DLPFC and LIPC. Interpretation of this study in context of memory function is difficult, because the experimental task was not memory-related. A recent fMRI study of dexmedetomidine (0.15 ng/mL) reported a generalized effect of bilateral prefrontal suppression in Brodmann areas 9 and 10 during an emotional picture memory task, but no detailed analysis of cortical encoding activation was conducted.[212]

Studies of the Relationship Between Encoding and Attention or Arousal

A convergence of evidence suggests that the effect of anesthetic drugs on encoding processes is related to the modulation of attention. Attention is necessary for the successful establishment of declarative memory,[213] with distinct networks required for maintaining an alert state, orienting to targets, and for exerting executive control of thought.[214] Attention is thus a prime modulator of the assembly of an integrated conscious percept and the depth of its processing, although the degree to which attention and consciousness are dissociable remains a topic of current debate. The dominant effect on attention for most anesthetic drugs is that of decreasing arousal, which of course progresses to profound sedation and unconsciousness as dose is increased. The NMDA antagonist ketamine is a notable exception, with dominant effects on orienting and selection.[215] A complete understanding of anesthetic amnesia cannot be achieved unless the effect of modulating arousal and attention is dissociated from effects on memory-specific processes, a principle articulated by Veselis and colleagues[216] and followed in a series of studies.

In PET neuroimaging, the effect of thiopental on LIPC mimicked that of adding an attentional challenge task to the memory paradigm in placebo subjects.[211] A study of propofol (0.3 to 2.5 μg/mL), thiopental (2 to 7 μg/mL), and dexmedetomidine (0.25 to 0.8 ng/mL) demonstrated that memory retention at 33 seconds—an interval sufficiently short so as to be dominated by encoding strength rather than consolidation—was related to the level of arousal.[196] Arousal was also predictive of memory at 225 minutes for thiopental and dexmedetomidine, whereas propofol caused a significantly greater loss of memory than would be predicted by modulation of arousal alone. Thus, arousal was found to be predictive of subsequent memory only for drugs that cause memory impairment through encoding failure.

Further evidence for the relationships among arousal, attention, and encoding come from the mathematical modeling study described earlier.[195] In that study, arousal predicted the coefficient of encoding strength (λ) with remarkable precision for dexmedetomidine, thiopental, midazolam, and the propofol 0.45 μg/mL. The one exception was subjects receiving propofol 0.90 μg/mL; they had better encoding strength than would be predicted for their level of sedation. Notably, this paradoxic effect was observed at the same concentration at which excitatory phenomena emerge in neuronal network models, wherein an interaction between $GABA_A$ current and an intrinsic membrane slow potassium current (M-current) lead to interneuron asynchrony.[217] Paradoxic improvements in cognitive function following the administration of low concentrations of GABAergic drugs are also reported in patients in pathologic, minimally conscious states, probably because of the release of inhibitory control signals.[218]

Studies of Hippocampal Function

Despite its critical role in memory, few neuroimaging or electrophysiologic studies have been directed toward evaluating hippocampal function during anesthetic amnesia in humans. The deep location of the hippocampus makes it inaccessible to surface EEG, and in standard fMRI acquisition protocols it is susceptible to signal artifact from the pharyngeal air-tissue interface (although contemporary acquisition techniques have reduced this limitation). PET studies require signal to be acquired as a block of multiple stimuli that cannot be individually separated and analyzed based on subsequent memory behavior. Only event-related fMRI, which is technically challenging, permits individual hippocampal activations to be grouped and analyzed according to the ultimate fate of the memory—something that cannot be known at the time the image is captured.

Two recent studies have used event-related fMRI to evaluate hippocampal activation during amnestic infusions of propofol (0.90 μg/mL)[219] and dexmedetomidine (0.15 ng/mL).[212] Although earlier reports found that propofol does not significantly attenuate hippocampal and peri-hippocampal activity at rest,[84,220] the event-related fMRI study demonstrated that propofol causes a generalized attenuation of hippocampal activation in response to all stimuli, and the degree of this attenuation correlates with the degree of amnesia. The study design provided solid behavioral confirmation that encoding had occurred; therefore, the hippocampal attenuation likely corresponded to a failure of consolidation processes. Dexmedetomidine attenuates the subsequent-memory effect—that is, dynamics of hippocampal activation become less predictive of subsequent memory, but the overall level of hippocampal activity appears preserved. In contrast to propofol, the explanation offered here is that upstream cortical actions of dexmedetomidine weaken encoding, with attenuated hippocampal dynamics reflecting a downstream effect. Hippocampal attenuation during encoding has also been correlated with amnesia for face-name pairs for the benzodiazepine lorazepam and the cholinergic antagonist scopolamine.[221]

Attenuation was also found in DLFPC and fusiform cortex, more suggestive of an effect on distributed encoding processes than a restricted consolidation effect.[222] In a largely exploratory investigation, 0.25% sevoflurane was found to reduce hippocampal activation in response to auditory and visual stimuli, but no memory performance was assessed.[223]

A single electrophysiologic study used implanted intracranial depth electrodes in epileptic patients to evaluate the effects of propofol on hippocampal spectral coherence and power characteristics at rest.[224] At amnestic serum concentrations (0.5 to 1.0 μg/mL), there is a minimal and quite possibly nonsignificant increase in spectral power across frequency bands ranging from δ (1 to 4 Hz) through γ (32 to 48 Hz). There is a significant increase in hippocampus-rhinal spontaneous coherence in the δ band, but minimal changes in other bands: the trend is toward a slight loss of spontaneous coherence in the θ (4 to 8 Hz), α (8 to 12 Hz), β_1 (12 to 20 Hz), and β_2 (20 to 32 Hz) bands, and a slight increase in the γ band. Cortico-hippocampal coherence was not assessed. Hippocampal coherence dynamics, especially in the θ and γ bands, are of critical importance to memory function, but interpretation of rest data must be limited. This is especially true for θ coherence, for which the role in memory appears to involve phase reset in response to a stimulus. Although electrophysiologic studies of the human hippocampus are of tremendous interest, they are currently restricted to epileptic patients and introduce the possibility that data are being acquired from regions of abnormal brain.

Studies of Cortical Event-Related Potentials

The event-related potential (ERP) is a stereotypic signal fluctuation in the EEG that is time-locked to a stimulus. For any individual event, the ERP signal is overwhelmed by non–stimulus-locked EEG activity. However, by repeating the stimulus task over multiple trials (usually at least 50) and then averaging, the non–stimulus-locked EEG behaves as random noise and subtracts to zero, revealing the ERP signal. The ERP itself is a series of positive and negative fluctuations. For decades, the origin of these fluctuations was believed to be stimulus-induced activation of dormant neuronal clusters. More recently, however, consensus has favored the theory that ERPs emerge not because new oscillations are induced, but because of a stimulus-induced phase resetting of ongoing oscillations.[225] Modulations of the ERP have been associated with a significant number of cognitive processes, including many related to memory.

