  - routine protein restriction is no longer recommended given patients generally have concurrent malnutrition and muscle wasting; however, vegetable protein (as opposed to animal protein) may help reduce risk of encephalopathy
  - lactulose or lactitol: titrated to achieve 2-3 soft stools/d
    - prevents diffusion of  $\text{NH}_3$  (ammonia) from the colon into blood by lowering pH and forming non-diffusible  $\text{NH}_4^+$  (ammonium)
    - serves as a substrate for incorporation of ammonia by bacteria, promotes growth in bowel lumen of bacteria which produce minimal ammonia
    - also acts as a laxative to eliminate nitrogen-producing bacteria from colon
- oral rifaximin for both acute treatment and maintenance therapy has high level evidence for efficacy
- best acute treatment in patients who cannot take medication orally is lactulose or lactitol enemas

### Precipitating Factors for Hepatic Encephalopathy

**HEPATICS**  
 Hemorrhage in GI tract/Hypokalemia  
 Excess dietary protein  
 Paracentesis  
 Alkalosis/Anemia  
 Trauma  
 Infection  
 Colon surgery  
 Sedatives

### A Randomized, Double-Blind, Controlled Trial Comparing Rifaximin plus Lactulose with Lactulose Alone in Treatment of Overt Hepatic Encephalopathy

American J Gastroenterol 2013;108:1458-1463  
**Study:** Prospective double-blind RCT.  
**Purpose:** Efficacy and safety of rifaximin plus lactulose vs. lactulose alone for treatment of overt HE.  
**Results:** Of the patients, 48 (76%) in group A (lactulose plus rifaximin 1200 mg/d, n=63) compared with 29 (50.8%) in group B (lactulose plus placebo, n=57) had complete reversal of HE (P<0.004). There was a significant decrease in mortality after treatment with lactulose plus rifaximin vs. lactulose plus placebo (23.8% vs. 49.1%, P=0.05). There were significantly more deaths in group B because of sepsis (group A vs. group B: 7:17, P=0.01), whereas there were no differences because of GI bleed (group A vs. group B: 4:4, P=non-significant (NS)) and HRS (group A vs. group B: 4:7, P=NS). Patients in the lactulose plus rifaximin group had shorter hospital stay [5.8±3.4 vs. 8.2±4.6 d, P=0.001].  
**Conclusion:** Combination of lactulose plus rifaximin is more effective than lactulose alone in the treatment of overt HE.

## Ascites

### Definition

- accumulation of excess fluid in the peritoneal cavity

### Etiology

**Table 23. Serum-Ascites Albumin Gradient in the Evaluation of Ascites**

Serum [Alb] – Ascitic [Alb] >11 g/L (1.1 g/dL) Portal Hypertension Related	Serum [Alb] – Ascitic [Alb] <11 g/L (1.1 g/dL) Non-Portal Hypertension Related
Cirrhosis/severe hepatitis	Peritoneal carcinomatosis
Chronic hepatic congestion (right heart failure, Budd-Chiari)	Peritoneal TB
Massive liver metastases	Pancreatic disease
Portal vein thrombosis	Serositis
Idiopathic portal fibrosis	Nephrotic syndrome*

\* In nephrotic syndrome: decreased serum [Alb] to begin with, therefore gradient not helpful

### Pathophysiology

- key factor in pathogenesis is increased sodium (and water) retention by the kidney for reasons not fully understood. Theories include:
  - underfill hypothesis
  - overfill hypothesis
  - peripheral arterial vasodilation theory (most popular): as portal hypertension develops in cirrhosis, production of local mediators such as nitric oxide leads to splanchnic arterial vasodilation, ultimately pulling blood away from the systemic circulation and resulting in reduced effective arterial volume, which causes compensatory sodium and fluid retention by the kidneys (i.e. circulatory volume is increased, as per the overfill hypothesis, but effective volume is decreased as per the underfill hypothesis)

### Diagnosis

- abdominal U/S
- physical exam (clinically detectable when >500 mL)
  - bulging flanks, flank dullness, shifting dullness, fluid-wave test positive
  - most sensitive symptom: ankle swelling

### Investigations

- diagnostic paracentesis
  - 1st aliquot: cell count and differential
  - 2nd aliquot: chemistry (especially albumin, but also total protein; amylase if pancreatitis; TG and chylomicrons if turbid and suspect chylous ascites)
  - 3rd aliquot: C&S, Gram stain
  - 4th aliquot: cytology (usually positive in peritoneal carcinomatosis)

### Treatment

- diuretic-sensitive ascites
  - Na<sup>+</sup> restriction (daily sodium intake <2 g)
  - no need for fluid restriction unless significant hyponatremia (e.g. Na<sup>+</sup> <120-125 mmol/L)
  - diuretics: spironolactone, furosemide
  - aim for weight loss 0.5-1 kg/d, more if concomitant peripheral edema (which is mobilized quicker than ascitic fluid); overly rapid weight loss increases risk of renal failure
  - if target weight loss is not achieved and there are no complications, increase dose to achieve target while monitoring for complications
- refractory ascites (diuretics are inadequate or not tolerated)
  - therapeutic paracentesis with IV albumin
  - TIPS in an appropriate patient (no contraindications) with potential transplant-free survival advantage
  - liver transplantation should be considered in every case, since development of ascites in patients with cirrhosis is associated with a high 2 yr mortality

### Complication: Primary/Spontaneous Bacterial Peritonitis

- primary/SBP
  - complicates ascites, but does not cause it (occurs in 10% of cirrhotic ascites); higher risk in patients with GI bleed
  - 1/3 of patients are asymptomatic, thus do not hesitate to do a diagnostic paracentesis in ascites even if no clinical indication of infection
  - fever, chills, abdominal pain, ileus, hypotension, worsening encephalopathy, acute kidney injury
  - Gram-negatives compose 70% of pathogens: *E. coli* (most common), *Streptococcus*, *Klebsiella*

#### Underfill Hypothesis

First step in ascites formation is increased portal pressure and low oncotic pressure (e.g. low serum albumin) driving water out of the splanchnic portal circulation into abdominal cavity; the resulting decreased circulating volume causes secondary sodium retention by the kidney

#### Overfill Hypothesis

Cirrhosis directly causes increased sodium retention by the kidney in the absence of hypovolemia and ascites arises secondarily

#### Serum Ascites Albumin Gradient (SAAG) = serum albumin – ascites albumin

- >11 g/L portal HTN
- ascitic fluid total protein >25 g/L, suggests cardiac portal hypertension
- ascitic fluid total protein <25 g/L, suggests cirrhosis portal hypertension
- <11 g/L unrelated to portal HTN

- diagnosis
  - absolute neutrophil count in peritoneal fluid  $>0.25 \times 10^9$  cells/L (250 cells/mm<sup>3</sup>)
  - Gram stain positive in only 10-50% of patients
  - culture positive in  $<80\%$  of patients (not needed for diagnosis)
- prophylaxis: consider in patients with:
  - cirrhotic with GI bleed: ceftriaxone IV daily or norfloxacin BID x 7 d
  - previous episode of SBP: long-term prophylaxis with daily norfloxacin or TMP-SMX
- treatment
  - IV ABx (cefotaxime 2 g IV q8h or ceftriaxone 2 g IV daily is the treatment of choice for 5 d; modify if response inadequate or culture shows resistant organisms)
  - IV albumin (1.5 g/kg at time of diagnosis and 1 g/kg on day 3) decreases mortality by lowering risk of acute renal failure

## Biliary Tract

### Jaundice

- see Table 2, G5 and Figures 15 and 16

#### Definition

- yellowing of the skin, sclera, and/or mucous membranes due to abnormal deposition of pigmented bilirubin

#### Signs and Symptoms

- dark urine, pale stools: suggests that bilirubin elevation is from direct fraction
- pruritus: suggests chronic disease, cholestasis
- abdominal pain: suggests biliary tract obstruction from stone or pancreatic/biliary tumour (obstructive jaundice)
- painless jaundice in the elderly: think of pancreatic cancer
- kernicterus: rarely seen in adults due to maturation of blood brain barrier

#### Investigations

- blood work: CBC, bilirubin (direct and total), liver enzymes (AST, ALT, ALP, GGT), liver function tests (INR/PT, PTT, albumin),  $\pm$  amylase/lipase
- U/S or CT for evidence of bile duct obstruction (e.g. bile duct dilation)
- more detailed evaluation of bile duct  $\pm$  surrounding structures like pancreas:
  - MRCP: non-invasive
  - EUS: sensitive for stones and pancreatic tumours
  - ERCP: invasive, most accurate, allows for therapeutic intervention
  - PTC: if ERCP fails (endoscopic access not possible)

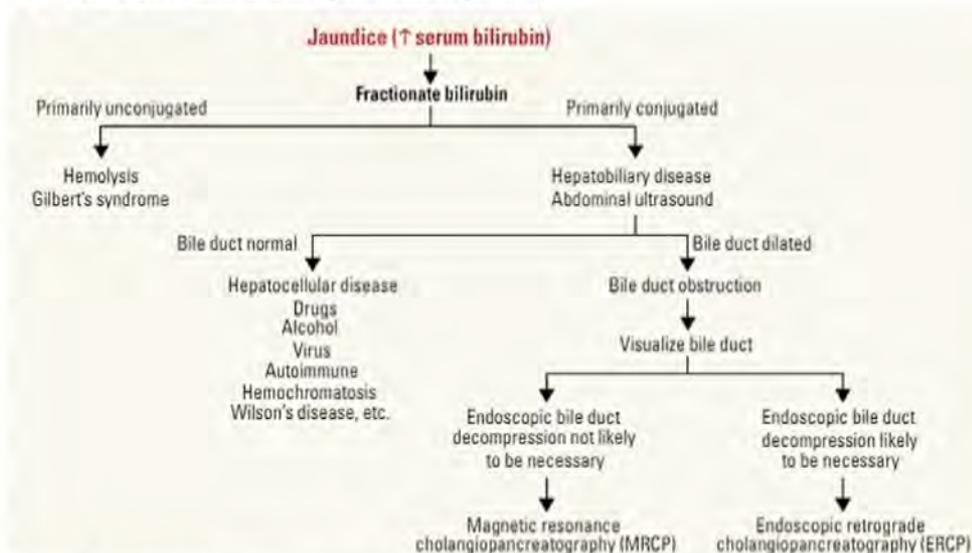

Figure 15. Approach to jaundice

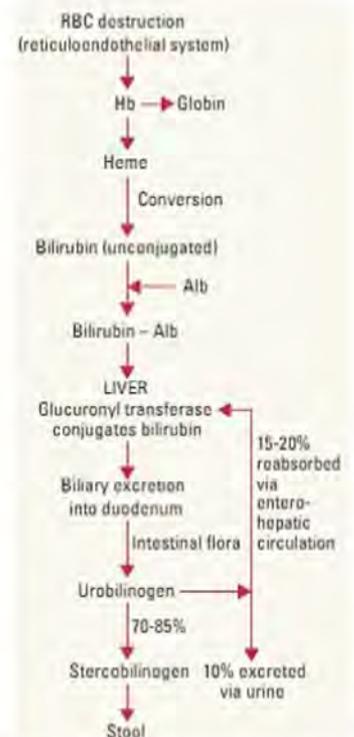

Figure 16. Production and excretion of bilirubin

## Gilbert's Syndrome

### Definition

- hereditary hyperbilirubinemia due to a deficiency of glucuronyl transferase characterized by repeat episodes of mild asymptomatic jaundice

### Etiology/Epidemiology

- some patients have decreased hepatobiliary uptake
- affects 7% of population, especially males
- autosomal dominant, 70% due to a mutation in the UGT gene

### Clinical Features

- presents in teens-20s, often an incidental finding
- only manifestation is intermittent jaundice with increased serum unconjugated bilirubin developing most characteristically while fasting, or at times of acute illness; no other clinical implications

### Treatment

- none indicated (entirely benign)

**Gilbert's Syndrome vs. Crigler-Najjar Syndrome**  
**Gilbert's Syndrome:** mild decrease in glucuronyltransferase activity  
**Crigler-Najjar Syndrome:** complete deficiency of glucuronyltransferase

## Primary Sclerosing Cholangitis

### Definition

- inflammation, fibrosis, and stricturing of biliary tree (intra- and/or extrahepatic bile ducts) from scarring

### Etiology

- primary/idiopathic (most common)
  - associated with IBD, more commonly UC, in up to 70-80% of patients (usually male) with PSC
- secondary (less common)
  - long-term choledocholithiasis
  - cholangiocarcinoma
  - surgical/traumatic injury (iatrogenic)
  - contiguous inflammatory process
  - post-ERCP
  - associated with HIV/AIDS ("HIV cholangiopathy")
  - IgG4-related disease
  - critical illness

### Signs and Symptoms

- often insidious, may present with fatigue and pruritus
- may present with signs of episodic bacterial cholangitis secondary to biliary obstruction
- may present with jaundice, hepatomegaly, splenomegaly, excoriations secondary to pruritus

### Investigations

- increased ALP (hallmark), less often increased bilirubin
- mildly increased AST, usually <300 U/L
- p-ANCA (30-80%), elevated IgM (40-50%)
- MRCP and ERCP shows narrowing and dilatations of bile ducts that may result in "beading," both intrahepatic and extrahepatic bile ducts
  - if intrahepatic narrowing only, do anti-mitochondrial antibody to rule out PBC
- consider liver biopsy if suspecting small duct variant

### Complications

- repeated bouts of cholangitis may lead to complete biliary obstruction with resultant secondary biliary cirrhosis and hepatic failure
- increased incidence of cholangiocarcinoma (10-15%); difficult to diagnose and treat
- increased incidence of colon cancer in those with concurrent IBD

### Treatment

- image bile duct (MRCP) at least annually for early detection of cholangiocarcinoma (controversial)
- endoscopic sphincterotomy, biliary stent in selected cases of dominant common bile duct stricture
- ABx for cholangitis
- suppurative cholangitis requires emergency drainage of pus in common bile duct
- liver transplantation appears to be the best treatment for advanced sclerosing cholangitis (>90% 1 yr survival; mean follow-up time from diagnosis to need for transplant is 10 yr)
- ursodiol: previously recommended, but studies suggest that it increases mortality if taken in high doses

### Prognosis

- unfavourable regardless of treatment
- mean survival after diagnosis remains 4-10 yr

## Primary Biliary Cholangitis (formerly Primary Biliary Cirrhosis)

### Definition

- chronic inflammation and fibrous obliteration of intrahepatic bile ductules

### Etiology/Epidemiology

- likely autoimmune (associated with Sjögren's syndrome, scleroderma, CREST syndrome (calcinosis, Raynaud's phenomenon, esophageal dysfunction, sclerodactyly, telangiectasia), RA, thyroiditis)
- affects mainly middle-aged women (M:F=1:9)

### Signs and Symptoms

- often asymptomatic
- initial symptoms: pruritus, fatigue
- chronic: jaundice and melanosis (darkening skin) and other signs of cholestasis
- end-stage: hepatocellular failure, portal HTN, ascites
- high incidence of osteoporosis

### Investigations

- increased ALP, GGT; bilirubin rises in later stage
- positive anti-mitochondrial antibodies (AMA; 95% specificity and sensitivity)
- elevated IgM
- increased serum cholesterol (mild increase in LDL, larger increase in HDL)
  - may have: xanthelasmas, xanthomas
- liver biopsy confirms diagnosis and stages severity
- normal bile duct on MRCP rules out bile duct obstruction which can mimic PBC
- "overlap" syndromes with autoimmune cholangitis, autoimmune hepatitis, sclerosing cholangitis are possible

### Treatment

- drugs that treat the underlying disease:
  - ursodiol (usual first line treatment)
  - obeticholic acid (particularly if inadequate response to ursodiol)
- cholestyramine (for pruritus and hypercholesterolemia)
- calcium and vitamin D for low bone density; bisphosphonates if osteoporosis severe
- repeated monitoring of LFTs (q 3-6 mo), TSH (annually), and BMD (q 2-4 yr)
- ensure vaccines are updated (notably HAV & HBV); avoid EtOH, smoking
- liver transplant if disease severe, progressive

### Prognosis

- can be fatal, although not all asymptomatic patients show progression

**Table 24. Primary Sclerosing Cholangitis vs. Primary Biliary Cholangitis**

	Primary Sclerosing Cholangitis	Primary Biliary Cholangitis
Predominant Gender	Male	Female
Associated Comorbidities	IBD, especially UC	Other autoimmune disorders (Sjögren's, CREST, RA)
Affected Ducts	Both intra- and extrahepatic	Intrahepatic only
Investigations	ERCP/MRCP (narrowing and dilatations of ducts visualized)	Anti-mitochondrial antibodies, IgM, increased lipids, liver biopsy (absence of duct narrowing on ERCP)

## Biliary Colic, Cholecystitis

- see [General Surgery and Thoracic Surgery, GS56](#)

## Ascending Cholangitis

- see [General Surgery and Thoracic Surgery, Acute Cholangitis, GS58](#)

### Definition

- infection of the biliary tree

### Etiology

- stasis in the biliary tract due to obstruction or stricture
- bacteria
  - E. coli*, *Klebsiella*, *Enterobacter*, *Enterococcus*
  - coinfection with *Bacteroides* and *Clostridia* can occur

### Signs and Symptoms

- Charcot's triad: fever, RUQ pain, jaundice (50-70%)
- Reynolds' pentad in patients with suppurative cholangitis: fever, RUQ pain, jaundice, hypotension, altered mental status

#### MRCP/ERCP

- Absence of narrowing in PBC
- Narrowing of intra- and extrahepatic ducts in PSC

#### Endoscopic or Surgical Step-Up Approach for Infected Necrotising Pancreatitis: A Multicentre Randomised Trial

Lancet 2018;391:51-58

**Purpose:** To compare the outcomes of endoscopic vs. the standard surgical removal of infected necrotising pancreatitis.

**Study:** RCT.

**Population:** 98 patients with pancreatic or extrapancreatic necrosis were randomized to either endoscopic removal or surgical removal of the infected necrosis.

**Outcomes:** Major complications and death at 6 mo follow-up.

**Results:** The primary endpoints of mortality and major complications were the same in the two groups, but the endoscopic group had shortened hospital stays and less pancreatic fistulae.

**Conclusions:** Three points are worth emphasizing: (1) necrotising pancreatitis is a severe disease: about 15% in each group died; (2) it is best to wait at least 4 wk after the necrosis has developed to allow it to be encapsulated; (3) the management of severe acute pancreatitis should include experts skilled in therapeutic endoscopy.

#### Charcot's Triad

- RUQ pain
- Fever
- Jaundice

#### Reynolds' Pentad

- Charcot's triad
- Hypotension
- Altered mental status

**Investigations**

- evidence of systemic inflammation (increased WBC, increased CRP)
- usually increased ALP and bilirubin, ALT variably elevated (can be markedly increased if acute obstruction from common bile duct (CBD) stone)
- blood culture
- abdominal U/S: CBD dilation, stricture, stones

**Treatment**

- most important is drainage, ideally via ERCP; perform by percutaneous biliary or by surgical routes (least often) if ERCP not possible
- antibiotic therapy: broad spectrum to cover Gram-negatives, Enterococcus, and anaerobes (especially if CBD manipulation); no clear consensus on antibiotic choice but consider:
  - ampicillin + sulbactam or piperacillin/tazobactam
  - metronidazole + 3rd generation cephalosporin (e.g. ceftriaxone) or fluoroquinolone (e.g. ciprofloxacin or levofloxacin)
  - carbapenem monotherapy (e.g. imipenem or meropenem)

**Prognosis**

- good with effective drainage and ABx in mild to moderate cases
- high mortality (~50%) in patients with Reynolds' pentad

## Pancreas

### Pancreatic Enzyme Abnormalities

**Causes of Increased Serum Amylase**

- pancreatic disease
  - pancreatitis, pancreatic duct obstruction (e.g. ampullary cancer), pseudocyst, abscess, ascites, trauma, cancer
- non-pancreatic abdominal disease
  - biliary tract disease, bowel obstruction/ischemia, perforated or penetrating ulcer, ruptured ectopic pregnancy, aneurysm, chronic liver disease, peritonitis
- non-abdominal disease
  - cancer (lung, ovary, esophagus, etc.), salivary gland lesions, bulimia, renal transplant/insufficiency, burns, ketoacidosis
  - macroamylasemia

**Causes of Increased Serum Lipase**

- pancreatic disease: same as above
- non-pancreatic abdominal disease (mild elevations only): same as above
- non-abdominal disease
  - macrolipasemia
  - renal failure

### Acute Pancreatitis

**Etiology (most common are alcohol and gallstones)**

- Idiopathic: thought to be hypertensive sphincter or microlithiasis
- Gallstones (45%)
- Ethanol (35%)
- Tumours: pancreas, ampulla, choledochocoele
- Scorpion stings
- Microbiological
  - bacterial: *Mycoplasma*, *Campylobacter*, TB, *M. avium intracellulare*, *Legionella*, *Leptospira*
  - viral: mumps, rubella, varicella, viral hepatitis, CMV, EBV, HIV, Coxsackie virus, echovirus, adenovirus
  - parasites: ascariasis, clonorchiasis, echinococcosis
- Autoimmune: IgG4-related disease, SLE, *polyarteritis nodosa* (PAN), CD
- Surgery/trauma
  - manipulation of sphincter of Oddi (e.g. ERCP), post-cardiac surgery, blunt trauma to abdomen, penetrating peptic ulcer
- Hyperlipidemia (TG >11.3 mmol/L; >1000 mg/dL), hypercalcemia, hypothermia
- Emboli or ischemia
- Drugs/toxins
  - azathioprine, mercaptopurine, furosemide, estrogens, methyldopa, H<sub>2</sub>-blockers, valproic acid, ABx, acetaminophen, salicylates, methanol, organophosphates, steroids (controversial)

**Pancreatic Enzymes**

TALC  
 Trypsin  
 Amylase  
 Lipase  
 Chymotrypsin

When serum amylase >5x normal, the cause is almost always pancreatitis or renal disease

When thinking about the causes of acute pancreatitis remember: **I GET SMASHED**, but vast majority due to gallstones or ethanol

### Pathophysiology

- activation of proteolytic enzymes within pancreatic cells, starting with trypsin, leading to local and systemic inflammatory response
- in gallstone pancreatitis, this is due to mechanical obstruction of the pancreatic duct by stones
- in ethanol-related pancreatitis, pathogenesis is unknown
- in rare genetic diseases, mutations prevent the physiological breakdown of trypsin required normally to stop proteolysis (e.g. mutant trypsin in hereditary pancreatitis or mutation in *SPINK1* gene, which normally inhibits activated trypsin); may be model for ethanol-related pancreatitis

### Pathology

- mild (interstitial)
  - peri-pancreatic fat necrosis
  - interstitial edema
- severe (necrotic)
  - extensive peri-pancreatic and intra-pancreatic fat necrosis
  - parenchymal necrosis and hemorrhage → infection in 60%
  - release of toxic factors into systemic circulation and peritoneal space (causes multi-organ failure)
- severity of clinical features may not always correlate with pathology
- 3 phases
  - local inflammation + necrosis → hypovolemia
  - systemic inflammation in multiple organs, especially in lungs, usually after IV fluids given → pulmonary edema
  - local complications >2 wk after presentation → fluid collection (pseudocyst) or tissue collection (necrosis), sterile or infected

### Signs and Symptoms

- pain: epigastric, noncolicky, constant
- can radiate to back
- may improve when leaning forward (Ingelfinger's sign)
- tender rigid abdomen; guarding
- N/V
- abdominal distention from paralytic ileus
- fever: chemical, not due to infection
- jaundice: compression or obstruction of bile duct
- Cullen's/Grey-Turner's signs
- tetany: transient hypocalcemia
- hypovolemic shock: can lead to renal failure
- acute respiratory distress syndrome
- coma

### Investigations

- increased serum pancreatic enzymes: amylase, lipase (more specific)
- ALT >150 specific for biliary cause
- increased WBC, glucose, low calcium
- imaging: CT most useful for diagnosis and prognosis
  - x-ray: "sentinel loop" (dilated proximal jejunum), calcification, and "colon cut-off sign" (colonic spasm)
  - U/S: useful for evaluating biliary tree (67% sensitivity, 100% specificity)
  - CT scan with IV contrast: most useful when done >1 d after presentation, helpful for diagnosis and prognosis because contrast seen only in viable pancreatic tissue, non-viable areas can be biopsied percutaneously to differentiate sterile from infected necrosis
  - ERCP or MRCP if cause uncertain, assess for duct stone, pancreatic or ampullary tumour, pancreas divisum

### Classification

- interstitial edematous vs. necrotizing
- mild, moderate, severe

### Prognosis

- usually a benign, self-limiting course, single or recurrent
- occasionally severe leading to:
  - shock
  - pulmonary edema
  - multi-organ dysfunction syndrome
  - GI ulceration due to stress
  - death
    - numerous scales to describe severity: probably most useful is proportion of pancreas not taking up contrast on CT done 48 h after presentation (necrotic pancreas does not take up the contrast dye)
    - presence of organ failure, particularly organ failure that persists >48 h, is associated with worse outcomes

**Table 25. Collections in Pancreatitis (Revised 2012 Atlanta Classification)**

	Liquid	Solid
Acute	Acute peripancreatic fluid collection (APFC)	Acute necrotic collection (ANC)
Chronic	Pancreatic pseudocyst	Walled-off necrosis (WON)

All of these collections are classified as infected or not infected

#### Cullen's Sign

- Sensitive, not specific for acute pancreatitis

#### Grey-Turner's Sign

- Flank ecchymosis

#### Increased Amylase

- Sensitive, not specific for acute pancreatitis

#### Increased Lipase

- Higher sensitivity and specificity
- Stays elevated longer

### Treatment

- goals (only supportive therapy available)
  1. hemodynamic stability
  2. analgesia
  3. oxygen
  4. stop progression of damage (difficult)
  5. treat local and systemic complications
- antibiotic use in infection (cephalosporins, imipenem), not indicated to prevent infection, although without aspiration/biopsy can be difficult to distinguish infection from non-infected inflammation
- aspirate necrotic areas of pancreas to diagnose infection; drain if infected
- IV fluids (crystalloid or colloid)
  - beware third spacing of fluid, monitor urine output carefully
- NG suction (lets pancreas rest) if vomiting, stomach very dilated
- endoscopic sphincterotomy if severe gallstone pancreatitis (i.e. cholangitis or ongoing obstruction)
- nutritional support: NJ feeding tube or TPN if cannot tolerate enteric feeds
  - recent evidence supports NG enteral (or oral if feasible) feeds
- no benefit: glucagon, atropine, aprotinin, H<sub>2</sub>-blockers, peritoneal lavage
- follow clinically and CT or U/S to exclude complications
- chief role of invasive intervention is to drain fluid collection, excise necrotic tissue (necrosectomy), especially indicated if pseudocyst or walled-off necrosis is infected,
  - try to delay for >2 wk to allow demarcation between viable and necrotic tissue, better done endoscopically or radiologically, rather than surgically if technically possible

### Late Complications

- pseudocysts: follow if asymptomatic, drain if symptomatic or growing
  - drain preferably: endoscopic, percutaneous under radiological guidance, surgical if less invasive methods fail
- infected necrosis/abscesses: ABx + percutaneous drainage, endoscopic preferable to surgical
- bleeding: (1) gastric varices if splenic vein thrombosis, (2) pseudoaneurysm of vessels in areas of necrosis, especially splenic artery, (3) duodenal ulcer related to compression of duodenum by enlarged pancreas
- splenic and portal vein thrombosis: no effective therapy described, anticoagulation not proven, hazardous
- rare: DM, pancreatic duct damage

## Chronic Pancreatitis

### Definition

- irreversible damage to pancreas characterized by
  1. pancreatic cell loss (from necrosis)
  2. inflammation
  3. fibrosis

### Etiology/Pathophysiology

- Toxic-metabolic
  - EtOH (most common)
    - causes a larger proportion (>90%) of chronic pancreatitis than acute pancreatitis
    - changes composition of pancreatic juice (e.g. increase viscosity)
    - decreases pancreatic secretion of pancreatic stone protein (lithostathine), which normally solubilizes calcium salts
      - precipitation of calcium within pancreatic duct results in duct and gland destruction
    - toxic effect on acinar and duct cells - directly or via increasing free radicals
    - acinar cell injury leads to cytokine release, which stimulates pancreatic stellate cells to form collagen (leading to fibrosis)
    - varying degrees of ductular dilatation, strictures, protein plugs, calcification
    - no satisfactory theory to explain why only a minority of individuals with EtOH use disorder develop pancreatitis
      - smoking
      - hypercalcemia
      - hypertriglyceridemia
      - medications
- Idiopathic
- Genetic
- Autoimmune pancreatitis/steroid-responsive pancreatitis (e.g. IgG4-related disease)
- Recurrent acute pancreatitis/severe acute pancreatitis
- Obstructive (e.g. pancreas divisum, ampullary stenosis)

### Signs and Symptoms

- early stages
  - recurrent attacks of severe abdominal pain (upper abdomen and back)
  - chronic painless pancreatitis: 10%
- late stages: occurs in 15% of patients
  - steatorrhea (maldigestion) when >90% of function is lost
  - diabetes, calcification, jaundice, weight loss, pseudocyst, ascites, GI bleed

Gallstones only cause acute pancreatitis (not chronic pancreatitis)

### Symptoms of Chronic Pancreatitis

- Abdominal pain
  - Diabetes
  - Steatorrhea
- Etiology = Almost Always Alcohol

### Treatment

- EtOH abstinence
- Pancreatic enzyme replacement
- Analgesics
- Pancreatic resection if ductular blockage

### When to Call the Surgeon in Acute Pancreatitis?

Endoscopic Transgastric vs. Surgical Necrosectomy for Infected Necrotizing Pancreatitis: A Randomized Trial JAMA 2012;307:1053-1061

Once it was recognized that severe acute (necrotizing) pancreatitis had a terrible prognosis because of an exuberant inflammatory response leading to multiorgan failure, pancreatectomy was attempted. However, contrary to the expected favourable results, clinical experience has shown that surgical pancreatectomy is usually not helpful, perhaps because once the inflammatory cascade starts, it persists as a self-perpetuating cycle. The problems caused by acute pancreatitis can be thought of as widespread burn initiated by inflammation in the pancreas, but having little to do with ongoing problems within the pancreas itself. Studies suggest that the only compelling indication for surgery is infected necrotizing pancreatitis not responding to ABx. As predicted, without removal of such infected pancreatic tissue, death is likely from sepsis. In this recent randomized trial, transgastric necrosectomy, an endoscopic technique that also removes infected necrotic pancreatic tissue, reduced both a composite endpoint of major pancreatitis complications (especially new onset organ failure) and the pro-inflammatory response (as measured by serum IL-6 levels) to a greater extent than surgical necrosectomy. Of course, not all necrotic collections are in areas amenable to endoscopic intervention, and the advice of an experienced surgeon should always be welcomed in severe acute pancreatitis, but the role of surgery in this previously considered surgical disease is rapidly diminishing.

Activate Windows

Go to Settings to activate Windows.

**Investigations**

- laboratory
  - increase in serum glucose
  - increase in serum ALP, less commonly bilirubin (jaundice)
  - serum amylase and lipase usually normal
  - stool elastase is low in steatorrhea
- abdominal x-ray: pancreatic calcifications
- U/S or CT: calcification, dilated pancreatic ducts, pseudocyst
- MRCP or ERCP: abnormalities of pancreatic ducts-narrowing and dilatation
- EUS: abnormalities of pancreatic parenchyma and pancreatic ducts, most sensitive test
- 72 h fecal fat test: measures exocrine function, fecal elastase preferable
- secretin test: gold standard, measures exocrine function but difficult to perform, unpleasant for patient, expensive

**Treatment**

- most common problem is pain, difficult to control
- general management
  - complete abstinence from EtOH
  - enzyme replacement may help pain by resting pancreas via negative feedback
  - analgesics
  - celiac ganglion blocks
  - time: pain decreases with time as pancreas "burns out"
- endoscopy: sphincterotomy, stent if duct is dilated, remove stones from pancreatic duct
- surgery: drain pancreatic duct (pancreaticojejunostomy) if duct is dilated (more effective than endoscopy); resect pancreas if duct is contracted
- steatorrhea
  - pancreatic enzyme replacement
  - neither endoscopy nor surgery can improve pancreatic function

**Autoimmune Pancreatitis**

- most commonly presents as a mimicker of pancreatic cancer (pancreatic mass detected because of jaundice ± abdominal pain)

**Investigations**

- histology: lymphocyte and plasma cell infiltration of pancreas
- imaging: focal or diffuse enlargement of pancreas on CT or MRI, sausage-shaped, low density rim around pancreas
- serology: increased serum IgG4 in type 1
- other organ involvement: sialadenitis, retroperitoneal fibrosis, biliary duct narrowing, nephritis

**Treatment**

- responds to prednisone
- for refractory patients, consider immunomodulators (azathioprine, mycophenolate mofetil, methotrexate) or rituximab

**Clinical Nutrition****Determination of Nutritional Status****Challenging to Differentiate Markers of Malnutrition from Markers of Disease**

- most important feature in assessing the need for nutritional support is weight loss (expressed as change in body mass index ( $\text{kg}/\text{m}^2$ ))
- Subjective Global Assessment divides nutritional status into A) adequately nourished, B) mild or moderate malnutrition, and C) severe malnutrition in order to identify those who will benefit from nutritional support
- includes weight change in past 6 mo, weight change in past 2 wk, dietary intake change, current dietary intake, GI symptoms, functional capacity, effect of disease on nutritional requirements and physical examination, including loss of subcutaneous fat/muscles wasting/edema/ascites

**Table 26. Small Bowel Nutrient Absorption**

	Fe <sup>3+</sup>	CHO	Proteins, Lipids Na <sup>+</sup> , H <sub>2</sub> O	Bile Acids	Vitamin B <sub>12</sub>
Duodenum	+++	+++	+++	+	
Jejunum	*	*	**	+	*
Ileum	*	*	**	+++	+++

### Determining Nutritional Requirements

- calories: total energy expenditure (TEE) = resting energy expenditure (REE) x stress factor (e.g. 1.7 for burns) usually works out to be 25-35 kcal/kg depending on how disease affects metabolism, with IV nutrition delivered as about 60% carbohydrate, 40% fat. Current trend is to provide fewer calories ("permissive underfeeding"), especially in ICU, to prevent hyperglycemia
- protein: 1-2 g/kg/d, depending on effect of disease on protein metabolism. In disease, a greater proportion of energy expenditure comes from protein than in health
- electrolytes, minerals, and vitamins also required

### Indications for Aggressive Nutritional Support:

- inability to meet nutritional needs; logical, but convincing evidence from literature not available for ICU and other acute illnesses
- evidence that nutritional support improves outcome available for (1) short bowel syndrome (home TPN), (2) before major abdominal or thoracic surgery if there is substantial malnutrition, (3) before therapy for cancer of esophagus, head, and neck, (4) decompensated alcoholic liver disease, (5) pancreatitis (acute and chronic). May be helpful for other indications also, but insufficient data
- nutritional support at best prevents protein loss but usually no gain

## Enteral Nutrition

### Definition

- EN (tube feeding) is a way of providing food through a tube placed in the stomach or the small intestine
  - nasogastric (NG), or nasojejunal (NJ) if nutritional support required for brief time; percutaneous endoscopic gastrostomy ("G-tube" or "PEG tube")/percutaneous endoscopic jejunostomy (J-tube) if nutritional support required for more than 1 mo
- tubes can be placed endoscopically, radiologically, or surgically

### Indications

- oral feeding inadequate or contraindicated

### Feeds

- polymeric feeds contain whole protein, carbohydrates, fat as a liquid, and may or may not have fibre added
- elemental feeds contain protein (as amino acids), carbohydrates (as simple sugars), and are low in fat content (are therefore high in osmolarity)
- specific diets: low carbohydrate/high fat solution for ventilated patients (carbohydrate has a high respiratory quotient so minimizes carbon dioxide production), high energy, low electrolyte solutions for dialysis patients

### Relative Contraindications

- non-functioning gut (e.g. intestinal obstruction, enteroenteral or enterocutaneous fistulae)
- uncontrolled diarrhea
- GI bleeding

### Complications

- aspiration
- diarrhea
- refeeding syndrome (rare): carbohydrate can stimulate excessive insulin release, leading to cellular uptake and low serum levels of phosphate, magnesium, potassium
- overfeeding syndrome (rare): hypertonic dehydration, hyperglycemia, hypercapnia, azotemia (from excess protein)

## Parenteral Nutrition

### Definition

- PN is the practice of feeding a person intravenously, bypassing the usual process of eating and digestion

### Indications

- short-term (<1 mo)
  - use whenever GI tract not functioning
  - only situations where PN has been well shown to increase survival are after bone marrow transplant and in short bowel syndrome, some evidence for benefit in gastric cancer, but often used in ICU, perioperatively, and in difficult-to-control sepsis
  - preoperative: only useful in severely malnourished (e.g. loss of >15% of pre-morbid weight, serum albumin <28 g/L or <2.8 g/dL), and only if given for ≥2 wk
  - renal failure: PN shown to increase rate of recovery; no increase in survival
  - liver disease: branched chain amino acids may shorten duration of encephalopathy; no increase in survival
  - IBD: PN closes fistulae and heals acute exacerbations of mucosal inflammation, but effect is transient (EN is equally effective)

#### Most Common Indications for Artificial Nutrition Support

- Preexisting nutritional deprivation
- Anticipated or actual inadequate energy intake by mouth
- Significant multiorgan system disease

Whenever possible, EN is ALWAYS preferable over PN

- some evidence for efficacy, but convincing data not available for:
  - radiation/chemotherapy-induced enteritis
  - AIDS with wasting diarrhea
  - severe acute pancreatitis
- long-term (>1 mo): can be given at home
  - severe untreatable small bowel disease (e.g. radiation enteritis, extensive CD, high output fistulae)
  - following surgical resection of >70% of small bowel (e.g. small bowel infarction)
  - severe motility diseases (e.g. scleroderma affecting bowel)

### Relative Contraindications

- functional GI tract available for EN
- active infection; at least until appropriate antibiotic coverage
- inadequate venous access; triple-lumen central venous lines usually prevent this problem

### Complications of PN

- sepsis; most serious of the common complications
- mechanical pneumothorax from insertion of central line, catheter migration and thrombosis, air embolus
- metabolic: congestive heart failure, hyperglycemia, gallstones, cholestasis, electrolyte abnormalities, micronutrient deficiency

### Enteral Nutrition Preferable to Parenteral Nutrition

- fewer serious complications (especially sepsis)
- nutritional requirements better understood
- can supply gut-specific fuels such as glutamine and short chain fatty acids with EN
- nutrients in the intestinal lumen have a trophic effect (prevent atrophy of the gut and pancreas)
- prevents gallstones by stimulating gallbladder motility
- much less expensive

Hypomagnesemia may be an initial sign of short bowel syndrome in patients who have undergone surgical bowel resection

Enteral vs. Parenteral Nutrition for Acute Pancreatitis  
Cochrane DB Syst Rev 2010;1:C0002837

**Purpose:** Compare EN vs. TPN on mortality, morbidity, and hospital stay in patients with pancreatitis.

**Study Selection:** RCTs of TPN vs. EN in pancreatitis.

**Results:** Eight trials (n=348) were included. EN decreases RR of death (0.50), multiple organ failure (0.55), infection (0.39), and other local complications (0.70). It also decreased hospital stay by 2.37 d.

**Conclusion:** EN reduces mortality, organ failure, infections, and length of hospital stay in patients with pancreatitis.