Curran and colleagues[226] used ERPs to demonstrate that drug-induced effects on arousal and memory may be electrophysiologically dissociable. The GABAergic benzodiazepine lorazepam (2 mg orally) and cholinergic antagonist scopolamine (0.6 mg subcutaneously) were compared with diphenhydramine (25/50 mg orally), which provided a nonamnestic, equally sedative control. Changes in the P1N1 and N1P2 early complexes, associated with arousal, were seen for all three drugs. However, changes in later complexes associated with memory, notably the P3 and N2P3, were seen only with the amnestic drugs. No ERP distinction could be made between lorazepam and scopolamine, despite their different receptor mechanisms. Interpretation of the study was limited because the paradigm used to elicit the ERPs (oddball detection) did not directly assess memory behavior.

The work of Curran and colleagues[226] was extended in a series of studies by Veselis[216,227] evaluating intravenous anesthetics. An early investigation demonstrated that propofol amnesia was associated with decreased P3 amplitude.[227] In a more sophisticated auditory memory task, with drugs dosed to cause equal levels of sedation, propofol and midazolam possessed markedly greater amnestic potency than thiopental.[216] Indeed, the relative amnestic potency of thiopental was not substantially greater than that of fentanyl. This finding provided key evidence that GABAergic agonism per se does not explain the amnestic potential of a drug: propofol and midazolam clearly possess selective memory actions that are not shared by thiopental. In a subsequent analysis, it was shown that central frontoparietal N2P3 amplitude was the best predictor of memory. N2 latency was related to the reaction time, which was interpreted to measure arousal, although some exceptions suggested that the relationship does not hold true for all drugs.

The mathematical modeling study described earlier examined early-latency and mid-latency ERPs originating from the midline parietal precuneal region (Pz).[195] The decay coefficient ψ, which indexed modulation of consolidation, was tightly correlated with the P2 amplitude and N2 latency observed at the time of encoding. As the correlation between P2N2 changes and ψ was remarkably consistent across drugs from multiple classes and at multiple doses, it suggests that while substantial variation exists in the potency of anesthetic drugs in causing consolidation failure, a common mechanistic pathway may be involved. Furthermore, the observation supports the assertion that the underlying mechanism involves induction events in the consolidation cascade; consolidation failure evolving over several hours could be predicted by electrophysiologic events occurring within several hundred milliseconds of exposure to the stimulus. An alternate analysis[228] of the study examined the "old/new effect," a robust phenomenon observed in the parietal ERP that distinguishes the response to initial item exposure from subsequent exposures. At a presentation interval of 27 seconds, no degradation in memory performance was evident, but significant attenuation of the old/new effect was observed with propofol and midazolam. In contrast, no change was observed with thiopental and dexmedetomidine. Again, the analysis distinguished the dominantly amnestic drugs from the dominantly sedative drugs and constrained the mechanism to early in the consolidation cascade.

An intriguing possibility raised by the relationship between modulation of P2N2 and consolidation failure lies in the origin of the complex. P2N2 is known to derive largely from synchronous θ oscillations,[229] which as discussed earlier are critical to non-Hebbian plasticity and strongly correlated with memory behavior. As such, one interpretation is that a common mechanism underlying the selective effect of anesthetic drugs on the induction of consolidation involves changes in θ oscillations across a distributed cortico-hippocampal network. Unfortunately, no direct measures of θ synchrony in an

appropriate memory paradigm have yet been performed, and the location of the hippocampus confers enormous methodologic barriers.

Another intriguing finding from the study was a pristine correlation between reaction time, P2N2, and the consolidation coefficient ψ, which was preserved across all drugs and dosages. In nonpharmacologic studies, reaction time has long been interpreted as an index of sedation, but in the anesthetic study, no relationship with sedation was identified; this suggests caution in interpreting it as a behavioral marker of sedation in future drug studies. Reaction time has been related to interregional synchrony.[230] Therefore, what functionally connects the effect of amnestic drugs on θ-dependent elements of the ERP and reaction time is that they may both represent a loss of synchronous activity across distributed networks.

NONHUMAN STUDIES OF ANESTHETIC EFFECTS ON HIPPOCAMPAL MEMORY PROCESSES AND BEHAVIOR

Anesthetic Effects on Hippocampal Memory Processes In Vivo

GABAergic interneurons project within and across subregions of the hippocampus,[231] providing an abundant density of rational targets for anesthetic drugs. In a study using tetanic stimulation of the Schaffer collateral-commissural pathway,[232] isoflurane (0.2 to 0.3 mM) blocked the induction of LTP. Isoflurane similarly blocked the induction of long-term depression (LTD) by low-frequency stimulation. The effect of isoflurane on both LTP and LTD was blocked by the addition of the $GABA_A$ receptor antagonist picrotoxin (50 μM), providing strong evidence that the effect of isoflurane on LTP is GABAergically mediated. In a similar protocol, amnestic concentrations of sevoflurane (0.04 mM) allow posttetanic potentiation but cause a failure of LTP, which is prevented by the addition of the $GABA_A$ antagonist bicuculline (10 μM).[233]

An early study of propofol conducted in live rats with electrodes implanted in CA1 neurons yielded unexpected results. It was suggested that propofol had little effect on the induction of LTP, but significant effects on maintenance, and that LTD was enhanced.[234] Subsequent investigations do not support these findings and have instead demonstrated that propofol inhibits the induction, but not the maintenance of LTP. Furthermore, the effect is blocked by the addition of picrotoxin, implicating a $GABA_A$ receptor-mediated mechanism.[235-237] Notably, one study found that propofol inhibited LTP only at anesthetic concentrations (50 μM), and not at amnestic concentrations (5 to 20 μM).[236] Other notable observations from this cluster of work are that propofol also inhibits NMDA-receptor–independent LTP, and the LTP-associated downregulation of the K^+/Cl^- cotransporter 2. Propofol (1 to 10 μM) has also been demonstrated to inhibit NMDA receptor-dependent activation of extracellular signal-regulated protein kinase 1/2,[238,239] an important subclass of MAPKs, which as previously discussed are a critical component of the LTP cascade. Finally, propofol reduces expression of activity-related cytoskeleton-associated protein (Arc) in the hippocampus in response to inhibitory avoidance training but does not appear to reduce Arc mRNA.[240] This finding is notable because it suggests a posttranscriptional mechanism. This effect is blocked by infusion of the GABAergic antagonist bicuculline into the basolateral amygdala (BLA), implicating an amygdalo-hippocampal network.

The hippocampal $GABA_A$ergic interneuron population is notable for a high density of the α_5-subunit subtype, which is far less common in other regions.[241] This observation has driven a series of studies by Orser[242-246] using α_5-$GABA_A$-knockout mice. The α_5 –/– mutants are resistant to the amnestic effects of etomidate, but not to its general anesthetic effects. Furthermore, etomidate blocks LTP measured in CA1 neurons in wild type mice, but not in α_5 –/– mutants.[242] In wild type mice, the effects of etomidate on LTP and memory behaviors are reversed by the addition of L-655,708, which selectively reduces the activity of α_5-$GABA_A$ receptors.[243] A later study evaluated the enduring memory effects of 1 minimum alveolar concentration isoflurane and sevoflurane by examining performance 24 hours after anesthetic administration. Memory deficits were observed in wild type mice, but not in α_5 –/– mutants or in wild types receiving L-655,708.[244,245] The amnestic effect of etomidate and volatile anesthetics thus appears to critically involve the α_5-$GABA_A$ receptor. Significantly, the α_5-$GABA_A$ receptor has recently been shown to regulate the threshold for LTP, but only in response to stimulus frequencies in the θ range,[246] thus converging with other lines of investigation suggesting that θ is a key mechanistic target.

The association of amnesia with the α_5-$GABA_A$ receptor is not exclusive. α_4-$GABA_A$ receptors are concentrated in the dentate gyrus and dorsal thalamus, and α_4 knockouts are resistant to the amnestic effects of isoflurane but not to its general anesthetic effects.[247] Likewise, β_3-$GABA_A$ receptor knockout mice are resistant to the amnestic effects of isoflurane,[248] although in an earlier study using β_3-$GABA_A$ receptor knock-in mutants, it appeared that the β_3 subtype was not a significant mediator of isoflurane amnesia.[249] Other studies have demonstrated that the α_2 subunit is not a mediator of isoflurane amnesia. A study of α_1-$GABA_A$ receptor knock-in mice suggested that the α_1 subunit was not involved in the amnestic actions of isoflurane,[250] in contrast to an earlier study using α_1 knockouts in a fear-conditioning paradigm suggesting that the α_1 subtype was a mediator of isoflurane amnesia.[251]

The effect of anesthetics have been studied on hippocampal θ oscillations in vivo. Perouansky and colleagues[252] used a fear conditioning paradigm to study isoflurane 0.32%, nitrous oxide 60%, and halothane 0.24%, and reported that suppression of hippocampal-dependent contextual conditioning was proportionate to slowing of θ peak frequency. An earlier study also demonstrated that isoflurane caused slowing of θ oscillations in the CA1 neuronal bundle without changing absolute power. In some contrast, the nonimmobilizer F6, which causes amnesia without sedation or a loss of motor activity, caused a loss of θ oscillatory power without θ slowing.[253] This finding suggests that the disruption of hippocampal θ oscillations required to cause amnesia might not be specific. In fact, although isoflurane and F6 amnesia are both associated with changes in θ, isoflurane

appears to antagonize the amnestic potential of F6, suggesting that they do not share a common mechanism.[254] Scopolamine causes amnesia at doses associated with acceleration of θ oscillations, which might otherwise be expected to improve learning.[255] However, a significant loss of absolute power is also observed.

ANESTHETIC EFFECTS ON AMYGDALA-DEPENDENT MEMORY PROCESSES

The amygdala sits immediately anterior to the hippocampus and is a cluster of interconnected nuclei with afferent and efferent projections to a wide distribution of cortical and subcortical structures. The amygdala is recognized as critical to fear learning and memory, and the systematic study of amygdala-dependent classical (Pavlovian) fear conditioning has produced much information regarding the mechanisms of associative learning.[142,256,257] The basolateral nucleus of the amygdala (i.e., the BLA) also functions to modulate the encoding and consolidation of memory in the hippocampus and elsewhere in response to emotion, arousal, and stress.[258,259] This modulatory function largely explains why emotionally significant experiences are better remembered. The mechanism is dependent on noradrenergic projections terminating on both α and β receptors within the BLA,[260] but can also be triggered by systemic epinephrine binding to β-adrenoreceptors in the vagus nerve and projecting to the nucleus of the solitary tract,[261] with downstream modulation of norepinephrine release in the BLA either directly or via the locus ceruleus. Amygdalo-hippocampal connectivity occurs via direct and indirect projections, and it is dependent on θ oscillatory synchrony.[185-187,262] Local α_1 and α_2-rich GABAergic circuits situated in the BLA and intercalated bundles gate the noradrenergic processes, providing rational targets for anesthetic drugs.[263]

Lesions of the BLA block anterograde amnesia for an inhibitory avoidance task in rats receiving diazepam,[264] propofol,[265] and sevoflurane.[266] Conversely, when the BLA is injected with the selective GABA antagonist bicuculline, the amnesia for inhibitory avoidance caused by propofol is blocked.[240] Further, this intra-amygdalar injection reverses the propofol-induced suppression of Arc protein expression in the hippocampus via a $GABA_A$ receptor mechanism. Thus, the amygdala is a key mechanistic site for anesthetic amnesia in certain experimental contexts. However, inhibitory avoidance, like many associative learning experimental paradigms performed in animals, is selectively amygdala dependent. Finding that the amygdala is critical to anesthetic amnesia in an amygdala-dependent paradigm does not necessarily extrapolate to its importance in the sort of contextually rich, non–fear-based memory that is fundamental to the human experience, which is difficult to model in animals.

The effects of anesthetic drugs on amygdala-dependent memory modulation in human subjects have been studied (Figure 13-5). The experimental paradigms all involve the presentation of emotionally negative and arousing images. Such items are established to activate the amygdalo-hippocampal modulatory axis[267,268] and should be better remembered than emotionally neutral items. An early behavioral study demonstrated that negative-arousing items were more resistant to the amnestic effect of thiopental than were neutral items, suggesting that amygdala-dependent modulatory processes remained intact.[194] At the same level of overall memory performance (50% retention), no significant mnemonic advantage for negative-arousing items was retained in subjects receiving propofol or dexmedetomidine, suggesting that in contrast to thiopental, these anesthetics could attenuate amygdala-dependent modulatory processes. However, the small numbers of subjects in the dexmedetomidine cohort limit interpretation of the negative finding.

Two recent, event-related fMRI studies developing these concepts have provided significant mechanistic insight. Pryor and colleagues[219] reported that activation of the amygdala in response to negative-arousing items remains robust in the presence of propofol (0.90 μg/mL), but activation of the hippocampus is markedly attenuated, with corresponding amnesia and loss of mnemonic advantage. This finding suggests that the afferent processes serving higher-order interpretative functions and amygdala activation are unaffected by amnestic levels of propofol, whereas efferent processes underlying amygdala-dependent modulation of hippocampal plasticity are disrupted. Hayama and colleagues[212] studied dexmedetomidine (0.15 ng/mL) and similarly reported that activation of the amygdala in response to negative-arousing items is preserved. However, unlike propofol, a mnemonic advantage for those items is seen, and subsequent memory is correlated with activation in the amygdala and hippocampus on the left side. Taken together, these studies suggest that propofol is more effective at attenuating the amygdalo-hippocampal modulatory axis. One suggested explanation is that amygdalo-hippocampal connectivity is markedly disrupted by the loss of θ oscillatory synchrony caused by propofol, whereas α_{2A} antagonism at the locus ceruleus causes only limited downstream attenuation of noradrenergic signaling in the BLA.