## Common Medications

Table 27. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
Proton Pump Inhibitors (H <sup>+</sup> /K <sup>+</sup> -ATPase inhibitors)	omeprazole	Losec <sup>®</sup> / Prilosec <sup>®</sup>	20 mg PO once daily	Inhibits gastric enzymes H <sup>+</sup> /K <sup>+</sup> -ATPase (proton pump)	Duodenal ulcer, gastric ulcer, NSAID-associated gastric and duodenal ulcers, reflux esophagitis, symptomatic GERD, dyspepsia, Zollinger-Ellison syndrome, eradication of <i>H. pylori</i> (combined with ABx)	Hypersensitivity to drug	Dizziness, headache, flatulence, abdominal pain, nausea, rash, increased risk of osteoporotic fracture (secondary to impaired calcium absorption)
	lansoprazole or dexlansoprazole	Prevacid <sup>®</sup> / Dexilant <sup>®</sup>	Oral therapy: lansoprazole 15-30 mg once daily (before breakfast), dexlansoprazole 30-60 mg once daily (does not need to be taken before breakfast)	Same as above	Same as above	Same as above	Same as above
	pantoprazole	Pantoloc <sup>®</sup> / Protonix <sup>®</sup>	40 mg PO once daily for UGIB; 80 mg IV bolus then 8 mg/h infusion	Same as above	Same as above and UGIB	Same as above	Same as above
	rabeprazole	Pariet <sup>®</sup> / Aciphex <sup>®</sup>	40 mg PO once daily	Same as above	Same as above	Same as above	Same as above
	esomeprazole	Nexium <sup>®</sup>	20-40 mg PO once daily	Same as above	Same as above	Same as above	Same as above
Histamine H <sub>2</sub> Receptor Antagonists	ranitidine* *ranitidine drugs recalled in 2019 due to impurity concerns	Zantac <sup>®</sup> *	300 mg PO once daily or 150 mg BID IV therapy: 50 mg q8 h (but tachyphylaxis a problem)	Inhibits gastric histamine H <sub>2</sub> receptors	Duodenal ulcer, gastric ulcer, NSAID-associated gastric and duodenal ulcers, ulcer prophylaxis, reflux esophagitis, symptomatic GERD; not useful for acute GI bleeds	Hypersensitivity to drug	Confusion, dizziness, headache, arrhythmias, constipation, nausea, agranulocytosis, pancytopenia, depression
	famotidine	Pepcid <sup>®</sup>	Oral therapy: duodenal/gastric ulcers: 40 mg qhs GERD: 20 mg BID IV therapy: 20 mg BID	Same as above	Same as above	Same as above	Same as above
Stool Softener	docusate sodium	Colace <sup>®</sup>	100-400 mg PO once daily, divided in 1-4 doses	Promotes incorporation of water into stool	Relief of constipation	Presence of abdominal pain, fever, N/V	Throat irritation, abdominal cramps, rashes

Table 27. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
Osmotic Laxatives	lactulose	Lactulose Constulose <sup>®</sup>	Constipation: 15-30 mL PO once daily to BID Encephalopathy: 15-30 mL BID to QID	Poorly absorbed in GI tract and is broken down by colonic bacteria into lactic acid in the colon, increases osmotic colonic contents, increases stool volume	Chronic constipation, prevention, and treatment of portal-systemic encephalopathy	Patients who require a low galactose diet	Flatulence, intestinal cramps, nausea, diarrhea if excessive dosage
	PEG3350	Lax-a-day <sup>®</sup> RestoraLAX <sup>®</sup> Golytely <sup>®</sup>	Constipation: 17 g powder dissolved in 4-8 oz liquid PO once daily	Osmotic agent causes water retention in stool and promotes frequency of stool	Relief of constipation Colonoscopy prep	Hypersensitivity to drug	Abdominal distension, pain, anal pain, thirst, nausea, rigor, tonic-clonic seizures (rare)
	magnesium hydroxide	Milk of Magnesia/ Pedia-Lax <sup>®</sup>	Constipation (adult): 400 mg/5 mL: 30-60 mL PO qhs	Osmotic retention of fluid which distends the colon and increases peristaltic activity	Relief of constipation	Patients with myasthenia gravis or other neuromuscular disease	Renal impairment Abdominal pain, vomiting, diarrhea
Stimulant Laxatives	senna	Senokot <sup>®</sup>	Tablets: 1-4 PO qhs Syrup: 10-15 mL PO qhs	Induce peristalsis in lower colon	Constipation	Patients with acute abdomen	Abdominal cramps, discoloration of breast milk, urine, feces, melanosis coli and atonic colon from prolonged use (controversial)
	bisacodyl	Bisacodyl <sup>®</sup>	5-30 mg PO once daily (start at 10 mg for bowel preparation)	Enteric nerve stimulation and local contact-induced secretory effects Colonic movements	Constipation Preparation of bowel for procedure	GI obstruction Gastroenteritis	Abdominal colic, abdominal discomfort, proctitis (with suppository use), diarrhea
Bulk Laxatives	psyllium	Metamucil <sup>®</sup>	Start at one heaping tablespoon daily	Increases stool bulk → water retention in stool	Constipation	Hypersensitivity to drug GI obstruction	GI obstruction, diarrhea, constipation, abdominal cramps
Guanylate Cyclase C Agonist	linaclotide	Constella <sup>®</sup>	75-145 µg once daily	Opens water channels in bowel epithelial cells to add water to stool	Chronic constipation IBS-constipation	Children	Diarrhea
Antidiarrheal Agents	loperamide	Imodium <sup>®</sup>	Acute diarrhea: 4 mg PO initially, followed by 2 mg after each unformed stool	Acts as antidiarrheal via cholinergic, noncholinergic, opiate, and non-opiate receptor-mediated mechanisms; decreases activity of myenteric plexus	Adjunctive therapy for acute non-specific diarrhea, chronic diarrhea associated with IBD and for reducing the volume of discharge for ileostomies, colostomies, and other intestinal resections	Children <2 yr, known hypersensitivity to drug, acute dysentery characterized by blood in stools and fever, acute UC or pseudomembranous colitis associated with broad-spectrum ABx	Abdominal pain or discomfort, drowsiness or dizziness, tiredness, dry mouth, N/V, hypersensitivity reaction
	diphenoxylate/atropine	Lomotil <sup>®</sup>	5 mg PO TID to QID	Inhibits GI propulsion via direct action on smooth muscle, resulting in a decrease in peristaltic action and increase in transit time	Adjunctive therapy for diarrhea, as above	Hypersensitivity to diphenoxylate or atropine, jaundice, pseudomembranous enterocolitis, diarrhea caused by enterotoxin producing bacteria	Dizziness, drowsiness, insomnia, headache, N/V, cramps, allergic reaction
	eluxadolone	Viberzil <sup>®</sup>	75-100 mg BID	Bowel opioid modulator	IBS Diarrhea	Pancreatic disease, excess EtOH, gallstones or other biliary disease	Pancreaticobiliary pain including sphincter of Oddi dysfunction
Antiemetics	dimenhydrinate	Gravol <sup>®</sup>	25-50 mg PO/IV/IM q4-6 h PRN	Competitive H1 receptor antagonist in GI tract, blood vessels, and respiratory tract. Blocks chemoreceptor trigger zone. Diminishes vestibular stimulation and disrupts labyrinthine function through central anticholinergic action	Motion sickness, radiation sickness, postoperative vomiting, and drug-induced N/V	Hypersensitivity to drug	Xerostomia, sedation
	prochlorperazine	Stemetil <sup>®</sup>	5-10 mg PO/IV/IM BID-TID PRN	D1, D2 receptor antagonist in chemoreceptor trigger zone and α-adrenergic and anticholinergic effects Depresses reticular activating system (RAS) affecting emesis	Postoperative N/V, antipsychotic, anxiety	Hypersensitivity to drug	Dystonia, extrapyramidal symptoms (EPS), seizure, NMS (rarely)
	metoclopramide	Maxeran <sup>®</sup>	10 mg IV/IM q2-3 h pm, 10-15 mg PO QID (30 min before meals and qhs)	Dopamine and 5-HT receptor antagonist in chemoreceptor trigger zone. Enhances response to ACh in upper GI tract, enhancing motility and gastric emptying. Increases LES tone	GERD, diabetic gastroparesis, postoperative and chemotherapy induced N/V, migraines, constipation	Hypersensitivity to drug, GI obstruction, perforation, hemorrhage, pheochromocytoma, seizures, and EPS	Restlessness, drowsiness, dizziness, fatigue, EPS, some rare serious side effects include NMS, agranulocytosis

Table 27. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
	ondansetron	Zofran <sup>®</sup>	Depends on procedure, generally 8-16 mg PO	Selective 5-HT <sub>3</sub> receptor antagonist in central chemoreceptor trigger zone and peripherally on vagus nerve	N/V caused by cancer chemotherapy and radiation therapy; multiple off label uses, including gastroenteritis N/V	Morphine, hypersensitivity to drug	Constipation, diarrhea, increased liver enzymes, headache, fatigue, malaise, cardiac dysrhythmia
	granisetron	Kytril <sup>®</sup>	1 mg PO BID (for nausea from chemotherapy/radiation)	Same as above	N/V caused by cancer chemotherapy and radiation therapy	Same as above	Constipation, prolonged QT interval (rarely)
Prokinetic Agents	domperidone	Motilium <sup>®</sup>	GI motility disorder (e.g. gastroparesis): 10 mg TID	peripherally acting D <sub>2</sub> receptor blocker, main effect in the upper GI tract (i.e. increased esophageal peristalsis, gastric motility), antiemetic properties	upper GI motility disorders (e.g. gastroparesis, subacute gastritis), prevention of nausea associated with dopamine-agonists	hypersensitivity to domperidone, prolonged QT interval, prolactinoma, electrolyte disturbances, CYP3A4 inhibitors, mechanical GI obstruction or perforation, GI hemorrhage, severe hepatic dysfunction, children <2 yr	cardiac arrhythmia (use lowest dose for shortest duration) and hyperprolactinemia causing hypogonadism, breast engorgement, and galactorrhea
	prucalopride	Resotran <sup>®</sup> Motegrity <sup>®</sup>	2 mg PO OD	high affinity 5-HT <sub>4</sub> agonist, main effect in the lower GI tract (i.e. increased colonic peristalsis, ameliorates gastroparesis)	chronic idiopathic constipation	hypersensitivity to prucalopride, GI obstruction or perforation, severe inflammation co-morbidity (e.g. Crohn's disease, UC, toxic megacolon)	headache, fatigue, dizziness, abdominal pain, N/V, diarrhea, abdominal distention
Aminosalicylates (5-ASAs)	mesalamine	Pentasa <sup>®</sup> Salofalk <sup>®</sup> Asacol <sup>®</sup> Mesasal <sup>®</sup>	CD: 1 g PO TID/QID Active UC: 1 g PO QID Maintenance UC: 1.6 g PO divided doses daily also as suppositories and enemas	5-ASA: Blocks arachidonic acid metabolism to prostaglandins and leukotrienes	Mild to moderate UC	Hypersensitivity to mesalamine salicylates; Asacol <sup>®</sup> contains phthalate, potential urogenital teratogenicity for male fetus	Abdominal pain, constipation, arthralgia, headache
	sulfasalazine	Salazopyrin <sup>®</sup>	3-4 g/d PO in divided doses	Compound composed of 5-ASA bound to sulfapyridine, hydrolysis by intestinal bacteria releases 5-ASA, the active component	Mild to moderate UC	Hypersensitivity to sulfasalazine, sulfa drugs, salicylates; intestinal or urinary obstruction, porphyria	Rash, loss of appetite, N/V, headache, oligospermia (reversible)
Immuno-suppressive Agents	6-mercaptopurine (6-MP)	Purinethol <sup>®</sup>	CD: 1.5 mg/kg/d PO	Immunosuppressive	IBD: active inflammation and to maintain remission	Hypersensitivity to mercaptopurine, prior resistance to mercaptopurine or thioguanine, history of treatment with alkylating agents, hypersensitivity to azathioprine, pregnancy	Pancreatitis, bone marrow suppression, increased risk of cancer
	azathioprine	Azasan <sup>®</sup> Imuran <sup>®</sup>	IBD: 2-3 mg/kg/d PO	Same as above	Same as above	Same as above	Same as above
	prednisone		Induction of remission for acute exacerbations: 20-40 mg PO once daily; taper 2.5-5 mg/wk until discontinued	Anti-inflammatory	Symptomatic moderate to severe CD and UC	Hypersensitivity to prednisone, systemic fungal infections	Hyperglycemia, insomnia, osteoporosis, weight gain, increased risk of infections
Biologics	infliximab	Remicade <sup>®</sup>	5-10 mg/kg IV over 2 h	Monoclonal antibody to TNF $\alpha$	Medically refractory CD	Heart failure, moderate to severe, doses >5 mg/kg	Reported cases of reactivated TB, PCP, lymphoma, other infections Other TNF $\alpha$ share similar serious side effects
	adalimumab	Humira <sup>®</sup>	CD induction: four 40 mg SC on day 1, then 80 mg 2 wk later (day 15) CD maintenance: 40 mg every other wk beginning day 29	Monoclonal antibody to TNF $\alpha$	Medically refractory CD or poor response to infliximab	Hypersensitivity to adalimumab Severe infection Moderate-to-severe heart failure	Headaches, skin rashes, upper respiratory tract infection
	golimumab	Simponi <sup>®</sup>	RA: 2 mg/kg at wk 0, 4, and then every 8 wk thereafter (use with methotrexate) UC induction: 200 mg SC at wk 0, then 100 mg at wk 2 UC maintenance: 50 mg every 4 wk	Monoclonal antibody to TNF $\alpha$	Active ankylosing spondylitis Psoriatic arthritis Moderate-to-severe active RA (combined with methotrexate) UC: medically refractory UC	Hypersensitivity to golimumab or latex Severe infection Moderate-to-severe heart failure	
	vedolizumab	Entyvio <sup>®</sup>	CD/UC: 300 mg at 0, 2, 6 wk and then every 8 wk thereafter	Monoclonal antibody to $\alpha$ 4 $\beta$ 7 integrin	Medically refractory CD/UC, including other TNF $\alpha$ inhibitors and corticosteroids	Hypersensitivity to vedolizumab	Infections, liver injury, and progressive multifocal leukoencephalopathy
	ustekinumab	Stelara <sup>®</sup>	Induction: single IV weight-based dose on day 1 Maintenance: 90 mg subcutaneous injection every 8 wk	Monoclonal antibody to IgG1K, inhibits signals by IL-12 and IL-23	Moderate to severe CD and UC	Hypersensitivity to ustekinumab	Infections, headaches, joint pain, fever, N/V

Table 27. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
Small Molecules	tofacitinib	Xeljanz <sup>®</sup>	5-10 mg BID	JAK inhibitor	UC	TB, hepatitis B	Infections, macro-cardiac events, thrombosis (e.g. PE, DVT)
Antibiotics	rifaximin	Zaxine <sup>®</sup>	550 mg BID or TID	Non-absorbable antibiotic, affects dysbiosis of microbiome	Hepatic encephalopathy Non-constipation IBS Traveller's diarrhea	Nil	Nil

## Landmark Gastroenterology Trials

Trial Name	Reference	Clinical Trial Details
<b>PEPTIC ULCER DISEASE</b>		
FAMOUS	Lancet 2009;374:119-25	<p><b>Title:</b> Famotidine for the Prevention of Peptic Ulcers and Oesophagitis in Patients Taking Low-dose Aspirin (FAMOUS): A Phase III, Randomised, Double-blind, Placebo-controlled Trial</p> <p><b>Purpose:</b> Evaluate the efficacy of famotidine in the prevention of peptic ulcers and erosive esophagitis, in patients receiving low-dose aspirin.</p> <p><b>Methods:</b> Patients without erosions or ulcers on upper endoscopy, currently on low-dose aspirin, were randomized to famotidine 20 mg BID or placebo. The primary endpoint was development of new stomach ulcers.</p> <p><b>Results:</b> At 12 wk, gastric ulcers occurred in 3.4% of famotidine patients and 15% of placebo-matched patients (OR 0.20; 95% CI 0.09 to 0.47; P=0.0002). Duodenal ulcers developed in 0.5% of famotidine patients and 8.5% of placebo patients (OR 0.05; 95% CI 0.01 to 0.40; P=0.0045).</p> <p><b>Conclusions:</b> Famotidine is effective in the prevention of gastric and duodenal ulcers, and erosive esophagitis in patients taking low-dose aspirin.</p>
<b>INFLAMMATORY BOWEL DISEASE</b>		
SONIC	NEJM 2010;362:1383-95	<p><b>Title:</b> Infliximab, Azathioprine, or Combination Therapy for Crohn's Disease</p> <p><b>Purpose:</b> Compare the efficacy and safety of infliximab and azathioprine therapy alone or in combination, in patients with CD.</p> <p><b>Methods:</b> CD patients who had not undergone previous biologic or immunosuppressive therapy were randomized to infliximab 5 mg/kg IV infusion or 2.5 mg oral azathioprine, or combination therapy of both drugs.</p> <p><b>Results:</b> Among patients receiving combination therapy, 56.8% were in steroid-free remission, compared with 44.4% of patients receiving infliximab monotherapy, and 30% receiving azathioprine monotherapy (P&lt;0.001 for comparison with combination; P=0.06 for comparison with infliximab).</p> <p><b>Conclusions:</b> Patients' CD treated with infliximab monotherapy or infliximab-azathioprine combination had better corticosteroid-free remission than azathioprine monotherapy recipients.</p>
A Comparison of Methotrexate with Placebo for the Maintenance of Remission in Crohn's Disease	NEJM 2000;342:1627-32	<p><b>Title:</b> A Comparison of Methotrexate with Placebo for the Maintenance of Remission in Crohn's Disease</p> <p><b>Purpose:</b> Evaluate the role of methotrexate in maintaining remission of CD.</p> <p><b>Methods:</b> Patients with chronically active CD who entered remission were randomized to methotrexate 15 mg IM or placebo for 15 wk. The primary endpoint was rates of remission at wk 40.</p> <p><b>Results:</b> At the follow-up period of 40 wk, 65% of methotrexate patients were in remission compared to 39% of patients in the placebo group (risk reduction 26.1%; 95% CI 4% to 47.8%; P=0.04). None of the methotrexate patients reported serious adverse events.</p> <p><b>Conclusions:</b> Patients with CD in remission saw increased remission rates and fewer relapse treatments at 40 wk.</p>
Adalimumab Induction Therapy for Crohn's Disease Previously Treated with Infliximab	Ann Intern Med 2007;146:829-38	<p><b>Title:</b> Adalimumab Induction Therapy for Crohn's Disease Previously Treated with Infliximab</p> <p><b>Purpose:</b> Determine the efficacy of adalimumab in symptomatic CD patients despite infliximab treatment.</p> <p><b>Methods:</b> 325 adults with moderate-severe active CD were randomized to induction doses of adalimumab 160 mg and 80 mg at 0 and 2 wk respectively, or time-matched placebo. The primary endpoint was induction of remission at 4 wk.</p> <p><b>Results:</b> Remission was achieved at 4 wk in 21% of adalimumab patients compared with 7% of placebo patients (95% CI 6.7% to 21.6%).</p> <p><b>Conclusions:</b> Adalimumab induces remission more frequently than placebo in adult patients with symptomatic CD despite infliximab therapy.</p>
UNIFI	NEJM 2019;381:1201-14	<p><b>Title:</b> Ustekinumab as Induction and Maintenance Therapy for Ulcerative Colitis</p> <p><b>Purpose:</b> Determine the effectiveness of ustekinumab as induction and maintenance therapy in patients with UC.</p> <p><b>Methods:</b> 961 patients with moderate-severe UC were randomized to IV induction ustekinumab (130 mg), or placebo. The primary endpoint was clinical remission determined by the Mayo scale.</p> <p><b>Results:</b> The primary endpoint occurred in 15.6% of patients in the intervention group compared with 5.3% of placebo patients (P&lt;0.001). The incidence of serious adverse events was similar between groups.</p> <p><b>Conclusions:</b> Ustekinumab was more effective than placebo for inducing and maintaining remission in patients with moderate-to-severe UC.</p>
VARSIITY	NEJM 2019;381:1215-26	<p><b>Title:</b> Vedolizumab versus Adalimumab for Moderate-to-Severe Ulcerative Colitis</p> <p><b>Purpose:</b> Compare efficacy of vedolizumab versus adalimumab in patients with moderate-severe UC.</p> <p><b>Methods:</b> Adults with moderate-severe active UC were randomized to IV infusions of vedolizumab 300 mg or subcutaneous adalimumab 40 mg (total weekly dose 160 mg). The primary outcome was clinical remission at wk 52 as determined by the Mayo scale.</p> <p><b>Results:</b> At wk 52, clinical remission was observed in 31.3% of vedolizumab patients compared to 22.5% of adalimumab patients (95% CI 2.5 to 15.0; P=0.006). Steroid-free remission occurred in 12.6% of vedolizumab patients and 21.8% of adalimumab patients (95% CI 18.9 to 0.4).</p> <p><b>Conclusions:</b> In patients with moderate-to-severe UC, vedolizumab was superior to adalimumab with respect to achievement of clinical remission and endoscopic improvement, but not corticosteroid-free clinical remission.</p>

Trial Name	Reference	Clinical Trial Details
<b>LIVER DISEASE</b>		
MELD Score as A Predictor Of Death in Chronic Liver Disease	Gastroenterology 2003;124:91-96	<b>Title:</b> MELD Score as A Predictor Of Death in Chronic Liver Disease <b>Purpose:</b> Assess the capability for the MELD score to correctly rank potential liver transplant recipients. <b>Methods:</b> The MELD score was prospectively applied to estimate 3-mo mortality in 3437 adult liver transplant candidates with chronic liver disease. <b>Results:</b> Waiting list mortality increased directly in proportion to the MELD score. Using 3-mo mortality as the endpoint, the ROC curve for MELD was 0.83 compared to 0.76 for the Child-Turcotte-Pugh score. <b>Conclusions:</b> MELD score can be applied for allocation of donor livers as it accurately predicts 3-mo mortality in patients with chronic liver failure.
PROVE 3	NEJM 2010;362:1292-1303	<b>Title:</b> Telaprevir for Previously Treated Chronic HCV Infection <b>Purpose:</b> Study the efficacy of telaprevir in patients without a sustained virologic response to peginterferon therapy. <b>Methods:</b> Patients with HCV genotype 1 without sustained virologic response to peginterferon therapy were randomized to one of four telaprevir and peginterferon treatment groups. The primary endpoint was sustained virologic response 24 wk after the last dose. <b>Results:</b> The rates of sustained virologic response in the three telaprevir groups were significantly higher than the control group rates (14%, $P < 0.001$ , $P < 0.001$ , $P < 0.02$ ). Discontinuation of the drugs due to adverse events was more frequent in the telaprevir groups than in the control group (15% vs. 4%). <b>Conclusions:</b> In HCV-infected patients in whom initial peginterferon therapy failed, retreatment with telaprevir in combination with peginterferon and ribavirin was more effective than the latter two alone.
SPRINT-2	NEJM 2011;364:1195-1206	<b>Title:</b> Boceprevir for Untreated Chronic HCV Genotype 1 Infection <b>Purpose:</b> Evaluate virologic response with additional boceprevir treatment in patients with HCV genotype 1 infection. <b>Methods:</b> Previously untreated adults with HCV genotype 1 infection were randomized to placebo plus peginterferon-ribavirin or boceprevir plus peginterferon-ribavirin. The primary endpoint was sustained virologic response. <b>Results:</b> A virologic response was achieved in 40% of group 1, 67% in group 2 and 68% in group 3. <b>Conclusions:</b> The addition of boceprevir to standard therapy of peginterferon-ribavirin, compared with standard therapy alone, increased rates of sustained virologic response in chronically HCV infected adults.
Rifaximin Treatment in Hepatic Encephalopathy	NEJM 2010;362:1071-81	<b>Title:</b> Rifaximin Treatment in Hepatic Encephalopathy <b>Purpose:</b> Evaluate the efficacy of rifaximin in the prevention of hepatic encephalopathy secondary to cirrhosis. <b>Methods:</b> 299 patients in remission from recurrent hepatic encephalopathy were randomized to rifaximin 550 mg BID or placebo for 6 mo. The primary endpoint was time for the first breakthrough episode. <b>Results:</b> Rifaximin reduced the risk of a hepatic encephalopathy episode (hazard ratio 0.42; 95% CI 0.28 to 0.64; $P < 0.001$ ). A breakthrough episode occurred in 22.1% of rifaximin-treated patients compared to 45.9% of placebo patients (hazard ratio 0.5; 95% CI 0.29 to 0.87; $P = 0.01$ ). The incidence of adverse events was similar between groups. <b>Conclusions:</b> The antibiotic rifaximin was successful in maintaining remission from hepatic encephalopathy and reducing hospitalizations.
Prednisolone or Pentoxifylline For Alcoholic Hepatitis	NEJM 2015;372:1619-28	<b>Title:</b> Prednisolone or Pentoxifylline For Alcoholic Hepatitis <b>Purpose:</b> To elucidate the benefits of pentoxifylline and prednisolone for the treatments of severe alcoholic hepatitis. <b>Methods:</b> Patients with severe alcoholic hepatitis were randomized to one of four groups: double-matched placebo, prednisolone plus matched placebo, pentoxifylline plus matched placebo, or prednisolone plus pentoxifylline. The primary endpoint was mortality at 28 d. <b>Results:</b> Mortality at 28 d was 17% in the first group, 14% in the second group, 19% in the third group, and 13% in the fourth group. At 90 d and 1 yr, there were no significant differences between groups. <b>Conclusions:</b> For alcoholic hepatitis, prednisolone improved survival at a level below statistical significance. Pentoxifylline did not improve survival.

## Basic Anatomy Review

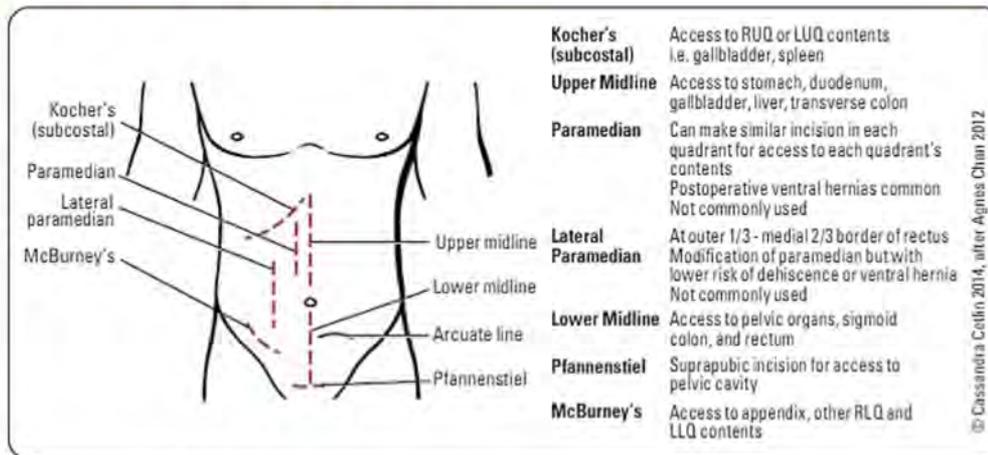

Figure 1. Abdominal incisions

### Lateral Abdominal Wall Layers and their Continuous Spermatic and Scrotal Structures (superficial to deep)

1. skin (epidermis, dermis, subcutaneous fat)
2. superficial fascia
  - Camper's fascia (fatty) → Dartos muscle/fascia
  - Scarpa's fascia (membranous) → Colles' superficial perineal fascia
3. muscle (see Figure 2 and Figure 3)
  - external oblique → inguinal ligament → external spermatic fascia
  - internal oblique → cremasteric muscle/fascia
  - transversus abdominis → posterior inguinal wall
4. transversalis fascia → internal spermatic fascia
5. preperitoneal fat
6. peritoneum → tunica vaginalis

### Midline Abdominal Wall Layers (superficial to deep)

1. skin
2. superficial fascia
3. rectus abdominis muscle: in rectus sheath, divided by linea alba (see Figure 3)
  - above arcuate line (midway between symphysis pubis and umbilicus)
    - ♦ anterior rectus sheath = external oblique aponeurosis and anterior leaf of internal oblique aponeurosis
    - ♦ posterior rectus sheath = posterior leaf of internal oblique aponeurosis and transversus abdominis aponeurosis
  - below arcuate line
    - ♦ aponeuroses of external oblique, internal oblique, and transversus abdominis all pass in front of rectus abdominis

4. arteries: superior epigastric (branch of internal thoracic), inferior epigastric (branch of external iliac); both arteries anastomose and lie behind the rectus muscle (superficial to posterior rectus sheath above arcuate line)
5. transversalis fascia
6. peritoneum

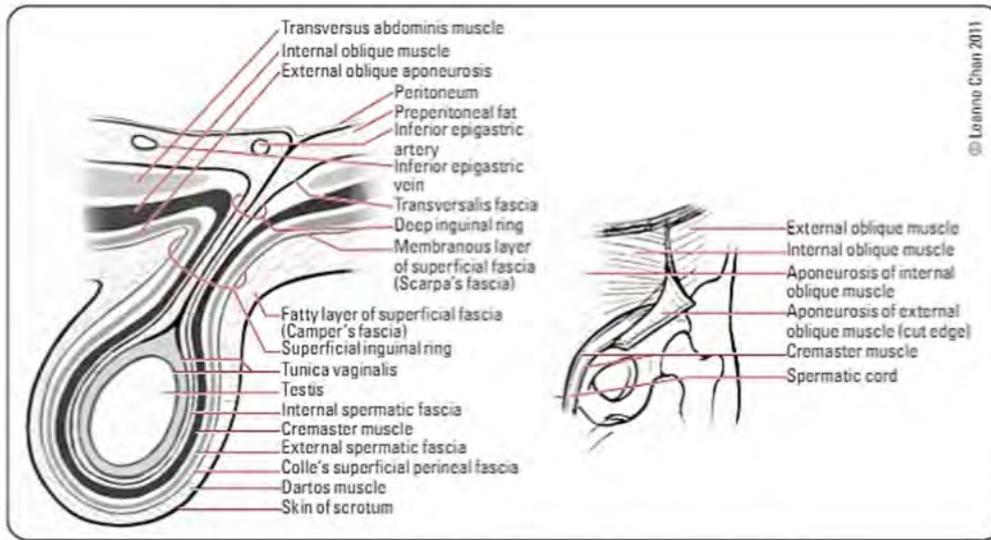

Figure 2. Continuity of the abdominal wall with layers of the scrotum and spermatic cord

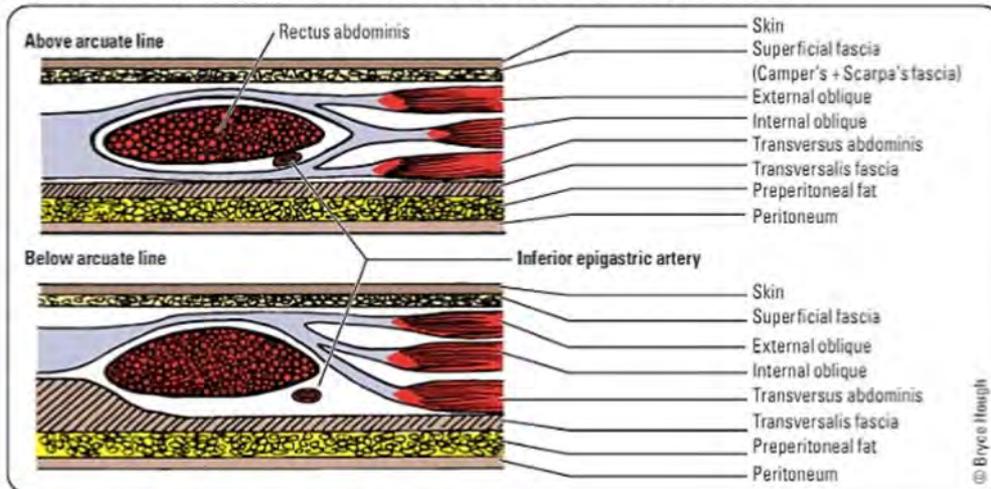

Figure 3. Midline cross-section of abdominal wall

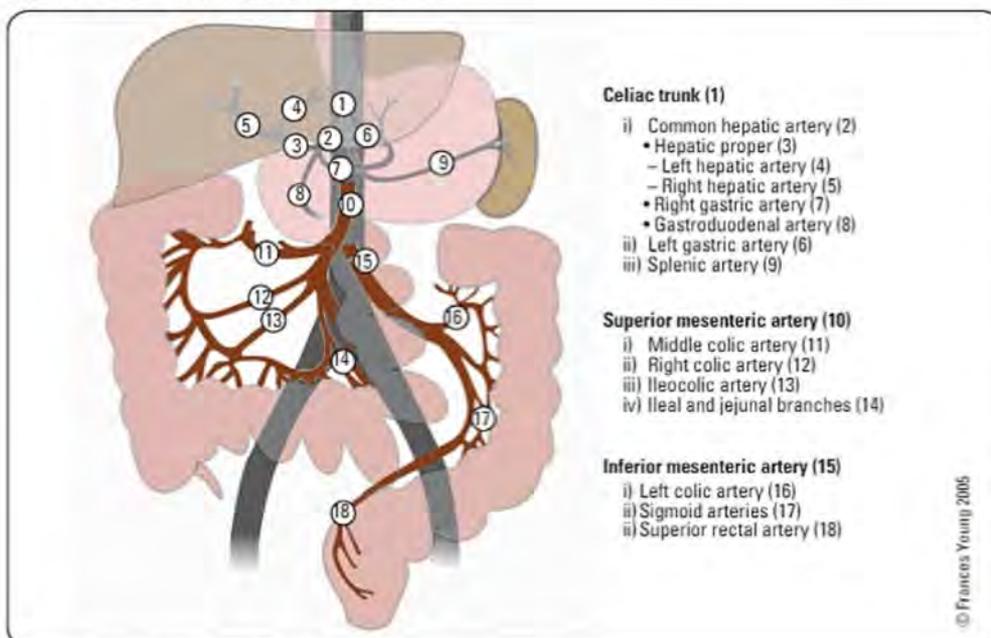

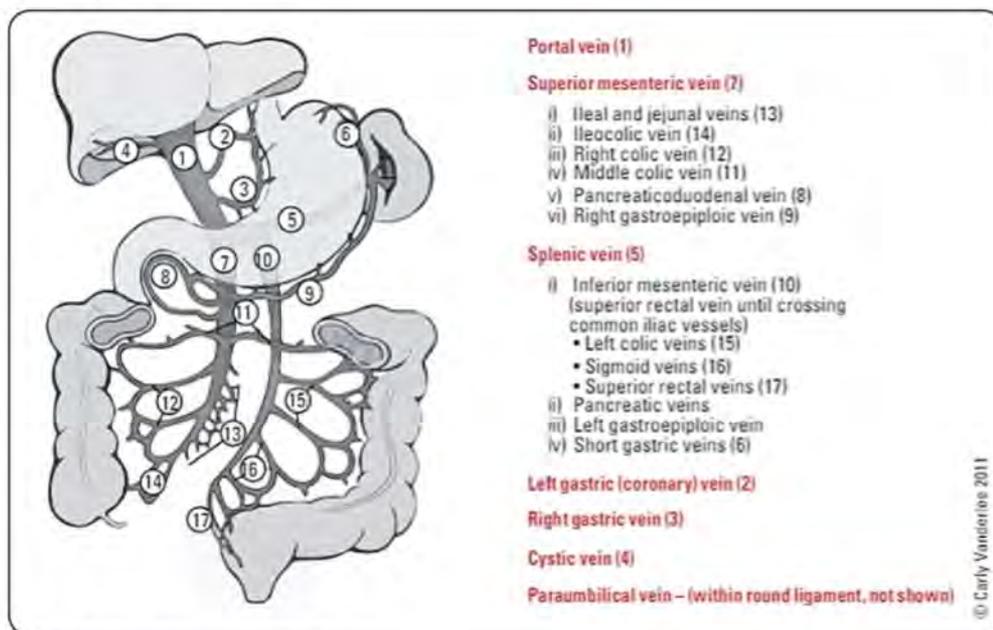

Figure 4. Arterial blood supply to the GI tract

Organ	Arterial Blood Supply
Liver	Left and right hepatic (branches of hepatic proper)
Spleen	Splenic
Gallbladder	Cystic (branch of right hepatic)
Stomach	1. Lesser curvature: right and left gastric 2. Greater curvature: right (branch of gastroduodenal) and left (branch of splenic) gastroepiploic 3. Fundus: short gastrics (branches of splenic)
Duodenum	1. Gastroduodenal 2. Pancreaticoduodenals (superior branch of gastroduodenal, inferior branch of superior mesenteric)
Pancreas	1. Pancreatic branches of splenic 2. Pancreaticoduodenals
Small intestine	Superior mesenteric branches: jejunal, ileal, ileocolic
Large intestine	1. Superior mesenteric branches: right colic, middle colic 2. Inferior mesenteric branches: left colic, sigmoid, superior rectal

**Venous Flow**

- Portal vein (1)**
- Superior mesenteric vein (7)**
  - i) Ileal and jejunal veins (13)
  - ii) Ileocolic vein (14)
  - iii) Right colic vein (12)
  - iv) Middle colic vein (11)
  - v) Pancreaticoduodenal vein (8)
  - vi) Right gastroepiploic vein (9)
- Splenic vein (5)**
  - i) Inferior mesenteric vein (10) (superior rectal vein until crossing common iliac vessels)
    - Left colic veins (15)
    - Sigmoid veins (16)
    - Superior rectal veins (17)
  - ii) Pancreatic veins
  - iii) Left gastroepiploic vein
  - iv) Short gastric veins (6)
- Left gastric (coronary) vein (2)**
- Right gastric vein (3)**
- Cystic vein (4)**
- Paraumbilical vein – (within round ligament, not shown)**

© Carly Vandorpe 2011

Figure 5. Venous drainage of the GI tract

**In All Patients Presenting with an Acute Abdomen, Order the Following:**  
**Key Tests for Specific Diagnosis**

- ALP, ALT, AST, bilirubin
- Lipase/ amylase
- Urinalysis
- β-hCG (in women of childbearing age)
- Troponins
- Lactate

**Key Tests for OR Preparation**

- CBC, electrolytes, creatinine, glucose
- INR/PTT
- CXR (if history of cardiac or pulmonary disease)
- ECG if clinically indicated by history or if >69 yr and no risk factors

**Note:** Choosing Wisely does not recommend routine preoperative blood work for ambulatory/elective surgery

**Types of Peritonitis**

- Primary peritonitis: spontaneous without clear etiology
- Secondary peritonitis: due to a perforated viscus
- Tertiary peritonitis: recurrent secondary peritonitis more often with resistant organisms

**Localization of Pain**

- Most digestive tract pain is perceived in the midline because of bilaterally symmetric innervation; kidney, ureter, ovary, or somatically innervated structures are more likely to cause lateralized pain
- Parietal peritoneum: supplied by somatic sensory nerves of body wall. Pain is sharp and well-localized
- Visceral peritoneum: supplied by autonomic sensory fibres. Pain is colicky and poorly localized

## Differential Diagnoses of Common Presentations

### Acute Abdominal Pain

- acute abdomen = severe abdominal pain of acute onset and requires urgent medical attention
- in patients with acute abdominal pain, the first diagnoses that you should consider are those requiring potential urgent surgical intervention, including:
  - peritonitis
  - bowel obstruction

Table 1. Differential Diagnosis of Acute Abdominal Pain

Right Upper Quadrant (RUQ)	Right Lower Quadrant (RLQ)
<b>Hepatobiliary</b> Biliary colic Cholecystitis* Cholangitis CBD obstruction (e.g. stone, tumour) Hepatitis (includes perihepatitis/Fitz-Hugh-Curtis syndrome) Portal vein thrombosis Budd-Chiari syndrome Hepatic abscess/mass Right subphrenic abscess*	<b>Gastrointestinal</b> Appendicitis* Crohn's disease Tuberculosis of the ileocecal junction Cecal tumour Intussusception Mesenteric lymphadenitis (Yersinia) Cecal diverticulitis Cecal volvulus* Hernia: femoral, inguinal obstruction, Amyand's (and resulting cecal distention)
<b>Gastrointestinal</b> Pancreatitis Presentation of gastric, duodenal, or pancreatic pathology Hepatic flexure pathology (e.g. CRC, subcostal incisional hernia)	<b>Gynaecological</b> See 'suprapubic' <b>Genitourinary</b> See 'suprapubic' <b>Extrapertitoneal</b> Abdominal wall hematoma/abscess Psoas abscess
<b>Genitourinary</b> Nephrolithiasis* Pyelonephritis Renal: mass, ischemia, trauma	
<b>Cardiopulmonary</b> Right lower lobe pneumonia Effusion/empyema CHF (causing hepatic congestion and right pleural effusion) MI Pericarditis Pleuritis	
<b>Miscellaneous</b> Herpes zoster Trauma Costochondritis (Infectious*)	

\*indicated need for urgent surgical evaluation

**Table 1. Differential Diagnosis of Acute Abdominal Pain**

Left Upper Quadrant (LUQ)		Left Lower Quadrant (LLO)
<b>Pancreatic</b> Pancreatitis (acute vs. chronic) Pancreatic pseudocyst Pancreatic tumours*		<b>Gastrointestinal</b> Diverticulitis* Diverticulosis Colon/sigmoid/rectal cancer Fecal impaction Proctitis (e.g. UC, infectious; i.e. gonococcus or <i>Chlamydia</i> ) Sigmoid volvulus* Hernia (incarcerated/strangulated*)
<b>Gastrointestinal</b> Gastritis PUD Splenic flexure pathology (e.g. CRC, ischemia)		<b>Gynaecological</b> See 'suprapubic'
<b>Splenic</b> Splenic infarct/abscess* Splenomegaly Splenic rupture* Splenic artery aneurysm		<b>Genitourinary</b> See 'suprapubic'
<b>Cardiopulmonary (see RUQ and Epigastric)</b>		<b>Extrapertitoneal</b> Abdominal wall hematoma/abscess* Psoas abscess
See <a href="#">Gynaecology</a> , <a href="#">Urology</a> , <a href="#">Respirology</a> , and <a href="#">Cardiology and Cardiac Surgery</a> for further details regarding respective etiologies of acute abdominal pain		
EPIGASTRIC	SUPRAPUBIC	DIFFUSE
<b>Cardiac</b> Aortic dissection/ruptured AAA* MI Pericarditis	<b>Gastrointestinal (see RLO/LLO)</b> Acute appendicitis* IBD	<b>Gastrointestinal</b> Peritonitis* Early appendicitis, perforated appendicitis* Mesenteric ischemia* Gastroenteritis/colitis Constipation Bowel obstruction* Pancreatitis IBD Irritable bowel syndrome Ogilvie's syndrome
<b>Gastrointestinal</b> Gastritis GERD/esophagitis PUD Pancreatitis Mallory-Weiss tear	<b>Gynaecological</b> Ectopic pregnancy* Pelvic inflammatory disease Endometriosis Threatened/incomplete abortion* Hydrosalpinx/salpingitis Ovarian torsion* Hemorrhagic fibroid Tubo-ovarian abscess Gynaecological tumours	<b>Cardiovascular/Hematological</b> Aortic dissection* Ruptured AAA* Sickle cell crisis
	<b>Genitourinary</b> Cystitis (infectious, hemorrhagic) Hydroureter/urinary colic Epididymitis Testicular torsion* Acute urinary retention	<b>Genitourinary/Gynaecological</b> Perforated ectopic pregnancy* Pelvic inflammatory disease Acute urinary retention
	<b>Extrapertitoneal</b> Rectus sheath hematoma	<b>Endocrinological</b> Carcinoid syndrome* Diabetic ketoacidosis Addisonian crisis Hypercalcemia
		<b>Other</b> Lead poisoning Tertiary syphilis

\*Indicated need for urgent surgical evaluation

## Abdominal Mass

**Table 2. Differential Diagnosis of Abdominal Mass**

RUQ	Upper Midline	LUQ
<b>Gallbladder:</b> cholecystitis, cholangiocarcinoma, peri-ampullary malignancy, cholelithiasis <b>Biliary tract:</b> Klatskin tumour <b>Liver:</b> hepatomegaly, hepatitis, abscess, tumour (hepatocellular carcinoma, metastatic tumour, etc.)	<b>Pancreas:</b> pancreatic adenocarcinoma, other pancreatic neoplasms, pseudocyst <b>Abdominal aorta:</b> AAA (pulsatile) <b>G1:</b> gastric tumour (adenocarcinoma, gastrointestinal stromal tumour, carcinoid tumour), MALT lymphoma	<b>Spleen:</b> splenomegaly, tumour, abscess, subcapsular splenic hemorrhage, can also present as RLO mass if extreme splenomegaly <b>Stomach:</b> tumour
RLO	Lower Midline	LLO
<b>Intestine:</b> stool, tumour (CRC), mesenteric adenitis, appendicitis, appendiceal phlegmon or other abscess, typhilitis, intussusception, Crohn's inflammation <b>Ovary:</b> ectopic pregnancy, cyst (physiological vs. pathological), tumour (serous, mucinous, struma ovarii, germ cell, Krukenberg) <b>Fallopian tube:</b> ectopic pregnancy, tubo-ovarian abscess, hydrosalpinx, tumour	<b>Uterus:</b> pregnancy, leiomyoma (fibroid), uterine cancer, pyometra, hematometra <b>GU:</b> bladder distention, tumour	<b>Intestine:</b> stool, tumour, abscess (see RLO) <b>Ovary:</b> see RLO <b>Fallopian tube:</b> see RLO