An earlier PET study by Alkire and colleagues[269] demonstrated that the mnemonic advantage for negative-arousing items was preserved at 0.1% and 0.2% sevoflurane, but lost at 0.25%. Structural equation modeling of the PET data demonstrated that this was associated suppression of amygdalo-hippocampal effective connectivity.

Amygdala hyperreactivity is of importance in a number of fear-based psychopathologies, including anxiety, phobia, panic disorder, and posttraumatic stress disorder.[270,271] The neurohumoral stress response to surgery provides a number of potential substrates for amygdala activation, and as such there is basis for concern that this activation might induce plastic changes that could prime the development of long-term changes in neuropsychological functioning. Thus, anesthetics might not be potent attenuators of amygdala activation, even if they are highly effective at preventing downstream modulation of the hippocampus and memory. This is particularly relevant to the frequent incidence of posttraumatic stress disorder following intraoperative awareness[272] and intensive care therapy,[273,274] but further investigation is required before any clinical strategies can be offered.

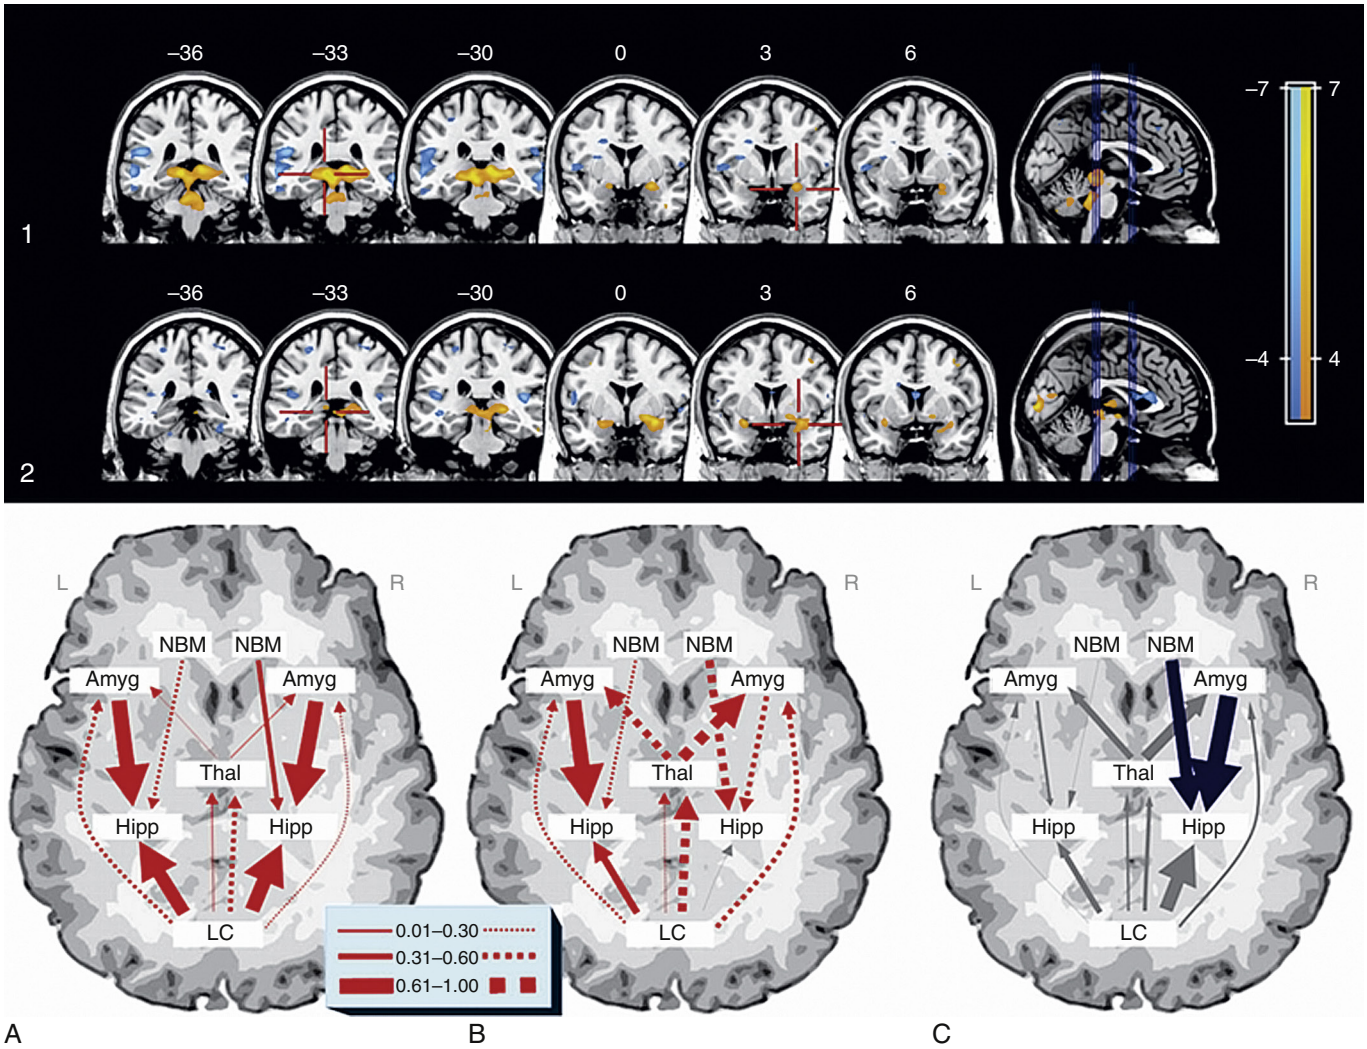

Figure 13-5. The effects of GABAergic anesthetics on the amygdalo-hippocampal axis in humans. *(Top)* Shown is the contrast between exposure to negative-arousing items and exposure to neutral items in human subjects receiving either placebo *(row 1)* or propofol 0.90 μg/mL *(row 2)*. Six coronal slices through the hippocampus (three leftmost slices, marked above by *y* coordinates –36, –33, –30) and amygdala (coordinates 0, 3, 6) are selected, with the coronal planes shown on the sagittal slice on right. In the placebo group, significant activations (negative-arousing > neutral) are seen in both right and left amygdala, and in both right and left hippocampus. In the propofol group, similar significant activations are seen in the right and left amygdala, but no significant activations are observed in the hippocampi. The scale shows color rendering of the group-wise *t* values obtained from Statistical Parametric Mapping. The threshold for color rendering is $|t| \geq 3.37$. *(Bottom)* Shown is a positron emission tomography study applying structural equation modeling (connectivity) analysis in human subjects at rest, receiving either no anesthetic **(A)** or sevoflurane 0.25% **(B).** Positive influences of one region onto another are shown as solid lines, and negative influences are shown as dotted lines. Line width represents the magnitude of the effective influence, with larger widths indicating a larger influence, according to the scale shown. The numerical difference in path weights between conditions is shown in **C.** Paths that significantly contribute to the network model more in the placebo state versus the anesthesia state are highlighted; all other paths are shown grayed out. A large change in path weights is noted for the effective influence of the amygdala and the nucleus basalis of Meynert on the hippocampus during sevoflurane. *Amyg,* Amygdala; *Hipp,* hippocampus; *LC,* locus ceruleus; *NBM,* nucleus basalis of Meynert; *Thal,* thalamus. *(*Top *from Pryor KO, Root JC, Mehta M, et al. ANESTHETIC EFFECTS ON IMPLICIT MEMORY FUNCTION