### Referred Pain

- Biliary colic: to right shoulder or scapula
- Renal colic: to groin
- Appendicitis: periumbilical to RLO
- Pancreatitis: to back
- Ruptured AAA: to back or flank
- Perforated ulcer: to RLO (right paracolic gutter)
- Hip pain: to groin
- Ovarian torsion: to flank or groin

### Most Common Presentations of Surgical Pain

- Sudden onset with rigid abdomen = perforated viscus
- Pain out of proportion to physical findings = ischemic bowel
- Vague pain that subsequently localizes = appendicitis or other intra-abdominal process that irritates the parietal peritoneum
- Waves of colicky pain = bowel obstruction

### Acute Abdominal Pain Mnemonic

- ABDOMINAL**
- Appendicitis
  - Biliary tract disease
  - Diverticulitis
  - Ovarian disease
  - Malignancy
  - Intestinal obstruction
  - Nephritic disorders
  - Acute pancreatitis
  - Liquor/ethanol

Pancreatitis can look like a surgical abdomen, but is rarely an indication for immediate surgical intervention

## Gastrointestinal Bleeding

• see [Gastroenterology](#), G28 and G30

### Indications for Surgery

- failure of medical management (after at least 2 endoscopic attempts at management)
- exsanguinating hemorrhage: hemodynamic instability despite vigorous resuscitation
- recurrent hemorrhage with up to two attempts of endoscopic hemostasis
- prolonged bleeding with transfusion requirement >3 units
- bleeding at rate >1 unit/8h

### Surgical Management of GI Bleeding

- UGIB
  - bleeding from a source proximal to the ligament of Treitz
  - often presents with hematemesis and melena unless very brisk (then can present with hematochezia), may present with anemia, hypovolemic shock
  - initial management with PPIs and endoscopy; if fails, then consider surgical management appropriate to etiology
  - PUD accounts for approximately 55% of severe UGIB
- LGIB
  - bleeding from a source distal to the ligament of Treitz
  - often presents with BRBPR unless proximal to transverse colon, rarely melena (right-sided colonic bleeding)
  - initial management with colonoscopy to detect and potentially stop source of bleeding
  - 75% of patients will spontaneously stop bleeding, however if bleeding continues, barium enema should NOT be performed
  - angiography or RBC scan to determine source as indicated
  - surgery indicated if bleeding is persistent - aimed at resection of area containing source of bleeding
  - for obscure bleed conduct wireless capsule endoscopy, may require blind total colectomy if the source is not found
  - diverticular bleeding is the most common cause of LGIB (accounting for 40% of cases)

Table 3. Differential Diagnosis of GI Bleeding

Anatomical Source	Etiology	
<b>Hematological</b>	Excess anticoagulation (warfarin, heparin, etc.) Excess antiplatelet (clopidogrel, ASA)	DIC Congenital bleeding disorders
<b>Nose</b>	Epistaxis	
<b>Esophagus</b>	Esophageal varices Mallory-Weiss tear Esophagitis	Aorto-esophageal fistula (generally post endovascular aortic repair)* Esophageal cancer
<b>Stomach</b>	Gastritis Gastric varices Dieulafoy's lesion	Gastric ulcer Gastric cancer*
<b>Duodenum</b>	Duodenal ulcer Perforated duodenal ulcer*	Duodenal cancer*
<b>Jejunum</b>	Tumours* Polyps Ulcers	
<b>Ileum and Ileocecal Junction</b>	Meckel's diverticulum Small bowel obstruction	Crohn's disease* Tuberculosis of ileocecal junction
<b>Large Intestine</b>	Colorectal cancer* Mesenteric thrombosis/ischemic bowel* UC* (subtotal colectomy if failure of medical management) Angiodysplasia Diverticulosis (*if bleeding is persistent)	Crohn's disease (less frequently presents with bleeding)* Pancolitis (infectious, chemotherapy, or radiation induced) Bleeding post-gastrointestinal anastomosis
<b>Sigmoid</b>	Diverticulosis (*if bleeding is persistent) Sigmoid cancer* Bleeding post-polypectomy	Polyps (*if not amenable to colonoscopic polypectomy) IBD
<b>Rectum and Anus</b>	Hemorrhoids Fissures Rectal cancer* Anal varices	Polyps (*if not amenable to colonoscopic polypectomy) Crohn's or UC* Solitary rectal ulcer syndrome

\*Managed surgically in most cases

## Jaundice

• see [Gastroenterology](#), G45

### Indications for Urgent Operation

- IHOP
- Isc hernia
- Hemorrhage
- Obstruction
- Perforation

**Overt Bleeding:** obvious hematemesis, hematochezia or melena per rectum (i.e. visible to naked eye)  
**Occult Bleeding:** bleeding per rectum is not obvious to naked eye (e.g. positive guaiac FOBT)  
**Obscure Bleeding:** bleeding with no identifiable source after colonoscopy and endoscopy (source usually in small bowel). Can be either overt or occult

### Bloodwork for GI Bleeds

CBC (including platelet count), serum chemistries (electrolytes, BUN, LFTs, etc.), coagulation studies (INR, PT, PTT), blood type and crossmatch if anticipate transfusion

### Biochemical Signs for Differentiating Jaundice

**Hepatocellular:** Elevated bilirubin + elevated ALT/AST  
**Cholestatic:** Elevated bilirubin + elevated ALP/GGT ± duct dilatation upon biliary U/S  
**Hemolysis:** ↑ haptoglobin + LDH

Note: cholestatic jaundice is often surgical

# Preoperative Preparations

## Considerations

- informed consent (see [Ethical, Legal, and Organizational Medicine, ELOM11](#))
- screening questionnaire to determine risk factors e.g. age, exercise capacity, medication use, allergies, exposure to people with infection (i.e. COVID-19)
- consider preoperative anesthesia, medicine consult as indicated to optimize patient status
- NPO according to fasting guidelines (see [Anesthesia, A6](#))
- IV-balanced crystalloid at maintenance rate (4:2:1 rule for paediatrics, roughly 100-125 cc/h for adults); NS or RL (RL most common); bolus to catch up on estimated losses including losses from bowel prep
  - appropriate use of fluids perioperatively decreases risk of cardiorespiratory complications
- patients can take their regular medications except for hypoglycemic agents, diuretics, and ACEis
- patients with primary adrenal insufficiency (e.g. Addison's disease) or secondary adrenal insufficiency (e.g. glucocorticoid use) may require additional glucocorticoid stress dose coverage
- anticoagulation/antiplatelet medication must be managed to decrease surgical bleeding but not put patient at risk for increased thrombotic events (e.g. Bridging: switching from warfarin to LMWH, easier to start/stop as needed)
- prophylactic antibiotics depending on wound class (immediately/within 1 h prior to incision): cefazolin (skin flora coverage) ± metronidazole (GI flora coverage) for contaminated cases
- role of MBP: Current evidence suggests that use of MBP preoperatively has no impact on postoperative complications, and therefore, routine use of MBP for non-LAR elective colorectal surgery is not recommended
  - MBP is indicated in open or laparoscopic anterior resection i.e. rectal resection where anastomosis is at or below sacral promontory; given with antibiotics
- assess risk for postoperative VTE prior to surgery based on procedure- and patient-related factors; tools such as Caprini Score can be used
  - only hold VTE prophylaxis if epidural is expected
- smoking cessation and weight loss preoperatively can significantly decrease postoperative complications
- infection: delay elective surgery until infection managed, including respiratory infection (particularly in asthma patients)
- when scheduling elective surgeries following a COVID-19 diagnosis, consider the severity of COVID-19 illness, the risks of complications, and risks of delaying surgery

**Table 4. Recommendations for Timing of Surgery following Recovery from COVID-19 with Consideration of Individual Risk/Benefits**

Priority of Surgical Procedure	Clinical Severity of COVID-19 Infection			
	Mild	Moderate	Severe	Critically ill
	Mild (suspected or confirmed) COVID-19 and/or asymptomatic and/or upper respiratory tract infection	Moderate symptomatic COVID-19 not requiring hospitalization and/or persistent symptoms	Lung involvement requiring hospitalization and/or significant comorbidities and/or immunocompromised	Severe COVID-19 with ICU admission and/or meet criteria for severe disease and/or severely immunocompromised
<b>Urgent or Emergent &lt;2 wk ACATS and PCATS Urgent within 3, 7 or 14 days</b>	Do case urgently/emergently	Do case urgently/emergently	<7 wk post-infection consider non-operative options if safe and available	<7 wk post-infection consider non-operative options if safe and available
<b>Urgent (28 or 42 days) 2-6 wk ACATS/PCATS</b>	4-7 wk post infection	7 wk post infection	7 wk post infection	12 wk post infection
<b>Elective (&gt;43 days) &gt;6 wk ACATS/PCATS</b>				

## Investigations

- see [Anesthesia, A4](#)
- routine preoperative laboratory investigations for elective procedures should be selective
  - only ASA class and surgical risk have been found to independently predict postoperative adverse effects
- blood components: group and screen or cross and type depending on procedure
- CBC, electrolytes, creatinine
- INR/PT, PTT
- CXR (PA and lateral) for patients with history of cardiac or pulmonary disease
- ECG as indicated by history or age >69 and no risk factors
- β-hCG testing in all women of reproductive age
- for patients undergoing low-risk surgery without systemic disease (ASA I or II), routine preoperative chest x-rays, CBC, INR, and PTT should be avoided

### Bilirubin Levels

	Pre-hepatic	Intra-hepatic	Post-hepatic
<b>Serum Bilirubin</b>			
Indirect	↑	↑	N
Direct	N	↑	↑
<b>Urine</b>			
Urobilinogen	↑	↑	-
Bilirubin	-	-	-
<b>Fecal</b>			
Urobilinogen	↓	↓	-

In patients with liver disease and an acute abdomen, spontaneous bacterial peritonitis must be ruled out

Surgical Emergencies: Take an AMPLE History

Last meal  
Events – HPI

**Best Practice in General Surgery (BPIGS)**  
<http://www.bpigs.ca/>  
Best Practice in Surgery is a resource from the quality improvement program at the University of Toronto Department of Surgery. Since its inception, it has expanded beyond general surgery best practices and provides EBM guidelines for a variety of fields and procedures

**Mechanical Bowel Preparation Strategies: A Clinical Practice Guideline developed by the University of Toronto's Best Practice in Surgery**  
Informed by: Can J Surg 2010;53:385-395  
14 RCTs (5071 participants), 8 meta-analyses

- All open/laparoscopic colorectal procedures (excluding LARs + diverting stoma)
  - No MBP
  - No dietary restrictions before NPO
  - Fleet enema for left colon anastomoses with transrectal stapling
- Open/laparoscopic LAR + diverting stoma
  - MBP
  - No dietary restrictions before MBP; clear fluids after MBP complete

**Drain Size**

Measured by the unit French:  
French = diameter (mm) x 3

**Drains**

- NG tube
  - indications: gastric decompression, analysis of gastric contents, irrigation/dilution of gastric contents, feeding, and/or administration of medications, if necessary
  - 2 types: NG tube (for drainage or feeding) and Dobhoff (for feeding only)
  - insertion should be done in stages with x-ray protocol to avoid injury
  - contraindications: suspected basal skull fracture, obstruction of nasal passages, esophageal stricture, esophageal varices
- Foley catheter with urometer
  - indications: to accurately monitor urine output, decompression of bladder, relieve obstruction, rapidly expanding suprapubic mass
  - contraindications: suspected urethral injury and difficult insertion of catheter

## Surgical Complications

- general principles in preventing complications during the postoperative period include:
  - frequent examination of the patient (daily or more) and their wound
  - removal of surgical tubes as soon as possible (e.g. Foley catheters and surgical drains)
  - early mobilization
  - monitor fluid balance and electrolytes
  - analgesia - enough to adequately address pain (minimize opioids through routine use of anti-inflammatories and acetaminophen)

## Postoperative Fever

- postoperative fever is considered a temperature higher than 38C on two consecutive postoperative days or higher than 39 C on any postoperative day
- fever does not necessarily imply infection, particularly in the first 24-48 h postoperatively
- fever may not be present or may be blunted if patient is receiving chemotherapy, glucocorticoids, or other immunosuppressive agents
- timing of fever may help identify cause
- hours after surgery - POD #1
  - inflammatory reaction in response to physiological stress from surgery; most common cause of fever on POD #1-3 and unlikely to be infectious (unless necrotizing fasciitis or another severe infection)
  - reaction to blood products received during surgery
  - malignant hyperthermia
- POD #1-2 (acute)
  - atelectasis
  - early necrotizing fasciitis wound infection (especially *Clostridium perfringens*,  $\beta$ -hemolytic Group A *Streptococcus*); feel for crepitus and look for "dishwater" drainage
  - aspiration pneumonitis
  - other: acute adrenal insufficiency, thyroid storm, and transfusion reaction
- POD #3-7: likely infectious
  - UTI, surgical site infection, IV site/line infection (commonly with *Staphylococcus*), septic thrombophlebitis, and leakage at bowel anastomosis (tachycardia, hypotension, oliguria, and abdominal pain)
- POD #8+
  - intra-abdominal abscess, DVT/PE (can be anytime postoperative, most commonly POD #8-10, may occur earlier but recognition is often delayed), and drug fever
  - other: URTI, infected seroma/biloma/hematoma, *C. difficile* colitis, and endocarditis

**Treatment**

- resuscitation then treat primary cause

## Wound/Incisional Complications

**WOUND CARE (see [Plastic Surgery, PL8](#))**

- can shower POD #2-3 after epithelialization of wound (or earlier depending on dressing)
- most dressings can be removed POD #2 and left uncovered if dry
- Steri strips or dermabond glue should be left on for up to 2 wk
- examine wound for wet dressing, signs of infection (fever, tachycardia, and pain)
- skin sutures and staples can be removed POD #7-10
  - exceptions: incision crosses crease (groin), closed under tension, in extremities (hand) or patient factors (elderly, corticosteroid use, or immunosuppressed) removed POD #14 or earlier if there are signs of infection
- negative pressure dressings consist of foam and suction, promote granulation
  - ideal for large (grafted sites) or non-healing wounds (irradiated skin or ulcer)

**DRAINS**

- drains may be placed selectively at the time of surgery to prevent fluid accumulation (blood, pus, serum, bile, and urine)
  - can be used to assess quantity of third space fluid accumulation postoperatively
- potential route of infection; to decrease risk of wound infection bring out through separate incision (vs. operative wound) and remove as soon as possible
- types of drains
  - open (e.g. Penrose), higher risk of infection
  - closed: 1) gravity drainage (e.g. Foley catheter); 2) underwater-seal drainage system (e.g. chest tube); 3) suction drainage (e.g. Jackson-Pratt)
  - sump (e.g. NG tube)
- monitor drain outputs daily
- drains should be removed once drainage is minimal (usually <30-50 cc/24 h)
- drains do not guarantee that the patient will not form a collection of fluid
- ridged drains can erode through internal structures, and excessive suction can cause necrosis
- evidence does not support routine postoperative drainage of abdominal cavity

**SURGICAL SITE INFECTION**

**Etiology**

- most surgical wounds are contaminated by bacteria often consisting of normal endogenous flora from skin, respiratory, GU, or GI tracts (depending on surgery)
  - e.g. skin flora (Gram positive cocci: *S. aureus*, *Streptococcus* spp.) and GI flora (Gram positive microbes: *Enterococcus* spp., *Clostridium* spp.; Gram negative rods: *E. coli*; anaerobic species)

**Risk Factors**

**Table 5. Classification of Surgical Wound Contamination**

Classification	Clean	Clean-Contaminated	Contaminated	Dirty/Infected
<b>Definition</b>	Incision under sterile conditions; nontraumatic; no entrance of hollow organ	Incision under sterile conditions; ENTRANCE of hollow viscus with no spillage; no evidence of active infection; minimal contamination with no spillage	Incision under sterile conditions; MAJOR contamination of wound during procedure (i.e. gross spillage of stool, infection in biliary, respiratory, or GU systems)	Established infection present before wound is made in skin; traumatic wound with delayed treatment Traumatic wound with delayed treatment
<b>Example</b>	Hernia repair	Routine cholecystectomy; colon resection	Bowel obstruction with enterotomy and spillage of contents; necrotic bowel resection; fresh traumatic wounds	Appendiceal abscess; traumatic wound with contaminated devitalized tissue; perforated viscus
<b>Infection Rate</b>	<2%	3-4%	7-10%	30-40%
<b>Wound Closure</b>	Primary closure	Primary closure	Often secondary closure	Secondary closure

- patient characteristics
  - age, DM, steroids, immunosuppression, smoking, obesity, burn, malnutrition, patient with other infections, traumatic wound, radiation, and chemotherapy
- other factors
  - prolonged preoperative hospitalization, skin preparation, multiple antibiotics, reduced blood flow, break in sterile technique, foreign bodies (drains, sutures, grafts), excessive tension, hematoma, seroma, hypoxemia, and hypothermia

**Prophylaxis**

- preoperative antibiotics for most surgeries (cefazolin ± metronidazole or if β-lactam allergy, clindamycin ± gentamicin or vancomycin)
  - within 1 h pre-incision; can re-dose at 1-2 half-lives (~q4-8 h) in the OR
  - not required for low-risk or clean surgery, e.g. elective thyroidectomy, cholecystectomy, hemorrhoidectomy, fistulotomy, and sphincterotomy for fissure
  - important to review patient factors and clinical context; immunosuppression (transplant, Cushing's, malignancy, etc.) would likely warrant preoperative antibiotics
  - some evidence suggests role in breast surgery
  - important that redosing antibiotics is performed if surgery is longer than the half-life of antibiotics
- reserve postoperative antibiotics for treatment of suspected or documented intra-abdominal infection
- normothermia (maintain patient temperature 36-38°C in the OR)
- hyperoxygenation (consider FiO<sub>2</sub> of 80% in OR)
- chlorhexidine-alcohol wash of surgical site
- hair removal should not be performed unless necessary; if so, clipping superior to shaving done at the time of surgery
- consider delayed primary closure of incision for contaminated wounds
- use sterile closing tray for laparotomy

Complication	Laboratory/Imaging Tests
<b>Wound Complication</b>	Wound culture, CBC, CT scan
<b>Fever</b>	CBC, electrolytes, glucose, creatinine, BUN, U/A, CXR, urine/blood/sputum and wound culture if applicable
<b>Respiratory Distress</b>	EKG, echo, CXR, ABG, CT-angiography of the chest
<b>AKI/Oliguria</b>	Electrolytes, glucose, creatinine, BUN, U/A with microscopy, urine electrolytes, EKG, renal US
<b>Hypotension</b>	CBC, electrolytes, glucose, creatinine, BUN, lactate, ABG, ACTH stimulation testing, cortisol level, and coagulation studies
<b>Ileus</b>	Electrolytes, glucose, creatinine, BUN, AXR
<b>Stress Ulcer</b>	CBC, upper endoscopy

**Preoperative Skin Antiseptics for Preventing Surgical Wound Infections after Clean Surgery**  
Cochrane DB Syst Rev 2015;4:CD003949

**Purpose:** To determine whether preoperative skin antiseptic prior to clean surgery prevents surgical-site infection (SSI) and to compare the effectiveness of other antiseptics.

**Methods:** Systematic review of RCTs part of the Cochrane Wounds Group Specialised Register and the Cochrane Central Register of Controlled Trials (CENTRAL). Main outcome was SSI. Secondary outcomes included quality of life, mortality, and resource use.

**Results:** 13 RCTs (n=2623 patients) were included that made 11 total comparisons between skin antiseptics. A single study found that 0.5% chlorhexidine solution in methylated spirits was significantly superior in preventing SSIs after clean surgery compared to alcohol-based povidone iodine solution. No other statistically significant differences were found.

**Conclusions:** Further research is warranted to determine the effectiveness of one antiseptic over the others at preventing SSI post clean surgery.

**Primary vs. Delayed Primary Incision Closure in Contaminated Abdominal Surgery: A Meta-Analysis**  
J Surg Res 2019;239:22-30

**Purpose:** To determine if delayed primary incision closure (DPC) has lower rates of surgical site infections (SSI) and length of stay (LOS) compared to primary incision closure (PC) in contaminated abdominal surgery.

**Methods:** Systematic review and meta-analysis of RCTs in Medline, Embase, and Cochrane database between 1980-2017.

**Results:** 12 RCTs were included and analyzed. Using a fixed-effect model, DPC showed significantly reduced SSI with risk ratio of 0.64 (95% CI 0.51-0.79; P<0.0001) and reduced LOS with a mean difference of less than one day compared with PC. However, using a random-effect model, there was no significant difference in SSI or LOS.

**Conclusions:** DPC may be the preferential option in contaminated abdominal incisions, however higher quality research is required to provide a more comprehensive evidence base.

**Clinical Features**

- typically fever POD #5-8 (*Streptococcus* and *Clostridium* can present in 24 h)
- localized pain, blanchable erythema, induration, purulent discharge, and warmth
- complications: fistula, sinus tracts, sepsis, abscess, suppressed wound healing, superinfection, spreading infection to myonecrosis or fascial necrosis (necrotizing fasciitis), wound dehiscence, evisceration, and hernia

**Treatment**

- examination of the wound: inspect, compress adjacent areas, swab drainage for C&S and Gram stain
- reopen affected part of incision, drain, pack, heal by secondary intention in most cases
- for deeper or necrotizing infections, debride necrotic and non-viable tissue
- antibiotics and demarcation of erythema only if cellulitis or immunodeficiency

**WOUND HEMORRHAGE/HEMATOMA****Risk Factors**

- anticoagulant therapy, coagulopathies, thrombocytopenia, DIC, severe liver disease, myeloproliferative disorders, severe arterial HTN, and severe cough
- more common with transverse incisions through muscle due to vascularity of muscle
- more clinically relevant in small working spaces such as breast or thyroid surgery (airway edema/compression)

**Clinical Features**

- pain, swelling, discoloration of wound edges, and leakage
- rapidly expanding neck hematoma can compromise airway and is a surgical emergency: consider having a suture kit at bedside in all neck surgery in the event of having to open the wound emergently (most important treatment in this case is to protect the airway with intubation)

**Treatment**

- pressure dressing
- open drainage ± wound packing (large hematoma only)
- if significant bleeding, may need to re-operate to find source (often do not find a discrete source)

**SEROMA**

- fluid collection related to serous lymph drainage
- secondary to transection of lymph vessels
- increased infection risk if drained

**Treatment**

- observation
- consider pressure dressing ± needle drainage (this may increase infection risk)

**WOUND DEHISCENCE**

- disruption of a wound that was primarily closed, causing loss of barrier of skin or fascia

**Risk Factors**

- local: technical failure of closure, excessive tension on the wound, increased intra-abdominal pressure (e.g. COPD, ileus, bowel obstruction), hematoma, infection, poor blood supply, radiation, and transverse incision
- systemic: male, smoking, malnutrition (hypoalbuminemia, vitamin C deficiency), connective tissue diseases, immunosuppression, pulmonary disease, ascites, poor nutrition, steroids, chemotherapy, obesity, and other (e.g. age, sepsis, and uremia)
- DM alone is not a risk factor

**Clinical Features**

- typically POD #1-3 or #7-10; most common presentation sign is serosanguinous (salmon-coloured) drainage from wound; erythema or leakage of enteric material
- ± evisceration
- palpation of wound edge: should normally feel a "healing ridge" from abdominal wall closure (raised area of tissue under incision)

**Treatment**

- place moist dressing over wound with binder around abdomen and transfer to OR
- may consider conservative management with debridement of fascial and/or skin margins
- evisceration (i.e. 'burst abdomen') is a surgical emergency: take patient for operative re-closure

**INCISIONAL HERNIA**

- a late complication of fascial dehiscence and failure of fascial closure; GI contents are still contained within sack of peritoneum
  - hernia can develop 6-8 wk postoperatively due to poor wound healing and/or increased stress on abdominal wall
- symptoms aggravated by coughing or straining
- smaller fascial defects such as laparoscopic port sites have a higher risk of incarceration
- definitive treatment: surgical repair
  - large hernias that pose little risk of incarceration do not need to be repaired as minimal chance of bowel obstruction

**Small Bites vs. Large Bites for Closure of Abdominal Midline Incisions (Stitch): A Double-Blind, Multicentre, Randomised Controlled Trial**  
Lancet 2015;386:1254-1260

**Purpose:** To compare the large bites suture technique with the small bites technique for fascial closure of midline laparotomy incisions.

**Methods:** RCT conducted at 10 hospitals in the Netherlands. Patients undergoing elective abdominal surgery randomized (1:1) to small or large bite technique. Primary outcome was incisional hernia occurrence.

**Results:** At one year follow-up, the large bites group had a greater incidence of incisional hernia occurrence than the small bites group (21% vs. 13%, respectively). Rates of adverse events did not differ between the groups.

**Conclusion:** Small bites suture technique is superior to the large bites technique for prevention of incisional hernia in midline incisions and is not associated with a higher rate of adverse events.

## Urinary and Renal Complications

### URINARY RETENTION

- may occur after any operation with general anesthesia or more commonly with spinal anesthesia
- more likely in older males with history of benign prostatic hyperplasia and patients on anticholinergics but can also happen in young, healthy patients

### Clinical Features

- abdominal discomfort, palpable bladder, overflow incontinence, post-void residual urine volume >100 mL

### Treatment

- Foley catheter to rest bladder, then trial of voiding
- often accompanied by an  $\alpha$ -blocker such as tamsulosin (does not start working for 48 h)
- if postoperative retention: patients may need to be sent home with foley catheter to follow-up within the week for trial-of-void

### OLIGURIA/ANURIA

#### Etiology

- prerenal (e.g. hypovolemia due to transient renal hypoperfusion) vs. renal (e.g. ATN, acute interstitial nephritis (AIN), acute glomerulonephritis) vs. postrenal (e.g. urinary tract obstruction)
- most common postoperative cause is prerenal  $\pm$  ischemic ATN
  - external fluid loss: hemorrhage, dehydration, and diarrhea
  - internal fluid loss: third-spacing due to bowel obstruction and pancreatitis

#### Clinical Features

- urine output <0.5 cc/kg/h (e.g. <450 cc in 75 kg patient in 12 h), increasing Cr and BUN

#### Treatment

- according to underlying cause; fluid deficit is treated with crystalloid (NS or RL)

## Postoperative Dyspnea

- see *Respiratory Complications* and *Cardiac Complications*, GS12

#### Etiology

- respiratory: atelectasis, pneumonia/pneumonitis, pulmonary embolism (PE), ARDS, asthma, and pleural effusion
- cardiac: MI, arrhythmia, and CHF
- inadequate pain control

## Respiratory Complications

### ATELECTASIS

- comprises 90% of postoperative pulmonary complications

#### Risk Factors

- COPD, smoking, obesity, and elderly persons
- upper abdominal/thoracic surgery, oversedation, significant postoperative pain, and poor inspiratory effort

#### Clinical Features

- postoperative atelectasis may be asymptomatic or present as low-grade fever on POD #1, tachycardia, crackles, decreased breath sounds, bronchial breathing, and tachypnea

#### Treatment

- preoperative prophylaxis
  - smoking cessation (best if >8 wk preoperative)
- postoperative prophylaxis
  - incentive spirometry, deep breathing exercise, chest physiotherapy, and intermittent positive-pressure breathing
  - short-acting neuromuscular blocking agents
  - minimize use of respiratory depressive drugs, and ensure adequate pain control, and early ambulation

### PNEUMONIA/PNEUMONITIS

- may be secondary to aspiration of gastric contents during anesthetic induction or extubation causing a chemical pneumonitis

#### Risk Factors

- aspiration: general anesthetic, decreased LOC, GERD, full stomach, bowel/gastric outlet obstruction + non-functioning NG tube, pregnancy, and seizure disorder
- non-aspiration: atelectasis, immobility, and pre-existing respiratory disease

**Clinical Features**

- productive cough and fever
- tachycardia, cyanosis, respiratory failure, and decreased LOC
- CXR: pulmonary infiltrate

**Treatment**

- prophylaxis: see atelectasis prophylaxis, preoperative NPO/NG tube, and rapid sequence anesthetic induction
- immediate removal of debris and fluid from airway
- consider endotracheal intubation and flexible bronchoscopic aspiration
- empiric IV antibiotics to cover oral nosocomial aerobes and anaerobes (e.g. piperacillin-tazobactam, ceftipime + metronidazole)

**PULMONARY EMBOLUS****Clinical Features**

- unilateral leg swelling and pain (DVT as a source of PE), sudden onset dyspnea, pleuritic chest pain, tachycardia, and fever
- most commonly POD #8-10, but can occur anytime postoperatively, even after discharge
- diagnosis made by chest CT scan usually

**Treatment**

- initial treatment: IV heparin or subcutaneous LMWH, bridging to therapeutic anticoagulation is required for a minimum of 3 mo (usually 6 mo); for patients with cancer, or other risk factors for hypercoagulability, the duration of anticoagulation may be longer; severe cases may require endovascular thrombectomy and thrombolysis
- Greenfield (IVC) filter if contraindications to anticoagulation helps prevent worsening of PE
- prophylaxis: subcutaneous heparin (5000 units BID) or LMWH, compression stockings (TED™ Hose), and sequential compression devices

**PULMONARY EDEMA****Etiology**

- cardiogenic vs. noncardiogenic
- circulatory overload: excess fluid overload, left ventricular (LV) failure, shift of fluid from peripheral to pulmonary vascular bed, negative airway pressure, and alveolar injury due to toxins (e.g. ARDS)
  - more common with pre-existing cardiac disease
- negative pressure pulmonary edema due to inspiratory efforts against a closed glottis upon awakening from general anesthesia

**Clinical Features**

- shortness of breath, crackles at lung bases, and CXR abnormal

**Treatment (LMNOP)**

- Lasix® (furosemide)
- Morphine (decreases symptoms of dyspnea, venodilator, and afterload reduction)
- Nitrates (venodilator)
- Oxygen + non-invasive ventilation
- Position (sit patient up)

**RESPIRATORY FAILURE****Clinical Features**

- dyspnea, cyanosis, and evidence of obstructive lung disease
- earliest manifestations - tachypnea and hypoxemia (RR >25, PO<sub>2</sub> <60)
- pulmonary edema and unexplained decrease in SaO<sub>2</sub>

**Treatment**

- ABCs, O<sub>2</sub>, ± positive pressure ventilation, and intubation
- bronchodilators and diuretics to treat CHF
- adequate blood pressure to maintain pulmonary perfusion
- if these measures fail to keep PaO<sub>2</sub> >60, consider ARDS (see [Respirology, R26](#))

**Cardiac Complications**

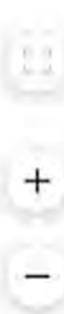

- abnormal ECGs common in postoperative period (compare to preoperative ECG)
- common arrhythmias: supraventricular tachycardia, atrial fibrillation (secondary to fluid overload, PE, and MI)

**MYOCARDIAL INFARCTION**

- see [Cardiology and Cardiac Surgery, C9](#)
- surgery increases risk of MI
- Incidence
  - 0.5% in previously asymptomatic men ages >50
  - 40-fold increase in men ages >50 with previous MI

New onset "asthma" and wheezing in the elderly is cardiogenic until proven otherwise

**Risk Factors**

- preoperative HTN, CHF
- previous MI (highest risk  $\leq 6$  mo, but risk never returns to baseline)
- increased age
- intraoperative hypotension
- operations  $> 3$  h
- angina

**Clinical Features**

- majority of cases on day of operation or POD #3-4 (shifting of third space fluid back into intravascular compartment)
- often silent without chest pain, may only present with new-onset CHF (dyspnea), arrhythmias, and hypotension

**Intra-Abdominal Abscess****Definition**

- collection of pus walled-off from rest of peritoneal cavity by inflammatory adhesions and viscera

**Etiology**

- usually polymicrobial: Gram-negative bacteria, and anaerobes
  - consider Gram-positives if coexisting cellulitis

**Risk Factors**

- emergency surgery and contaminated OR
- GI surgery with anastomotic leak
- poor healing risk factors (DM, poor nutrition, etc.)
- may occur POD #3 after laparotomy when third space fluid redistribution occurs

**Clinical Features**

- manifests at least 5-7 d after surgery. Cannot manifest earlier as it takes time to form collection
- persistent spiking fever, dull pain, and weight loss
- peritoneal signs if abscess perforation and secondary peritonitis
- leukocytosis or leukopenia (immunocompromised and elderly)
- coexisting effusion (pleural effusion with subphrenic abscess)
- mass is often difficult to palpate
- common sites: pelvis, Morrison's pouch (space between kidney and liver), subphrenic, paracolic gutters, lesser sac, peri-appendiceal, post-surgical anastomosis, diverticular, and psoas

**Investigations**

- CBC, blood cultures x2
- CT  $\pm$  IV and water-soluble contrast
- DRE (pelvic abscess)

**Treatment**

- drain placement by interventional radiology (preferred), laparoscopy, and open drainage
- subsequent antibiotic coverage; ceftriaxone + metronidazole or piperacillin-tazobactam (Pip-Tazo)

**Paralytic Ileus**

- see *Paralytic Ileus, GS31*

**Delirium**

- see *Psychiatry, PS23* and *Neurology, N21*

**Thoracic and Foregut Surgery****Approach to the Solitary Pulmonary Nodule**

- see *Medical Imaging, M18*

**Definition**

- lesion up to 3 cm, which may or may not be calcified and is surrounded by normal lung
- can be benign or malignant

**Differential Diagnosis of Upper GI Symptoms**

GI Causes	Non-GI Causes
Cholelithiasis	MI
Diverticulitis	Angina
Peptic ulcer	Pericarditis
Achalasia	
Pancreatitis	
GERD	
Gastritis	
Hiatus hernia	

Horner has a MAP of the Coast  
A Pancoast tumour compresses the cervical sympathetic plexus causing Horner's syndrome:  
Miosis  
Anhidrosis  
Ptosis

**Differential of an Anterior Compartment Mass**

4 Ts  
Thymoma  
Thyroid enlargement (goitre)  
Teratoma  
Tumours (lymphoma, parathyroid, esophageal, angiomatous)

Activate Windows

Go to Settings to activate Windows.

**Table 6. Differential Diagnosis for Benign vs. Malignant Solitary Nodule**

Benign (70%)	Malignant (30%)	
<b>Infectious granuloma</b> (histoplasmosis, coccidiomycosis, TB, atypical mycobacteria) - most common	<b>Bronchogenic carcinoma</b>	<b>Metastatic lesions</b>
<b>Other infections</b> (bacterial abscess, PCP, aspergilloma)	Adenocarcinoma	Breast
<b>Benign neoplasms</b> (hamartoma, lipoma, fibroma)	SCC	Head and neck
<b>Vascular</b> (AV malformation, pulmonary varix)	Large cell carcinoma	Melanoma
<b>Developmental</b> (bronchogenic cyst)	Small cell carcinoma	Colon
<b>Inflammatory</b> (granulomatosis with polyangiitis, rheumatoid nodule, sarcoidosis, amyloidosis)	Small cell lung cancer	Kidney
<b>Other</b> (infarct, pseudotumour, rounded atelectasis, lymph nodes, amyloidoma)		Sarcoma
		Germ cell tumours

**Investigations**

- CXR: always compare with previous CXR
- CT and contrast-enhanced CT of thorax
- biopsy (bronchoscopic or percutaneous) or excision (thoracoscopy): if clinical and radiographic features do not help distinguish between benign or malignant lesion
  - if at risk for lung cancer, biopsy may be performed regardless of radiographic features
  - if a biopsy is non-diagnostic, whether to observe, re-biopsy, or resect will depend on the level of suspicion
- watchful waiting: repeat CT scan at 3, 6, 12 mo depending on nodule characteristics and patient risk
- PET scan can narrow the differential diagnosis

**Table 7. CT Characteristics of Benign vs. Malignant Solitary Nodule**

Parameters	Benign	Malignant
<b>Size</b>	Nodule (<3 cm)	Mass (>3 cm)
<b>Borders</b>	Smooth or lobulated	Irregular or spiculated
<b>Features</b>	Calcified pattern: diffuse, central, laminated, "popcorn" pattern if hamartoma, usually no cavitation; if cavitating, wall is smooth and thin, no other lung pathology	Usually not calcified; if calcified, pattern is eccentric, stippled, no satellite lesions, cavitation with thick wall, may have pleural effusions, lymphadenopathy
<b>Doubling Time</b>	Doubles in <20 or >400 d	Doubles between 20 and 400 d

**Table 8. Evaluation of a Solitary Pulmonary Nodule**

Nodule Type	SOLID NODULES		
	Size <6 mm (<100 mm <sup>2</sup> )	Size 6-8 mm (100-250 mm <sup>2</sup> )	Size >8 mm (>250 mm <sup>2</sup> )
<b>Single</b>			
<b>Low-Risk</b>	No routine follow-up	CT at 6-12 mo, then consider CT at 18-24 mo	Consider CT at 3 mo, PET/CT or tissue sampling
<b>High-Risk</b>	Optional CT at 12 mo	CT at 6-12 mo, then at 18-24 mo	Consider CT at 3 mo, PET/CT or tissue sampling
<b>Multiple</b>			
<b>Low-Risk</b>	No routine follow-up	CT at 3-6 mo, then consider CT at 18-24 mo	CT at 3-6 mo, then consider CT at 18-24 mo
<b>High-Risk</b>	Optional CT at 12 mo	CT at 3-6 mo, then at 18-24 mo	CT at 3-6 mo then at 18-24 mo
Nodule Type	SUBSOLID NODULES		
	Size <6 mm (<100 mm <sup>2</sup> )	Size ≥6 mm (>100 mm <sup>2</sup> )	
<b>Single</b>			
<b>Ground Glass</b>	No routine follow-up	CT at 6-12 mo to confirm persistence then CT every 2 yr until 5 yr	
<b>Part Solid</b>	No routine follow-up	CT at 3-6 mo to confirm persistence If unchanged and solid component remains <6 mm, annual CT should be performed for 5 yr	
<b>Multiple</b>	CT at 3-6 mo, if stable consider CT at 2 and 4 yr	CT at 3-6 mo Subsequent management based on the most suspicious nodule(s)	

Adapted from: MacMahon H, Naidich DP, Goo JM, et al. Guidelines for Management of Incidental Pulmonary Nodules Detected on CT Images. The Fleischner Society 2017. *Radiology Journal*. doi:10.1148/radiol.2017161659. Feb 23 2017.

**Lung Cancer****Classification**

- lung tumours can be classified as:
  - primary or secondary
  - benign or malignant
  - endobronchial or parenchymal
- bronchogenic carcinoma (epithelial lung tumours) are the most common type of primary lung tumour (other types make up less than 1%)
  - small cell lung cancer (SCLC): 10-15%

- non-small-cell lung cancer (NSCLC): 85-90%
  - SCC: arise from the proximal respiratory epithelium
  - adenocarcinoma: incidence is increasing; most common subtype in nonsmokers
    - mucinous adenocarcinoma: grows along the alveolar wall in the periphery; may arise at sites of previous lung scarring
  - large cell carcinoma
- benign epithelial lung tumours can be classified as papillomas or adenomas

**Table 9. Characteristics of Lung Cancer**

Cell Type	Percentage of Lung Cancer	Correlation with Smoking	Location	Histology	Metastasis	5 Yr Survival Rates
SCLC	10-15%	Strong	Central	Oat cell, neuroendocrine	Disseminated at presentation Origin in endobronchial cells	10-13% limited stage, 1-2% extensive stage
Adenocarcinoma	M: 35% F: 40%	Moderate	Peripheral	Papillary, lepidic, acinar, mucinous, solid	Early, distant	70% limited stage, 7% extensive stage
SCC	30%	Strong	Central	Keratin, intercellular bridges	Local invasion and distant spread, may cavitate	47% limited stage, 6% extensive stage
Large Cell Carcinoma	10-15%	Strong	Peripheral	Anaplastic, undifferentiated	Early, distant	53% limited stage, 5% extensive stage

US Mortality Files, National Center for Health Statistics, CDC

**Risk Factors**

- cigarette smoking: the relative risk of developing lung cancer is 10-30 times higher for smokers than for nonsmokers
- risk of lung cancer increases with number of cigarettes smoked per day (linear) and duration of smoking (exponential)
- other risk factors: cigar smoking, pipe smoking, second-hand smoke, asbestos without smoking (relative risk is 5), asbestos with smoking (relative risk is 92), metals (e.g. chromium, arsenic, nickel), radon gas, ionizing radiation, and genetics

**Clinical Features**

- may be due to primary lesion, metastasis, or paraneoplastic syndrome
- primary lesion
  - cough (75%): beware of chronic cough that changes in character
  - dyspnea (60%)
  - chest pain (45%)
  - hemoptysis (35%)
  - other pain (25%)
  - clubbing (21%)
  - constitutional symptoms: anorexia, weight loss, fever, and fatigue
- metastasis
  - lung, hilum, mediastinum, pleura: pleural effusion, atelectasis, wheezing, post-obstructive pneumonia
  - pericardium: pericardial effusion, pericardial tamponade
  - esophageal compression: dysphagia
  - phrenic nerve: paralyzed diaphragm, dyspnea
  - recurrent laryngeal nerve: hoarseness
  - superior vena cava syndrome
    - obstruction of SVC causing neck and facial swelling
    - other symptoms: dyspnea, cough, hoarseness, tongue swelling, epistaxis, and hemoptysis
    - physical findings: dilated neck veins, increased number of collateral veins covering the anterior chest wall, cyanosis, edema of the face, arms, and chest, Pemberton's sign (facial flushing, cyanosis, and distension of neck veins upon raising both arms above head)
    - milder symptoms if obstruction is above the azygos vein
  - lung apex (Pancoast tumour): Horner's syndrome, brachial plexus palsy (most commonly C8 and T1 nerve roots)
  - rib and vertebrae: erosion, pain
  - distant metastasis to brain, bone, liver, and adrenals
- paraneoplastic syndromes
  - most often associated with SCLC

**Canadian Task Force on Preventive Health (2016)**

Screening with low-dose CT recommended for high-risk patients only:

- 55-74 yr
- ≥30 pack-yr smoking Hx
- Current smoker or quit within last 15 yr
- Annual screening low-dose CT up to 3 yr ONLY in centres with expertise in diagnosis and treatment of lung cancer

Malignant lung tumours are the most common cause of cancer mortality in both men and women worldwide

**Endobronchial Ultrasound (EBUS)**

- Allows visualization of peri-bronchial structures and lung lesions
- Allows for guided biopsies of lymph nodes and tumours
- Used for diagnosis and staging

Table 10. Paraneoplastic Syndromes

System	Clinical Features	Associated Malignancy
Skeletal	Clubbing, hypertrophic pulmonary osteoarthropathy (HPOA)	Non-small cell lung cancer (NSCLC)
Dermatologic	Acanthosis nigricans Dermatomyositis	Lung cancer
Endocrine	Hypercalcemia (osteolysis or PTHrP) Hypophosphatemia Hypoglycemia Cushing's syndrome (ACTH) Carcinoid syndrome SIADH	SCC SCC Sarcoma Small cell lung cancer (SCLC) Bronchial carcinoid SCLC
Neuromyopathic	Lambert-Eaton syndrome Polymyositis Subacute cerebellar degeneration Spinocerebellar degeneration Peripheral neuropathy	SCLC
Vascular/Hematologic	Nonbacterial endocarditis Trousseau's syndrome (migratory thrombophlebitis) DIC	Lung cancer NSCLC
Renal	Nephrotic syndrome	Lung carcinoma

### Investigations

- initial diagnosis
  - imaging: CXR, CT chest + abdomen, PET scan
  - biopsy: bronchoscopy, EBUS, CT-guided percutaneous needle biopsy
- staging workup
  - TNM staging system: T – primary tumour (size); N – regional lymph nodes; M – distant metastasis
  - blood work: electrolytes, LFTs, calcium, ALP
  - imaging: CXR, CT thorax and abdomen, PET scan, bone scan (-in confirmed stage 4 cancer), neuroimaging (MRI Brain)
  - invasive: bronchoscopy (EBUS), mediastinoscopy, VATS

Table 11. SCLC vs. NSCLC

	Stage	Definition	Treatment	Median Survival
SCLC	Limited stage	Confined to single radiation port (one hemithorax and regional lymph nodes)	Radiation ± chemotherapy ± prophylactic to brain	1-2 yr (12 wk without treatment)
	Extensive stage	Extension beyond a single radiation port	Chemotherapy	6 mo (5 wk without treatment)
	Stage	TNM	Treatment	5 Yr Survival (%)*
NSCLC	0	TisN0M0	1st line is complete surgical resection (VATS or open thoracotomy) with possible postoperative adjuvant chemotherapy with stage IB and stage II; radiotherapy for non-surgical candidates	90-92
	IA1	T1aN0M0		
	IA2	T1bN0M0		
	IA3	T1cN0M0		
	IB	T2aN0M0		
	IIA	T2bN0M0		
	IIB	T3N0M0 or T1N1M0 or T2N1M0		
	IIIA	T4N0M0 or T4N1M0 or T3M1N0 or T1N2M0 or T2N2M0		
	IIIB	T3N2M0 or T4M2N0 or T1N3M0 or T2N3M0		
	IIC	T3N3M0 or T4N3M0		
	IVA	T1-4N0-3M1a-1b		
	IVB	T1-4N0-3M1c		
			0	

\* Depends on clinical vs. pathologic stage Refer to AJCC Cancer Staging Manual, 8th ed. 2017 for complete TNM classification

### Treatment

- options include surgery, radiotherapy, ablation, chemotherapy, and palliative care for end-stage disease
- surgery not usually performed for SCLC since it is generally non-curable
- contraindications for surgery
  - spread to contralateral mediastinal lymph nodes or distant sites
    - patients with potentially resectable disease must undergo mediastinal node sampling since CT thorax is not accurate in 20-40% of cases
  - poor pulmonary status (e.g. unable to tolerate resection of lung)
    - postoperative estimated FEV<sub>1</sub> and DLCO must be at least 40% of predicted to tolerate surgery
- chemotherapy (used in combination with other treatments)
  - common agents: cisplatin-vinorelbine (standard of care), etoposide, ifosfamide, vincristine, anthracyclines, paclitaxel, irinotecan, gefitinib (an endothelial growth factor receptor inhibitor)
  - pembrolizumab, a PD-1 monoclonal antibody is used in those with tumour PD-L1 levels >50%; for those with PD-L1 levels <50%, combination of doublet chemotherapy and pembrolizumab is initiated

2/3 of primary lung cancer is found in the upper lung; 2/3 of metastases occur in the lower lung (hematogenous spread secondary to increased blood flow to the base of the lung)

#### Prevention

- Smoking cessation
- Avoidance of exposures
- Early detection

#### Terminology

- "Nodule" <3 cm
- "Mass" >3 cm

Mutations in endothelial growth factor receptor are more common in non-smoking patients with adenocarcinoma

#### Corona Radiata Sign on Chest CT

- Fine striations that extend linearly from a nodule in a spiculated fashion
- Highly associated with malignancy

#### Carcinoids

- Early onset (40-60 yr)
- Most are central and can produce symptoms and signs of bronchial obstruction
- Hemoptysis is present in ~50% of cases
- Assuming adequate pulmonary function, surgical resection (i.e. segmentectomy, wedge resections, and lobectomy) is the preferred treatment approach

- targeted therapies such as EGFR tyrosine kinase inhibitors and ALK tyrosine kinase inhibitors are used if tumour tests positive for these mutations
- complications
  - acute: tumour lysis syndrome, infection, bleeding, myelosuppression, hemorrhagic cystitis (cyclophosphamide), cardiotoxicity (doxorubicin), renal toxicity (cisplatin), peripheral neuropathy (vincristine)
  - chronic: neurologic damage, leukemia, additional primary neoplasms

## Pleura, Lung, and Mediastinum

- see [Respirology, R23](#)

### Complicated Parapneumonic Effusion

#### Definition

- persistent bacteria in the pleural space but fluid is non-purulent
- neutrophils, pleural fluid acidosis (pH < 7.20), low glucose (< 40 mg/dL)
- often no bacteria grown since rapidly cleared from pleural space

#### Clinical Features

- fever, pleuritic chest pain, dyspnea, and sputum production

#### Treatment

- antibiotics depending on Gram stain and culture
- chest tube drainage

### Empyema

#### Definition

- bacteria in pleural space or an effusion with organisms seen on a Gram stain or culture (e.g. pleural fluid is grossly purulent in advanced stage empyema)
- positive culture is not required for diagnosis

#### Etiology

- contiguous spread from lung infection (most commonly anaerobes) or infection through chest wall (e.g. trauma, surgery)

#### Clinical Features

- fever, pleuritic chest pain, dyspnea, and sputum production

#### Investigations

- CT chest
- thoracentesis
  - PMNs (lymphocytes in TB)  $\pm$  visible organisms on Gram stain

#### Treatment

- antibiotic therapy for at least 4-6 wk (rarely effective alone)
- complete pleural drainage with chest tube
- if loculated, more difficult to drain – may require surgical drainage with VATS, or fibrinolysis (surgical or tPA/DNase) to allow lung re-expansion (decortication)

### Pneumothorax

#### Definition

- presence of air in the pleural space
- can be classified as:
  - primary or secondary
  - open or closed
  - simple or tension or occult (only visible on CT scan)

#### Pathophysiology

- entry of air into pleural space raises intrapleural pressure causing partial or complete lung deflation

#### Etiology

- traumatic: penetrating or non-penetrating chest injuries
- iatrogenic: central venous catheter, thoracentesis, mechanical ventilation with barotrauma, surgery

#### Hamartomas

- 10% of benign lung lesions
- Composed of tissues normally present in lung (fat, epithelium, fibrous tissue, and cartilage), but they exhibit disorganized growth
- Peak incidence is age 60, more common in men
- Usually peripheral and clinically silent
- CXR shows clustered "popcorn" pattern of calcification (pathognomonic for hamartoma)
- Peripheral small hamartomas can generally be observed with occasional follow-up to monitor growth; symptomatic endobronchial hamartomas are removed via rigid transbronchial resection

- spontaneous: no history of trauma or other underlying cause
  - primary (no underlying lung disease)
    - spontaneous rupture of apical subpleural bleb (pockets of air) of lung into pleural space
    - smoker, male, family history, Marfan's syndrome
  - secondary (underlying lung disease)
    - rupture of subpleural bleb in the pleural space which can migrate along bronchioalveolar bronchoalveolar sheath to the mediastinum then to the intrapleural space
    - necrosis of lung tissue adjacent to pleural surface
    - pneumonia, abscess, PCP, lung cancer, COPD, CF, TB, lymphangioleiomyomatosis (LAM), pulmonary Langerhans cell histiocytosis (PLCH), lung metastasis (e.g. sarcoma)

### Clinical Features

- can be asymptomatic
- acute-onset pleuritic chest pain, dyspnea
- tachypnea, tachycardia
- tracheal deviation (contralateral deviation in tension pneumothorax)
- shock (in tension pneumothorax)
- ipsilateral diminished chest expansion
- decreased tactile/vocal fremitus
- hyperresonance
- ipsilateral diminished breath sounds

### Investigations

- CXR
  - small: separation of visceral and parietal pleura seen as fine crescentic line parallel to chest wall at apex
  - large: decreased density and decreased volume of lung on side of pneumothorax
  - see [Medical Imaging](#), M14 and M19

### Treatment

- primary spontaneous pneumothorax
  - stable, small (<3 cm), minimal symptoms: observation + O<sub>2</sub>
  - symptomatic or large (>3 cm): aspiration or chest tube
  - unstable/tension pneumothorax: needle decompression then chest tube, VATS bullectomy, and pleurodesis if unsuccessful (25-50%)
- secondary spontaneous pneumothorax
  - stable, small (<3 cm), minimal symptoms: observation + O<sub>2</sub>
  - symptomatic, large, or unstable: chest tube and VATS pleurodesis with or without bullectomy if unsuccessful

## Tube Thoracostomy

### Indications

- to drain abnormal air or fluid collections in the pleural space
  - hemothorax, pleural effusion, chylothorax, and empyema
  - pneumothorax, if:
    - large or progressive
    - patient is on mechanical ventilation
    - bronchopleural fistula
    - tension pneumothorax
- to treat symptomatic and/or recurrent pleural effusion
  - see [Respirology](#), R23
  - for long-term drainage of malignant effusions use: 1. Tunneled pleural catheter; 2. Pleural drainage and Talc pleurodesis
  - via facilitation of pleurodesis - obliteration of the pleural space by instilling talc or betadine (less common) to cause fusion of parietal and visceral pleura

### Complications

- overall complications are rare (1-3%)
- malposition (most common complication), especially by inexperienced operators
  - tubes may dissect along the external chest wall, or may be placed below the diaphragm
- bleeding (anticoagulation is a relative contraindication)
- local infection, empyema
- perforation of lung parenchyma or vasculature
- risk of re-expansion pulmonary edema when large volumes of air or fluid are drawn off quickly (>1.0-1.5 L)

Tube thoracostomy can be completed under U/S guidance

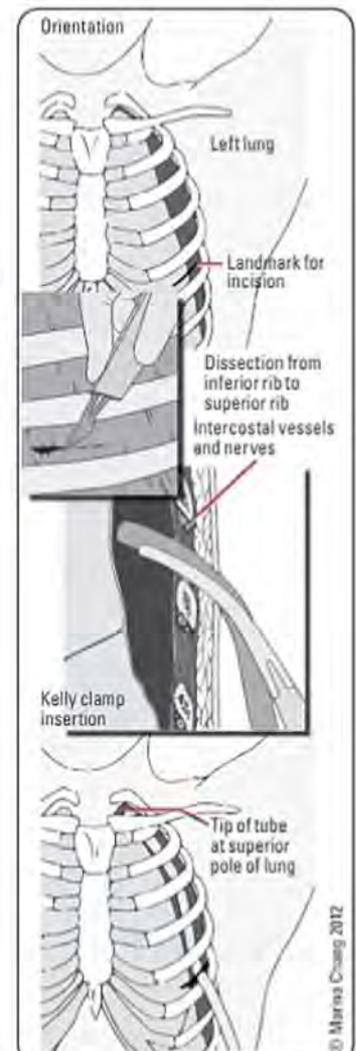

Figure 6. Tube thoracostomy

## Lung Transplantation

### Conditions Leading to Transplantation

- obstructive: chronic acquired lung disease (e.g. COPD), CF, and emphysema due to  $\alpha$ -1 antitrypsin deficiency
- restrictive interstitial lung disease: IPF, hypersensitivity pneumonitis
- vascular: idiopathic pulmonary arterial HTN (IPAH), secondary pulmonary HTN, and Eisenmenger's syndrome
- other: sarcoidosis, lymphangioleiomyomatosis, and pulmonary Langerhans cell histiocytosis

### Clinical Indications

- transplantation should be considered for patients with advanced lung disease refractory to maximal medical or surgical therapy
- patients who are symptomatic during activities of daily living and have risk of death >50% over the next 2 yr

### Criteria for Transplantation

- lung allocation score based on: 1) post-transplant survival measure, and 2) waiting list urgency measure
- transplant benefit = post-transplant survival (days) – waitlist survival (days)

### Absolute Contraindications

- uncontrolled or untreatable pulmonary or extrapulmonary infection
- active TB infection
- malignancy in the last 2 yr
- dysfunction of vital organs including glomerular filtration rate of  $<40$  mL/min/1.73 m<sup>3</sup>, stroke within 30 d, acute liver failure or cirrhosis, acute coronary syndrome within 30 d or heart disease not amenable to revascularization, and untreatable hematologic disorders
- active cigarette smoking
- BMI  $\geq 35$  kg/m<sup>2</sup>
- unresolved psychosocial problems or non-adherence to medical therapy
- smoking
- absence of social support system

### Relative Contraindications

- ages >70 years and low physiologic reserve
- BMI 30-34.9 kg/m<sup>2</sup>
- limited functional status including severe malnutrition or osteoporosis
- HIV infection, HBV infection
- alcohol (required to stay within healthy drinking guidelines)

### Postoperative Complications

- primary graft dysfunction
- airway anastomotic complications (bronchial necrosis and dehiscence, tracheobronchomalacia, stenosis)
- chronic lung allograft dysfunction (bronchiolitis obliterans syndrome and restrictive allograft syndrome)
- infectious complications (bacterial, fungal, CMV, community-acquired respiratory viruses, and mycobacteria)
- malignancy (non-melanoma skin cancer, post-transplant lymphoproliferative disorders, colon, breast, Kaposi's sarcoma, and bladder)

### Prognosis

- median survival for all adult recipients: 6.5 yr; bilateral transplant survival higher than single (7.6 vs. 4.7 yr, respectively)
- 1 yr survival: COPD > IPF > IPAH
- 10 yr survival: CF,  $\alpha$ -1 antitrypsin deficiency > IPAH > COPD, IPF

## Chronic Obstructive Pulmonary Disease

- see [Respirology, R9](#)

### Treatment

- indications for surgical management
  - dyspnea despite maximal medical therapy and pulmonary rehabilitation
  - CT showing hyperinflation and heterogeneously distributed emphysema predominant in the upper lung zone
  - may be used as a bridging procedure to lung transplantation

- contraindications
  - ages >75, cigarette smoking within the prior 6 mo, higher risk of surgical mortality (e.g. severe CAD or HF)
  - homogeneously distributed emphysematous changes without areas of preserved lung tissue
  - severe cachexia or obesity, chest wall deformity, or pulmonary HTN (PA systolic pressure >45 mmHg)
  - diffusing capacity of lung for carbon monoxide <20% of predicted, PaCO<sub>2</sub> >60 mmHg, PaO<sub>2</sub> <45 mmHg
- surgical procedures
  - lung volume reduction surgery: wedge excision of emphysematous tissue
  - bilateral or unilateral, thoracotomy or VATS (preferred)

### Complications of Treatment

- arrhythmias, pneumonia (may require reintubation and mechanical ventilation), prolonged air leak from chest tube

### Prognosis

- worse early mortality but better exercise capacity and quality of life with LVRS

## Mediastinal Masses

### Definition

- mediastinum: bound by the thoracic inlet, diaphragm, sternum, vertebral bodies, and the pleura
- can be broken down into 3 compartments: anterior, middle, and posterior

### Etiology and Pathophysiology

- diagnosis is aided by location and patient's age
- anterior compartment: more likely to be malignant
  - "Four T's" (see sidebar), lymphadenopathy, lipoma, pericardial cyst, goitre, and ascending aortic aneurysm thymic tumours/cysts
- middle compartment
  - pericardial cyst, bronchogenic cyst/tumour, lymphadenopathy, aortic aneurysm
- posterior compartment
  - neurogenic tumours, meningocele, enteric cysts, lymphadenopathy, diaphragmatic hernias, esophageal tumours, aortic aneurysm

### Clinical Features

- 50% asymptomatic (mainly benign); when symptomatic, 50% are malignant
- chest pain, cough, dyspnea, recurrent respiratory infections
- hoarseness, dysphagia, Horner's syndrome (see sidebar), facial/upper extremity edema (SVC compression)
- paraneoplastic syndromes (e.g. myasthenia gravis (thymomas))

### Investigations

- CXR (compare to previous)
- CT with contrast (anatomic location, density, relation to mediastinal vascular structures)
- MRI: specifically indicated in the evaluation of neurogenic tumours
- Echo: best for assessment of structures in close proximity to the heart and pericardium
- radionuclide scanning: <sup>131</sup>I (for thyroid), gallium (for lymphoma), PET/CT
- biochemical studies: thyroid function, serum calcium, phosphate, PTH, AFP, β-hCG, LDH
- biopsy (mediastinoscopy, bronchoscopy, and EBUS, percutaneous needle aspiration)

### Management

- excision – symptomatic benign mass that is enlarging or a mass with concerns for malignancy
- resect bronchogenic cysts and localized neurogenic tumours via VATS or open surgery
- diagnostic biopsy rather than major operation if mass is likely to be a lymphoma, germ cell tumour, or unresectable invasive malignancy
- no biopsy if AFP, β-hCG, LDH elevated – pathognomonic for germ cell tumour

## Thymoma

### Definition

- rare neoplasms in thymus, located in anterior mediastinum

### Epidemiology

- patients between 40 and 60 yr
- M=F
- no known risk factors, strong association with myasthenia gravis and other paraneoplastic syndromes

### Differential of an Anterior Compartment Mass

#### 4 Ts

- Thymoma
- Thyroid enlargement (goitre)
- Teratoma
- Tumours (lymphoma, parathyroid, esophageal, angiomatous)

### Mediastinal Components

- Anterior:** sternum to pericardium and great vessels. Includes: thymus, extra-pericardial aorta and branches, great veins, lymphatic tissues
- Middle:** pericardium (anteriorly), posterior pericardial reflection, diaphragm, thoracic inlet. Includes: heart, intrapericardial great vessels, trachea
- Posterior:** posterior pericardial reflection, posterior border of vertebral bodies, first rib to the diaphragm. Includes: esophagus, vagus nerve, thoracic duct, sympathetic chain, azygous venous system

### Masaoka Staging System

- Stage I: completely encapsulated
- Stage II: invasion beyond capsule
- Stage III: into another organ
- Stage IVa: pleural/pericardial mets
- Stage IVb: hematogenous/lymphatic mets

**Clinical Features**

- frequently asymptomatic: incidental finding on imaging
- symptoms related to tumour size and location (chest pain, SOB, cough, and phrenic nerve palsy)
- DDX includes intrathoracic goitre, lymphoma, and other anterior mediastinal tumours (see *Mediastinal Masses, GS20*)

**Investigations**

- CT chest (and/or MRI): assess resectability
- germ cell tumour markers ( $\beta$ -hCG,  $\alpha$  fetoprotein), thyroid function, acetylcholinesterase antibodies (to rule out myasthenia gravis), and PFTs
- Masaoka staging system widely used

**Treatment**

- for patients with resectable disease
  - surgical resection of the thymoma and the thymus via median sternotomy or VATS depending on the size
  - $\pm$  postoperative radiation based on Masaoka staging
    - radiation considered for stage II/III disease
- for potentially unresectable disease (i.e. invasion into heart and great vessels) or non-surgical patients
  - definitive or palliative chemo and radiation therapy
- re-evaluation if debulking procedure feasible in situations where preoperative chemo- and radiation therapy is offered
- common chemotherapy regimens include: 1) cyclophosphamide, doxorubicin, and cisplatin, or 2) cisplatin and etoposide

**Prognosis**

- depends upon stage of disease and resectability
- generally slow-growing tumours and have good prognosis

## Esophageal Carcinoma

**Epidemiology**

- M:F=3:1
- onset 50-60 yr
- upper (20-33%), middle (33%), and lower (33-50%)
- main types
  - most common worldwide: SCC in upper 2/3 of esophagus
  - most common in Western countries: adenocarcinoma in lower 1/3 of esophagus

**Risk Factors**

- SCC
  - underlying esophageal disease such as strictures, diverticula, and achalasia
  - smoking, alcohol, and hot liquids
  - more common in Black and Asian populations
- adenocarcinoma
  - Barrett's esophagus (most important), smoking, obesity (increased reflux), and GERD
  - more common in White populations

**Clinical Features**

- progressive dysphagia (mechanical): first solids then liquids, then saliva
- odynophagia then constant pain
- constitutional symptoms
- regurgitation and aspiration (aspiration pneumonia)
- hematemesis and anemia
- direct, hematogenous, or lymphatic spread
  - trachea (coughing), recurrent laryngeal nerves (hoarseness, vocal paralysis), aortic, liver, lung, bone, celiac, and mediastinal nodes

**Investigations and Staging**

- barium swallow: shows narrowing – suggestive but not diagnostic
- endoscopic biopsy to assess location, resectability, and confirm diagnosis
- both SCC and adenocarcinoma use TNM staging system but have separate stage groupings according to histology
- endoscopic U/S (EUS)
  - visualize local disease
  - regional nodal involvement (number of nodes may be more important than location)
- bronchoscopy and laryngoscopy
  - rule out airway invasion in tumours of the upper and middle esophagus
- full metastatic workup (CXR, bone scan, CT head, CT chest/abdomen/pelvis, and LFTs, etc.)
- PET scan more sensitive than CT in detecting metastatic disease

### Treatment

- if early stage (non-transmural and without evidence of nodal disease)
  - endoscopic mucosal resection can be considered for early mucosal cancer or high-grade dysplasia
  - esophagectomy (transthoracic or trans-hiatal approach) and lymphadenectomy
    - anastomosis in chest or neck
    - stomach is used for reconstruction; colon is rarely used
- if locally advanced (locally invasive disease or nodal disease on CT or EUS)
  - multimodal therapy
    - concurrent external beam radiation and chemotherapy (cisplatin and fluorouracil)
    - possibility of curative esophagectomy after chemoradiation if disease responds well
  - if unable to tolerate multimodal therapy or if highly advanced disease, consider palliative resection, brachytherapy, or endoscopic dilatation/stenting/laser ablation for palliation
- if present with distant metastatic disease, treat with systemic therapy and treat symptoms (esophageal stent or radiation)

### Prognosis

- TNM status - usually poor because presentation is usually at advanced stage

### OTHER DISORDERS

- esophageal motor disorders (see [Gastroenterology, G8](#))
- esophageal varices (see [Gastroenterology, G9](#))
- Mallory-Weiss tear (see [Gastroenterology, G30](#))

## Esophageal Perforation

### Etiology

- iatrogenic (most common)
  - endoscopic, dilatation, biopsy, intubation, operative, and NG tube placement (rare)
- barogenic
  - trauma
  - repeated, forceful vomiting (Boerhaave's syndrome)
  - other: convulsions, defecation, or labour (rare)
- ingestion injury
  - foreign body or corrosive substance
- carcinoma
- penetrating trauma

### Clinical Features

- neck or chest pain
- fever, tachycardia, hypotension, dyspnea, and respiratory compromise
- subcutaneous emphysema, pneumothorax, pleural effusion, voice changes, and hematemesis

### Investigations

- CXR: subcutaneous emphysema, pneumothorax, pneumomediastinum, pleural effusion, subdiaphragmatic air, and widened mediastinum
- CT chest with oral and IV contrast: pneumomediastinum, pleural effusion, pneumothorax, contrast in the chest, and subcutaneous emphysema
- contrast esophagram
  - Gastrografin® (water-soluble contrast) upper GI study is the first choice
  - if negative, followed by dilute barium upper GI study: contrast extravasation

### Treatment

- supportive if rupture is contained (see sidebar Cameron's Criteria)
- NPO, antibiotics, IV fluids, percutaneous drainage of mediastinal collections/abscess if needed, enteral/parenteral feed, and repeat imaging
- surgical (preferred treatment in progressively deteriorating or toxic patient)
  - <24 h from perforation
    - primary closure of a healthy esophagus with buttressed intercostal muscle flap or resection of diseased esophagus
  - >24 h from perforation, non-viable esophagus, or morbidly toxic patient
    - diversion and exclusion followed by delayed reconstruction (i.e. esophagostomy proximally, close esophagus distally, and gastrostomy/jejunostomy for decompression/feeding)

### Complications

- sepsis, abscess, fistula, empyema, mediastinitis, and death
- postoperative esophageal leak
- mortality 10-50% depending on timing of diagnosis, or etiology of the perforation, and underlying health and age of the patient

#### Cameron's Criteria for Conservative Management of Esophageal Perforation

- Perforation contained in mediastinum
- Contrast drains back into esophagus
- No signs of sepsis
- Minimal symptoms

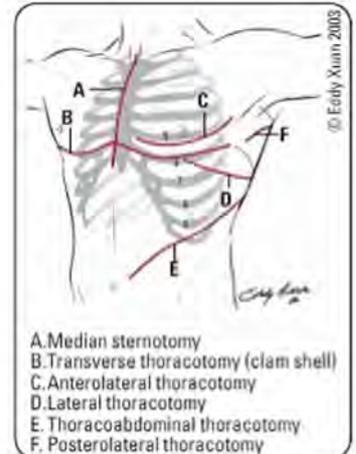

Figure 7. Typical thoracic surgery incisions

#### Boerhaave's syndrome: transmural esophageal perforation

**Mallory-Weiss tear:** non-transmural esophageal tear (partial thickness tear)  
Both are associated with forceful emesis

#### Standard of Care in 2019

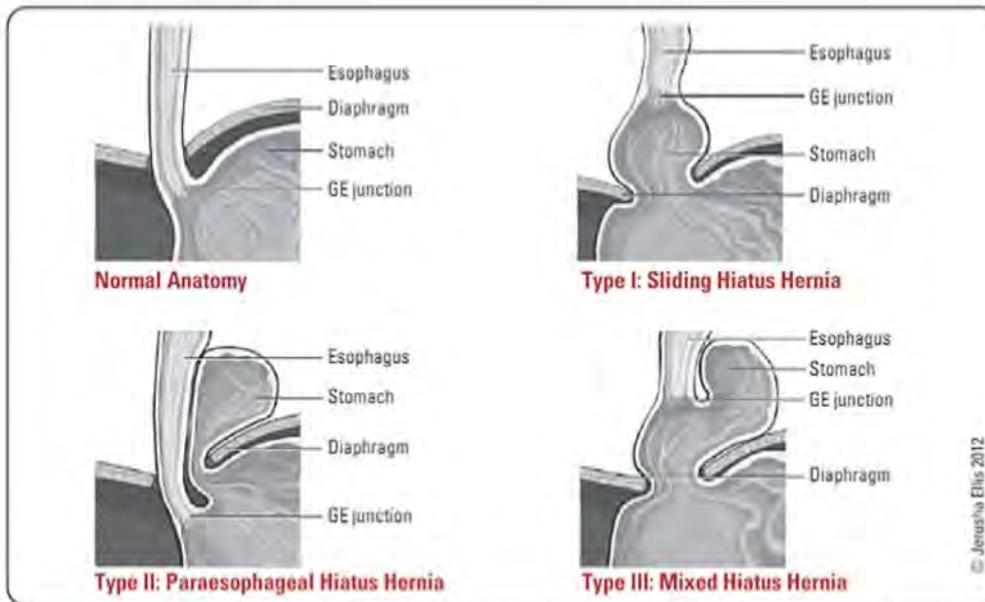

1. Pre- and postoperative FLOT chemotherapy for gastric and GE junction adenocarcinoma (docetaxel, oxaliplatin, and fluorouracil/leucovorin)
2. Neoadjuvant CROSS chemoradiotherapy for esophageal cancer with squamous histology or mid-body adenocarcinoma (carboplatin and paclitaxel plus radiotherapy)

#### 6Ss of SCC

Smoking  
Spirits (alcohol)  
Seeds (betel nut)  
Scalding (hot liquid)  
Strictures  
Sack (diverticula)

## Hiatus Hernia

**Figure 8. Types of hiatus hernia:** Type I: Sliding (GE junction above the level of the diaphragm) Type II: Paraesophageal (GE junction below the diaphragm, fundus rolls past it) Type III: Mixed and Type IV: Massive (not shown) (containing another intra-abdominal organ: bowel/spleen/etc.)

### SLIDING HIATUS HERNIA (TYPE I)

- reducible and/or limited herniation of both the stomach and the gastroesophageal (GE) junction into thorax
- 90% of esophageal hernias

### Risk Factors

- age
- increased intra-abdominal pressure (e.g. obesity, pregnancy, coughing, and heavy lifting)
- smoking

### Clinical Features

- majority are asymptomatic
- symptoms in decreasing frequency are heartburn, regurgitation, eructation, sour taste, and cough

### Complications

- complications are due to acid reflux when clinically significant and include these three categories:
  - esophagitis (dysphagia and heartburn)
  - consequences of esophagitis (peptic stricture, Barrett's esophagus, and esophageal carcinoma)
  - extra-esophageal complications (aspiration pneumonitis/pneumonia, bronchospasm, cough, and laryngitis)

### Investigations

- barium study
- CXR or CT scan
- 24 h esophageal pH monitoring to quantify reflux and esophageal manometry (technique for measuring LES pressure)
- endoscopy with biopsy to document type and extent of tissue damage and rule out esophagitis, Barrett's esophagus, and cancer

### Treatment

- lifestyle modification
  - smoking cessation, weight loss, elevate head of bed, no meals <3 h prior to sleeping, smaller and more frequent meals, avoid alcohol, coffee, mint, chocolate, and fatty foods
- medical
  - PPI, antacid, H<sub>2</sub>-antagonist, prokinetic agent
- surgical (<15% of cases)
  - consider if: volume regurgitation, patient unwilling or unable to stay on PPI indefinitely, suboptimal medical therapy, complications of GERD such as pharyngitis, esophageal stricture, recurrent nocturnal aspiration, Barrett's esophagus, patient preference
  - laparoscopic hiatus hernia repair and fundoplication
    - fundus of stomach is wrapped around the gastroesophageal junction and sutured in place

- operative principles are reduction of hernia, removal of hernia sac, fundoplication, and partial closure of hiatus
- 360 degree wrap: Nissen Fundoplication (most commonly performed). Dor, and Toupet are partial fundoplications
- expect transient postoperative clinical changes: dysphagia, bloating, excessive gas
- long-term complications may include post-prandial diarrhea and hernia recurrence in minority of patients
- dysphagia and gas bloat may be less with partial fundoplications (Toupet/Dor), however accompanied with higher risk of mild reflux symptoms
- 90% success rate for alleviating GERD

### PARAESOPHAGEAL HIATUS HERNIA (TYPE II)

- least common esophageal hernia (<10%)
- herniation of all or part of the stomach through the esophageal hiatus into the thorax with an undisplaced GE junction

#### Clinical Features

- usually asymptomatic due to normal GE junction
- dysphagia (most common), chest pain, and pressure sensation in lower chest

#### Complications

- hemorrhage, incarceration, strangulation (gastric volvulus), obstruction, gastric stasis ulcer (Cameron's lesion – causes Fe-deficiency anemia)

### MIXED HIATUS HERNIA (TYPE III)

- most common indication for surgical repair
- second most common type of hernia – combination of types I and II
- includes giant hernias or intrathoracic stomach
- rare incidence of gastric volvulus (Borschadt's Triad: chest pain, retching, inability to pass NG tube)
- may present with long-standing Fe-deficiency anemia of unknown etiology

#### Clinical Features

- symptoms may include reflux or heartburn
- most common symptoms: abnormal postprandial fullness after normal-sized meal, chest pain or retrosternal discomfort (gastric angina), and bloating
- can present with gastric outlet obstruction or gastric necrosis secondary to strangulation in the setting of gastric volvulus

#### Treatment

- surgery to address symptoms or treat/prevent complications
- reduce hernia and excise hernia sac, repair defect at hiatus, and anti-reflux procedure (e.g. Nissen fundoplication)
- may consider suturing stomach to anterior abdominal wall (gastropexy) to reduce the risk of gastric reherniation
- in very elderly patients at high surgical risk consider reduction of hernia and PEG (percutaneous endoscopic gastrostomy) insertion to anchor the stomach in the abdomen

### TYPE IV HERNIA

- herniation of stomach and other abdominal organs into thorax: colon, spleen, pancreas, and small bowel
- similar presentation as type III hernia and may include intermittent large bowel symptoms (pain, hematochezia, constipation, etc.) if it is herniated

#### WebSurg

<https://websurg.com/en/>

WebSurg is an excellent resource which allows trainees to learn many different surgical techniques via videos and lectures. This resource primarily focuses on laparoscopic surgeries

Elective laparoscopic procedures for paraesophageal hiatal hernia repair are associated with relatively low mortality. However, this value increases greatly with emergency repairs (7.5% vs. 0.5%)

## Achalasia

- esophageal smooth muscle motility disorder which occurs because the lower esophageal sphincter fails to relax
- esophagus does not have peristalsis
- in 50% of patients, the lower esophageal tone is hypertensive resulting in obstruction at the GE junction

#### Risk Factors

- spinal cord injury

#### Clinical Features

- dysphagia, initially solid than to liquids though a majority of patients will initially present with dysphagia to both solids and liquids
- regurgitation
- late symptoms include chest pain, nocturnal cough, and weight loss from difficulty eating

**Investigations**

- barium esophagram with a classic finding of smooth tapering of the lower esophagus to a "bird's beak" appearance
- upper endoscopy
- esophageal manometry will show incomplete lower esophageal sphincter relaxation in response to swallowing and sometimes a lack of peristalsis in the lower esophagus

**Treatment**

- non-surgical treatment:
  - pharmacologic: nitrates, calcium channel blockers, and phosphodiesterase-5 inhibitors to reduce LES pressure
  - endoscopic botulinum toxin injection
  - pneumatic dilation
- surgical treatment options:
  - laparoscopic Heller myotomy
  - peroral endoscopic myotomy

**Complications**

- esophageal perforation
- GERD
- bloating

## Stomach and Duodenum

### Peptic Ulcer Disease

**GASTRIC ULCERS**

- see [Gastroenterology, GI1](#)

**Indications for Surgery**

- treat complications: bleeding (common indication for emergency management), perforation, obstruction (3x greater risk compared to duodenal ulcers)
- refractory to medical management time period is unclear but generally after 8-12 wk of medical therapy
- suspicion of malignancy (even if biopsy benign) especially if ulcer fails to heal after 12 wk of medical therapy
- surgery increasingly rare due to *H. pylori* eradication, medical treatment, and endoscopic treatments (injection therapy with adrenaline, polidocanol, or fibrin glue) or coagulation therapy (heater probe or argon plasma)

**Procedures**

- ligation of bleeding vessels
- distal gastrectomy with ulcer excision: Billroth II, Roux-en-Y gastrojejunostomy, or Billroth I (rarely) reconstruction
- vagotomy and pyloroplasty only if acid hypersecretion (very rare)
- wedge resection if possible
- biopsy for suspicion of malignancy, followed by gastroscopy to minimize further bleeding and aid with healing

**DUODENAL ULCERS**

- see [Gastroenterology, Peptic Ulcer Disease, GI1](#)
- most within 2 cm of pylorus (duodenal bulb)

**Indications for Surgery**

- hemorrhage, rebleed in hospital, perforation, gastric outlet obstruction
- refractory to medical and endoscopic management

**Procedures**

- omental (Graham) patch: plication of perforated ulcer supported by overlying omental patch
- oversewing of bleeding ulcer  $\pm$  pyloroplasty
- treat with *H. pylori* eradication protocol postoperatively

**Complications of Gastric Surgery**

- retained antrum
- fistula (gastrocolic/gastrojejunal)
- dumping syndrome, postvagotomy diarrhea, afferent loop syndrome

**Table 12. Complications of Duodenal Ulceration**

Complication	Clinical Features	Management
<b>Perforated Ulcer (typically on anterior surface)</b>	Sudden onset of pain (possibly in RLO due to track down right paracolic gutter) Acute abdomen: rigid, diffuse guarding Ileus Initial chemical peritonitis followed by bacterial peritonitis	Investigation CXR free air under diaphragm (70% of patients)  Treatment Oversew ulcer (plication) and omental (Graham) patch most common treatment
<b>Penetration to Nearby Organs</b>	Elevated amylase/lipase if penetration into pancreas Elevated hepatic transaminases if penetration into liver (rare, but serious) Constant mid-epigastric pain burrowing into back, unrelated to meals	Management should follow the intensive measures for refractory ulcers
<b>Hemorrhage (typically on posterior surface)</b>	Gastroduodenal artery involvement	Resuscitation initially with crystalloids; blood transfusion if necessary Diagnostic and/or therapeutic endoscopy (laser, cautery, or injection); if recurs, may have second scope Consider interventional radiology: angiography with embolization/coiling Surgery if severe or recurrent bleeding, hemodynamically unstable, or failure of endoscopy and IR: oversewing of ulcer, pyloroplasty
<b>Gastric Outlet Obstruction</b>	Ulcer can lead to edema, fibrosis of pyloric channel, and neoplasm N/V (undigested food, non-bilious), dilated stomach, and crampy abdominal pain Succussion splash (splashing noise heard with stethoscope over the stomach when patient is shaken) Auscultate gas and fluid movement in obstructed organ	NG tube decompression and correction of hypochloremic, hypokalemic metabolic alkalosis Medical management initially: high-dose PPI therapy Surgical resection if obstruction does not resolve: either Billroth I, pyloroplasty, or gastrojejunostomy

## Gastric Carcinoma

### Epidemiology

- 5th most common cancer in the world
- M:F=3:2
- most common age group = 50-59 yr
- incidence has decreased by 2/3 in past 50 yr
- incidence highest in Asian, Latin American, and Caribbean countries

### Risk Factors

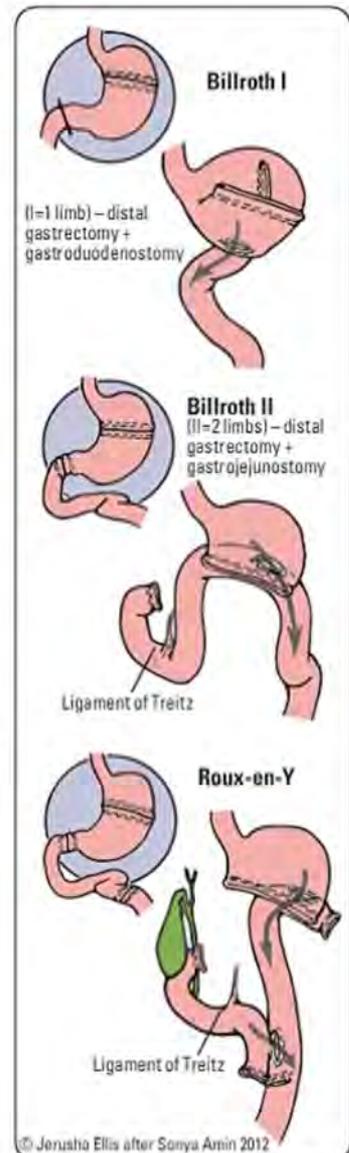

- compensatory epithelial cell proliferation via gastric atrophy from:
  - *H. pylori*, causing chronic atrophic gastritis
  - pernicious anemia associated with achlorhydria and chronic atrophic gastritis
  - previous partial gastrectomy (>10 yr post-gastrectomy)
- lifestyle and environmental factors:
  - salt and salt-preserved food (e.g. salted fish, cured meat, and salted vegetables)
  - obesity
  - cigarette smoking
  - EBV infection
  - abdominal radiation therapy
- host-related factors
  - blood type A – also associated with pernicious anemia
  - hereditary nonpolyposis colorectal cancer (HNPCC), hereditary diffuse gastric carcinoma (HDGC)
  - gastric adenomatous polyps
  - hypertrophic gastropathy
  - genetic syndromes: hereditary diffuse gastric cancer e.g. E-cadherin (CDH1) gene

### Clinical Features

- clinical suspicion
  - ulcer fails to heal
  - lesion on greater curvature of stomach or cardia
- asymptomatic, insidious, or late onset of symptoms
  - postprandial abdominal fullness, pseudoachalasia (in older patients), vague epigastric pain
  - anorexia or weight loss
  - eructation, N/V, dyspepsia, and dysphagia
  - hepatomegaly, epigastric mass (25%)
  - hematemesis, fecal occult blood, melena, and iron-deficiency anemia
- metastasis
  - peritoneum, ovarian, liver, lung, and brain

### Investigations

- OGD and biopsy; consider EUS to assess preoperative T-stage and N-stage
- CT chest/abdomen/pelvis

**Figure 9. Billroth I and Billroth II with Roux-en-Y reconstruction (gastrojejunostomy)**

**Kissing Ulcer:** combination of perforation and bleeding

**Signs of Metastatic Gastric Carcinoma**  
**Virchow's Node:** left supraclavicular node  
**Blumer's Shelf:** mass in pouch of Douglas  
**Krukenberg Tumour:** metastases to ovary  
**Sister Mary Joseph Node:** umbilical metastases  
**Irish's Node:** left axillary nodes

**Table 13. TNM Classification System for Staging of Gastric Carcinoma (AJCC/IUCC 2017, 8th edition)**

Primary Tumour (T)		Regional Lymph Nodes (N)		Distant Metastasis (M)	
<b>TX</b>	Primary tumour cannot be assessed	<b>NX</b>	Cannot be assessed	<b>M0</b>	No distant metastasis
<b>T0</b>	No evidence of primary tumour	<b>N0</b>	No regional node metastasis	<b>M1</b>	Distant metastasis
<b>Tis</b>	Carcinoma <i>in situ</i>	<b>N1</b>	Metastasis in 1-2 regional nodes		
<b>T1a</b>	Invasion into lamina propria or muscularis mucosae	<b>N2</b>	Metastasis in 3-6 regional nodes		
<b>T1b</b>	Invasion into submucosa	<b>N3a</b>	Metastasis in 7-15 regional nodes		
<b>T2</b>	Invasion into muscularis propria	<b>N3b</b>	Metastasis in ≥16 regional nodes		
<b>T3</b>	Penetration of subserosal connective tissue without tissue invasion of visceral peritoneum or adjacent structures				
<b>T4a</b>	Invasion into serosa				
<b>T4b</b>	Invasion into adjacent structures				

**Treatment**

- adenocarcinoma
  - proximal lesions
    - total gastrectomy and Roux-en-Y esophagojejunostomy
  - distal lesions
    - subtotal gastrectomy: wide margins, en bloc removal of omentum and lymph nodes (D2 lymphadenectomy) with Roux-en-Y or Billroth II reconstruction
  - adjuvant therapies
    - perioperative chemotherapy or postoperative chemoradiotherapy in addition to surgery is standard of care in curative intent strategy
  - palliation
    - limited gastric resection or endoscopic stenting to decrease bleeding and relieve obstruction, enables the patient to eat
    - radiation therapy
    - studies are showing larger role for adjuvant/neoadjuvant and palliative chemotherapy
- lymphoma
  - *H. pylori* eradication, chemotherapy ± radiation, and surgery in limited cases (perforation, bleeding, and obstruction)

**Gastrointestinal Stromal Tumour****Epidemiology**

- most common mesenchymal neoplasm of GI tract
- derived from interstitial cells of Cajal (cells associated with Auerbach's plexus that have autonomous pacemaker function which coordinate peristalsis throughout the GI tract)
- 75-80% associated with tyrosine kinase (c-KIT) mutations
- most common in stomach (50%) and proximal small intestine (25%), but can occur anywhere along GI tract
- often discovered incidentally on CT, laparotomy, or endoscopy

**Risk Factors**

- Carney triad: gastric GISTs, extra-adrenal paraganglioma, and pulmonary chondroma
- type I neurofibromatosis
- Carney-Stratakis syndrome

**Clinical Features**

- most commonly in stomach (40-60%) and jejunum (25-30%)
- typically present with vague abdominal mass, feeling of abdominal fullness, or with secondary symptoms of bleeding and anemia
- sometimes asymptomatic (13-18%)
- nonspecific symptoms (8-17%): bloating, early satiety, abdominal pain/discomfort
- overt or occult GI bleeding (50% of gastric GISTs)

**Investigations**

- contrast-enhanced CT is preferred imaging for screening and staging; MRI if IV contrast not feasible
- preoperative biopsy (endoscopic ultrasound): useful for indeterminate lesions (not recommended if high index of suspicion for GIST)
- given that lesion is submucosal, biopsy is sometimes not helpful

**Staging and 5 Yr Survival Rates for Gastric Cancer**

Stage	TNM	5 Yr Survival
<b>IA</b>	T1N0M0	71%
<b>IB</b>	T2N0M0	57%
	T1N1M0	
<b>IIA</b>	T3N0M0	45%
	T2N1M0	
	T1T2M0	
<b>IIB</b>	T4aN0M0	33%
	T3N1M0	
	T2N2M0	
	T1N3M0	
<b>IIIA</b>	T4aN1M0	20%
	T3T2M0	
	T2N3M0	
<b>IIIB</b>	T4bN0M0	14%
	T4bN1M0	
	T4aN2M0	
	T3N3M0	
<b>IIIC</b>	T4bN2M0	9%
	T4bN3M0	
	T4aN3M0	
<b>IV</b>	TxNxM1	4%

**Neoadjuvant Chemotherapy in Advanced Gastric and Esophago-Gastric Cancer. Meta-Analysis of Randomized Trials**

Int J Surg 2018;51:120-127

**Study:** Meta-analysis evaluating the effects of neoadjuvant chemotherapy on advanced gastric cancer.**Results/Conclusions:** Neoadjuvant chemotherapy and resection reduces overall mortality at 3 and 5 yr in advanced gastric cancer (RR=0.74; 0.82 respectively). Morbidity and perioperative mortality rate are not influenced by NACT. Recurrence rate is reduced by NACT + surgery in EGC (RR=0.80).