In contrast to declarative memory, implicit memory processes do not axiomatically require a conscious substrate, nor are they dependent on hippocampal plasticity. Therefore, there is no a priori basis to assume that the effect of anesthetic drugs on implicit memory function will parallel those on declarative memory. A number of investigations have sought evidence for implicit processing in unconscious subjects. More rigorous studies have used variants of a word stem completion task: subjects are exposed to a word item during anesthesia, and implicit memory is evidenced by an increased propensity to think of that word when later presented with the first few letters. A more rigorous variant—termed the *process dissociation procedure*—enables the separation of explicit from implicit processes.

Two early studies in patients undergoing coronary artery[275] and gynecologic[276] procedures showed evidence of implicit learning using word completion tests. Another early study demonstrating implicit recall in cardiac surgery patients correlated performance with preservation of the midlatency auditory evoked potential, and in particular with the early cortical Pa and Na complexes[277]. Lubke and colleagues[278] later demonstrated implicit memory in both trauma patients (see Chapter 81) and patients undergoing an emergency cesarean section[279] (see Chapter 77) using the process dissociation procedure, and further demonstrated that the degree of processing is related to depth of hypnosis as measured by the bispectral index (see Chapter 50). However, other studies using similar procedures either have failed to show significant implicit priming effects or have been equivocal.[280-283] Synthesis of these disparate results is difficult, and although differences in patient populations and anesthetic regimens may be of relevance, most concern has been raised about the validity of the experimental techniques; errors in the assumptions of the process dissociation procedure might explain false-positive results.[283] Recent investigations evaluating implicit memory processes in children under anesthesia have also offered conflicting results. Phelan and colleagues[284] reported an increased ability to distinguish a primed animal sound from white noise, but other investigations found no evidence of priming.[285,286]

CONCLUSION

Consciousness and memory are among the most fascinating and complex functions of the brain. Further scientific investigation in the twenty-first century is likely to deepen the connections between the fields of anesthesiology and neuroscience. Hopefully, a more precise understanding of anesthetic effects on consciousness and cognition will enrich both fields and, ultimately, improve patient care.

Chapter 14

Sleep Medicine

SEBASTIAN ZAREMBA • NANCY L. CHAMBERLIN • MATTHIAS EIKERMANN

Key Points

- Sleep is a dynamic neuronal and behavioral state that can be characterized using specific electroencephalographic, electrophysiologic, and behavioral findings.
- Associations with sleep are sometimes investigated using questionnaires, actigraphy, or respiratory polygraphy. However, polysomnography, including electroencephalogram, electrooculogram, submental electromyogram, and analysis of breathing, is required to identify and characterize sleep and its disorders.
- Activation of hypothalamic sleep promoting pathways including the ventrolateral preoptic nucleus and the median preoptic nucleus produce the physiological switch from wakefulness to sleep.
- Sleep and anesthesia can look similar from a distance. Although small doses of anesthetics can induce sleep by activating sleep-promoting pathways, immobilization cannot be induced by these circuits.
- Control of breathing is altered during sleep and anesthesia, typically leading to a decreased drive to upper airway dilator and respiratory pump muscles.
- Persistent respiratory depressant effects of anesthetics and neuromuscular blocking drugs increase the risk of postoperative respiratory complications, particularly in patients with obstructive sleep apnea.
- Anesthesia and surgery, as well as treatment in the intensive care unit, alter sleep duration and sleep architecture, which leads to impaired outcome.

Probably the earliest mention of "overpowering sleep" as a metaphor describing what possibly characterizes anesthesia can be found in Genesis 2:21, "And the Eternal God caused an overpowering sleep to fall upon the man and he slept. He took one of his ribs and shut in flesh instead thereof." Although this "overpowering sleep" allegedly occurred by divine intervention and did not represent drug-induced unconsciousness and immobility that characterizes the definition of anesthesia, the basic narrative is an example of antiquarian history that implicates the concept that deep sleep may be a viable condition that allows a surgical procedure to be completed successfully.[1]

In the twenty-first century, an increasing body of knowledge has revealed the common ground between sleep and anesthesia, as well as their fundamental differences in clinical picture and underlying mechanisms.

Sleep is required for survival. Rats deprived of sleep will die within 2 to 3 weeks, a time frame similar to death due to starvation.[2] In humans, sleepiness can be deadly. Approximately 100,000 motor vehicle crashes each year result from drivers who are "asleep at the wheel." In a survey of drivers in New York State, approximately 25% reported they had fallen asleep at the wheel at some time.[3] Perioperative sleep deprivation occurs frequently, particularly in critically ill patients and translates to harmful pathophysiologic conditions and morbidity. Primary sleep disorders result in chronic sleep deficiency, a state of inadequate or mistimed sleep of any mechanism, an underappreciated determinant of disease. Among sleep disorders, sleep apnea has probably the most meaningful consequences for perioperative treatment.[4]

Therefore, high-quality physiologic sleep is a key domain of public health that needs to be considered as we are in the process of evaluating how to translate bench-research discoveries effectively into high-quality perioperative medicine.

DEFINITION OF SLEEP

Sleep is the natural periodic suspension of consciousness during which the powers of the body are restored. A behavioral definition of sleep includes a species-specific posture and behavioral quiescence, as well as elevated