**Treatment**

- surgical resection if >2 cm; follow with serial endoscopy if <2 cm and resect if growing or symptomatic
- localized GIST
  - surgical resection with preservation of intact pseudocapsule
  - lymphadenectomy NOT required, as GISTs rarely metastasize to lymph nodes
  - consider adjuvant treatment with imatinib (Gleevec®) if high-risk of relapse (large, >4 cm with significant mitotic activity)
- advanced disease (i.e. metastases to liver and/or peritoneal cavity)
  - palliative intent chemotherapy with imatinib
  - metastasectomy may be considered for liver limited disease

**Prognosis**

- risk of metastatic potential depends on
  - tumour size (worse if >10 cm)
  - mitotic activity (worse if >5 mitotic figures/50 HPF)
  - degree of nuclear pleomorphism
  - location: with identical sizes, extra-gastric location has a higher risk of progression than GISTs in the stomach
- frequently metastasize to the liver and omentum; nodal and lung metastases rare

**Bariatric Surgery**

- weight reduction surgery for morbid obesity
- indications: BMI  $\geq 40$  without illness or BMI  $\geq 35$  with 1+ serious comorbidity (e.g. DM, CAD, sleep apnea, GERD, or severe joint disease)
  - Asian patients: growing evidence to lower BMI criteria by 2.5, BMI  $\geq 37.5$  or BMI  $\geq 35.5$  (higher prevalence of truncal obesity)
- consult with a multidisciplinary bariatric team: nutrition, psychological deterrents, life modifications, lifelong surveillance, reliable bariatric program (details realistic outcomes) to optimize success post-operation

**Surgical Options**

- combination malabsorptive and restrictive
  - laparoscopic Roux-en-Y gastric bypass (most common, most effective; higher complication rates)
    - small gastric pouch (restrictive), from distal stomach, anastomosed with Roux limb of small bowel (malabsorptive); connect to biliopancreatic limb to maintain digestive enzymes and bile
    - complications: gastric remnant distention, stomal stenosis, marginal ulcers, cholelithiasis, ventral incisional hernia, short bowel syndrome, dumping syndrome, metabolic perturbations, gastrogastroic fistula
  - restrictive laparoscopic sleeve gastrectomy
    - creation of tubular stomach via removal of majority of greater curvature
    - complications: bleeding from gastric or short gastric vessels from dissection of greater curve, stenosis at the gastroesophageal junction, gastric leaks
- malabsorptive
  - biliopancreatic diversion with duodenal switch (performed as a rescue operation after traditional Roux-en-Y)
    - anastomosis of stomach to distal ileum, anastomosis of biliopancreatic limb to terminal ileum
    - complications: protein calorie malnutrition, anemia, metabolic bone disease, fat-soluble vitamin deficiency

**Complications of Gastric Surgery**

- most resolve within 1 yr
- important to note that morbidly obese patients usually do not present with the symptoms and signs shown below; often times, the only presenting sign is tachycardia

**Alkaline Reflux Gastritis**

- duodenal contents (bilious) reflux into stomach causing gastritis  $\pm$  esophagitis
- treatment
  - medical: H2-blocker, metoclopramide, cholestyramine (bile acid sequestrant)
  - surgical: conversion of Billroth I or II to Roux-en-Y

**Afferent Loop Syndrome**

- accumulation of bile and pancreatic secretions causes intermittent mechanical obstruction and distention of afferent limb
- clinical features
  - early postprandial distention, RUQ pain, nausea, bilious vomiting, anemia
- treatment: surgery (conversion to Roux-en-Y increases afferent loop drainage)

**Extent of Lymph Node Dissection for Adenocarcinoma of the Stomach**

Cochrane DB Syst Rev 2015;12:CD0101954

**Study:** Systematic review and meta-analysis on the evidence that existed regarding the impact of the three main types of progressively more extended lymph node dissection (that is, D1, D2 and D3 lymphadenectomy) on the clinical outcome of patients with primary resectable carcinoma of the stomach.

**Results/Conclusions:** Data suggested no significant difference in overall survival between D2 and D3 type dissection. There was no significant difference in overall survival between D1 and D2 type node dissection. In contrast, D2 lymphadenectomy was associated with a significantly better disease specific survival compared to D1 lymphadenectomy but was also associated with a higher postoperative mortality rate.

**Surgery for Weight Loss in Adults**

Cochrane DB Syst Rev 2014;8:CD003641

**Study:** Update of a 2003 Cochrane review assessing the effects of bariatric surgery and control of comorbidities.

**Conclusions:** Surgery resulted in decreased BMI one to two years postoperative. 3 RCTs found that laparoscopic Roux-en-Y gastric bypass achieved significantly greater weight loss and BMI reduction up to 5 yr after surgery compared with laparoscopic adjustable gastric banding (mean difference -5.2 kg m<sup>-2</sup>; 95% CI -6.4 to -4.0). More patients experienced remission of diabetes with lap R-en-Y, however, different definitions were used. Risks of surgery include leaks, hernias, infection, pulmonary embolism, cholecystitis, and postoperative mortality.

**Dumping Syndrome**

- early: 15-30 min postprandial
  - etiology
    - rapid emptying of hyperosmotic chyme leads to jejunal distention, stimulating release of vasoactive hormones
  - clinical features
    - postprandial epigastric cramping, bloating, emesis, nausea, and vasomotor symptoms (dizziness, palpitations, tachycardia, diaphoresis)
  - treatment
    - frequent small meals high in fibre and protein, low in carbohydrates; avoidance of liquids with meals
    - last resort is interposition of antiperistaltic jejunal loop between stomach and small bowel to delay gastric emptying
- late: 3 h postprandial
  - etiology: hypoglycemia following postprandial insulin peak
  - treatment: small snack 2 h after meals

**Blind-Loop Syndrome**

- bacterial overgrowth of colonic Gram-negative bacteria in afferent limb
- clinical features
  - anemia/weakness, diarrhea, malnutrition, abdominal pain, and hypocalcemia
- treatment: broad-spectrum antibiotics and surgery (conversion to Billroth I)

**Postvagotomy Diarrhea**

- up to 25%
- bile salts in colon inhibit water resorption
- treatment: medical (cholestyramine) and surgical (reversed interposition jejunal segment)

**SMALL INTESTINE**

**Small Bowel Obstruction**

**Mechanical Small Bowel Obstruction**

**Pathophysiology**

- obstruction → gas and fluid (swallowed or GI secretions) accumulate proximal to site of obstruction and distal decompression → intestinal activity increases to overcome obstruction → colicky pain and diarrhea (initially)

**Etiology**

**Table 14. Common Causes of SBO**

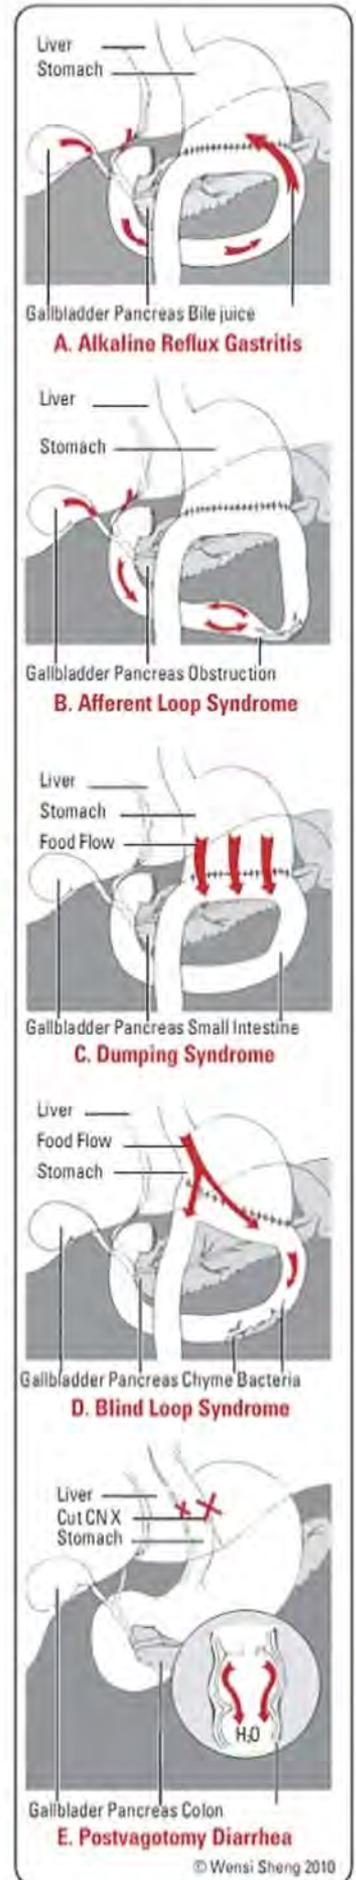

Intraluminal Foreign Body	Intramural	Extramural (>85% of causes)
Intussusception	Crohn's	Adhesions from previous surgeries (75% SBO)
Gallstones (gallstone ileus)	Radiation stricture	Incarcerated hernia
Bezoars	Neoplasm (adenocarcinoma, carcinoid, lymphoma, sarcoma)	Peritoneal carcinomatosis
Foreign Body		

• AAST grading system for severity (Grade - "Operative Criteria")

- partial SBO - minimal intestinal distension with no evidence of obstruction
- complete SBO with viable bowel - intestinal distension with transition point: no bowel compromise
- complete SBO with compromised but viable bowel - intestinal distension with impending bowel compromise
- complete SBO with nonviable bowel or perforation and localized spillage - intestinal distension with localized perforation or free fluid
- small bowel perforation with diffuse peritoneal contamination - intestinal distension with perforation, free fluid, and diffuse peritonitis
- closed-loop obstruction is when a segment is obstructed in two separate locations, creating a segment with no proximal or distal outlet and can rapidly progress to complications and require immediate abdominal exploration

**Risk Factors**

- prior abdominal or pelvic surgery (adhesions)
- abdominal wall or groin hernia
- personal history or increased risk of malignancy
- prior radiation

**Figure 10. Complications of gastric surgery**

- IBD
- history of foreign body ingestion

### Clinical Features

- symptoms: colicky periumbilical abdominal pain, N/V, obstipation, delayed passage/inability to pass flatus, inability to tolerate an oral diet
  - more feculent vomitus suggests more established obstruction because of bacterial overgrowth
  - passage of gas and/or stool that continues 6-12 h after onset of symptoms suggests partial rather than complete obstruction
  - inability to pass flatus is the most useful indicator
- signs: abdominal distention (most prominent if obstruction at distal ileum), hyperactive proceeding to minimal bowel sounds, bloating, hypovolemia, hyperresonance with percussion
- strangulated obstruction: abdominal pain disproportionate to physical exam findings suggest intestinal ischemia
  - may have tachycardia, localized abdominal tenderness, fever, marked leukocytosis, and lactic acidosis

### Investigations

- approach
  1. distinguish mechanical obstruction from ileus
  2. determine likely and easily reversible etiology of obstruction
  3. differentiate complicated (e.g. strangulated) obstruction
- imaging
  - AXR (3 views): triad of dilated small bowel (>3 cm in diameter), air-fluid levels on upright film, paucity of air in colon (high sensitivity, low specificity as ileus and LBO can present similarly)
  - CT with IV contrast: discrete transition zone/point with proximal bowel dilation, distal bowel decompression, and intraluminal contrast does not pass the transition zone
    - most importantly to rule out ischemic bowel/strangulation: pneumatosis intestinalis (free air in bowel wall) and thickened bowel wall, air in portal vein, free intraperitoneal fluid, and differential wall enhancements (poor uptake of IV contrast into the wall of the affected bowel)
  - other (less common)
    - upper GI series/small bowel series (if no cause apparent, i.e. no hernias, and no previous surgeries)
    - serial CTs with oral contrast
    - may consider U/S or MRI in pregnant patients
- laboratory
  - may be normal early in disease course
  - CBC, electrolytes, BUN, creatinine, lactate
  - creatinine and hematocrit to assess degree of dehydration
  - may have fluid and electrolyte abnormalities with metabolic alkalosis due to frequent emesis
  - if strangulation: leukocytosis with left shift, elevated lactate (late signs)

### Treatment

- IV isotonic fluid resuscitation and urine output monitoring with catheter
  - SBO related vomiting and decreased PO intake leads to volume depletion
- NG tube in the stomach for gastric decompression; decrease nausea, distention, and risk of aspiration from vomiting
- NPO
- if partial SBO/Crohn's/Carcinomatosis: conservative management with fluid resuscitation and NG tube decompression
  - 48 h of watchful waiting; if no improvement or develops complications, surgery
  - for Crohn's patients, consider GI consult for steroid management
- if no clinical features of ischemia: short course of conservative management with fluid resuscitation and NG tube decompression with frequent re-examination by surgical team
  - duration of observation varies from hours to a few days
  - if SBO fails to resolve, or if symptoms of ischemia develop, then surgery
- if high-risk for ischemia based on clinical symptoms: urgent surgery to prevent irreversible ischemia
  - early postoperative SBO: if bowel function does not return within 3-5 d after surgery; usually partial, extended conservative therapy (2-3 wk) with bowel rest, fluids, and TPN is appropriate
- immediate surgery if ischemia, necrosis, and perforation
  - clinical signs: fever, leukocytosis, tachycardia, worsening pain, metabolic and lactic acidosis, and tachypnea
  - radiologic signs: free air on radiographs or CT, closed-loop obstruction, abnormal course of a mesenteric vessel, and high-density free fluid

### Prognosis

- related to etiology; mortality: non-strangulating <1%, strangulating 8% (25% if >36 h), ischemic = up to 50%
- surgical intervention associated with a lower risk of recurrence

### Prevention

- open surgery has four-fold increase in risk of SBO in 5 yr compared to laparoscopic surgery

#### Increased Risk of Perforation with Distention as seen on Abdomen Imaging

- Small bowel  $\geq 3$  cm
- Distal colon  $\geq 6$  cm
- Proximal colon  $\geq 9$  cm
- Cecum  $\geq 12$  cm

Important to know if chronic vs. acute. Chronic distention is more likely to be tolerated without perforation

#### Patients with NO Abdominal Surgery History ("Virgin Abdomen")

Presenting with a SBO should have surgery ASAP (EXCEPTION: malignant obstruction from history and imaging)

#### Patients with Abdominal Surgery History ("Non-virgin Abdomen")

Adhesional SBOs resolve spontaneously with NG tube decompression 70% of time

#### Top 3 Causes of SBO (in order)

ABC  
Adhesions  
Bulge (hernias)  
Cancer (neoplasms)

#### Causes of SBO

SHAVING  
Stricture  
Hernia  
Adhesions  
Volvulus  
Intussusception/IBD  
Neoplasm  
Gallstones

## Paralytic Ileus

### Pathogenesis

- temporary, reversible impairment of intestinal motility; most frequently caused by:
  - abdominal operations, infections and inflammation, medications (opiates, anesthetics, psychotropics), and electrolyte abnormalities
  - often seen for patients in the postoperative setting from intra-abdominal sepsis (perforated appendicitis, diverticulitis, etc.)
  - pathophysiology related to inhibitory splanchnic reflexes, inhibitory sympathetic activity, inflammatory stress response, peptides (VIP, substance P, Calcitonin gene-related peptide (CGRP))
- NOT the same as intestinal pseudo-obstruction
  - chronic pseudo-obstruction refers to specific disorders that affect the smooth muscle and myenteric plexus, leading to irreversible intestinal dysmotility

### Clinical Features

- symptoms and signs of intestinal obstruction without mechanical obstruction
  - bowel sounds are diminished or absent (in contrast to initial hyperactive bowel sounds in SBO)
  - pain is often diffuse and less frequently has the colicky pattern present in mechanical obstruction
  - passing gas is the most useful indicator
- postoperative: gastric and small bowel motility returns by 24–48 h, colonic motility by 3–5 d

### Investigations

- routine postoperative ileus: expected, no investigation needed
- if ileus persists or occurs without abdominal surgery
  - review patient medications (especially opiates)
  - measure serum electrolyte to monitor for electrolyte abnormalities (including extended electrolytes like  $Mg^{2+}$ ,  $Ca^{2+}$ ,  $PO_4^{3-}$ )
  - creatinine and BUN
  - LFTs
  - CT scan to rule out abscess or peritoneal sepsis, or to exclude mechanical obstruction

### Treatment

- address underlying cause
- most important initial treatment: NPO + fluid resuscitation
- for prolonged ileus: NG tube decompression, TPN, and pain management

## Intestinal Ischemia

### Etiology

- acute
  - arterio-occlusive mesenteric ischemia (AOMI)
    - thrombotic, embolic, and extrinsic compression (e.g. strangulating hernia)
  - non-occlusive mesenteric ischemia (NOMI)
    - mesenteric vasoconstriction secondary to systemic hypoperfusion (preserves supply to vital organs)
  - mesenteric venous thrombosis (MVT)
    - consider hypercoagulable state (i.e. rule out malignancy) and DVT (prevents venous outflow)
- chronic: usually due to atherosclerotic disease – look for CVD risk factors
- can lead to occlusion in vessels that supplies the small intestine and the large intestine

### Clinical Features

- acute: severe abdominal pain out of proportion to physical findings, vomiting, bloody diarrhea, bloating, minimal peritoneal signs early in course, hypotension, shock, and sepsis
- chronic: postprandial pain (from mesenteric angina), fear of eating, and weight loss
- common sites: SMA supplied territory, “watershed” areas of colon – splenic flexure, left colon, and sigmoid colon

### Investigations

- laboratory: leukocytosis (non-specific) and lactic acidosis (late finding)
  - amylase, lactate, CK, and ALP can be used to observe progress
  - hypercoagulability workup if suspect venous thrombosis
- AXR: portal venous gas, intestinal pneumatosis, and free air if perforation
- contrast CT: thickened bowel wall, luminal dilatation, SMA or SMV thrombus, mesenteric/portal venous gas, and pneumatosis
- CT angiography is the gold standard for acute arterial ischemia

### Treatment

- fluid resuscitation, correct metabolic acidosis, NPO, NG tube decompression of stomach, and prophylactic broad-spectrum antibiotics; avoid vasoconstrictors and digitalis
- exploratory laparotomy/laparoscopy to assess extent of viability ± segmental resection of necrotic intestine
  - if extent of bowel viability is uncertain, a second-look laparotomy 12–24 h later is mandatory
- angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, anticoagulation therapy, and percutaneous transluminal angioplasty ± stent

Pain “out of keeping with physical findings” is the hallmark of early intestinal ischemia

An acute abdomen + metabolic acidosis is bowel ischemia until proven otherwise

## Tumours of Small Intestine

### BENIGN TUMOURS

- 10x more common than malignant
- usually asymptomatic until large
- most common sites: terminal ileum and proximal jejunum
- polyps
  - adenomas
  - hamartomas
  - FAP (see *Familial Colon Cancer Syndromes, GS42*)
  - juvenile polyps
- other: leiomyomas, lipomas, and hemangiomas

**Table 15. Malignant Tumours of the Small Intestine**

	Adenocarcinoma	Carcinoid/GI NET- Neuroendocrine Tumour	Lymphoma	Metastatic
<b>Epidemiology</b>	Usually 50-70 yr M>F	Increased incidence 50-60 yr	Highest incidence in 70s M-F Usually non-Hodgkin's lymphoma	Most common site of GI metastases in patients with metastatic melanoma
<b>Risk Factors</b>	Crohn's, FAP, history of CRC, HNPCC		Crohn's, celiac disease, autoimmune disease, immunosuppression, radiation therapy, and nodular lymphoid hyperplasia	Melanoma, breast, lung, ovary, colon, and cervical cancer
<b>Origin/Location</b>	Usually in proximal small bowel, incidence decreases distally	Classified based on embryological origin (foregut, midgut, and hindgut) Originate from gut enterochromaffin cell Appendix 46%, distal ileum 28%, rectum 17%	Usually distal ileum Proximal jejunum in patients with celiac disease	Hematogenous spread from breast, lung, and kidney Direct extension from cervix, ovaries, and colon
<b>Clinical Features</b>	Early metastasis to lymph nodes 80% metastatic at time of operation Abdominal pain (common)	N/V, anemia, GI bleeding, jaundice, and weight loss (less common) Often slow-growing Usually asymptomatic, incidental finding Obstruction, bleeding, crampy abdominal pain, and intussusception Carcinoid syndrome (<10%) Hot flashes, hypotension, diarrhea, bronchoconstriction, and right heart failure Requires liver involvement: lesion secretes serotonin, kinins, and vasoactive peptides directly to systemic circulation (normally inactivated by liver)	Fatigue, weight loss, fever malabsorption, abdominal pain, anorexia, vomiting, constipation, and mass Rarely perforation, obstruction, bleeding, and intussusception	Obstruction and bleeding
<b>Investigations</b>	CT abdomen/pelvis Endoscopy	Most found incidentally at surgery for obstruction or appendectomy CT thorax/abdomen/pelvis Consider small bowel enteroclysis to look for primary Serum chromogranin A as a tumour marker Elevated 5-HIAA (breakdown product of serotonin) in urine or increased 5-HT in blood Some nuclear medicine testing available but should be done by endocrine oncologist. Testing includes Gallium DOTATATE and octreotide scans	CT abdomen/pelvis	CT abdomen/pelvis
<b>Treatment</b>	Surgical resection ± chemotherapy	Surgical resection ± chemotherapy Carcinoid syndrome treated with octreotide Metastatic risk 2% if size <1 cm, 90% if >2 cm	Low-grade: chemotherapy with cyclophosphamide High-grade: surgical resection, and radiation Palliative: somatostatin, doxorubicin	Palliation
<b>Prognosis</b>	5 yr survival 25% (if node positive)	5 yr survival 70%; 20% with liver metastases Based on the Ki67 index	5 yr survival 40%	Poor
<b>Staging System</b>	TNM	TNM	Ann Arbor	

### Carcinoid Syndrome Symptoms

- FDR**  
Flushing  
Diarrhea  
Right-sided heart failure

### Indirect Inguinal Hernias: Rule of 5s

- 5% lifetime incidence in males
- 5x more common than direct inguinal hernias
- 5-10x more common in males than females
- Generally occur by 5th decade of life

## Short Gut Syndrome

### Definition

- reduced surface area (length) of small bowel causing insufficient intestinal absorption leading to diarrhea, malnutrition, and dehydration

### Etiology

- due to surgical resection
  - large amount of bowel at once (acute mesenteric ischemia, trauma, malignancies)
  - cumulative resections (Crohn's disease)
- in infant and paediatric patients, the most common causes are necrotizing enterocolitis, abdominal wall defects, jejunal ileal atresia, and midgut volvulus

### Prognostic Factors

- residual small bowel length, residual colon length (reabsorption of water and electrolytes and some reabsorption of nutrients), condition of the remnant small bowel (healthier bowel facilitate better reabsorption), presence of ileocecal valve (delay transition into colon leading to more reabsorption)
- resection of ileum is less tolerated than resection of jejunum (ileum reabsorbs bile salt and vitamin B<sub>12</sub>)

### Therapy

- medical
  - IV fluids in acute management (initial 3-4 wk following resection) and TPN once stabilized to replenish lost fluid and electrolytes in diarrhea
  - histamine 2-receptor antagonist or PPI to prevent gastric acid secretion
  - antimotility agent to prolong transit time in the small intestine
  - consider octreotide to decrease GI secretion and cholestyramine for bile acid absorption
- surgical: non-transplant
  - to slow transit time: small bowel segmental reversal, intestinal valve construction, or electrical pacing of small bowel
  - to increase intestinal length:
    - LILT (longitudinal intestinal lengthening and tailoring) procedure
    - STEP (serial transverse enteroplasty procedure) in dilated small bowels
- surgical: small bowel transplant
  - indication: life-threatening complication from intestinal failure or long-term TPN, including liver failure, thrombosis of major central veins, recurrent catheter-related sepsis, and recurrent severe dehydration

## Abdominal Hernia

- see *Hiatus Hernia*, GS23

### Definition

- defect in abdominal wall causing abnormal protrusion of intra-abdominal contents

### Epidemiology

- M:F=9:1
- lifetime risk of developing a hernia: males 20-25%, females 2%
- frequency of occurrence: 50% indirect inguinal, 25% direct inguinal, 8-10% incisional (ventral), 5% femoral, and 3-8% umbilical
- most common surgical disease in males

### Risk Factors

- activities which increase intra-abdominal pressure
  - obesity, chronic cough, asthma, COPD, pregnancy, constipation, bladder outlet obstruction, ascites, and heavy lifting
- congenital abnormality (e.g. patent processus vaginalis and indirect inguinal hernia)
- previous hernia repair, especially if complicated by wound infection
- loss of tissue strength and elasticity (e.g. hiatal hernia, aging, and repetitive stress)
- family history

### Clinical Features

- mass of variable size
- tenderness worse at end of day, relieved with supine position or with reduction
- abdominal fullness, vomiting, constipation
- transmits palpable impulse with coughing or straining

### Investigations

- physical examination usually sufficient
- U/S ± CT (CT required for obturator hernias, internal abdominal hernias, and Spigelian and/or femoral hernias in obese patients)

### Inguinal Hernias

#### MD's don't Lie

**MD:** Medial to the inferior epigastric a.  
= Direct inguinal hernia

**LI:** Lateral to the inferior epigastric a. = Indirect inguinal hernia

Inguinal Canal Walls = MALT x 2

**2 M Roof** 2 muscles (internal oblique, transversus abdominis)

**2 A Ant. wall** 2 aponeuroses (external and internal oblique)

**2 L Floor** 2 ligaments (inguinal and lacunar)

**2 T Post. wall** 2T (transversalis fascia, conjoint tendon)

### Borders of Hesselbach's Triangle

- Lateral: inferior epigastric artery
- Inferior: inguinal ligament
- Medial: lateral margin of rectus sheath

### Shouldice Technique vs. Other Open Techniques for Inguinal Hernia Repair

Cochrane DB Syst Rev 2012;4:CD001543.

**Purpose:** To evaluate the efficacy and safety of the Shouldice technique compared to other non-laparoscopic techniques.

**Results/Conclusions:** 16 RCTs or quasi-randomized RCTs with 2566 hernias (1121 mesh; 1608 non-mesh). The recurrence rate with Shouldice was higher than mesh (OR 3.80, 95% CI 1.99-7.26) but lower than non-mesh (OR 0.62, 95% CI 0.45-0.85). There was no difference in chronic pain or complications. In conclusion, with respect to recurrence rates, Shouldice herniorrhaphy is the best non-mesh technique, although inferior to mesh. However, it is also more time consuming and results in slightly longer postoperative hospital stays.

### Long-Term Results of a Randomized Controlled Trial of a Nonoperative Strategy (Watchful Waiting) for Men with Minimally Symptomatic Inguinal Hernias

Ann Surg 2013;258:508-514

**Purpose:** Ascertain the long-term crossover (CO) rate in patients with asymptomatic or minimally symptomatic inguinal hernias undergoing watchful-waiting (WW) as their primary treatment modality.

**Background:** A 2006 RCT comparing WW with routine inguinal hernia repair, concluded that WW was an acceptable option in the management of male patients with minimal symptoms (JAMA 2006;295(3):285-292). This study analyzes the WW group after 7 years of follow-up.

**Conclusions:** The estimated CO rate for the WW cohort was 68%, while men older than 65 had a rate of 79%. Therefore, while WW is a safe strategy, it is likely that symptoms will progress, and definitive surgical management will be indicated.

### Outcomes of Laparoscopic vs. Open Repair of Primary Ventral Hernias

JAMA Surg 2013;148:1043-1048

See Landmark General and Thoracic Surgery Trials table for more information on outcomes of patients electively undergoing laparoscopic ventral hernia repair (LVHR) vs. open ventral hernia repair (OVHR)

### Classification

- complete: hernia sac and contents protrude through defect
- incomplete: partial protrusion through the defect
- internal hernia: sac herniating into or involving intra-abdominal structure
- external hernia: sac protrudes completely through abdominal wall
- strangulated hernia: vascular supply of protruded viscus is compromised (ischemia)
  - requires emergency repair
- incarcerated hernia: irreducible hernia, not necessarily strangulated
- Richter's hernia: only part of bowel circumference (usually anti-mesenteric border) is incarcerated or strangulated so may not be obstructed
  - a strangulated Richter's hernia may self-reduce and thus be overlooked, leaving a gangrenous segment at risk of perforation in the absence of obstructive symptoms
- sliding hernia: part of wall of hernia sac formed by retroperitoneal structure (usually colon)

### Anatomical Types

- groin
  - indirect and direct inguinal, femoral
  - pantaloon: combined direct and indirect hernias, peritoneum draped over inferior epigastric vessels
- epigastric: defect in linea alba above umbilicus
- incisional: ventral hernia at site of wound closure, may be secondary to wound infection
- other: Littre's (involving Meckel's), Amyand's (containing appendix), lumbar, obturator, peristomal, umbilical, Spigelian (ventral hernia through linea semilunaris)

### Complications

- incarceration
- strangulation
  - small, new hernias more likely to strangulate
  - femoral > indirect inguinal > direct inguinal
  - intense pain followed by tenderness
  - intestinal obstruction, gangrenous bowel, sepsis
  - surgical emergency
  - DO NOT attempt to manually reduce hernia if septic or if contents of hernial sac gangrenous. This will result in reduction of gangrenous contents and subsequent need for laparotomy

### Treatment

- surgical treatment (herniorrhaphy) is only to prevent strangulation and evisceration, for symptomatic relief, for cosmesis; if asymptomatic can delay surgery. Data has shown that prophylactic surgery does not affect rate of strangulation in ASYMPTOMATIC patients.
- repair may be done open or laparoscopic and may use mesh for tension-free closure
- most repairs are now done using tension free techniques – a plug in the hernial defect and a patch over it or patch alone
- observation is acceptable for small asymptomatic inguinal hernias

### Postoperative Complications

- recurrence (15-20%)
  - risk factors: recurrent hernia, ages >50, smoking, BMI >25, poor preoperative functional status (ASA ≥3 – see [Anesthesia, A4](#)), associated medical conditions: T2DM, hyperlipidemia, immunosuppression, and any comorbid conditions increasing intra-abdominal pressure
  - less common with mesh/"tension-free" repair
- scrotal hematoma (3%)
  - painful scrotal swelling from compromised venous return of testes
  - deep bleeding: may enter retroperitoneal space and not be initially apparent
  - difficulty voiding
- nerve entrapment
  - ilioinguinal (causes numbness of inner thigh or lateral scrotum)
  - genital branch of genitofemoral (in spermatic cord)
- stenosis/occlusion of femoral vein
  - acute leg swelling
- ischemic colitis
- minimally invasive repair for ventral and umbilical hernia

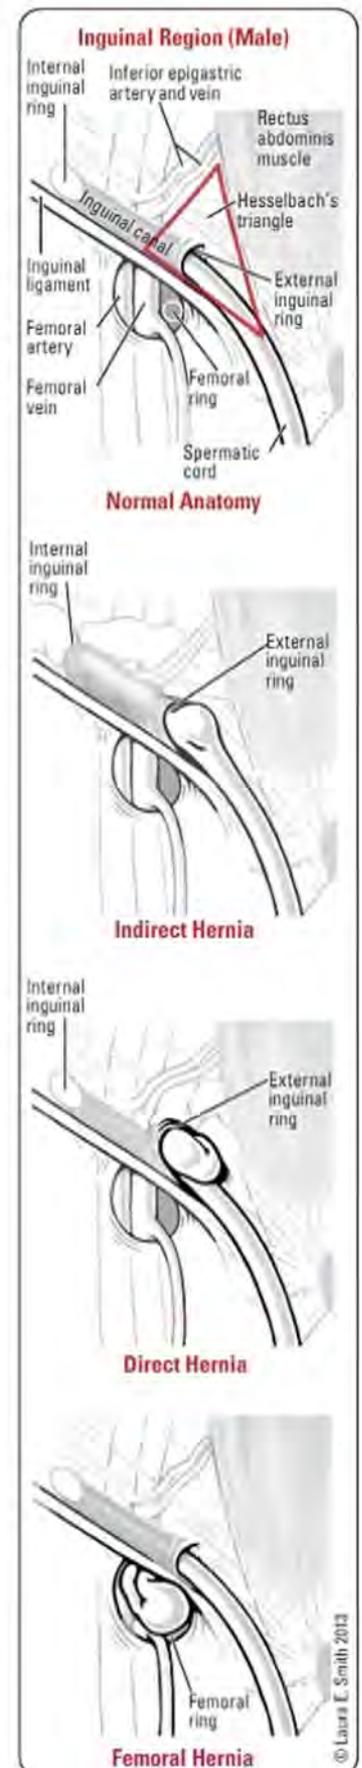

Figure 11. Schematic of inguinal (direct and indirect) and femoral hernias

## Groin Hernias

Table 16. Groin Hernias

	Direct Inguinal	Indirect Inguinal	Femoral
<b>Epidemiology</b>	1% of all men	Most common hernia in men and women M>F	Affects mostly females
<b>Etiology</b>	Acquired weakness of transversalis fascia "Wear and tear" Increased intra-abdominal pressure	Congenital persistence of processus vaginalis in 20% of adults	Pregnancy weakness of pelvic floor musculature Increased intra-abdominal pressure
<b>Anatomy</b>	Through Hesselbach's triangle Medial to inferior epigastric artery Usually does not descend into scrotal sac	Originates in deep inguinal ring Lateral to inferior epigastric artery Often descends into scrotal sac (or labia majora)	Into femoral canal, below inguinal ligament but may override it Medial to femoral vein within femoral canal
<b>Treatment</b>	Surgical repair	Surgical repair	Surgical repair
<b>Prognosis</b>	3-4% risk of recurrence	<1% risk of recurrence	

Table 17. Superficial Inguinal Ring vs. Deep Inguinal Ring\*

Superficial Inguinal Ring	Deep Inguinal Ring
Opening in external abdominal aponeurosis; palpable superior and lateral to pubic tubercle	Opening in transversalis fascia; palpable superior to mid-inguinal ligament
Medial border: medial crus of external oblique aponeurosis	Medial border: inferior epigastric vessels
Lateral border: lateral crus of external oblique aponeurosis	Superior-lateral border: internal oblique and transversus abdominis muscles
Roof: intercrural fibres	Inferior border: inguinal ligament

\*see Basic Anatomy Review, Figure 2, G3

### Robotic Inguinal vs. Transabdominal Laparoscopic Inguinal Hernia Repair: The RIVAL Randomized Clinical Trial

JAMA Surg. 2020;155(5):380-387

**Purpose:** To determine whether a robotic approach to inguinal hernia repair results in improved postoperative outcomes compared with the traditional laparoscopic inguinal hernia repairs.

**Results:** At preoperative, 1-week and 30-day assessments there were no differences between the groups on wound events, readmissions, pain, or quality of life. However, the robotic approach was associated with increased cost, operative time, and surgeon frustration compared to the laparoscopic approach.

**Conclusions:** There is no benefit of the robotic approach compared with the laparoscopic approach.

## Appendix

### Appendicitis

#### Epidemiology

- 6% of population, M>F (1.4:1)
- 80% between ages 5-35

#### Pathogenesis

- luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess (walled off by omentum) or peritonitis
- etiology
  - children or young adult: hyperplasia of lymphoid follicles, initiated by infection
  - adult: fibrosis/stricture, fecalith, or obstructing neoplasm
  - other causes: parasites or foreign body

#### Clinical Features

- most reliable feature is progression of signs and symptoms
- low-grade fever (38°C), rises if perforation
- abdominal pain then anorexia, N/V
- classic pattern: pain initially periumbilical; constant, dull, poorly localized, then well-localized pain over McBurney's point
  - due to progression of disease from visceral irritation (causing referred pain from structures of the embryonic midgut, including the appendix) to irritation of parietal structures
- signs
  - inferior appendix: McBurney's sign (see sidebar), Rovsing's sign (palpation pressure to left abdomen causes McBurney's point tenderness). McBurney's sign is present whenever the opening of the appendix at the cecum is directly under McBurney's point; therefore McBurney's sign is present even when the appendix is in different locations
  - retrocecal appendix: psoas sign (pain on flexion of hip against resistance or passive hyperextension of hip)
  - pelvic appendix: obturator sign (flexion then external or internal rotation about right hip causes pain)

#### Complications

- perforation (especially if >24 h duration)
- abscess, phlegmon
- sepsis

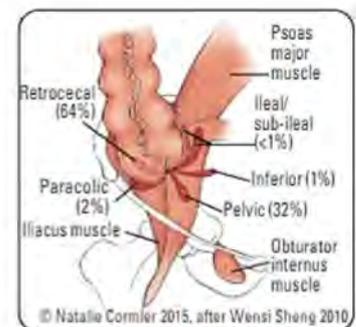

Figure 12. Appendix anatomy

### McBurney's Sign

Tenderness 1/3 the distance from the ASIS to the umbilicus on the right side

### Investigations

- laboratory
  - mild leukocytosis with left shift (may have normal WBC counts)
  - higher leukocyte count with perforation
  - $\beta$ -hCG to rule out ectopic pregnancy
  - urinalysis
- imaging
  - U/S: may visualize appendix, but also helps rule out gynaecological causes – overall accuracy 90-94%, can rule in but CANNOT rule out appendicitis (if >6 mm, SENS/SPEC/NPV/PPV 98%)
  - CT scan: thick wall, enlarged (>6 mm), wall enhancement, appendicolith, and inflammatory changes – overall accuracy 94-100%, optimal investigation

### Treatment

- hydrate, correct electrolyte abnormalities
- appendectomy (gold standard)
  - laparoscopic is standard
  - complications: intra-abdominal abscess, appendiceal stump leak
  - perioperative antibiotics: cefazolin + metronidazole, if uncomplicated perioperative dose is adequate
- consider treatment with postoperative antibiotics for perforated appendicitis
- for patients who present with an abscess (palpable mass or phlegmon on imaging and often delayed diagnosis with symptoms for >4-5 d), consider radiologic drainage + antibiotics x14 d  $\pm$  interval appendectomy once inflammation has resolved = (controversial)
- medical management with antibiotic therapy should be reserved for those who are unfit for or refuse surgery
- colonoscopy in those >50 yr to rule out concurrent etiology (neoplasm)

### Prognosis

- mortality rate: 0.09-0.24%

## Inflammatory Bowel Disease

- see [Gastroenterology, G22](#)

### Principles of Surgical Management

- medical management remains first line, but surgery can alleviate symptoms, address complications, and improve quality of life
- conserve bowel: resect as little as possible to avoid short gut syndrome
- perioperative management
  - optimize medical status: may require TPN (especially if >7 d NPO) and bowel rest
  - hold immunosuppressive therapy preoperative, provide preoperative stress dose of corticosteroid; if patient had recent steroid therapy, taper steroids postoperative
  - VTE prophylaxis: LMWH or heparin (IBD patients at increased risk of thromboembolic events)

## Crohn's Disease

- see [Gastroenterology, G23](#)

### Treatment

- surgery is for symptom management; it is NOT curative, but over lifetime ~70% of Crohn's patients will have surgery
- indications for surgical management
  - failure of medical management
  - SBO (due to stricture/inflammation): indication in 50% of surgical cases
  - abscess, fistula (enterocolic, vesicular, vaginal, cutaneous abscess), quality of life, perforation, hemorrhage, chronic disability, failure to thrive (children), and perianal disease
- surgical procedures
  - resection and anastomosis/stoma if active or subacute inflammation, perforation, or fistula
  - surgery should be attempted in the elective setting ideally off steroids
- resection margin only has to be free of gross disease (microscopic disease irrelevant to prognosis)
  - stricturoplasty – widens lumen in chronically scarred bowel: relieves obstruction without resecting bowel (contraindicated in acute inflammation)

### Complications of Treatment

- anastomotic leak
- dehydration
- short gut syndrome (diarrhea, steatorrhea, malnutrition)
- fistulas
- gallstones (if terminal ileum resected, decreased bile salt resorption  $\rightarrow$  increased cholesterol precipitation)
- kidney stones (loss of calcium in diarrhea  $\rightarrow$  increased oxalate absorption and hyperoxaluria  $\rightarrow$  stones)

#### Antibiotics versus Appendectomy for Acute Appendicitis - Longer-Term Outcomes

*N Engl J Med* 2021;385(25):2395. Epub 2021 Oct 25.