arousal thresholds. However, sleep is much more than an absence of activity. The brain is highly active during sleep, especially during rapid eye movement (REM) sleep, during which atonia, phasic muscle movements (driven by different activation levels in distinct areas of the brain), and vivid dreaming occur. Sleep is not a single phenomenon. At different stages of sleep, brain activities can be as distinct from each other as they are from wakefulness.[5] In humans and other vertebrates (see Evolution) sleep has two major stages: REM sleep and non-REM (NREM) sleep, with each of these further divided into sub-states. Most of sleep time is spent in NREM sleep, which is characterized by relatively low electroencephalogram (EEG) frequencies with higher amplitudes compared with waking EEG frequencies (Figure 14-1). In the transition from wake to NREM sleep, the fast activity of waking disappears (α-θ transition) and then in the deeper stages of NREM large, slow waves (i.e., Δ waves) emerge. Thus, deep NREM sleep is also referred to as *slow-wave sleep*. NREM sleep is associated with waxing and waning muscle tone, as well as decreased body temperature, and heart rate. By contrast, REM sleep is characterized by muscle atonia, loss of slow waves in the EEG (see Figure 14-1), and bursts of rapid eye movements that give this state its name.[6] Other prominent features of REM include marked irregularities of respiration and heart rate, as well as penile and clitoral erection. REM sleep is associated with the high likelihood of vivid dreaming. A distinct property of REM sleep is the operation of a system that suppresses motor activity, which is responsible for baseline atonia and suppression of motor commands that would otherwise result in acting out of dreams, a phenomenon known as *REM sleep behavior disorder*. This REM atonia system is not absolute, as it periodically allows breakthrough muscle activity that comprises REM sleep and twitching of the extremities. Therefore, REM sleep is not homogeneous but can be subdivided into *tonic REM sleep* (i.e., a period with muscle atonia and without eye movements) and *phasic REM sleep*, which is interrupted by short phasic events of eye and other movements.[7] The patterning and amounts of NREM sleep, REM sleep, and wakefulness throughout the night is referred to as *sleep architecture*, and there are many physiologic and pathophysiologic processes that can affect sleep architecture. For example, many antidepressant medications selectively suppress REM sleep. A disease example is narcolepsy, in which individuals often transition directly from wake to REM, whereas normally REM is nearly always entered from an NREM state. To investigate both physiologic and pathologic sleep in humans, different methods for assessments in clinical and research settings have been developed.

HOW TO ASSESS SLEEP

The complexity of signs and symptoms of sleep suggests that different instruments need to be applied to capture all the important elements of sleep.

QUESTIONNAIRES

Several questionnaires are used for the assessment of sleep duration, sleep quality, and the related physiologic and pathophysiologic consequences. Quality of sleep is a frequent target of generic health surveys for measuring patient-reported outcomes, using instruments such as the World Health Organization Quality of Life questionnaire, the Beck Depression Inventory, and Patient Health Questionnaire-9-item. Other questionnaires quantify the consequences of sleep deprivation, specific sleep disorders, or both (Table 14-1). The most commonly used instrument in sleep medicine is probably the Epworth Sleepiness Scale, a short questionnaire to assess symptoms of daytime sleepiness, expressed as intolerance to monotony. The questionnaire asks the subject to rate the probability of falling asleep on a scale of increasing probability from 0 to 3 for eight different situations such as such as watching TV, reading, lying down in the afternoon, and so on.[10] Despite the fact that the Epworth Sleepiness Scale is reliable for detection of daytime sleepiness[8,9,13] in multiple sleep centers, the instrument does not help determine the mechanism of daytime sleepiness.[14,15]

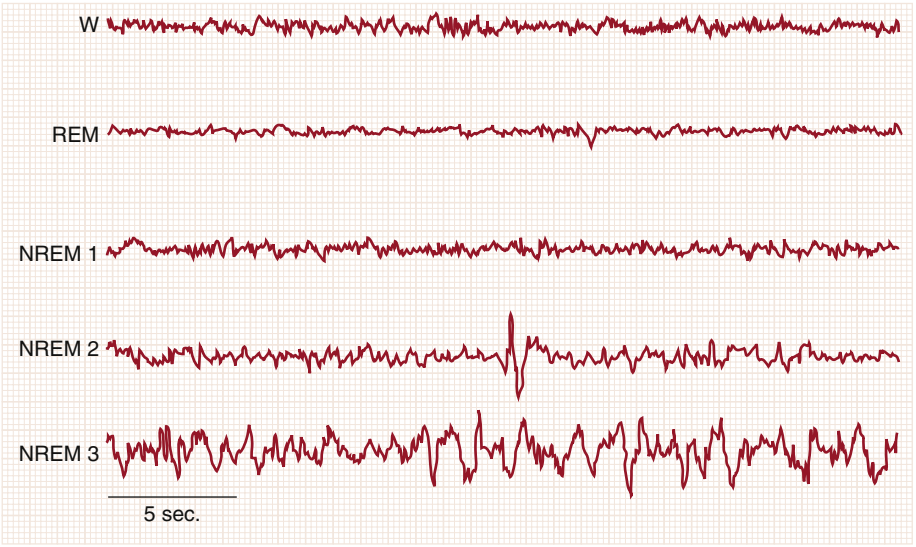

Figure 14-1. Representative electroencephalogram activity seen during different behavioral states. Electroencephalogram recordings of one patient during wakefulness (eyes closed; [W]), rapid eye movement sleep [REM] (B), and non-REM [NREM] sleep stages 1 to 3.

Other clinically useful questionnaires are focused on the detection of signs and symptoms of sleep disorders (e.g., Pittsburgh Sleep Quality Index[8,9,13]; the STOP-Bang). Questionnaires for specific subpopulations are available (e.g., patients with gastroesophageal reflux, Parkinson disease[16]), which is important because the prevalence of sleep pathologies typically varies in a wide range across populations.

An effective process for clinical assessment of sleep-related diseases might be a stepwise assessment using a screening tool first (e.g., Epworth Sleepiness Scale), followed by a more specific questionnaire that helps to identify individual mechanisms or consequences of sleepiness.

A special form of sleep questionnaires are sleep diaries, or sleep logs, and "morningness-eveningness" questionnaires. In these questionnaires, daily sleep habits are documented by the patient before going to sleep in the evening and after waking in the morning. This documentation includes factors such as sleep time, sleep duration, number of nocturnal awakenings, and subjective sleep quality, with the advantage of being less prone to recall bias.[17]

Although questionnaires allow a quick and easy screening for daytime symptoms of sleep disturbances, they cannot be used to quantify sleep architecture. Furthermore, subjective and objective measurements of sleep time, such as actigraphy, do not agree consistently well with the results of subjective measurements,[18] for which the patient is the major source of measurement variability. Subjective methods of assessing sleep are influenced by the spectrum of disease within a tested group, actual clinical change over time, the testing conditions, and recall bias.[17] Although a questionnaire cannot replace a medical history or objective assessment for sleep disorders, sleep questionnaires are important tools for measuring health improvement or decline, predicting medical expenses, assessing treatment effects, or comparing disease burden across populations.

TABLE 14-1 SLEEP QUESTIONNAIRES: QUESTIONNAIRES COMMONLY USED FOR CLINICAL AND RESEARCH PURPOSES AND THEIR FOCUS

Questionnaire	Focus	References
*Pittsburgh Sleep Quality Index (PSQI)**	Sleep and sleep disorders	8, 9, 10
Sleep Quality Scale (SQS)	Sleep quality	11
Functional Outcome of Sleep Questionnaire (FOSQ)	Impact of daytime sleepiness on daily living	12
Pediatric Sleep Questionnaire	Sleep and SDB in children	13
Child Sleep Habits Questionnaire (CSHQ)	Sleep	14
Epworth Sleepiness Scale (ESS)	Daytime sleepiness	8, 9, 15
Sleep Diaries / Sleep Logs	Sleeping times, sleep duration	16
Morningness-Eveningness Questionnaire	Sleeping times, sleep duration, circadian rhythm	17
Loughborough Occupational Impact of Sleep Scale (LOISS)	Sleep quality	18
Insomnia Sleep Questionnaire (ISQ)	Insomnia	19
Berlin Questionnaire	SDB in surgical patients	20
STOP/STOP-Bang Questionnaire	Obstructive sleep apnea	21, 22
Brief Insomnia Questionnaire (BIQ),	Insomnia	23
International Restless Legs Syndrome Study Group Rating Scale (IRLS)	Restless legs syndrome	24, 25
Clinical Global Impression (CGI) Scale	Restless legs syndrome	25

*Recommended questionnaires are italicized.
SDB, Sleep-disordered breathing; *STOP,* snoring, tiredness, observed apneas, and high blood pressure.

ACTIGRAPHY

Actigraphy has been used to study sleep-wake patterns for more than 20 years. This method detects motion of the wrist with linear accelerometers in single or multiple axes. Based on movement-derived data combined with calibration data on file, predictions of the time spent during sleep and wakefulness can be made, and even assumptions on sleep staging are made. Actigraphy can be used conveniently in a patient's home for several nights, weeks, or longer. Actigraphy has a high reliability and validity for detecting transitions from wakefulness to sleep,[19] but some studies have shown a low specificity for the diagnosis of wakefulness when compared with the golden standard polysomnography,[20-22] especially in patients with high levels of sleep fragmentation.[19,23] In the clinical setting, actigraphy is reliable for evaluating sleep patterns in patients with insomnia, for diagnosis of circadian rhythm disorders (including shift work), and in evaluating sleep in individuals who are less likely to tolerate polysomnography, such as infants and demented elderly. In addition, actigraphy allows for convenient follow-up measurements to evaluate the effects of treatments designed to improve sleep.[24]

RESPIRATORY POLYGRAPHY

Home respiratory polygraphy can be a cost-effective alternative to polysomnography (PSG) for the diagnosis of sleep apnea-hypopnea syndrome. Respiratory polygraphy (RP) usually calculates airflow through nasal pressure changes taken via nasal cannula. Thoracic and abdominal movements are measured by piezoelectric bands, which also measure body position and blood oxygen saturation by pulse oximetry. Using these parameters, RP can identify respiratory events (i.e., apnea and hypopnea), and categorize their mechanisms into obstructive versus central. Furthermore, similar to actigraphy, RP provides some analysis of sleep duration and time spent awake, using its body position sensor. However, the quality of the latter can be more precisely evaluated by a combination of sleep diary and actigraphy with an EEG required to make final determinations as to whether a subject was awake or sleeping (Table 14-2).

TABLE 14-2 **PROS AND CONS OF DIFFERENT METHODS OF SLEEP EVALUATION**

Method	Pros	Cons	Recommendation
Sleep questionnaire	Low costs Good compliance Easy to use	Recall bias Limited reliability in some populations Limited validity	Should be combined with interview
Sleep diary	Less recall bias Easy to administer Low costs Documentation of daily variability	Lower compliance compared with other questionnaires Biased by daily mood and expectations on sleep	Should be combined with other measurement of sleet duration (e.g., actigraphy)
Actigraphy	Provides objective information about daily variability and sleep duration Provide information on sleep habits at home Not influenced by patient expectations, recall bias, or memory impairments Lower costs than laboratory polysomnography	Limited assessment of sleep stages and sleep onset latency Higher cost than questionnaires	Should be combined with other measurement of sleep duration (e.g., sleep diary)
Polygraphy	Lower costs than laboratory polysomnography Objective assessment of respiratory events Provide information on sleep habits at home	Limited assessment of sleep Higher cost than questionnaires Limited assessment of sleep disorders other than sleep-disordered breathing	Should be accompanied by questionnaires and clinical interview
Laboratory polysomnography	Objective assessment of sleep, sleep stages and sleep disorders	High costs First-night effect Limited capacity High costs No information about sleep habits at home	Should be last step in sleep evaluation with previous questionnaires and ambulatory screening (e.g., polygraphy)
Out-of-center polysomnography	Objective assessment of sleep, sleep stages and sleep disorders Less first-night effect Lower costs than laboratory polysomnography Can provide information about sleep habits at home	Limited observation may lead to decreased recoding quality	Good patient education mandatory If possible, surveillance recording preferred

POLYSOMNOGRAPHY

Polysomnography is the only method that can precisely determine the actual sleep stage and is a diagnostic reference tool (i.e., gold standard) that is required for the diagnosis of several sleep disorders.[25] PSG measurements include EEG, electrooculography for the measurement of eye movements, and at least electromyographic measurement of muscle activity of the chin.[26] These three measurements are typically supplemented by further channels for the detection of sleep disordered breathing such as a nasal sensor to detect apneas and hypopneas, oximetry, inductance plethysmography for respiratory effort of the chest and abdomen, and a body position sensor and leg electromyogram[27] to identify periodic limb movement syndrome or REM sleep behavior disorder, respectively.[28] A sample of such a typical PSG recording is shown in Figure 14-2. More than 40 years ago, Rechtschaffen and Kales[26] standardized the method of scoring polysomnographic recordings—the R&K criteria. Since then, major innovations in technology have transformed the science and clinical practice of sleep medicine. The new criteria of the American Academy of Sleep Medicine (AASM)[27] capture the full potential of innovations resulting from computerization of data, including automation of sleep scoring, recognition of disorders that occur during sleep, and integration with other procedures, such as positive airway pressure titration. Nevertheless, the R&K criteria are still sufficient for clinical and research purposes and consequently are used in sleep centers around the world.

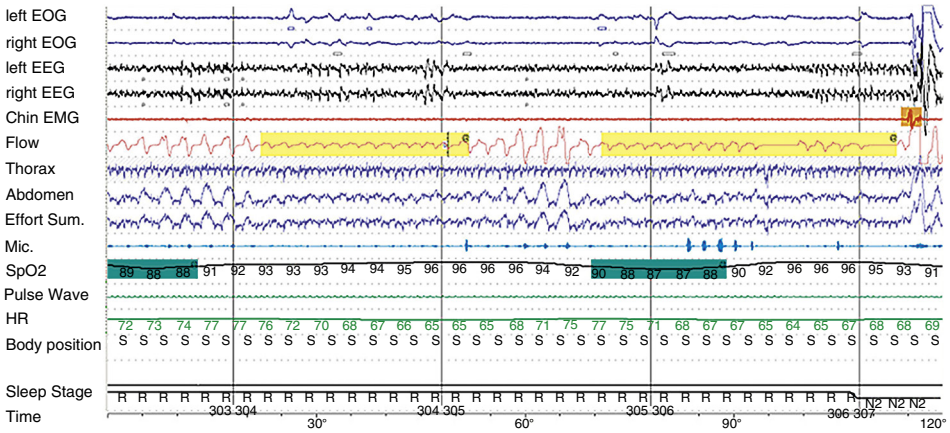

Figure 14-2. Polysomnographic recording. Left and right electrooculogram (EOG), two electroencephalogram (EEG) channels, and mental electromyogram (Chin EMG) allow scoring of sleep stage (REM sleep [R] with typical eye movements in the electrooculogram channels). Additional channels (e.g., respiratory flow [Flow], respiratory effort of thorax [Thorax] and abdomen [Abdomen], microphone [Mic.] oxygen saturation [SpO_2]) allow diagnosis of sleep disordered breathing. In this patient, apneas *(yellow boxes)* led to oxygen desaturation *(blue boxes)* and finally to arousal *(far right, brown box).*