**Purpose:** Compare the efficacy of antibiotics vs. an appendectomy for acute appendicitis with respect to long-term outcomes.

**Method:** Randomized trial comparing antibiotic treatment with appendectomy in patients with appendicitis.

**Results:** The 30-day general health status of patients treated with antibiotics was comparable to the appendectomy group. However, 29 percent of medically-treated patients required appendectomy by 90 days. Longer-term data from this trial now confirm high rates of subsequent appendectomy after initial medical therapy: 40 percent at one year, 46 percent at two years, and 49 percent at three and four years.

**Conclusions:** Surgery should continue to be recommended for uncomplicated appendicitis and antibiotic therapy should be reserved for those who are medically unfit for or decline surgery.

#### Crohn's 3 Major Patterns

- Ileocecal 40% (RLQ pain, fever, weight loss)
- Small intestine 30% (especially terminal ileum)
- Colon 25% (diarrhea)

#### Findings in Crohn's

- "Cobblestoning" on mucosal surface due to edema and linear ulcerations
- "Skip lesions": normal mucosa in between
- "Creeping fat": mesentery infiltrated by fat
- Granulomas: 25-30%

**Prognosis**

- recurrence rate at 10 yr: ileocolic (25-50%), small bowel (50%), colonic (40-50%)
- re-operation at 5 yr: primary resection (20%), bypass (50%), stricturoplasty (10% at 1 yr)
- 80-85% of patients who need surgery lead normal lives
- mortality: 15% at 30 yr

**Ulcerative Colitis**

• see *Gastroenterology*, G25

**Treatment**

- indications for surgical management
  - failure of medical management (including inability to taper steroids)
  - complications: hemorrhage, obstruction, perforation, toxic megacolon (emergency), failure to thrive (children)
  - reduce cancer risk (1-2% risk per yr after 10 yr of disease)
- surgical procedures
  - proctocolectomy and ileal pouch-anal anastomosis (IPAA) ± rectal mucosectomy (operation of choice)
  - proctocolectomy with permanent end ileostomy (if not a candidate for ileoanal procedures)
  - colectomy and IPAA ± rectal mucosectomy
  - in emergency: total colectomy and ileostomy with Hartmann closure of the rectum, rectal preservation

**Complications of Treatment**

- early: bowel obstruction, transient urinary dysfunction, dehydration (high stoma output), anastomotic leak
- late: stricture, anal fistula/abscess, pouchitis, poor anorectal function, reduced fertility

**Prognosis**

- mortality: 5% over 10 yr
- total proctocolectomy will eliminate risk of cancer
- perforation of the colon is the leading cause of death from UC

**LARGE INTESTINE**

**Large Bowel Obstruction**

**Mechanical Large Bowel Obstruction**

**Etiology**

**Table 18. Common Causes of LBO**

Intraluminal	Intramural	Extramural
Constipation	Adenocarcinoma	Volvulus
Foreign bodies	Diverticulitis (edema, stricture)	Adhesions
	IBD stricture	Hernias (sigmoid colon in a large groin hernia)
	Radiation stricture	

**Clinical Features (unique to LBO)**

- open loop (10-20%)
  - incompetent ileocecal valve allows relief of colonic pressure as contents reflux into ileum, therefore clinical features similar to SBO
- closed loop (80-90%) (dangerous)
  - competent ileocecal valve, resulting in proximal and distal occlusions
  - massive colonic distention → increased pressure in cecum → bowel wall ischemia → necrosis → perforation

**Investigations**

- CBC with differential, BUN, electrolyte panel, creatinine, CEA if patient is suspected to have malignancy, and lactate for level of ischemia
- imaging: AXR and CT scan

**Top 3 Causes of LBO (in order)**

- Cancer (>60%)
- Volvulus (10-15%)
- Diverticulitis (10%)

**In a patient with a clinical LBO consider impending perforation when:**

- Cecum ≥12 cm in diameter
- Tenderness present over cecum

**Treatment**

- supportive management: IV fluids, gastrointestinal decompression
- surgical intervention (75% of cases)
  - volvulus: initial decompression with flexible sigmoidoscopy, operative reduction or sigmoid resection dependent on severity
  - colorectal obstruction: ostomy alone (fecal diversion), colectomy with primary anastomosis, or Hartmann procedure
- may pursue stenting as a bridge to surgery or palliation

**Prognosis**

- overall mortality: 10%
- cecal perforation + feculent peritonitis: 20% mortality

**Table 19. Bowel Obstruction vs. Paralytic Ileus**

	<b>SBO</b>	<b>LBO</b>	<b>Paralytic Ileus</b>
<b>N/V</b>	Early, may be bilious	Late, may be feculent	Present
<b>Abdominal Pain</b>	Colicky	Colicky	Minimal or absent
<b>Abdominal Distention</b>	+ (prox SBO), ++ (distal SBO)	++	+
<b>Constipation</b>	+	+	+
<b>Bowel Sounds</b>	Normal, increased Absent if secondary ileus (delayed presentation)	Normal, increased (borborygmi) Absent if secondary ileus (delayed presentation)	Decreased, absent
<b>AXR Findings</b>	Air-fluid levels "Ladder" pattern (plicae circulares) Proximal distention (>3 cm) + no colonic gas	Air-fluid levels "Picture frame" appearance Proximal distention + distal decompression No small bowel air if competent ileocecal valve Coffee bean sign (sigmoid volvulus)	Air throughout small bowel and colon

## Functional Large Bowel Obstruction: Colonic Pseudo-Obstruction (Ogilvie's Syndrome)

**Definition**

- acute pseudo-obstruction
- distention of colon without mechanical obstruction in distal colon
- exact mechanism unknown, likely autonomic motor dysregulation

**Associations**

- most common: trauma, infection, and cardiac (MI, CHF)
- disability (long-term debilitation, chronic disease, bed-bound nursing home patients, and paraplegia), drugs (narcotic use, laxative abuse, and polypharmacy), and other (recent orthopaedic or neurosurgery, post-partum, electrolyte abnormalities including hypokalemia, retroperitoneal hematoma, and diffuse carcinomatosis)

**Clinical Features**

- classically presents with abdominal distention (acute or gradual over 3-7 d)
- abdominal pain, N/V, constipation or diarrhea
- watch out for fever, leukocytosis, and presence of peritoneal signs (suggestive of colonic ischemia or perforation)

**Investigations**

- AXR: cecal dilatation (if diameter  $\geq 12$  cm, increased risk of perforation)

**Treatment**

- treat underlying cause
- NPO, NG tube
- decompression: rectal tube, colonoscopy, neostigmine (cholinergic drug), or surgical (ostomy/resection)
- surgery (extremely rare): if perforation, ischemia, or failure of conservative management

**Prognosis**

- most resolve with conservative management

## Diverticular Disease

### Definitions

- diverticulum: abnormal outpouching from the wall of a hollow organ
- diverticulosis: presence of multiple diverticula
- diverticulitis: inflammation of diverticula
- true (congenital) diverticuli: contain all layers of colonic wall, often right-sided
- false (acquired) diverticuli: contain mucosa and submucosa, often left-sided

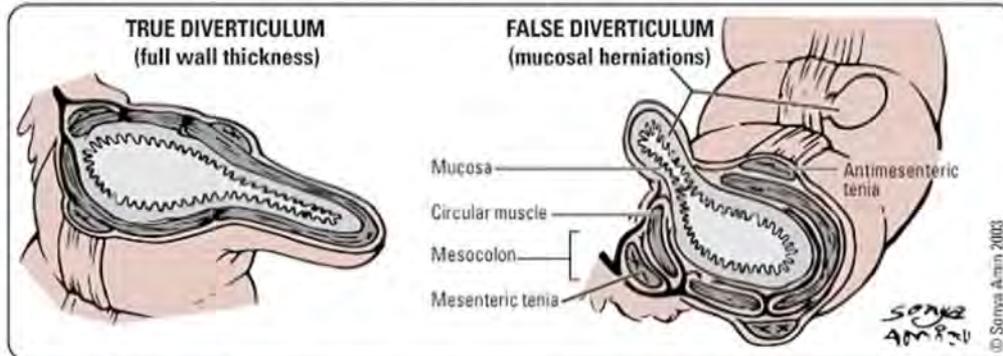

Figure 13. Diverticular disease – cross-sections of true and false diverticula

## Diverticulosis

### Epidemiology

- 5-50% of Western population, lower incidence in non-Western countries, M=F
- prevalence is age dependent: <5% by age 40, 30% by age 60, 65% by age 85
- 95% involve sigmoid colon (site of highest pressure)

### Pathogenesis

- risk factors
  - lifestyle: diet (low-fibre, high fat, red meat), inactivity, and obesity
  - muscle wall weakness from aging and illness (e.g. Ehlers-Danlos, Marfan's)
- high intraluminal pressures cause outpouching to occur at points of greatest weakness, most commonly where vasa recta penetrate the circular muscle layer leading to an increased risk of hemorrhage

### Clinical Features

- uncomplicated diverticulosis: asymptomatic (70-80%)
- episodic abdominal pain (often LLQ), bloating, flatulence, constipation, diarrhea
- absence of fever/leukocytosis
- no physical exam findings or poorly localized LLQ tenderness
- complications:
  - diverticulitis (15-25%): 25% of which are complicated (i.e. abscess, obstruction, perforation, fistula)
  - bleeding (5-15%): PAINLESS rectal bleeding, 30-50% of massive LGIB
  - diverticular colitis (rare): diarrhea, hematochezia, tenesmus, and abdominal pain

### Treatment

- uncomplicated diverticulosis: high fibre, education
- diverticular bleed
  - initially workup and treat as any LGIB
  - if hemorrhage does not stop, resect involved region

## Diverticulitis

### Epidemiology

- 95% left-sided in patients of Western countries, 75% right-sided in Asian populations

### Pathogenesis

- erosion of the wall by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro or macroscopic perforation
- usually mild inflammation with perforation walled off by pericolic fat and mesentery; abscess, fistula, or obstruction can ensue
- poor containment results in free perforation and peritonitis

### Diverticulosis vs. Diverticulitis

Diverticulosis represents the presence of diverticuli (bulging pouches) within the colonic wall, whereas diverticulitis is the inflammation of one or more diverticuli

### Clinical Features

- depend on severity of inflammation and whether or not complications are present; hence ranges from asymptomatic to generalized peritonitis
- LLQ pain/tenderness (2/3 of patients) often for several days before admission
- constipation, diarrhea, N/V, and urinary symptoms (with adjacent inflammation)
- low-grade fever, mild leukocytosis, and occult or gross blood in stool rarely coexist with acute diverticulitis
- complications (25% of cases)
  - abscess: palpable, tender abdominal mass
  - fistula: colovesical (most common), coloenteric, colovaginal, and colocutaneous
  - colonic obstruction: due to scarring from repeated inflammation
  - perforation: generalized peritonitis (feculent vs. purulent)
- recurrent attacks rarely lead to peritonitis

### Investigations

- CT scan (test of choice)
  - very useful for assessment of severity and prognosis (97% sensitive, 99% specific)
  - usually done with rectal contrast
  - increased soft tissue density within pericolic fat secondary to inflammation, diverticula secondary to inflammation, bowel wall thickening, soft tissue mass (pericolic fluid, abscesses), and fistula
  - 10% of diverticulitis cannot be distinguished from carcinoma
- AXR, upright CXR
  - localized diverticulitis (ileus, thickened wall, SBO, and partial colonic obstruction)
  - free air may be seen in 30% with perforation and generalized peritonitis
- colonoscopy or barium enema and flexible sigmoidoscopy (elective evaluation)
  - establish extent of disease and rule out other diagnoses (polyps and malignancy) AFTER resolution of acute episode

### Treatment

- uncomplicated: conservative management
- outpatient: clear fluids only until improvement. Avoid treatment with antibiotics for those with uncomplicated acute diverticulitis
- hospitalize: if severe presentation, inability to tolerate oral intake, significant comorbidities, or fail to improve with outpatient management
  - treat with NPO, IV fluids, and IV antibiotics (e.g. IV ceftriaxone + metronidazole)
- image-guided (CT) percutaneous drainage of abscesses reduces the urgency of surgical resection in most patients
- surgery:
  - indications:
    - unstable patient with peritonitis
    - Hinchey stage 3-4 (see Table 19)
    - after 1 attack if immunosuppressed
    - consider if recurrent episodes of diverticulitis ( $\geq 3$ ); recent trend is toward conservative management of recurrent mild/moderate attacks
  - procedures:
    - Hartmann resection (for unstable or complex cases)
    - colon resection + colostomy and rectal stump  $\rightarrow$  colostomy reversal in 3-6 mo
  - for more stable patients with Hinchey stage 3 and 4 acute diverticulitis: colonic resection, primary anastomosis + diverting loop ileostomy is becoming more common, with benefits for mortality and morbidity
  - for Hinchey stage 3: laparoscopic peritoneal lavage with drain placement near the affected colon, in addition to 4 antibiotics (NO resection), has been proposed
  - complications: perforation, abscess, fistula, obstruction, hemorrhage, inability to rule out colon cancer on endoscopy, or failure of medical management

### Prognosis

- mortality rates: 6% for purulent peritonitis, 35% for feculent peritonitis
- recurrence rates: 13-30% after first attack, 30-50% after second attack

**Table 20. Hinchey Staging and Treatment for Diverticulitis**

Hinchey Stage	Description	Acute Treatment
1	Phlegmon/small pericolic abscess	Medical
2	Large abscess/fistula	Medical, abscess drainage $\pm$ resection with primary anastomosis
3	Purulent peritonitis (ruptured abscess)	Resection or Hartmann procedure
4	Feculent peritonitis	Hartmann procedure

#### Efficacy and Safety of Nonantibiotic Outpatient Treatment in Mild Acute Diverticulitis (DINAMO-study): A Multicentre, Randomised, Open-label, Noninferiority Trial

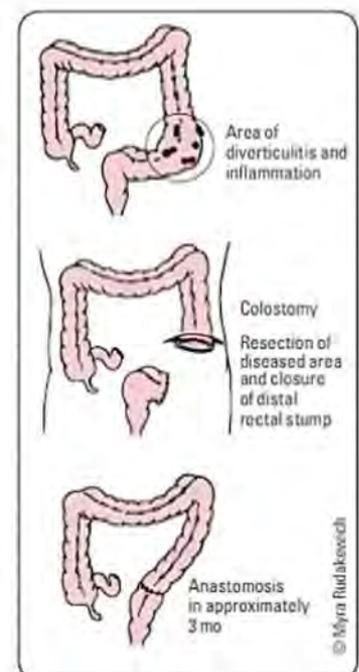

Ann Surg 2021;274(5):e435.

**Background:** In recent years, it has shown no benefit of antibiotics (AB) in the treatment of uncomplicated AD in hospitalized patients.

**Methods:** Prospective, multicentre, open-label, noninferiority, randomized controlled trial.

**Results:** Differences in hospitalization rates, revisits, and poor pain control at 2 days follow-up were within the non-inferiority margin.

**Conclusions:** Nonantibiotic outpatient treatment of mild AD is safe and effective and is not inferior to current standard treatment.

**Figure 14. Hartmann procedure**

# Colorectal Neoplasms

## Colorectal Polyps

### Definition

- polyp: protuberance into the lumen of normally flat colonic mucosa
  - sessile (flat) or pedunculated (on a stalk)

### Epidemiology

- 30% of the population have polyps by age 50, 40% by age 60, 50% by age 70; M>F

### Clinical Features

- 50% in the rectosigmoid region, 50% are multiple
- usually asymptomatic, do not typically bleed, tenesmus, intestinal obstruction, and mucus
- usually detected during routine endoscopy or familial/high-risk screening

### Pathology

- non-neoplastic/non-adenomatous
  - hyperplastic: most common non-neoplastic polyp
  - mucosal polyps: small <5 mm, no clinical significance
  - hamartomas: juvenile polyps (large bowel), Peutz-Jegher syndrome (small bowel)
    - malignant risk due to associated adenomas (large bowel)
    - low malignant potential → most spontaneously regress or autoamputate
  - inflammatory pseudopolyps: associated with IBD, no malignant potential
  - submucosal polyps: lymphoid aggregates, lipomas, leiomyomas, and carcinoids
- neoplastic/adenomatous
  - adenomas: premalignant, considered carcinoma *in situ* if high-grade dysplasia
    - may contain invasive carcinoma ("malignant polyp" – 3-9%): invasion into submucosa
    - malignant potential related to histological type: villous > tubulovillous > tubular

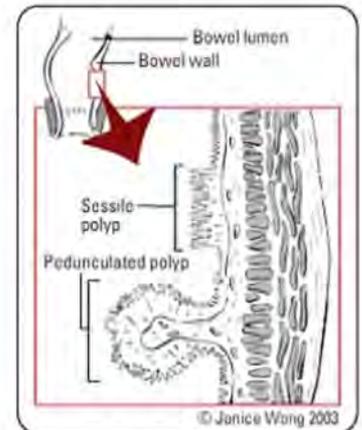

Figure 15. Sessile and pedunculated polyps

Table 21. Characteristics of Tubular vs. Villous Polyps

	Tubular	Villous
Incidence	Common (60-80%)	Less common (10%)
Size	Small (<2 cm)	Large (usually >2 cm)
Attachment	Pedunculated	Sessile
Malignant Potential	Lower	Higher
Distribution	Even	Left-sided predominance

### Investigations

- colonoscopy with biopsy/resection (gold standard)
- CT colonography: increasing in availability; patients still require bowel prep and will require colonoscopy if polyps are identified
- other: flexible sigmoidoscopy (if polyps are detected, proceed to colonoscopy for examination of entire bowel and biopsy)

### Treatment

- indications: symptoms, malignancy or risk of malignancy (i.e. adenomatous polyps)
- endoscopic removal of entire growth
- indications for segmental resection for malignant polyps: 1) lymphovascular invasion; 2) tumour budding; 3) positive resection margin; 4) poorly differentiated cells; 5) evidence of regional or distant metastases on staging
  - most of these cases are usually discussed at multi-disciplinary tumour boards
- follow-up endoscopy:
  - every 5 yr: if low-risk polyp (<10 mm tubular adenoma or <10 mm sessile serrated without dysplasia)
  - every 3 yr: if high-risk polyp (3-10 tubular adenomas, >10 mm tubular or serrated polyp, adenoma with villous features or high grade dysplasia, or sessile serrated with dysplasia)

## Familial Colon Cancer Syndromes

### FAMILIAL ADENOMATOUS POLYPOSIS

#### Epidemiology

- accounts for <1% of colorectal cancers, affects males and females equally

#### Pathogenesis

- autosomal dominant inheritance, mutation in adenomatous polyposis coli (APC) gene

#### Clinical Features

- hundreds to thousands of colorectal adenomas usually by age 20 (by 40's in attenuated FAP)
- virtually 100% lifetime risk of colon cancer (due to number of polyps)
- extracolonic manifestations
  - bile duct, pancreas, stomach, thyroid (large benign multinodular goitre), adrenal glands, and small bowel
  - congenital hypertrophy of retinal pigment epithelium presents early in life in 2/3 of patients; 97% sensitivity
- variants
  - Gardner's syndrome: FAP + extra-intestinal lesions (sebaceous cysts, osteomas, desmoid tumours)
  - Turcot syndrome: FAP + CNS tumours (childhood cerebellar medulloblastoma)

#### Investigations

- genetic testing (80-95% sensitive, 99-100% specific)
- if no polyposis found: annual flexible sigmoidoscopy from puberty to age 50, then routine screening
- if polyposis or APC gene mutation found: annual colonoscopy, consider surgery, and consider upper endoscopy to evaluate for periampullary tumours

#### Treatment

- surgery indicated by ages 17-20
- total proctocolectomy with ileostomy or total colectomy with ileorectal anastomosis
- doxorubicin-based chemotherapy
- NSAIDs for intra-abdominal desmoids

### HEREDITARY NON-POLYPOSIS COLORECTAL CANCER – LYNCH SYNDROME

#### Epidemiology

- most common inherited colorectal cancer susceptibility syndrome and accounts for 3% of colorectal cancer diagnoses

#### Pathogenesis

- autosomal dominant inheritance, mutation in a DNA mismatch repair gene (MSH2, MSH6, MLH1, PMS2) resulting in microsatellite genomic instability and subsequent mutations
- microsatellite instability account for approximately 15% of all CRCs

#### Clinical Features

- early age of onset, right > left colon, synchronous and metachronous lesions
- mean age of cancer presentation is 44 yr, lifetime risk 70-80%; M>F
  - HNPCC I: hereditary site-specific colon cancer
  - HNPCC II: cancer family syndrome → high rates of extracolonic tumours (endometrial, ovarian, hepatobiliary, small bowel, adrenal)

#### Diagnosis

- Amsterdam Criteria ("3-2-1 rule")
  - 3 or more relatives with verified Lynch syndrome associated cancers, and 1 must be 1st degree relative of the other 2
  - 2 or more generations involved
  - 1 case must be diagnosed before 50 yr
  - FAP is excluded
- genetic testing (80% sensitive)
  - refer individuals for genetic screening if they fulfill either the Amsterdam Criteria or the revised Bethesda Criteria
- colonoscopy (starting age 20) annually
- surveillance for extracolonic lesions

#### Treatment

- total colectomy and ileorectal anastomosis with annual proctoscopy

#### Referral Criteria for Genetic Screening for APC

- To confirm the diagnosis of FAP (in patients with ≥100 colorectal adenomas)
- To provide pre-symptomatic testing for individuals at risk for FAP (1st degree relatives who are ≥10 yr)
- To confirm the diagnosis of attenuated FAP (in patients with ≥20 colorectal adenomas)

#### Revised Bethesda Criteria for HNPCC and Microsatellite Instability (MSI)

- Tumours from individuals should be tested for MSI in the following situations:
- Colorectal cancer diagnosed in a patient who is <50 yr
  - Presence of synchronous, metachronous, colorectal, or other HNPCC-associated tumours, regardless of age
  - Colorectal cancer with the MSI-H histology diagnosed in a patient who is <60 yr
  - Colorectal cancer diagnosed in one or more first-degree relatives with an HNPCC-related tumour, with one of the cancers being diagnosed <50 yr
  - Colorectal cancer diagnosed in two or more first- or second-degree relatives with HNPCC-related tumours, regardless of age

Elderly persons who present with iron-deficiency anemia should be investigated for colon cancer

**APR** removes distal sigmoid colon, rectum, and anus; permanent end colostomy required  
**LAR** removes distal sigmoid and rectum with anastomosis of distal colon to distal rectum/anus

## Colorectal Carcinoma

### Epidemiology

- 3rd most common cancer (lung>breast>colon), 2nd most common cause of cancer death

### Risk Factors

- most patients have no specific risk factors
- ages >50 (dominant risk factor in sporadic cases), mean age is 70
- genetic: FAP, HNPCC, or family history of CRC
- colonic conditions
  - adenomatous polyps (especially if >1 cm, villous, multiple)
  - IBD (especially UC: risk is 1-2%/yr if UC >10 yr)
  - previous colorectal, gonadal, or breast cancer
- diet (increased fat, red meat, decreased fibre) and smoking
- DM and acromegaly (insulin and IGF-1 are growth factors for colonic mucosal cells)

### Pathogenesis

- adenoma-carcinoma sequence; rarely arise de novo

### Clinical Features

- often asymptomatic
- hematochezia/melena, abdominal pain, and change in bowel habits
- others: weakness, anemia, weight loss, palpable mass, and obstruction
- 20% patients have distant metastatic disease at time of presentation
- spread
  - direct extension, lymphatic, and hematogenous (liver most common, lung, bone, and brain; tumour of distal rectum → IVC → lungs)
  - peritoneal seeding: ovary and Blumer's shelf (pelvic cul-de-sac)

Table 22. Clinical Features of CRC

	Right Colon	Left Colon	Rectum
Frequency	25%	35%	30%
Pathology	Exophytic lesions with occult bleeding	Annular, invasive lesions	Ulcerating
Symptoms	Weight loss, weakness, rarely obstruction	Constipation ± overflow (alternating bowel patterns), abdominal pain, decreased stool calibre, rectal bleeding	Obstruction, tenesmus, rectal bleeding
Signs	Fe-deficiency anemia, RLO mass (10%)	BRBPR, LBO	Palpable mass on DRE, BRBPR

### Investigations

- colonoscopy (gold standard): look for synchronous lesions (3-5% of patients)
  - if a patient is FOBT positive, has microcytic anemia, or has a change in bowel habits → colonoscopy
  - alternative: air contrast barium enema ("apple core" lesion) + sigmoidoscopy
- laboratory: CBC, U/A, LFTs, CEA (preoperative for baseline, >5 ng/mL have worse prognosis)
- staging: CT chest/abdomen/pelvis; bone scan and CT head only if lesions suspected
- rectal cancer: pelvic MRI or endorectal U/S to determine T and N stage

Table 23. TNM Classification System for Staging of Colorectal Carcinoma (AJCC/UICC 8th edition)

Primary Tumour (T)		Regional Lymph Nodes (N)		Distant Metastasis (M)	
<b>Tx</b>	Primary tumour cannot be assessed	<b>Nx</b>	Regional nodes cannot be assessed	<b>M0</b>	No distant metastasis
<b>T0</b>	No primary tumour found	<b>N0</b>	No regional node metastasis and no tumour deposits	<b>M1a</b>	Distant metastasis to 1 organ or site and no peritoneal metastasis
<b>Tis</b>	Carcinoma <i>in situ</i> , limited to intraepithelial or invasive lamina propria	<b>N1a</b>	Metastasis in 1 regional node	<b>M1b</b>	Distant metastasis to >1 (2 or more organs/sites) and no peritoneal metastasis
<b>T1</b>	Invasion into submucosa	<b>N1b</b>	Metastasis in 2-3 regional nodes	<b>M1c</b>	Metastasis to peritoneal surface
<b>T2</b>	Invasion into muscularis propria	<b>N1c</b>	No regional node metastasis; tumour deposits were submucosal, mesangial or peritoneum-covered para-colorectal tissue		
<b>T3</b>	Invasion through muscularis propria and into pericolorectal tissues	<b>N2a</b>	Metastasis in 4-6 regional nodes		
<b>T4a</b>	Invasion through visceral peritoneum	<b>N2b</b>	Metastasis in ≥7 regional nodes		
<b>T4b</b>	Invasion or adherent to other organs or structures				

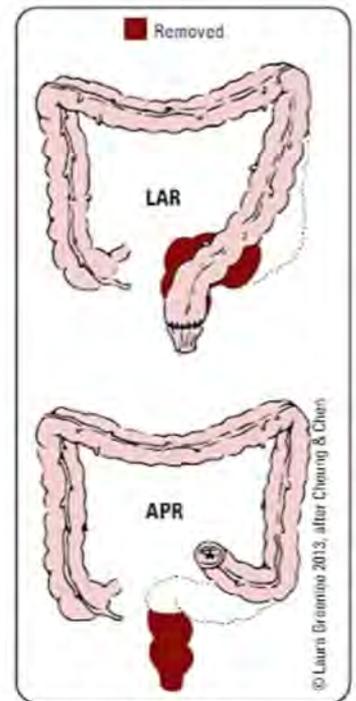

Figure 16. APR vs. LAR

### 5 Year Survival Rates for CRC

Stage	20-64 yr	≥65 yr
I	95.2%	89.1%
IIA	89.6%	84.4%
IIB	67.6%	55%
IIIA	91.3%	85.1%
IIIB	76.9%	64.6%
IIIC	61.8%	45.5%
IV	14.2%	7.4%

### Preoperative vs. Postoperative Chemoradiotherapy for Locally Advanced Rectal Cancer: Results of the German CAO/ARO/AIO-94 Randomized Phase III Trial after a Median Follow-Up of 11 Yr

J Clin Oncol 2012;30:1926-1933  
**Background:** The CAO/ARO/AIO-94 trial (published 2004) recommended preoperative chemoradiotherapy (CRT) as standard treatment for locally advanced rectal cancer. However, no survival benefit was shown after median follow-up of 46 mo, and this study reports long-term effects.

**Methods:** Patients with stage II to III rectal cancer (n=799) were randomly assigned to preoperative (n=404) or postoperative CRT (n=395) with fluorouracil (FU), radiation, and adjuvant FU (chemotherapy, in addition to total mesorectal excision surgery). Follow-up was designed to assess long-term overall survival as the primary endpoint and cumulative incidence of local and distant relapses as well as disease-free survival as secondary endpoints.

**Results:** 10 yr incidence of local relapse was significantly lower in the preoperative CRT group than in the postoperative group (7.1% vs. 10.1%, P=0.048). Overall survival at 10 yr was similar at ~60% for patients treated with preoperative or postoperative CRT (P=0.85). Disease-free survival rates at 10 yr was similar at ~68% for patients treated with preoperative or postoperative CRT (P=0.54). No significant difference was detected for 10 yr incidence of distant metastases (preoperative CRT 29.8% vs. postoperative CRT 29.6%, P=0.9).

**Conclusion:** There is long-term reduction in local recurrence of stage II to III rectal cancer with preoperative chemotherapy, but no improvement in overall survival or distant recurrence of disease.

**Treatment**

- colon cancer
  - wide surgical resection of lesion according to vascular distribution and regional lymphatic drainage; usually colectomy with primary anastomosis
  - curative: wide resection of lesion (5 cm margins) with nodes (>12) and mesentery
  - care is taken to not spread tumour by unnecessary palpation
  - adjuvant chemotherapy (oxaliplatin-based) for stage III and is considered in select stage II patients
  - palliative: if distant spread, local control for hemorrhage or obstruction
- metastatic lesions confined to the liver can be resected with curative intent
- rectal cancer
  - choice of operation depends on individual case
    - LAR: curative procedure of choice if adequate distal margins (~2 cm); uses technique of total mesorectal excision
      - APR: if adequate distal margins cannot be obtained; involves the removal of distal sigmoid colon, rectum, and anus permanent end colostomy required
    - transanal minimally invasive surgery (TAMIS)- local excision for select T1 lesions only
  - palliative procedures involve proximal diversion with an ostomy for obstruction and radiation for bleeding or pain
  - combined neoadjuvant chemoradiation therapy followed by postoperative adjuvant chemotherapy for stages II and III

**Follow-Up**

- stage I: mixed recommendations; either routine colonoscopy or screening like stage II & III
- stage II & III: regular follow-up q3-6 mo for 3 yr, then q6 mo until 5 yr, with regular measurement of serum CEA for at least 3 yr; annual CT chest/abdo/pelvis for at least 3 yr; colonoscopy at 1, 3, and 5 yr
- stage IV: no data on surveillance strategy

## Other Conditions of the Large Intestine

### Angiodysplasia

**Definition**

- vascular malformation: focal submucosal venous dilatation and tortuosity

**Clinical Features**

- most frequently in right colon of patients >60 yr
- predisposition in end-stage renal disease, and VWD, and aortic stenosis
- bleeding typically intermittent, rarely massive, and not usually hypotensive (melena, anemia, and occult blood positive stools)
- >90% of cases cease bleeding spontaneously

**Investigations**

- colonoscopy: cherry red spots, branching pattern from central vessel
- angiography: early-filling vein, vascular tuft, and delayed emptying vein; rarely active bleeding
- RBC technetium-99 scan
- barium enema is contraindicated (obscures other x-rays, i.e. angiogram)

**Treatment**

- none if asymptomatic
- cautery, embolization, vasopressin infusion, sclerotherapy, band ligation, laser, octreotide, and rarely segmental resection if other treatments fail

### Volvulus

**Definition**

- rotation of segment of bowel about its mesenteric axis
- sigmoid (65%), cecum (30%), transverse colon (3%), and splenic flexure (2%)
  - elderly >70 yr (sigmoid), adult 40-60yr (cecal), and neonates and infants (midgut)
- 5-10% of large bowel obstructions; 25% of intestinal obstructions during pregnancy

**Risk Factors**

- age (50% of patients >70 yr: stretching/elongation of bowel with age)
- high fibre diet (can cause elongated/redundant colon), chronic constipation, laxative abuse, pregnancy, bedridden, and institutionalization (less frequent evacuation of bowels)
- megacolon
- intestinal bands/adhesions

**Cecal Volvulus**  
 AXR: Central cleft of "coffee bean" sign points to RLQ

**Sigmoid Volvulus**  
 AXR: Central cleft of "coffee bean" sign points to LLQ  
 Barium enema: "ace of spades" or "bird's beak" sign

**Clinical Features**

- symptoms due to bowel obstruction (see *Large Bowel Obstruction, GS37*) or intestinal ischemia (see *Intestinal Ischemia, GS31*)
- colicky abdominal pain, persistence of pain between spasms, abdominal distention, and vomiting

**Investigations**

- AXR (classic findings): "omega," "bent inner-tube," "coffee-bean" signs, multiple air-fluid levels
- barium/Gastrografin® enema: "ace of spades" (or "bird's beak") appearance due to funnel-like luminal tapering of lower segment towards volvulus
- sigmoidoscopy or colonoscopy as appropriate
- CT: "whirl pattern" of mesenteric vessels twisting about the volvulus axis
  - barium contrast and colonoscopy are contraindicated due to risk of perforation

**Treatment**

- initial supportive management same as initial management for bowel obstruction (see *Large Bowel Obstruction, GS37*)
- cecum
  - colonoscopic detorsion and decompression; successful 15-20% of cases
    - surgical
      - right colectomy + ileotransverse colonic anastomosis
- sigmoid
  - decompression by flexible sigmoidoscopy and insertion of rectal tube past obstruction
  - subsequent elective surgery recommended (50-70% recurrence)
  - surgical
    - surgical resection with or without primary anastomosis
    - indications for urgent surgical management: strangulation, perforation, or unsuccessful endoscopic decompression

**Toxic Megacolon****Pathogenesis**

- extension of inflammation into smooth muscle layer causing paralysis and leading to non-obstructive colonic dilatation
- damage to myenteric plexus and electrolyte abnormalities are not consistently found

**Etiology**

- IBD (UC > Crohn's disease)
- infectious colitis: bacterial (*C. difficile*, *Salmonella*, *Shigella*, and *Campylobacter*), viral (cytomegalovirus), and parasitic (*E. histolytica*)

**Clinical Features**

- infectious colitis usually presents for >1 wk before colonic dilatation
- diarrhea ± blood (sudden improvement of diarrhea may signify onset of megacolon)
- abdominal distention, tenderness, ± local/general peritoneal signs (suggests perforation)
- triggers: hypokalemia, constipating agents (opioids, antidepressants, loperamide, and anticholinergics), barium enema, and colonoscopy

**Diagnostic Criteria**

- must have both colitis and systemic manifestations for diagnosis
- radiologic evidence of dilated colon >6 cm, and
- three of: fever, HR >120, WBC >10.5, anemia and
- one of: dehydration, electrolyte disturbances, hypotension, or altered LOC

**Investigations**

- CBC (leukocytosis with left shift and anemia from bloody diarrhea), electrolytes, elevated CRP, and ESR
  - metabolic alkalosis (volume contraction and hypokalemia) and hypoalbuminemia are late findings
- AXR: dilated colon >6 cm (right > transverse > left), loss of haustra
- CT: useful to assess underlying disease severity and possible complications (i.e. abscess, perforation, ascending pylephlebitis)

**Treatment**

- NPO, NG tube, stop constipating agents, correct fluid and electrolyte abnormalities, and transfusion
- serial AXRs
- broad-spectrum antibiotics (reduce sepsis and anticipate perforation)
- aggressive treatment of underlying disease (e.g. steroids in IBD and metronidazole for *C. difficile*)
- indications for surgery (50% improve on medical management)
  - worsening or persisting toxicity or dilation after 48-72 h
  - severe hemorrhage, perforation
  - high lactate and WBC, especially for *C. difficile*
- procedure: subtotal colectomy + end ileostomy (possible re-anastomosis later)

**Prognosis**

- 25-30% mortality

**Fistula****Definition**

- abnormal communication between two epithelialized surfaces (e.g. enterocutaneous, colovesical, aortoenteric, and entero-enteric)

**Etiology**

- foreign object erosion (e.g. drainage tube, gallstone, graft)
- inflammatory states (e.g. infection, IBD (Crohn's > UC), and diverticular disease)
- iatrogenic/surgery (e.g. postoperative anastomotic leak and radiation)
- congenital, trauma
- neoplastic

**Investigations**

- U/S, CT scan, fistulogram
- measure amount of drainage from fistula

**Treatment**

- decrease secretion: octreotide/somatostatin/omeprazole
- surgical intervention: dependent upon etiology (for non-closing fistulas)

**Stomas****Definition**

- an opening of the GI tract onto the surface of the abdomen wall
  - end stomas: the proximal end of the GI tract forms the stoma and the distal end of the GI tract is not part of the stoma
  - loop stomas: a loop of the GI tract is brought up to the skin and the anti-mesenteric surface of the bowel is matured as a stoma

**Ileostomy**

- usually positioned in RLQ; ileum is brought through rectus abdominis muscles
- indications: after proctocolectomy for UC, some cases of Crohn's disease or familial polyposis
- conventional ileostomy: discharges small quantities of liquid material continuously, appliance (plastic bag attached to a sheet of protective material) required at all times
- continent ileostomy: reservoir is constructed from distal ileum (ileal pouch anal anastomosis)

**Colostomy**

- indications: to decompress an obstructed colon, to protect a distal anastomosis after resection, or to evacuate stool after distal colon or rectum is removed
- colostomies can be done by making an opening in a loop of colon (loop colostomy) or by dividing the colon and bringing out one end (end colostomy)
- most common permanent colostomy is a sigmoid colostomy (expels stool/digital removal of feces)
- chronic paracolostomy hernia is a common complication

**Complications (10%)**

- obstruction: herniation, stenosis (skin and abdominal wall), adhesive bands, volvulus
- peri-ileostomy abscess and fistula
- skin irritation
- prolapse or retraction
- diarrhea (excessive output), which may lead to fluid, electrolyte, and nutritional imbalances

Use caution when giving antidiarrheal agents, especially with bloody diarrhea

Why Fistulae Stay Open

**FRIENDO**

For eign body  
Radiation  
Infection  
Epithelialization  
Neoplasm  
Distal obstruction (most common)  
Others: increased flow; steroids (may inhibit closure, usually will not maintain fistula)

**Colostomy/Ileostomy**

- Connection of proximal limb of colon or ileum to abdominal wall skin
- Mucous fistula
- Connection of distal limb of resection margin to abdominal wall skin
- Ileal Conduit
- Connection of bowel to ureter proximally and abdominal wall distally to drain urine

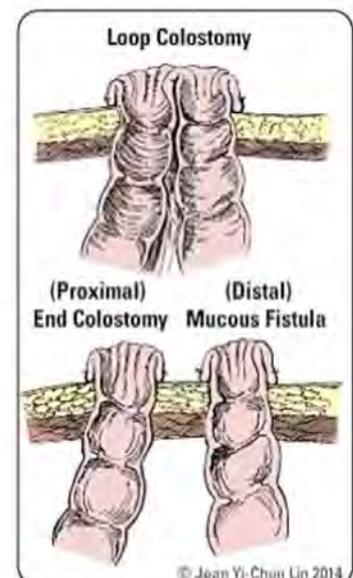

Figure 17. End vs. loop colostomy

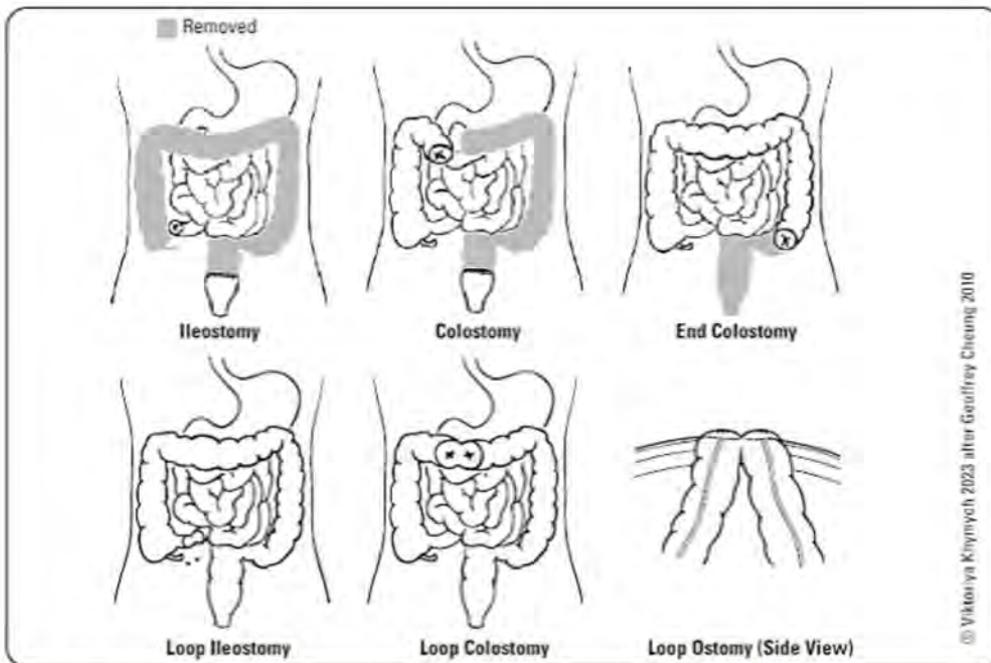

Figure 18. Ostomies

## Anorectum

### Hemorrhoids

#### Etiology

- vascular and connective tissue complexes form a plexus of dilated veins (cushion)
- internal: superior hemorrhoidal veins, above dentate line, portal circulation
- external: inferior hemorrhoidal veins, below dentate line, systemic circulation

#### Risk Factors

- increased intra-abdominal pressure: chronic constipation, pregnancy, obesity, portal HTN, heavy lifting

#### Clinical Features and Treatment

- internal hemorrhoids
  - engorged vascular cushions usually at 3, 7, 11 o'clock positions (patient in lithotomy position)
  - painless rectal bleeding, anemia, prolapse, mucus discharge, pruritus, burning pain, and rectal fullness
    - 1st degree:** bleed but do not prolapse through the anus
      - treatment: high fibre/bulk diet, sitz baths, steroid cream (short course), pramoxine (Anusol<sup>®</sup>), phlebotonics, rubber band ligation, sclerotherapy, and photocoagulation
    - 2nd degree:** bleed, prolapse with straining, and spontaneous reduction
      - treatment: rubber band ligation, and photocoagulation
    - 3rd degree:** bleed, prolapse, and require manual reduction
      - treatment: same as 2nd degree, but may require closed hemorrhoidectomy
    - 4th degree:** bleed, permanently prolapsed, and cannot be manually reduced
      - treatment: closed hemorrhoidectomy
- external hemorrhoids
  - dilated venules usually mildly symptomatic
    - pain after bowel movement, associated with poor hygiene
    - medical treatment: dietary fibre, stool softeners, steroid cream (short course), pramoxine (Anusol<sup>®</sup>), phlebotonics, and avoid prolonged straining
  - thrombosed hemorrhoids are very painful
    - resolve within 2 wk, may leave excess skin = perianal skin tag
    - treatment: consider surgical decompression within first 48 h of thrombosis, otherwise medical treatment
- indications for referral for endoscopic evaluation: history of melena, postural vital sign abnormalities, constitutional symptoms suggestive of malignancy, and family history of inherited colorectal syndromes

#### Prevention

- high fibre diets, prevent constipation, stool softeners

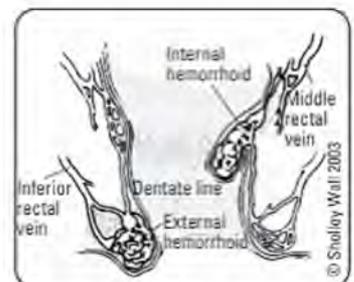

Figure 19. Hemorrhoids

Always rule out more serious causes (e.g. colon cancer or anal canal cancer) in a person with hemorrhoids and rectal bleeding

Band ligation can be done as outpatient

External hemorrhoids will often recur

**Table 24. Signs and Symptoms of Internal vs. External Hemorrhoids**

Internal Hemorrhoids	External Hemorrhoids
Painless BRBPR	Sudden severe perianal pain
Rectal fullness or discomfort	Perianal mass
Mucus discharge	

## Anal Fissures

### Definition

- tear of anal canal below dentate line (very sensitive squamous epithelium)
- 90% posterior midline because posteromedial area is poorly perfused, 10% anterior midline
- if off midline: consider other possible causes such as IBD, STIs, TB, leukemia, or anal carcinoma
- repetitive injury cycle after first tear
  - sphincter spasm occurs preventing edges from healing and leads to further tearing
  - ischemia may ensue and contribute to chronicity

### Etiology

- local trauma: constipation, irritation, diarrhea, vaginal delivery, anal intercourse
- secondary to: Crohn's disease, granulomatous diseases, malignancy, communicable diseases
- further tearing by internal anal sphincter spasm and hypertonicity

### Clinical Features

- acute fissure
  - very painful bright red bleeding especially after bowel movement, sphincter spasm on limited DRE
  - treatment is conservative: stool softeners, bulking agents, and sitz baths (heals 90%)
- chronic fissure (anal ulcer)
  - triad: fissure, sentinel skin tags, and hypertrophied papillae
  - treatment
    - stool softeners, increased fibre intake, and sitz baths
    - topical nitroglycerin or calcium channel blocker (nifedipine or diltiazem): increases local blood flow, promotes healing, and relieves sphincter spasm
    - lateral internal anal sphincterotomy (most effective): relieves sphincter spasm to increase blood flow and promote healing; reserved for medically-refractory cases due to 5% chance of fecal incontinence
    - alternative treatment: botulinum toxin A; inhibits release of acetylcholine (ACh), reducing sphincter spasm

### Prevention

- avoid diarrhea or constipation, avoid straining during defecation, high fibre diet, adequate fluids

## Anorectal Abscess

### Definition

- infection typically originating within an obstructed anal crypt which forms an abscess
- common bacterial: *E. coli*, *Proteus*, *Streptococci*, *Staphylococci*, *Bacteroides*, and anaerobes

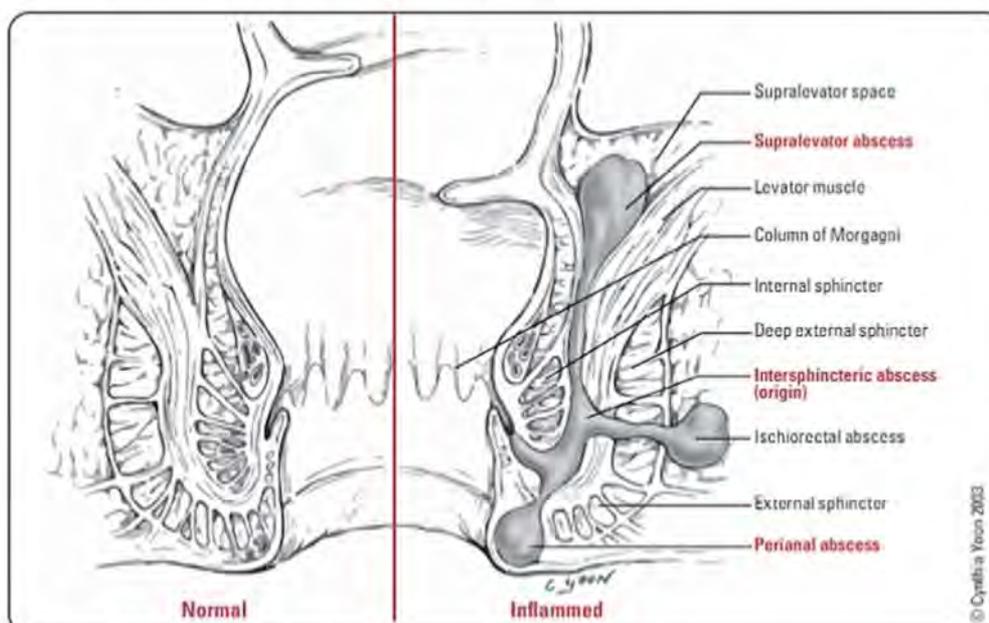

Figure 20. Different types of perianal abscesses

**Clinical Features**

- throbbing pain that may worsen with straining and ambulation
- abscess can spread vertically downward (perianal), vertically upward (supralelevator), or horizontally (ischioanal)
- tender perianal/rectal mass on exam

**Treatment**

- I&D
  - curative in 50% of cases
  - 50% develop anorectal fistulas
- may require antibiotics if patient has DM, a heart murmur, or cellulitis

**Fistula-In-Ano****Definition**

- fistula from anal canal to perianal skin
- an inflammatory tract with internal os at dentate line, external os on skin

**Etiology**

- see *Fistula, GS46*
- same processes that lead to the formation of an anal abscess
- other causes: postoperative, trauma, anal fissure, malignancy, and radiation proctitis

**Clinical Features**

- intermittent or constant purulent discharge from perianal opening
- pain
- palpable cord-like tract
- inflamed or excoriated perianal skin

**Treatment**

- identification
  - internal opening
    - ♦ Goodsall's rule: fistulas originating anterior to a transverse line through the anus will have a straight course and exit anteriorly, whereas those originating posterior to the transverse line will begin in the midline and have a curved tract
  - fistulous tract
    - ♦ probing or fistulography under anesthesia
- surgery
  - primary fistulotomy: unroof tract from external to internal opening, allows drainage, heals by secondary intention
    - ♦ best treatment for low lying fistula (does not involve external sphincter)
  - staged fistulotomy with Seton (rubber band or suture) placed through tract
    - ♦ used for high lying fistula (involves external sphincter)
    - ♦ promotes drainage, fibrosis, and decreases incidence of incontinence
    - ♦ delineates anatomy and usually done to spare muscle
  - ligation of intersphincteric fistula tract (LIFT) procedure
    - ♦ access fistula between sphincter muscles, sparing them
  - endoanal advancement flaps

**Postoperative**

- sitz baths, irrigation, and packing to ensure healing proceeds from inside to outside

**Complications**

- recurrence
- rarely fecal incontinence

**Pilonidal Disease****Definition**

- pilo = hair, nidal = nest; cyst or abscess near or on the intergluteal cleft of the sacrococcygeal area containing hair and skin debris

**Epidemiology**

- occurs most frequently in young men ages 15-35; rare in >50 yr

**Etiology**

- obstruction of the hair follicles in this area → formation of cysts, sinuses, or abscesses
- associated with occupations that require prolonged sitting, obesity, and high amounts of body hair

Recurrent perianal abscesses is associated with Crohn's disease

Antibiotics are not typically helpful in the treatment of perianal abscesses

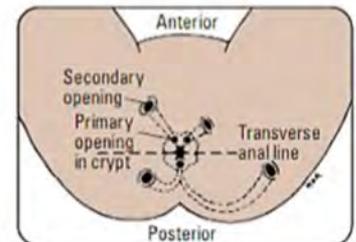

Figure 21. Goodsall's rule

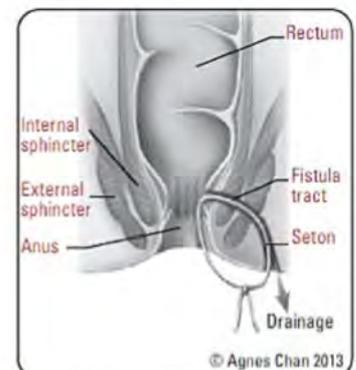

Figure 22. Fistulotomy with Seton suture

**Clinical Features**

- asymptomatic or chronically itchy until acutely infected, then pain/tenderness, purulent discharge, and increased moisture near the tailbone

**Treatment**

- acute abscess
  - I&D (often performed by primary care physicians)
  - wound packed open
  - 40% develop chronic pilonidal sinuses
- surgery
  - indication: failure of healing after I&D, recurrent disease, or complex disease
  - pilonidal cystotomy: excision of sinus tract and cyst; wound closed by secondary intention (vac dressing), primary closure with tissue flap, or marsupialization (cyst edge sewn to surrounding tissue to leave sinus tract open)

**Rectal Prolapse****Definition**

- protrusion of some or all of rectal mucosa through external anal sphincter

**Epidemiology**

- extremes of ages: <5 yr and >50 yr
- 85% women

**Etiology**

- lengthened attachment of rectum secondary to constant straining
- 2 types
  1. false/partial/mucosal: protrusion of mucosa only, radial furrows at junction with anal skin; most common type of rectal prolapse in childhood
  2. true/complete (most common): full-thickness extrusion of rectal wall, concentric folds in:
    - 1st degree: prolapse includes mucocutaneous junction
    - 2nd degree: without involvement of mucocutaneous junction
    - 3rd degree (internal intussusception): prolapse is internal, concealed, or occult

**Risk Factors**

- gynaecological surgery
- chronic neurologic/psychiatric disorders affecting motility e.g. chronic constipation
- multiparity
- weak pelvic floor

**Clinical Features**

- extrusion of mass with increased intra-abdominal pressure
- difficulty in bowel regulation
  - tenesmus, constipation, fecal incontinence
- permanently extruded rectum with excoriation, ulceration, and constant soiling
- may be associated with urinary incontinence or uterine prolapse
- pain is not common

**Treatment**

- type I
  - conservative: gentle manual reduction of prolapsed area, especially in children
  - mucosectomy with excision of redundant mucosa, mostly in adults
- type II
  - conservative: reduce if possible
  - surgery: abdominal, perineal, and trans-sacral approaches

**Anal Neoplasms****ANAL CANAL****Squamous Cell Carcinoma of Anal Canal (Distal to Dentate Line)**

- most common tumour of anal canal (75%)
- anus prone to human papillomavirus (HPV) infection, therefore at risk for anal squamous intra-epithelial lesions (ASIL)
  - high-grade squamous intra-epithelial lesion (HSIL) and low-grade squamous intra-epithelial lesion (LSIL) terminology used
- clinical features: anal bleeding, pain, mass, ulceration, and pruritus; 25% asymptomatic
- treatment: chemotherapy ± radiation ± surgery
- prognosis: 80% 5 yr survival

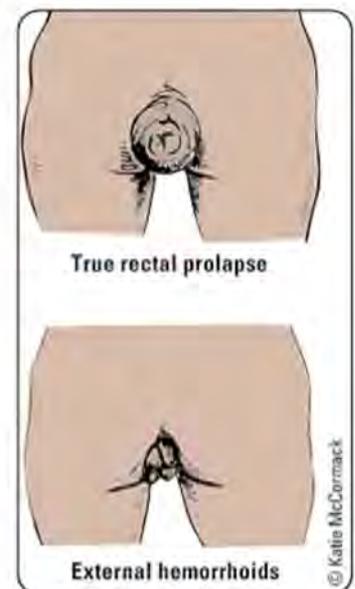

Figure 23. Rectal prolapse (true vs. false)

**Malignant Melanoma of Anal Canal**

- 3rd most common site for primary malignant melanoma after skin, eyes
- aggressive, distant metastases common at time of diagnosis
- occasionally an incidental finding in pathological evaluation of an anal specimen
- clinical features: bleeding, mass anorectal pain, change in bowel habits, pigmented in one third cases, regional lymph node involvement
- treatment: wide excision or APR ± chemoradiation
- prognosis: <5% 5 yr survival

**ANAL MARGIN**

- clinical features and treatment as for skin tumours elsewhere
- squamous and basal cell carcinoma, Bowen's disease (SCC in situ), and Paget's disease

**Liver**

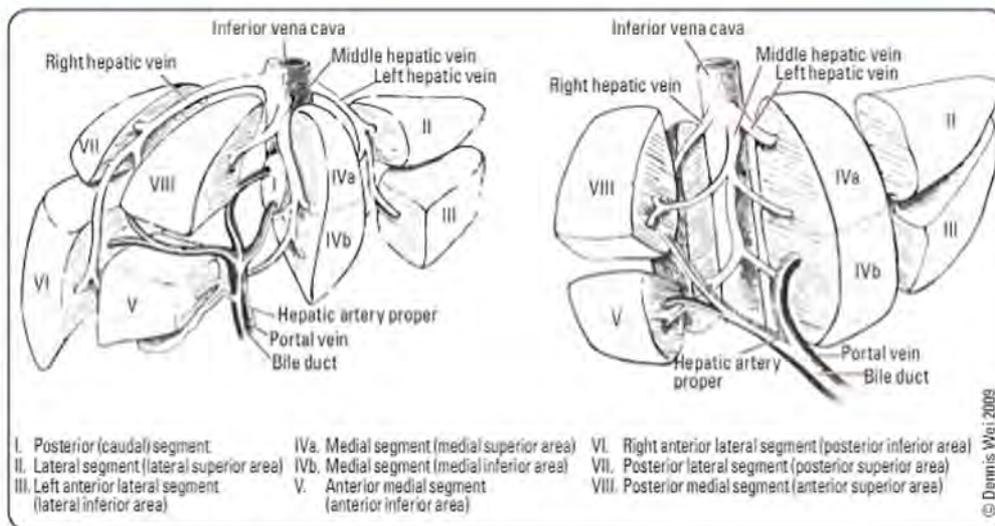

Figure 24. Anatomy of liver

**Liver Cysts**

Table 25. Characteristics of Liver Cysts

	Simple Cysts	Polycystic Liver Disease	Choledochal Cysts	Hydatid (Cystic Echinococcosis)	Cystadenoma (Premalignant)/Cystadenocarcinoma
<b>Description</b>	Form from biliary ducts that do not communicate with the intrahepatic biliary tree and contain clear fluid Most common May have multiple cysts Always benign Examples include congenital cysts, Caroli disease, biliary hamartomas, and polycystic liver disease (PCLD)	Several (>20) cysts that replace much of the liver parenchyma Autosomal-dominant condition More common in females	Congenital malformations of the bile ducts High-risk of malignancy Majority present before age 10 Todani classification based on anatomical characteristics within biliary tree	Infection with parasite <i>Echinococcus granulosus</i> Associated with exposure to dogs, sheep, horses, pigs, goats, camels, and cattle in Southern Europe, Middle East, Australasia, South America Ingested parasitic eggs hatch in the small intestine, where larvae enter blood and lymph	Cystadenomas are rare cystic neoplasms arising from the bile ducts Cystadenoma is the most common premalignant liver lesion Cystadenocarcinoma is an invasive carcinoma
<b>Clinical Features</b>	Usually asymptomatic Mass effect can cause: dull RUQ pain, N/V, bloating, and/or early satiety	Minority present with acute complications due to cyst rupture, hemorrhage, infection, and compression of adjacent structures Progressive 50% associated with polycystic kidney disease (if over age 60)	Recurrent abdominal pain Intermittent jaundice RUQ mass Cholangitis Symptomatic gallstones Pancreatitis Portal HTN	Usually asymptomatic May have palpable RUQ mass or hepatomegaly Chronic RUQ pain when symptomatic Nausea, fever, and dyspepsia are non-specific symptoms	Upper abdominal mass Abdominal pain Anorexia
<b>Investigations</b>	Labs: some have elevated GGT, CEA, CA 19-9 U/S: Used for diagnosis and follow-up CT: well demarcated lesion that does not enhance with contrast	U/S: cysts are well circumscribed and nonenhancing MRI: more sensitive and specific, used for preoperative planning	Labs: LFT abnormalities U/S CT Transhepatic cholangiography ERCP MRCP	Labs: anti-Echinococcus ab U/S CT: calcified cystic walls Needle biopsy	Labs: cystadenocarcinoma may have elevated LFTs, CEA, or CA 19-9 U/S: anechoic mass with internal septations that are highly echogenic CT MRI MRCP ERCP Need histology for definite diagnosis

Table 25. Characteristics of Liver Cysts

	Simple Cysts	Polycystic Liver Disease	Choledochal Cysts	Hydatid (Cystic Echinococcosis)	Cystadenoma (Premalignant)/ Cystadenocarcinoma
<b>Treatment</b>	Not required unless very large and/or symptomatic Monitor if >4 cm Laparoscopic or open cyst wall removal (unroofing) is established treatment and is usually curative Percutaneous aspiration and ethanol sclerotherapy also an option, but not curative	Symptomatic patients: cyst aspiration with sclerosis, cyst fenestration, hepatic resection, transarterial embolization, and transplantation	Complete excision of cysts Liver resection or transplantation if cystic dilatation involves intrahepatic bile ducts (Caroli's disease)	Systemic chemotherapy: Albendazole (anti-helminthic drug) cure up to 30% Surgical: radical (total pericystectomy, partial hepatectomy, or lobectomy) vs. conservative (drainage or open/closed cystectomy) Percutaneous:PAIR (puncture, aspiration, injection, re-aspiration)	All complex, multiloculated cysts (except echinococcal) should be excised because of malignancy risk
<b>Complications</b>	Hemorrhage, rupture, infection, and biliary obstruction more likely in larger cysts Intracystic hemorrhage is rare and presents with severe abdominal pain		Biliary cirrhosis, portal HTN, cyst rupture, or cholangiocarcinoma Increased risk of biliary malignancy	IVC compression Cyst rupture which can cause fever, pruritis, eosinophilia, biliary colic, jaundice, cholangitis, pancreatitis, or anaphylaxis	Cystadenocarcinoma can invade adjacent tissues and metastasize

## Liver Abscesses

### Etiology

- types
  - pyogenic (bacterial): most common etiology; most often polymicrobial – *Klebsiella*, *E. coli*, *Proteus*, *Streptococcus*, *Staphylococcus*, and anaerobes
  - parasitic (amoebic): *Entamoeba histolytica*, Echinococcal cyst
  - fungal: *Candida*
  - sources: direct spread from biliary tract infection, portal spread from GI infection, systemic infection (e.g. endocarditis)

### Clinical Features

- fever, malaise, chills, anorexia, weight loss, abdominal pain, and nausea
- RUQ tenderness, hepatomegaly, and jaundice

### Investigations

- CBC (leukocytosis, anemia), LFTs (elevated ALP and hypoalbuminemia common; elevated transaminases and bilirubin variable), blood cultures, INR/PTT, stool cultures, and serology (*E. histolytica* and *Echinococcus*)
- CT or U/S are the imaging modalities used for diagnosis with abscess drainage for C&S to confirm diagnosis; MRI can also be used.

### Treatment

- treat underlying cause
- pyogenic abscesses generally treated with antibiotic therapy (e.g. ceftriaxone and metronidazole or piperacillin-tazobactam) and U/S- or CT-guided percutaneous drainage or surgical drainage
- consider potential source of sepsis (e.g. biliary source, infected tumour)

### Prognosis

- overall mortality 15% – higher rate if delay in diagnosis, multiple abscesses, malnutrition, elderly, ICU admissions, shock, cancer, cirrhosis, CKD, acute respiratory failure, and biliary origin of abscess

Differential Diagnosis of Metastatic Liver Mass

Some GU Cancers Produce Bumpy Lumps

Stomach  
GenitoUrinary cancers (kidney, ovary, uterus)  
Colon  
Pancreas  
Breast  
Lung

## Neoplasms

### BENIGN LIVER NEOPLASMS

#### Hemangioma (cavernous)

- pathogenesis: most common benign hepatic tumour; results from malformation and proliferation of vascular endothelial cells
- risk factors: M:F=3:1
- clinical features
  - usually small and asymptomatic, those greater than 10 cm are considered giant and may cause abdominal pain or discomfort
  - consumptive coagulopathy if giant (in children)
- investigations
  - contrast CT (well-demarcated hypodense mass with peripheral enhancement on arterial phase with centripetal filling on delayed phases), U/S (homogeneous hyperechoic mass), MRI
  - avoid biopsy: may result in hemorrhage

• treatment

- none if asymptomatic
- in symptomatic patients or those with hemangiomas large enough causing mass effect, surgical resection should be considered after other causes of pain are excluded
- surgical resection options: liver resection, hepatic artery ligation, enucleation, and in severe cases liver transplantation.
- non-surgical treatment: hepatic artery embolization and radiotherapy

**Focal Nodular Hyperplasia**

- pathogenesis: unclear, hyperplastic response to vascular anomaly leading to disorganized growth of hepatocytes and bile ducts
- risk factors: female, reproductive age
- clinical features: usually asymptomatic, rarely grows or bleeds, and no malignant potential
- investigations: central stellate scar surrounded by homogenous lesion on CT scan; MRI, biopsy may be required
- treatment: may be difficult to distinguish from adenoma/fibrolamellar HCC (malignant potential)
  - if confirmed to be FNH → no treatment required

**Adenoma**

- pathogenesis: benign abnormal growth of glandular epithelium
- risk factors: female, ages 20-50, estrogen (OCP, pregnancy), obesity, anabolic androgen use, and type 1 glycogen storage disease
- clinical features: asymptomatic, 25% present with RUQ pain or mass, may present with bleeding
- investigations: CT (well-demarcated masses, often heterogeneous enhancement on arterial phase, isodense on venous phase without washout of contrast), U/S, MRI, biopsy can be considered, with bleeding risk taken into account
- treatment
  - stop anabolic steroids or OCP
  - excise, especially if large (>5 cm), due to risk of transformation to HCC and spontaneous rupture/hemorrhage

**MALIGNANT LIVER NEOPLASMS**

**Primary**

- most commonly HCC and cholangiocarcinoma
- others include angiosarcoma, hepatoblastoma, and hemangioendothelioma
- risk factors
  - chronic liver inflammation: cirrhosis from any cause, chronic hepatitis B (inherently oncogenic) and hepatitis C, hemochromatosis,  $\alpha$ 1-antitrypsin deficiency, and non-alcoholic steatohepatitis
  - medications: OCPs (3x increased risk), steroids
  - smoking, alcohol, betel nuts chewing
  - chemical carcinogens: aflatoxin, microcystin, and vinyl chloride (associated with angiosarcoma)
- clinical features
  - RUQ discomfort and right shoulder pain
  - jaundice, weakness, weight loss, and  $\pm$  fever (if central tumour necrosis)
  - hepatomegaly, bruit, and hepatic friction rub
  - ascites with blood (sudden intra-abdominal hemorrhage)
  - paraneoplastic syndromes: hypoglycemia, hypercalcemia, erythrocytosis, and watery diarrhea
  - metastasis: lung, intra-abdominal lymph nodes, bone, adrenal gland, brain, and peritoneal seeding
- investigations
  - INR and LFTs: AST, ALT, ALP, bilirubin, and albumin
  - elevated ALP, bilirubin, and  $\alpha$ -fetoprotein (80% of patients)
  - U/S (poorly-defined margins with internal echoes), triphasic CT (enhancement on arterial phase and washout on portal venous phase), and MRI
- treatment
  - cirrhosis is a relative contraindication to tumour resection due to decreased hepatic reserve
  - surgical: resection (10% of patients have resectable tumours)
  - liver transplant; may use bridging therapy while awaiting transplant
    - absolute contraindications: extrahepatic disease and vascular invasion
    - relative contraindications: dependent on liver transplant protocol based on staging criteria followed by transplant centre
  - non-surgical: radiofrequency ablation, percutaneous ethanol injection, transcatheter arterial chemoembolization (TACE), chemotherapy (consider sorafenib for HCC; preoperative chemotherapy for hepatoblastoma is standard of care), and radiotherapy
- prognosis
  - 5 yr survival: 18% of all patients; 40-70% of patients undergoing complete resection

**Liver Transplantation Criteria for Hepatocellular Carcinoma**

<b>Milan Criteria*</b>	1 tumour $\leq$ 5 cm Up to 3 tumours each $\leq$ 3 cm
<b>UCSF Criteria*</b>	1 tumour $\leq$ 6.5 cm Up to 3 tumours each $\leq$ 4.5 cm, total diameter $\leq$ 8 cm
<b>Toronto Criteria*</b>	No tumour size or number restrictions No systemic symptoms Not poorly differentiated

\*Each criteria assumes no extrahepatic and no macrovascular invasion

**Child-Turcotte-Pugh Score (Prognosis of Chronic Liver Disease/Cirrhosis, including Postoperatively)**

	1 Point	2 Points	3 Points
Albumin (g/L)	$>$ 35	28-35	$<$ 28
Ascites	Absent	Easily controlled	Poorly controlled
Bilirubin ( $\mu$ mol/L)	$<$ 34	34-51	$>$ 51
(mg/dL)	$<$ 2.0	2.0-3.0	$>$ 3.0
Coagulation (INR)	$<$ 1.7	1.7-2.3	$>$ 2.3
Hepatic Encephalopathy (Grade I-II)	None	Minimal	Advanced
(Grade III-IV)			
<b>Points</b>	<b>Class</b>	<b>One Yr Survival</b>	<b>Two Yr Survival</b>
5-6	A	100%	85%
7-9	B	81%	57%
10-15	C	45%	35%

### Secondary

- metastases to the liver are the most common malignant tumours found in the liver
- etiology
  - GI (colorectal most common), lung, breast, pancreas, GI NET, stomach, melanoma, ovary, uterus, kidney, gallbladder, and prostate
- treatment
  - depends on the primary cancer site and prognosis
    - often liver metastases are a manifestation of Stage IV disease and chemotherapy is indicated
  - metastasectomy may be appropriate for cancers either through surgical resection or local treatment (i.e. embolization)
    - hepatic resection of metastatic colorectal liver metastases is standard of care as part of multi-modality treatment that includes chemotherapy if complete resection of the primary cancer and metastases is possible
    - transplant also a new and emerging alternative for metastatic disease in the liver.
- prognosis
  - following liver resection for colorectal metastases is an overall survival of 30-60% at 5 yr

Secondary liver metastases are common in many cancers, with some studies showing a prevalence of 40-50% amongst patients with extrahepatic cancers. They commonly arise from colorectal, lung, and breast cancers. For metastases secondary to colorectal cancer, surgical resection offers the greatest likelihood of cure

## Liver Transplantation

Table 26. Conditions Leading to Transplantation

Parenchymal Disease	Cholestatic Disease	Inborn Errors	Tumours
Chronic hepatitis B or C*	Biliary atresia**	$\alpha$ 1-antitrypsin deficiency	Hepatocellular carcinoma
Alcoholic cirrhosis	Primary biliary cirrhosis	Wilson's disease	Hepatoblastoma
Acute liver failure	Sclerosing cholangitis	Hemochromatosis	Metastatic NETs
Budd-Chiari syndrome			Colorectal cancer
Congenital hepatic fibrosis			
CF			
Autoimmune hepatitis			
Cryptogenic cirrhosis			
Drug induced hepatotoxicity			
Non-alcoholic steatohepatitis			

\*leading cause in adults; \*\*leading cause in children

### Clinical Indications

- early referral for transplant should be considered for all patients with progressive liver disease not responsive to medical therapy, especially:
  - decompensated cirrhosis (ascites, esophageal variceal hemorrhage, spontaneous hepatic encephalopathy, coagulopathy, progressive jaundice, severe fatigue)
  - unresectable primary liver cancers
  - unresectable but localized liver metastasis of colorectal cancer - new emerging indication
  - acute liver failure
  - liver-based metabolic conditions including  $\alpha$ -1-antitrypsin deficiency
- end-stage liver disease with life expectancy <1 yr and if no other therapy is appropriate
  - suitable HCC not amenable to liver resection

### Criteria for Transplantation

- Model for End-Stage Liver Disease (MELD): prognostic model to estimate 3 mo survival following transjugular intrahepatic portosystemic shunt (TIPS) procedure and to prioritize patients awaiting liver transplant; based on creatinine, bilirubin, INR, sodium (MELD-Na), female sex, and serum albumin; MELD scores used to prioritize liver allocation
- Child-Turcotte-Pugh Score: classification system to assess the prognosis and the abdominal surgery perioperative mortality of chronic liver disease and cirrhosis; patient must have  $\geq 7$  points (Class B) for transplant evaluation

### Contraindications

- active alcohol/substance use
- extrahepatic malignancy within 5 yr
- advanced cardiopulmonary disease
- active uncontrolled infection

### Postoperative Complications

- primary non-function (graft failure): urgent re-transplantation is indicated
- acute and chronic rejection, ischemia-reperfusion injury
- vascular: hepatic artery or portal vein thrombosis, IVC obstruction
- biliary complications: fever, increasing bilirubin and ALP
- complications related to immunosuppression: HTN, renal disease, DM, obesity, hyperlipidemia, osteoporosis, malignancy, neurologic complications, infection (leading cause of mortality following transplant)

### Prognosis

- patient survival at 1 yr: 85%
- graft survival at 1 yr: >80%, at 5 yr: 60-70%

### Living Liver Donors vs. Deceased Liver Donors

The right lobe of a living donor liver is transplanted into the recipient, whereas whole livers from deceased donors are transplanted orthotopically into the recipient

# Biliary Tract

## Cholelithiasis

**Definition**

- the presence of stones in the gallbladder

**Pathogenesis**

- imbalance of cholesterol and its solubilizing agents (bile salts and lecithin)
- excess hepatic cholesterol secretion relative to bile salts and lecithin → supersaturated cholesterol which precipitates as gallstones
- North America: cholesterol stones (80%), pigment stones (20%)

**Risk Factors**

- cholesterol stones
  - obesity
  - increasing age
  - prevalence higher in females (especially females <50 yr)
  - estrogens: female, multiparity, OCPs
  - impaired gallbladder emptying: starvation, TPN, DM
  - rapid weight loss: rapid cholesterol mobilization and biliary stasis
- pigment stones (contain calcium bilirubinate)
  - cirrhosis
  - chronic hemolysis
  - biliary stasis (strictures, dilation, biliary infection)
  - terminal ileal resection or disease (e.g. Crohn's disease)
- protective factors
  - statins, physical activity, vitamin C, poly- and monounsaturated fats and nuts, coffee

**Risk Factors for Cholesterol Stones**

- 4Fs
- Fat
- Female
- Fertile
- Forties

**Summary of Biliary Tract Conditions**

Gallbladder	Asymptomatic	Pain Only	Infection + Pain
Cholelithiasis	✓ (majority)		
Biliary Colic		✓	
Cholecystitis			✓
Common Bile Duct	Asymptomatic	Pain Only	Infection + Pain
Choledocholithiasis	✓ (majority)	✓	
Cholangitis			✓ (majority)

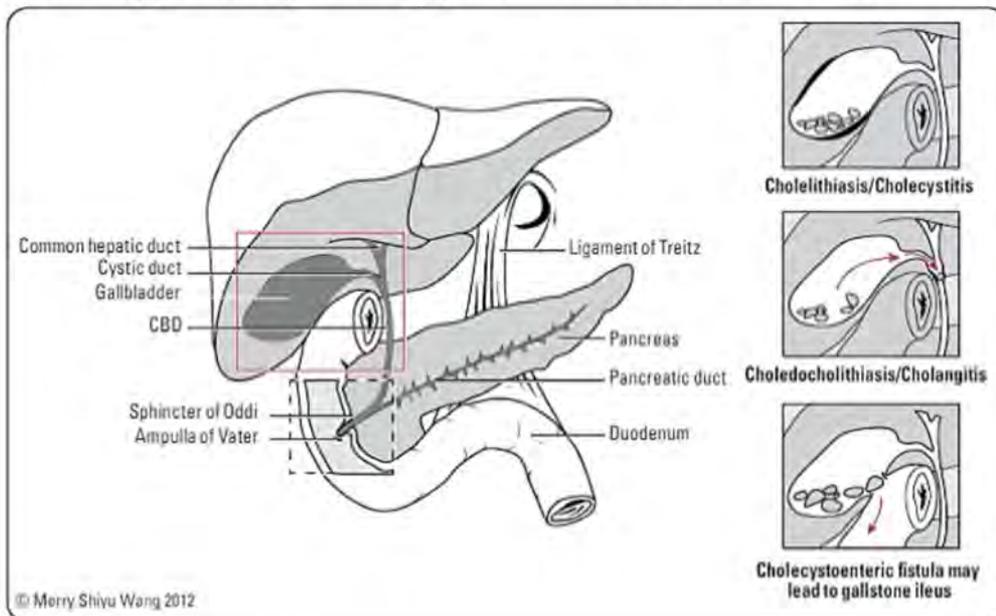

Figure 25. Gallstone disease

**Clinical Features**

- asymptomatic (80%): found incidentally
  - 18% risk of progression to symptomatic gallstone disease within 20 yr
  - most do NOT require treatment
  - consider cholecystectomy if: increased risk of malignancy (choledochal cysts, Caroli's disease, porcelain or calcified gallbladder), sickle cell disease, paediatric patient, bariatric surgery, and immunosuppression
- biliary colic (10-25%)

**Investigations**

- normal bloodwork: CBC, electrolytes, Cr, LFTs, bilirubin, lipase
- U/S: diagnostic procedure of choice
  - image for signs of inflammation, obstruction, and localization of stones
  - 95% specific for detecting stones

## Biliary Colic

### Pathogenesis

- gallstone transiently impacted in cystic duct, no infection

### Clinical Features

- an episode of steady, severe dull pain in the epigastrium or RUQ lasting minutes to hours (<6 h), crescendo-decrescendo pattern
- can present with chest pain, right shoulder tip pain, scapular pain
- N/V
- frequently occurs at night or after fatty meal, not after fasting
- no peritoneal findings, no systemic signs

### Investigations

- normal blood work: CBC, electrolytes, Cr, LFTs, bilirubin, lipase
- U/S shows cholelithiasis, may show stone in cystic duct

### Treatment

- analgesia, rehydration during colic episode
- elective cholecystectomy (95% success)
  - complications: CBD injury (0.3-0.5%), hollow viscus injury, bile peritonitis, and vessel injury leading to liver damage
  - laparoscopic cholecystectomy is the standard of care, no benefit to delaying surgery

## Acute Cholecystitis

### Pathogenesis

- inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or Hartmann's pouch
- no cholelithiasis in 5-10% (see *Acalculous Cholecystitis*, GS57)

### Clinical Features

- often have history of biliary colic
- severe constant (>6 h) epigastric or RUQ pain, anorexia, N/V, and low grade fever (<38.5°C)
- focal peritoneal findings: Murphy's sign, palpable, and tender gallbladder (in 33%)
- Boas' sign: right subscapular pain

### Investigations

- blood work: elevated WBC and left shift, mildly elevated bilirubin concerning for bile duct obstruction (either stones or Mirizzi syndrome)
- U/S: 98% sensitive, consider HIDA scan if U/S negative
  - signs: gallbladder wall thickening >4 mm, edema (double-wall sign), gallbladder sludge, cholelithiasis, pericholecystic fluid, and sonographic Murphy's sign

### Complications

- gangrenous gallbladder (20%) most common complication
- perforation (10%): result in abscess formation or rarely local peritonitis
- Mirizzi syndrome: extra-luminal compression of CBD/CHD due to large stone in cystic duct
- empyema of gallbladder: suppurative cholecystitis (pus in gallbladder) and sick patient
- emphysematous cholecystitis: bacterial gas present in gallbladder lumen, wall, or pericholecystic space (risk in diabetic patient); organisms involved in secondary infection: *C. welchii*, *E. coli*, *Klebsiella*, anaerobic streptococci, Enterococcus
- cholecystoenteric fistula (from repeated attacks of cholecystitis) can lead to gallstone ileus

### Treatment

- admit, hydrate, NPO, NG tube (if persistent vomiting from associated ileus), analgesics
- antibiotics
  - cefazolin if uncomplicated cholecystitis
- ERCP prior to surgery if CBD stones are present on US
  - MRCPC ± ERCP if CBD is markedly dilated or CBD stones suspected
- cholecystectomy
  - early (within 72 h) vs. delayed (after 6 wk)
    - equal morbidity and mortality
    - early cholecystectomy preferred: shorter hospitalization and recovery time, no benefit to delaying surgery
    - emergent OR indicated if high-risk, e.g. emphysematous
  - laparoscopic is standard of care (convert to open for complications or difficult case)
    - reduced risk of wound infections, shorter hospital stay, reduced postoperative pain, and increased risk of bile duct injury
- intraoperative cholangiography (IOC)
  - indications: clarify bile duct anatomy, history of biliary pancreatitis, small stones in gallbladder with a wide cystic duct (>15 mm), and jaundice

Biliary colic is a pain that comes and goes, but cholecystitis is a pain which is constant and usually increasing

### 2 Most Important Lab Tests for Biliary Pain

- Lipase: to determine if element of pancreatitis
- Bilirubin: to determine if bile duct obstruction

Biliary colic is treated with analgesia and elective cholecystectomy. Acute cholecystitis is treated with antibiotics and early cholecystectomy if surgical risk appropriate

### Toronto Video Atlas of Surgery: Standard Laparoscopic Cholecystectomy

TVASurg is an open access library of animation enhanced surgical videos created by surgeons in Toronto. For a video simulation of a standard laparoscopic cholecystectomy, see [pic.med.utoronto.ca/TVASurg/project/standardlapchole/](http://pic.med.utoronto.ca/TVASurg/project/standardlapchole/)

### Mirizzi Syndrome

Extrinsic compression of the CHD by a gallstone in the cystic duct or Hartmann's pouch. Impacted gallstone may erode into the CHD or CBD, creating a cholecystohepatic or cholecystocholedochal fistula; Mirizzi syndrome has an association with gallbladder cancer

### Rouviere's Sulcus

Fissure between right lobe and caudate process (segment I) of liver; keeping dissection anterior to this landmark can minimize bile duct injury

### Critical View of Safety (CVS)

Decreases risk of injury to CBD during laparoscopic cholecystectomy. 3 criteria are required to achieve the CVS:

- The hepatocystic triangle (formed by the cystic duct, CHD, and inferior edge of the liver) is cleared of fat and fibrous tissue
- The lower one third of the gallbladder is separated from the liver to expose the cystic plate
- Two and only two structures should be seen entering the gallbladder (cystic duct and artery)

- has been mostly replaced by preoperative MRCP
- percutaneous cholecystostomy tube: critically ill or if general anesthetic contraindicated
- some centres can perform percutaneous stone extraction to avoid cholecystectomy

## Acalculous Cholecystitis

### Definition

- acute or chronic cholecystitis in the absence of stones

### Pathogenesis

- typically due to gallbladder ischemia and stasis

### Risk Factors

- ICU admission (most common), DM, immunosuppression, trauma patient, TPN, and sepsis

### Clinical Features

- see *Acute Cholecystitis*, GS56
- occurs in 10% of cases of acute cholecystitis

### Investigations

- bloodwork: CBC, electrolytes, Cr, LFTs, liver enzymes, bilirubin, and lipase
- U/S: shows sludge in gallbladder, other U/S features of cholecystitis (see *Acute Cholecystitis*, GS56)
- CT or HIDA scan

### Treatment

- NPO, IV fluids, and pain management
- IV broad-spectrum antibiotics, cholecystectomy
- if patient unstable → percutaneous cholecystostomy

## Choledocholithiasis

### Definition

- stones in CBD

### Clinical Features

- often have history of biliary colic
- tenderness in RUQ or epigastrium
- acholic stool, dark urine, and fluctuating jaundice
- primary vs. secondary stones
  - primary: formed in bile duct, indicates bile duct pathology (e.g. benign biliary stricture, sclerosing cholangitis, choledochal cyst, and CF)
  - secondary: formed in gallbladder (85% of cases in the U.S.)