Sleep Laboratory Testing

For several decades, PSG was performed only within a sleep laboratory, but an increasing number of devices are now available offering the possibility of recording PSG in almost every environment, such as the patient's home, within the patient's hospital or nursing home room, and even within the recovery room. A current standard for the measurement of sleep is the attended sleep laboratory PSG with a trained technician.[27,29-32] The study is analyzed by a clinician trained in sleep medicine following the published guidelines by Rechtschaffen and Kales[33] or the newer guidelines published by the AASM.[27] Nevertheless, it is evident that there are many more patients potentially suffering from obstructive sleep apnea (OSA) than are being seen at sleep centers. A contributing factor could be that the waiting time for an in-laboratory PSG is several weeks for patients in the United States[34] and illustrates the need for other diagnostic procedures that are comparably sensitive and specific to laboratory PSG testing. Other limitations, such as the high cost and requirement of an overnight stay, can present socioeconomic challenges that affect the accessibility of this method. In addition, the in-center PSG provides only a momentary view of the patient's sleep, and the measurements themselves can impair the patient's sleep (the so-called first-night effect). Thus, in-center PSG does not provide information about the patient's sleep at home, and multiple repeated measurements to tailor treatment over time are challenging or even impossible from a logistic and healthcare economics perspective.

Out-of-Center Testing

Given the disadvantages of laboratory PSG, portable out-of-center PSG devices are a reasonable, reliable, and effective method for diagnosing OSA[35] that are not inferior to PSG recording performed within a sleep laboratory.[36-39] Guidelines published in 2007 by Collop and associates[35] for the Portable Monitoring Task Force of the AASM, as well as a recent review providing a score for the classification of portable devices for outpatient PSG,[40] support the reliability of such devices in subjects for clinical and research purposes and indicates a comparable quality of PSG data.

Scoring of Sleep and Sleep Disordered Breathing

Currently two different guidelines for the staging of sleep and sleep-related events are used.

Rechtschaffen and Kales Criteria. One of the first characterizations and scoring guidelines for the different sleep stages was published in 1968 by Rechtschaffen and Kales[26] and is still being used for clinical and research purposes in sleep medicine (Table 14-3). NREM sleep stage 1 (S1) is characterized by a low-voltage EEG of mixed frequencies (2 to 7 Hz) without REM sleep (see Figure 14-1, *C*). In humans, S1 usually occupies 1 to 7 minutes of sleep time, mostly during transition from wakefulness to sleep or after movements. Vertex sharp waves (amplitudes up to 200 μV) occasionally appear, predominantly during the late phase of S1 sleep. Additional sleep spindles (rhythmic discharges with a frequency of 12 to 14 Hz) or K-complexes, as well as slow waves with high amplitudes, characterize NREM sleep stage 2 (S2). S2 is the sleep stage in which a healthy person spends the most time of physiologic nighttime sleep. K-complexes are defined as a characteristic electric activity of more than 0.5 seconds duration comprised of a negative sharp wave immediately followed by a positive wave. K-complexes can occur spontaneously or as the result of external stimuli, and the characteristic EEG finding can be followed by slow-rolling eye movements. NREM sleep stages 3 and 4 are characterized by slow waves (≤2 Hz) with high amplitudes (>75 μV). During NREM sleep stage 3 (S3), slow waves occupy 20% to 50% of time. Amounts of more than 50% of slow waves are seen during NREM sleep stage 4.[41]

AASM Criteria. New guidelines of the AASM for sleep-stage scoring were published in 2007.[27] In contrast to the

TABLE 14-3 POLYSOMNOGRAPHIC CHARACTERISTIC OF THE DIFFERENT BEHAVIORAL STATES

	EEG and EOG Characteristics	R & K	AASM
Wakefulness	Alpha rhythm (8-13 Hz) present in more than 50% of an epoch	W	W
Non-REM sleep stage 1	Lower amplitudes and activity in range of 4–7 Hz (vertex sharp waves,* slow eye movements*)	S1	N1
Non-REM sleep stage 2	EEG of sleep stage 1 with additional a sleep spindles and K-complexes; slow waves not fulfilling the criteria for sleep stage 3	S2	N2
Non-REM slow wave sleep	20% to 50% of slow wave activity (0.5-2 Hz)	S3	N3
	>50 % of slow wave activity	S4	
REM sleep	EEG of low amplitude and mixed frequencies, low chin electromyogram activity, rapid eye movements	R	R
Movement time	High amplitude activity in electromyogram channels	MT	NS

AASM, American Academy of Sleep Medicine criteria; *EEG,* electroencephalography; *EOG,* electrooculogram; *MT,* movement; *N1,* stage 1 AASM; *N2,* stage 2 AASM; *N3,* Stage 3 AASM; *NS,* not scored; *R&K,* Rechtschaffen and Kales criteria; *REM,* rapid eye movement; *S1,* stage 1 R&K; *S2,* stage 2 R&K; *S3,* stage 3 R&K; *S4,* stage 4 R&K; *W,* awake.
*Not necessary but may be present
Electrophysiologic criteria used for sleep stage scoring according to R&K criteria,[26] and the AASM criteria.[27]

R&K criteria, EEG recording following the AASM guidelines is taken from three instead of two different EEG channels[42] to account for possible topographic differences in most sleep scoring features in the EEG.[42-44]

The main differences between R&K and AASM scoring criteria are summarized in Table 14-3. Importantly, the two NREM slow-wave sleep stages 3 and 4 are lumped and defined as slow-wave sleep stage N3. Furthermore, new AASM guidelines also include new standardized scoring rules for respiratory events during sleep,[27] as follows:

1. Apnea with drop in respiratory flow of 90% or more from baseline for at least 10 seconds, whereas a minimum of 90% of the event duration has to meet the criteria of respiratory flow reduction, and
2. Hypopneas—the signal of respiratory flow measurement drops at least 30%, whereas oxygen saturation (SpO_2) decreases by 4% or more compared to preevent baseline for at least 90% of the duration (minimum of 10 seconds).

Alternatively, hypoxia can also be defined as a decrease in respiratory flow measurement of at least 40% with a decrease in SpO_2 of only 3%.

3. *Respiratory event-related arousal* is defined as a sequence of breaths not meeting the criteria for apnea or hypopnea lasting at least 10 seconds characterized by increasing respiratory effort or flattering of the nasal pressure waveform leading to an arousal from sleep.[27]
4. *Hypoventilations* are defined as an increase of 10% or more in CO_2 pressure ($PaCO_2$).