### Investigations

- CBC: usually normal; leukocytosis suggests cholangitis
- LFTs: increased AST, ALT early in disease, increased bilirubin (more sensitive), ALP, GGT later
- lipase: to rule out gallstone pancreatitis
- U/S: intra-/extra-hepatic duct dilatation; differential diagnosis is choledochal cyst
- MRCP (90% sensitive)
  - visualization of ampullary region, biliary, and pancreatic anatomy
  - non-invasive diagnostic test of choice
- ERCP
  - CBD stones in periampullary region
  - diagnostic and therapeutic; removal of stones and sphincterotomy possible
  - complications: retained stones, ERCP pancreatitis (1-2%), pancreatic or biliary sepsis
- Percutaneous Transhepatic Cholangiography
  - percutaneous approach to the proximal biliary tree (i.e. intrahepatic biliary system) via the hepatic parenchyma
  - useful for proximal bile duct obstruction or when ERCP fails or not available
  - contraindications: ascites, peri/intrahepatic sepsis, and disease of right lower lung or pleura
  - complications: bile peritonitis, chylothorax, pneumothorax, biliary sepsis, and hemobilia
- Intraoperative Cholangiography (IOC)
  - intraoperative injection of radiographic contrast into the cystic duct to evaluate CBD during laparoscopic cholecystectomy
  - useful for identifying CBD stones, clarifying biliary anatomy, and preventing CBD injury during cholecystectomy

### Complications

- cholangitis, pancreatitis, biliary stricture, and biliary cirrhosis

American Society of Gastrointestinal Endoscopy 2019 Guideline on Role of Endoscopy in Evaluating Choledocholithiasis

#### Proceed directly to ERCP

- CBD stone on U/S
- Clinical ascending cholangitis
- Bilirubin >4mg/dL (>347umol/L) & dilated CBD on U/S

#### Perform U/S, MRCP, Laparoscopic IOC or Intraoperative US

- Abnormal liver tests
- Age >55 yr
- Dilated CBD on U/S

**Treatment**

- treat with ERCP for CBD stone extraction possibly followed by elective cholecystectomy in 25% of patients
- biliary tree flushing with laparoscopic cholecystectomy:
  - during a laparoscopic cholecystectomy  $\pm$  cholangiogram, the cystic duct can be flushed to the CBD with the use of glucagon to relax the sphincter between the CBD and duodenum. Can also use cholangiogram to confirm stones flushed into duodenum

**Acute Cholangitis****Pathogenesis**

- obstruction of CBD leading to biliary stasis, bacterial overgrowth, suppuration, and biliary sepsis – may be life-threatening, especially in elderly

**Etiology**

- choledocholithiasis (60%), stricture, neoplasm (pancreatic or biliary), extrinsic compression (pancreatic pseudocyst or pancreatitis), instrumentation of bile ducts (PTC, ERCP), and biliary stent
- organisms: *E. coli*, *Klebsiella*, *Enterobacter*, *Pseudomonas*, *Enterococcus*, *B. fragilis*, and *Proteus*

**Clinical Features**

- Charcot's triad: fever, RUQ pain, and jaundice
- Reynold's pentad: Charcot's triad, hypotension, and altered mental status
- may have N/V, abdominal distention, ileus, acholic stools, and tea-coloured urine (elevated direct bilirubin)

**Investigations**

- CBC: elevated WBC + left shift
- may have positive blood cultures
- LFTs: obstructive picture (elevated ALP, GGT, and conjugated bilirubin, possible mild increase in AST, ALT)
- lipase: rule out pancreatitis
- U/S: intra-/extra-hepatic duct dilatation
- CT: bile duct dilatation and can identify biliary stenosis
- MRCP when diagnosis is unclear

**Treatment**

- initial: NPO, fluid and electrolyte resuscitation,  $\pm$  NG tube, IV antibiotics (treats 80%)
- biliary decompression
  - ERCP + sphincterotomy: diagnostic and therapeutic
  - PTC with catheter drainage: if ERCP not available or unsuccessful
  - open or laparoscopic CBD exploration and T-tube placement if above fails
- in addition to biliary decompression, the underlying cause should be addressed. In the case of patients with choledocholithiasis, elective cholecystectomy is recommended after resolution of acute cholangitis to prevent re-occurrence

**Prognosis**

- suppurative cholangitis mortality rate: 20-30%

**Gallstone Ileus****Pathogenesis**

- repeated inflammation causes a cholecystoenteric fistula (usually duodenal)  $\rightarrow$  large gallstone enters the GI tract (impacting near the ileocecal valve) causing a mechanical bowel obstruction (note: ileus is a misnomer in this context)

**Clinical Features**

- crampy abdominal pain, N/V, constipation/obstipation (see *Large Bowel Obstruction, GS37*)

**Investigations**

- AXR: dilated small intestine, air fluid levels, may reveal radiopaque gallstone, and air in biliary tree (pneumobilia) (40%)
- CT: biliary tract air, obstruction, and gallstone in intestine
- Rigler's triad: pneumobilia, SBO (partial or complete), and gallstone (usually in right iliac fossa)

**Treatment**

- fluid resuscitation, NG tube decompression
- surgery: enterolithotomy and removal of stone, inspect small and large bowel for additional proximal stones
- may close fistula surgically or manage expectantly (can resolve spontaneously)
- cholecystectomy is generally not performed

**Charcot's Triad**  
Fever, RUQ pain, jaundice

**Reynolds' Pentad**  
Fever, RUQ pain, jaundice, shock, and altered mental status

**Common Bacteria in Biliary Tract**

KEEPS  
*Kl ebsiella*  
*Enterococcus*  
*E. coli*, *Enterobacter*  
*Proteus*, *Pseudomonas*  
*Serratia*

**Rigler's Triad of Gallstone Ileus**  
Pneumobilia  
Small bowel obstruction  
Gallstone

**Bouveret's Syndrome**  
Gastric outlet/duodenal obstruction caused by a large gallstone passing through a cholecystogastric or cholecystoduodenal fistula

## Carcinoma of the Gallbladder

### Risk Factors

- chronic symptomatic gallstones (70% of cases), old age, female, gallbladder polyps, porcelain gallbladder, chronic infection (Salmonella, Helicobacter), primary sclerosing cholangitis, and abnormal pancreaticobiliary duct junction

### Clinical Features

- majority are adenocarcinoma
- may be incidental finding on elective cholecystectomy (~1% of open cholecystectomies OR 0.1% in laparoscopic cholecystectomies)
- many patients are asymptomatic until late
- local: non-specific RUQ pain ± palpable RUQ mass
- Courvoisier's gallbladder sign: enlarged gallbladder and painless jaundice due to obstruction of CBD, suggestive of gallbladder or pancreatic malignancy
- systemic: jaundice (50%) due to invasion of CBD or compression of CBD by pericholedochal nodes, anorexia, N/V, weight loss, and malaise
- early local extension to liver, peritoneum, may extend to stomach, duodenum
- early metastasis common to lung, pleura, liver bone

### Investigations

- U/S: mural thickening, calcification, loss of interface between gallbladder and liver, and fixed mass
- endoscopic U/S (EUS): good for distinguishing carcinomas from other diagnoses such as, polyps, staging, allows sampling of bile for cytology
- abdominal CT: polypoid mass, mural thickening, liver invasion, nodal involvement, and distant metastases
- MRI/MRCP: good for distinguishing benign and malignant polyps

### Treatment

- if carcinoma of the gallbladder is suspected preoperatively, an open cholecystectomy should be considered to avoid tumour seeding of the peritoneal cavity
- confined to mucosa (rare): cholecystectomy
- beyond mucosa: cholecystectomy, en bloc wedge resection of 3-5 cm underlying liver, and dissection of hepatoduodenal lymph nodes

### Prognosis

- poor 5 yr survival (20%) as gallbladder carcinoma is often detected late
- better outcomes when detected incidentally following cholecystectomy

## Cholangiocarcinoma

### Definition

- malignancy of the epithelial cells of extra- or intrahepatic bile ducts

### Risk Factors

- ages 50-70, gallstones, UC, primary sclerosing cholangitis, choledochal cyst, Clonorchis sinensis infection (liver fluke), chronic intrahepatic stones (hepatolithiasis), genetic disorders (Lynch syndrome, CF, multiple biliary papillomatosis, BAP1 tumour predisposition syndrome)

### Clinical Features

- majority are adenocarcinomas
- gradual signs of biliary obstruction: jaundice, pruritus, dark urine, and pale stools
- anorexia, weight loss, RUQ pain, Courvoisier's sign (if CBD obstructed), hepatomegaly
- early metastases are uncommon, but commonly tumour grows into portal vein or hepatic artery, peritoneum, lungs, pleura, liver
- Klatskin tumour: cholangiocarcinoma located at bifurcation of CHD

### Investigations

- LFTs show obstructive picture, carbohydrate antigen 19-9 (CA 19-9), CEA may be elevated
- U/S, CT: bile ducts usually dilated, but not necessarily
- ERCP or PTIC: to determine resectability, for biopsies
- CXR, bone scan: for metastatic workup

### Treatment

- if resectable: biliary drainage and wide excision margin
- intrahepatic lesions: liver resection after clear discussion at multidisciplinary tumour boards and prognosis understood
  - upper third lesions: duct resection + Roux-en-Y hepaticojejunostomy, ± liver resection
  - middle third lesions (uncommon): duct resection + Roux-en-Y hepaticojejunostomy
  - lower third lesions: Whipple procedure

Obstructive jaundice is the most common presenting symptom for cholangiocarcinoma

- unresectable lesions: stent or choledochojejunostomy (surgical bypass)
- chemotherapy ± radiotherapy
- role for transplantation in select patients with Klatskin tumours or NET with no evidence of extrahepatic disease and relative stability

### Prognosis

- overall 5 yr survival: localized 30%, regional 24%, distant 2%

## Pancreas

### Acute Pancreatitis

- see [Gastroenterology, G48](#)

#### GALLSTONE PANCREATITIS (45% of Acute Pancreatitis)

#### Pathogenesis

- obstruction of pancreatic duct by large or small gallstones and biliary sludge
- backup of pancreatic enzymes can cause autodigestion of the pancreas

#### Clinical Features (Pancreatitis of Any Etiology)

- pain (epigastric pain radiating to back), N/V, ileus, peritoneal signs, jaundice, and fever
- Ingelfinger's sign: pain worse when supine, and better when sitting forward
- may have coexistent cholangitis or pancreatic necrosis
- Ranson's criteria for determining prognosis of acute pancreatitis (see sidebar)
  - APACHE II score for determining prognosis of severe acute pancreatitis
- physical exam may show tachypnea, tachycardia, hypotension, abdominal distention and tenderness, Cullen's sign, and Grey Turner's sign

#### Investigations

- lipase (most sensitive and specific), elevated amylase (higher than alcoholic pancreatitis), and leukocytosis
- elevated ALT (>150 IU/L), AST strongly suggest gallstone etiology of pancreatitis
- U/S may show multiple stones (may have passed spontaneously), and edematous pancreas
- CXR, AXR, and CT (if severe to evaluate for complications)

#### Treatment

- supportive: e.g. NPO, hydration, analgesia, and early enteral nutrition
- antibiotics are not indicated for initial diagnosis. This is reserved for clear signs of infection on imaging
- stone often passes spontaneously (~90%); usually no surgical management in uncomplicated acute pancreatitis
- cholecystectomy during same admission (25-60% recurrence if no surgery)
- may need urgent ERCP + sphincterotomy if CBD stone impacted or cholangitis
- surgical indications in acute pancreatitis (rare):
  - drain placement and debridement for necrotizing pancreatitis if refractory to medical management, if septic, or in ICU without other sources of sepsis

#### Complications

- local complications
  - acute fluid collections
  - walled-off pancreatic fluid collection/pseudocyst (>4 wk old)
  - abscess/infection, necrosis
- systemic complications
  - splenic/mesenteric/portal vessel thrombosis
  - pancreatic ascites/pancreatic pleural effusion
  - DM (b/c pancreatic & insulin insufficiency)
  - ARDS/sepsis/multiorgan failure
  - coagulopathy/DIC
  - severe hypocalcemia

#### Ranson's Criteria

##### A. At admission

1. Ages >55 yr
2. WBC >16 x 10<sup>9</sup>/L
3. Glucose >11 mmol/L
4. LDH ≥350 IU/L
5. AST >250 IU/L

##### B. During initial 48 h

1. Hct drop >10%
2. BUN rise >1.8 mmol/L
3. Arterial PO<sub>2</sub> <60 mmHg
4. Base deficit >4 mmol/L
5. Calcium <2 mmol/L
6. Fluid sequestration >6 L

##### C. Interpretation

- <3 = severe pancreatitis unlikely (2% mortality)
- ≥3 = high mortality (≥15%)

## Chronic Pancreatitis

- see [Gastroenterology, G50](#)

### Surgical Treatment

- treatment is generally medical
- indications for surgery
  - failure of medical treatment
  - debilitating abdominal pain
  - pseudocyst complications: persistence, hemorrhage, infection, and rupture
  - CBD obstruction (e.g. strictures) and duodenal obstruction
  - pancreatic fistula, variceal hemorrhage secondary to splenic vein obstruction
  - rule out pancreatic cancer (present in 15% of chronic pancreatitis treated surgically)
  - anatomical abnormality causing recurrent pancreatitis
- preoperative CT and/or ERCP are mandatory to delineate anatomy
- minimally invasive options
  - endoscopic pancreatic duct decompression: less effective than surgery
  - extracorporeal shockwave lithotripsy: if pancreatic duct stones
  - celiac plexus block: lasting benefit in 30% patients, less effective in those <45 yr or with prior pancreatic surgery
- surgical options
  - drainage procedures: only effective if ductal system is dilated
  - Puestow procedure (lateral pancreaticojejunostomy): improves pain in 80% of patients
  - pancreatectomy: best option in absence of dilated duct
  - Whipple procedure (pancreaticoduodenectomy): proximal disease
  - distal pancreatectomy ± Roux-en-Y pancreaticojejunostomy: distal disease
  - total pancreatectomy: refractory disease
- islet cells autotransplantation can be used to control insulin-related morbidity
  - denervation of celiac ganglion and splanchnic nerves

### WALLED-OFF PANCREATIC FLUID COLLECTIONS (PSEUDOCYSTS)

- localized fluid collections rich in pancreatic enzymes, with a non-epithelialized wall consisting of fibrous and granulation tissue
- complication of chronic and/or acute pancreatitis
- up to 40% resolve spontaneously
- cyst wall must be mature prior to drainage (4-6 wk)
- pseudoaneurysm an absolute contraindication to endoscopic drainage, must embolize first

### Pseudocyst Management

- if asymptomatic: expectant management
- if symptomatic: choice of drainage procedure depends on location of fluid collection
  - endoscopic drainage: transmural vs. transpapillary (pseudoaneurysm an absolute contraindication, must embolize first)
  - surgical drainage: cystogastrostomy vs. cystoduodenostomy vs. cystojejunostomy
  - percutaneous catheter drainage
  - resection
  - if draining, attempt to biopsy cyst wall to rule out cystadenocarcinoma

## Pancreatic Cancer

### Epidemiology

- 4th most common cause of cancer-related mortality in both men and women in Canada
- M:F=1.3:1, average ages: 50-70

### Risk Factors

- increased age
- smoking: 2-5x increased risk, most clearly established risk factor
- high fat/low fibre diets
- heavy alcohol use
- obesity
- DM, chronic pancreatitis
- partial gastrectomy
- cholecystectomy
- chemicals: β-naphthylamine, benzidine
- African descent

The hallmark of chronic pancreatitis is epigastric pain radiating to the back

### Total Pancreatectomy and Islet Autotransplantation: A Decade Nationwide Analysis

World J Transplant 2016;6(1):233-238

**Purpose:** To investigate outcomes and predictors of in-hospital morbidity and mortality after total pancreatectomy (TP) and islet autotransplantation. **Results:** A total of 923 patients underwent IAT after pancreatectomy during 2002-2012. The most common indication of surgery was chronic pancreatitis (86%) followed by acute pancreatitis (12%). Overall mortality and morbidity of patients were 0% and 57.8%, respectively. Post-surgical hypoinsulinemia was reported in 42.3% of patients, indicating that 57.7% of patients were insulin independent during hospitalization. Predictors of in-hospital morbidity were obesity, fluid and electrolyte disorders, alcohol use, and weight loss.

**Conclusion:** Total pancreatectomy + islet autotransplantation is a safe procedure with no mortality, acceptable morbidity, and achieved high rate of early insulin independence. Obesity is the most significant predictor of in-hospital morbidity.

### Clinical Features

- the most common presenting symptoms are abdominal pain, jaundice, and weight loss
- head of the pancreas (70%)
  - pancreatic head tumours typically present with jaundice, steatorrhea, and weight loss
  - other features include anorexia, dark urine, hepatomegaly, cachexia, Courvoisier's sign, recent onset DM
- body or tail of pancreas (30%)
  - tends to present later and usually inoperable (80% are unresectable at diagnosis)
  - weight loss, vague mid-epigastric pain
  - <10% jaundiced

### Investigations

- serum chemistry is non-specific, LFTs may show obstructive jaundice (elevated ALP and bilirubin)
- CA 19-9 most useful serum marker of pancreatic cancer
- U/S, CT (also evaluates metastasis and resectability) ± ERCP, MRI, EUS

### Pathology

- ductal adenocarcinoma: most common type (75-80%); exocrine pancreas
- intraductal papillary mucinous neoplasm (IPMN)
- other: pancreatic NETs (non-functional, insulinoma, gastrinoma, VIPoma, glucagonoma, somatostatinoma), mucinous cystic neoplasm (MCN), acinar cell carcinoma
- see *Surgical Endocrinology, GS71* for functional pancreatic NETs

### Treatment

- resectable (10-20% of pancreatic cancer)
  - no involvement of liver, peritoneum, or vasculature (hepatic artery, SMA, SMV, portal vein, IVC, aorta), no distant metastasis
  - Whipple procedure (pancreaticoduodenectomy) for cure <5% mortality
  - distal pancreatectomy ± splenectomy, lymphadenectomy if carcinoma of midbody and tail of pancreas
  - adjuvant chemotherapy recommended (gemcitabine ± capecitabine, 5-FU/leucovorin)
- locally advanced, borderline resectable
  - tumours that abut the SMA, SMV, portal vein, hepatic artery, or celiac artery
- locally advanced, non-resectable (palliative → relieve pain, obstruction)
  - encasement of major vascular structures including arteries
  - most body/tail tumours are not resectable (due to late presentation)
  - relieve biliary/duodenal obstruction with endoscopic stenting or double bypass procedure (choledochoenterostomy + gastroenterostomy)
  - palliative chemotherapy (gemcitabine + nab-paclitaxel, FOLFIRINOX) ± radiotherapy

### Prognosis

- most important poor prognostic indicators are lymph node status, margin status, size >3 cm, perineural invasion (invasion of tumour into microscopic nerves of pancreas)
- overall 5 yr survival for all patients with pancreas cancer is 1%; following surgical resection 5 yr survival is 20%
- median survival for unresectable disease: 3-6 mo if metastatic, 8-12 mo if locally advanced at presentation

**Table 27. TNM Classification System for Exocrine Tumours of the Pancreas (AJCC 8th edition)**

Primary Tumour (T)	Regional Lymph Nodes (N)	Distant Metastasis (M)
<b>TX</b> Primary tumour cannot be assessed	<b>NX</b> Regional lymph nodes cannot be assessed	<b>M0</b> No distant metastasis
<b>T0</b> No evidence of primary tumour	<b>N0</b> No regional lymph node metastasis	<b>M1</b> Distant metastasis
<b>Tis</b> Carcinoma <i>in situ</i>	<b>N1</b> Metastasis in one to three regional lymph nodes	
<b>T1</b> Tumour ≤2 cm in greatest dimension		
<b>N2</b> Metastasis in four or more regional lymph nodes		
<b>T2</b> Tumour >2 cm and ≤4 cm in greatest dimension		
<b>T3</b> Tumour >4 cm in greatest dimension		
<b>T4</b> Tumour involves celiac axis, SMA, or common hepatic artery		

#### Trousseau's Sign

Spontaneous peripheral venous thrombosis, often associated with pancreatic and other cancers

Vague abdominal pain with weight loss ± jaundice in a patient over 50 yr is pancreatic cancer until proven otherwise

#### Courvoisier's Sign

Palpable, nontender, distended gallbladder due to CBD obstruction. Present in 33% of patients with pancreatic carcinoma. The distended gallbladder could not be due to acute cholecystitis or stone disease because the gallbladder would actually be scarred and smaller, not larger

#### Steps of a Whipple Resection (Pancreaticoduodenectomy)

1. Assessment of metastatic disease (all peritoneal surfaces)
2. Mobilization of the hepatic flexure of the colon
3. Mobilization of the duodenum (Kocher maneuver) and head of the pancreas
4. Identification of the superior mesenteric vein and mobilization of the pancreatic neck
5. Mobilization of the stomach; dissection of the hepatoduodenal ligament and cholecystectomy
6. Division of the stomach, proximal jejunum, and CBD
7. Transection of the pancreatic neck and dissection of the uncinate process from the retroperitoneum
8. Restoration of gastrointestinal continuity: construction of a pancreaticojejunostomy, hepaticojejunostomy, gastrojejunostomy using a neoduodenum

#### Remove

- CBD
- Gallbladder
- Duodenum
- Pancreatic head
- Distal stomach (sometimes)

#### Oncological Benefits of Neoadjuvant

Chemoradiation with Gemcitabine vs. Upfront Surgery in Patients with Borderline Resectable Pancreatic Cancer: A Prospective, Randomized, Open-label, Multicenter Phase 2/3 Trial  
Ann Surg 2018;268:215-222

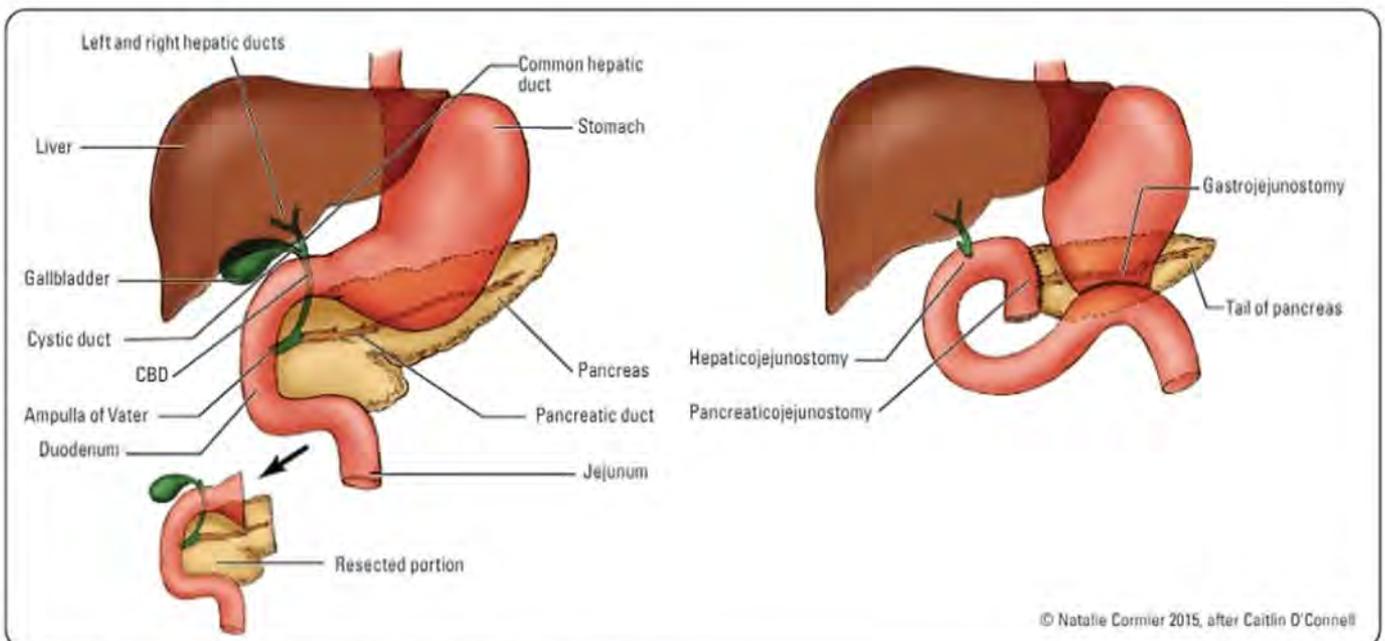

**Purpose:** To determine whether neoadjuvant treatment increases survival in patients with borderline resectable pancreatic cancer (BRPC).  
**Methods:** A total of 50 patients were randomized to neoadjuvant gemcitabine-based chemoradiotherapy or upfront surgery.

**Results:** The 2-yr survival rate (2YSR) and median survival of patients treated with neoadjuvant chemoradiation was significantly improved (40.7% 2YSR, 21 mo median survival) compared to upfront surgery (26.1% 2YSR, 12 mo median survival). The R0 resection rate was also significantly increased in the neoadjuvant chemoradiation group.

**Conclusion:** Neoadjuvant chemoradiation provides survival and surgical benefits in patients with BRPC.

**Table 28. Staging and Treatment of Pancreatic Cancer**

Stage	Classification	5 Yr Survival	Treatment
0	Tis, N0, M0		Surgical resection + chemotherapy
IA	T1, N0, M0	14%	Same as above
IB	T2, N0, M0	12%	Same as above
IIA	T3, N0, M0	7%	Same as above
IIB	T1-3, N1, M0	5%	Same as above
III	T1-3, N2, M0 T4, any N, M0	3%	Borderline resectable, trial of chemotherapy and radiation
IV	any T, any N, M1	1%	Non-resectable, palliative treatments

**Figure 26. Schematic of Whipple resection showing the resected components**

## Spleen

### Splenic Trauma

#### Clinical Features

- most common intra-abdominal organ injury in blunt trauma (especially can occur in people with splenomegaly)
- may have Kehr's sign
- patients may be hemodynamically unstable with altered mental status
- initial presentation may be masked by other injuries and contained ruptures may have few symptoms

#### Investigations

- FAST (used in trauma with hemodynamically unstable patients)
- CT with oral or IV contrast (once stable or when FAST negative)

#### Treatment

- non-operative
  - in stable patients: extended bed rest with serial hematocrit levels, close monitoring for 3-5 d; paediatric guidelines for days of bed rest is grade plus 1 (i.e. grade 3 splenic laceration requires 4 d of bed rest)
  - hemostatic control
  - splenic artery embolization if patient stable and one of: active contrast extravasation, splenic pseudoaneurysm, hemoperitoneum
- operative
  - hemodynamically unstable patients with positive FAST will undergo emergent operative surgical exploration
  - splenorrhaphy (suture of spleen) ± splenic wrapping with hemostatic mesh (if patient is hemodynamically stable)
  - splenectomy if patient unstable or high-grade injury or ongoing bleeding with hemodynamic instability
  - packing the spleen with temporary abdominal closure and relook laparotomy in 48 h

#### Kehr's Sign

Left shoulder pain due to diaphragmatic irritation from splenic rupture, worsens with inspiration

## Splenectomy

### Indications

- splenic trauma (most common reason for splenectomy), hereditary spherocytosis, primary hypersplenism, chronic immune thrombocytopenic purpura (ITP), splenic vein thrombosis causing esophageal varices, splenic abscess, thrombotic thrombocytopenic purpura (TTP), and sickle cell disease
- does not benefit all thrombocytopenic states (e.g. infection, most malignancies involving the bone marrow, drugs/toxins)
- probability of cure of ITP by splenectomy is 60-70%, may be predicted by response to IVIG

### Complications

- short-term
  - injury to surrounding structures (e.g. gastric wall, tail of pancreas) and their vascular supply
  - postoperative thrombocytosis, leukocytosis
  - thrombosis of portal, splenic, or mesenteric veins
  - subphrenic abscess
- long-term
  - post-splenectomy sepsis (encapsulated organisms): 4% of splenectomized patients (highest risk <16 yr)
  - splenosis: intra-abdominal "seeding" of splenic tissue during removal
  - increased risk of malignancy, DVT, and PE
- 50% mortality

### Prophylaxis

- vaccinations, ideally 2 wk pre- or postoperative (pneumococcal, *H. influenzae*, and meningococcus)
- liberal use of penicillin especially in children <6 yr

## Splenic Infarct

### Pathophysiology

- splenic artery occlusion or oxygen-delivery insufficiency leading to parenchymal ischemia and necrosis
- can occur in sickle cell disease, thromboembolism, myelofibrosis, CML, and hypercoagulable states

### Clinical Features

- patient can be asymptomatic or can have LUQ pain (70%), N/V, fever, chills, and Kehr's sign

### Investigations

- CT with contrast; MRI
- peripheral blood smear abnormalities

### Treatment

- non-operative: close follow-up, analgesia
- indications for splenectomy: complications such as rupture, abscess, persistent pseudocyst, bleeding, or sepsis

#### Indication of Splenectomy

##### SHIRTS

- Splenic abscess/splenomegaly
- Hereditary spherocytosis
- Immune thrombocytopenic purpura
- Rupture of spleen
- Thrombotic thrombocytopenic purpura
- Splenic vein thrombosis

# Breast

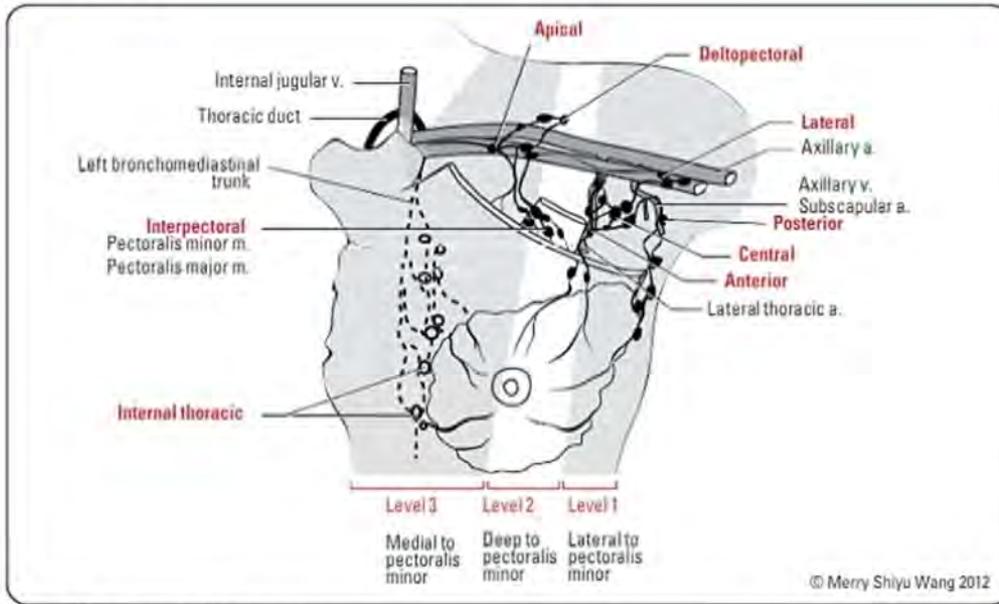

Figure 27. Anatomy of the breast

**Levels of Axillary Lymph Nodes**  
**Level I:** lateral to pectoralis minor  
**Level II:** deep to pectoralis minor  
**Level III:** medial to pectoralis minor  
 (higher level of nodal involvement = worse prognosis)

- DDx for Breast Mass**
- Benign**
- Fibrocystic changes
  - Fibroepithelial lesions (fibroadenoma most common; benign phyllodes)
  - Fat necrosis
  - Papilloma/papillomatosis
  - Galactocele
  - Duct ectasia
  - Ductal/lobular hyperplasia
  - Sclerosing adenosis
  - Lipoma
  - Neurofibroma
  - Granulomatous mastitis (e.g. TB, granulomatosis with polyangiitis, sarcoidosis)
  - Abscess
  - Silicone implant
- Malignant**
- Breast cancer (likely invasive, DCIS rarely forms a breast mass)
  - Malignant phyllodes
  - Angiosarcoma (rare)

## Benign Breast Lesions

### Three Categories

1. non-proliferative
2. proliferative without atypia
3. atypical hyperplasia

### NON-PROLIFERATIVE LESIONS

- benign breast condition characterized by fibrous and cystic changes in the breast (fibrocystic changes/disease)
- most common: breast cysts
- other lesions include papillary apocrine change, epithelial-related calcifications, and mild hyperplasia of the usual type
- no increased risk of breast cancer
- age 30 to menopause (and after if hormone replacement therapy (HRT) used)
- clinical features
  - breast pain, focal areas of nodularity or cysts often in the upper outer quadrant, frequently bilateral, mobile, varies with menstrual cycle, and nipple discharge (straw-like, brown, or green)
- treatment
  - evaluation of breast mass (U/S, mammography as indicated) and reassurance
  - analgesia (e.g. ibuprofen, ASA)
  - for severe symptoms: OCP, danazol, bromocriptine

### PROLIFERATIVE LESIONS – WITHOUT ATYPIA

Table 29. Proliferative Lesions - Without Atypia

	Clinical Features	Diagnosis	Treatment	Risk of Breast Cancer
<b>Fibroadenoma</b>	Most common breast tumour in women <30 yr	Nodules: firm, rubbery, discrete, well-circumscribed, non-tender, mobile, hormone-dependent (unlike cysts), needle aspiration yields no fluid	Core or excisional biopsy sometimes required if concerned about malignancy U/S and FNA alone cannot differentiate fibroadenoma from phyllodes tumour	Increased if complex, adjacent atypia or strong family history of breast cancer
<b>Intraductal Papilloma</b>	Solitary intraductal benign polyp	Can present as nipple discharge (most common cause of spontaneous, unilateral, bloody nipple discharge = pathologic nipple discharge), breast mass, nodule on U/S	Surgical excision of involved duct to ensure no atypia	Can harbour areas of atypia or DCIS
<b>Usual Ductal Hyperplasia</b>	Increased number of cells within the ductal space	Incidental finding on biopsy of mammographic abnormalities or breast masses	None required	Generally low-risk, slightly increased if moderate or florid hyperplasia
<b>Sclerosing Adenosis</b>	Lobular lesion with increased fibrous tissue and glandular cells	Mass or mammographic abnormality	None required	Low-risk

**ATYPICAL HYPERPLASIA**

- can involve ducts (atypical ductal hyperplasia) or lobules (atypical lobular hyperplasia)
- cells lose apical-basal orientation
- increased risk of breast cancer
- diagnosis: core or excisional biopsy
- treatment: complete resection, risk modification (avoid exogenous hormones), close follow-up

**OTHER LESIONS****Fat Necrosis**

- uncommon, result of trauma (may be minor, positive history in only 50%), after breast surgery (i.e. reduction)
- firm, ill-defined mass with skin or nipple retraction, ± tenderness, ± ecchymosis
- regress spontaneously, but complete imaging ± biopsy to rule out carcinoma
- oil cysts on mammography are pathognomonic for fat necrosis

**Mammary Duct Ectasia**

- obstruction of a subareolar duct (see [Obstetrics, Mastitis, OB48](#))

**Abscess**

- lactational vs. non-lactational (periductal/subareolar) (see [Obstetrics, Mastitis, OB48](#))

**Breast Cancer****Epidemiology**

- leading cancer diagnosis in women in North America, 2nd leading cause of cancer mortality in women
- 1 in 8 (12.9% lifetime risk) women in Canada will be diagnosed with breast cancer in their lifetime
- 1 in 31 women in Canada will die from breast cancer
- all age relative survival is 87%

**Risk Factors**

- sex (99% female)
- age (83% >50 yr)
- personal history of breast cancer and/or prior breast biopsy (regardless of pathology)
- family history of breast cancer (greater risk if relative was first degree and premenopausal)
- estrogen exposure
  - nulliparity, first pregnancy >30 yr, menarche <12 yr, or menopause >55 yr
  - decreased risk with lactation, early menopause, and early childbirth
  - >5 yr HRT use, >10 yr OCP use
- high breast density
- radiation exposure (e.g. mantle radiation for Hodgkin's disease)
- BRCA1 and BRCA2 gene mutations
- alcohol use, obesity, and sedentary lifestyle

**Male Breast Cancer (<1%)**

- most commonly invasive ductal carcinoma
- often diagnosed at later stages
- stage-for-stage similar prognosis to breast cancer in females
- consider genetic testing: most often hormone receptor positive

**Investigations**

- see margin for physical exam findings
- mammography
  - indications: screening guidelines (see [Family Medicine, FM4](#))
  - findings indicative of higher risk of malignancy
    - mass that is poorly defined, spiculated border
    - microcalcifications
    - architectural distortion
    - interval mammographic changes
  - normal mammogram does not rule out suspicion of cancer based on clinical findings
- other radiographic studies
  - U/S: differentiate between cystic and solid
  - MRI: high sensitivity, low specificity. Use annual MRI and mammography for patients with 25% lifetime risk of breast cancer
  - Digital Breast Tomosynthesis (DBT): improved lesion localization and characterization in noncalcified lesions
  - galactogram/ductogram (for nipple discharge): identifies lesions in ducts
  - metastatic workup indicated in Stage II-IV disease: bone scan, abdominal U/S, CXR (or CT chest/abdomen/pelvis), CT head (if specific neurological symptoms)

Female sex, followed by age, are the two greatest risk factors for breast cancer

Any palpable dominant breast mass requires further investigation

**Breast Lymphatic Drainage:**  
Axillary lymph nodes  
Internal mammary lymph nodes  
Infra-/supra-clavicular lymph nodes

**Physical Exam Findings in Breast Cancer:**

**Lump/mass:** Often firm, irregular, non-mobile, unilateral

**Pain:** Usually thought of as painless, however pain may be present with rapidly expanding tumours or inflammatory cancer

**Inflammation (and peau d'orange):** There are many benign causes of inflammation, however inflammatory cancer can present similarly

**Nipple or skin retractions/changes:** Nipple or skin retractions/changes: Attachment of the tumour to skin/nipple may cause retraction/distortion

**Nipple discharge:** Majority due to benign causes, bloody spontaneous discharge should be investigated for malignancy

**Diagnostic Procedures**

- “triple test” for diagnosis of breast cancer:
  - clinical breast exam
  - imaging
    - ≥30 yr: mammography and U/S
    - <30 yr or lactating or pregnant: U/S (high breast density)
  - pathology (biopsy)
    - U/S or mammography guided core needle biopsy: most common
    - needle aspiration: for palpable cystic lesions; send fluid for cytology if blood or cyst does not completely resolve
    - excisional biopsy: only performed as second choice to core needle biopsy; should not be done for diagnosis if possible

**Genetic Screening**

- consider testing for BRCA1/2 if:
  - young patient (<35 yr)
  - bilateral breast cancer in patients <50 yr
  - patient diagnosed with breast AND ovarian cancer
  - strong family history of breast/ovarian cancer
  - family history of male breast cancer

**Staging**

- patients are assigned a clinical stage preoperatively (cTNM); following surgery the pathologic stage is determined (pTNM)
- clinical
  - tumour size by palpation, mammogram, U/S, and/or MRI
  - nodal involvement by palpation, imaging
  - metastasis by physical exam, CXR, abdominal U/S (or CT chest/abdomen/pelvis), and bone scan (usually done postoperative if node-positive disease)
- pathological
  - tumour size and type
  - grade: modified Bloom and Richardson score (I to III) – histologic, nuclear, and mitotic grade
  - number of axillary nodes positive for malignancy out of total nodes resected, extranodal extension, and SLNB positive/negative
  - tumour biology: estrogen receptor (ER), progesterone receptor (PR), and HER2/neu oncogene status
  - margins: for invasive breast cancer, negative margin is sufficient; for DCIS prefer 2 mm margin
  - lymphovascular invasion (LVI)
  - extensive *in situ* component (EIC): DCIS in surrounding tissue
  - involvement of dermal lymphatics (inflammatory) – automatically Stage IIIb

Phyllodes tumours are rare fibroepithelial breast tumours that can be benign or malignant that mostly affect women from 35-55 yr

**Table 30. TNM Classification System for Staging of Breast Cancer (AJCC 2017)**

Primary Tumour (T)		Regional Lymph Nodes (N)		Distant Metastasis (M)	
<b>TX</b>	Primary tumour cannot be assessed	<b>NX</b>	Regional lymph nodes cannot be assessed	<b>M0</b>	No distant metastasis
<b>T0</b>	No evidence of primary tumour	<b>N0</b>	No regional lymph node metastasis	<b>M1</b>	Distant metastasis
<b>Tis</b>	Ductal carcinoma <i>in situ</i>	<b>N1</b>	Involvement of 1-3 axillary lymph nodes and/or clinically negative internal mammary nodes on sentinel node biopsy		
<b>T1</b>	Tumour ≤2 cm in greatest dimension				
<b>N2</b>	Involvement of 4-9 axillary lymph nodes or clinically positive ipsilateral internal mammary lymph node				
<b>T2</b>	Tumour >2 cm but ≤5 cm in greatest dimension				
<b>T3</b>	Tumour >5 cm in greatest dimension				
<b>T4</b>	Tumour of any size with direct extension to chest wall and/or skin				

Favourable Features	Unfavourable Features
• <2 cm	• >5 cm
• Grade I (low grade)	• Grade III (high grade)
• Node negative	• Node positive
• ER positive	• ER negative
• Mucinous pattern	• Inflammatory cancer
	• Her2/Neu positive
	• Positive margins
	• Lymphovascular invasion
	• Epidermal inclusion cyst
	• Dermal lymphatics involved

**Pathology**

**NON-INVASIVE**

**Ductal Carcinoma *in situ* (DCIS)**

- proliferation of malignant ductal epithelial cells completely contained within breast ducts, often multifocal
- 80% non-palpable; detected by screening mammogram as microcalcifications
- risk of invasive ductal carcinoma in same breast up to 35% in 10 yr
- treatment
  - lumpectomy with wide excision margins + radiation (5-10% risk of invasive cancer)
  - mastectomy if large area of disease, high grade, or multifocal (risk of invasive cancer reduced to 1%)
  - possibly tamoxifen as an adjuvant treatment
  - 99% 5 yr survival

**Analysis of Circulating Tumour DNA to Monitor Metastatic Breast Cancer**

NEJM 2013;368:1199-1209  
**Study:** The quantification of circulating tumour DNA, cancer antigen 15-3 (CA 15-3), and circulating tumour cells in 30 women with metastatic breast cancer receiving systemic therapy. The results were compared with radiographic imaging of tumours.  
**Results/Conclusions:** Circulating tumour DNA was detected in 97% of women and showed greater correlation with changes in tumour burden than did CA 15-3 or circulating tumour cells, providing the earliest measure of treatment response in 53% of women. CA 15-3 and circulating tumour cells were detected in 78% and 87% of women, respectively. Circulating tumour DNA may therefore be an informative biomarker for metastatic breast cancer.

**Lobular Carcinoma *in situ* (LCIS)**

- neoplastic cells completely contained within breast lobule
- no palpable mass and no mammographic findings; usually incidental finding on breast biopsy for another indication
- LCIS is a risk factor for invasive carcinoma (approximately 1%/yr)
- treatment
  - if diagnosed on core biopsy, excisional biopsy necessary to rule out malignancy
  - if diagnosed on excisional biopsy, wide excision not needed since LCIS is often multicentric and not managed as precursor lesion
  - clinical follow-up and surveillance; consider chemoprevention (e.g. tamoxifen)

**10 Year Survival after Breast-Conserving Surgery Plus Radiotherapy Compared with Mastectomy in Early Breast Cancer in The Netherlands: A Population-Based Study**

Lancet Oncol 2016; 17(8):1158

See Landmark General and Thoracic Surgery Trials table for more information on the 10-year survival after breast-conserving surgery plus radiotherapy compared with mastectomy in early breast cancer.

**INVASIVE****Invasive Ductal Carcinoma (most common 80%)**

- originates from ductal epithelium and infiltrates supporting stroma
- four types: tubular, mucinous, medullary, and inflammatory
- characteristics: hard, scirrhous, infiltrating tentacles, and gritty on cross-section
  - divided into three grades based on cytologic and architectural features: well differentiated (grade 1), moderately differentiated (grade 2), poorly differentiated (grade 3)

**Invasive Lobular Carcinoma (8-10%)**

- originates from lobular epithelium, 20% bilateral
- subtle thickening originating from lobes/lobules; usually positive for estrogen and progesterone receptors
- harder to detect on mammography due to lack of microcalcifications (may benefit from MRI)

**Paget's Disease of the Breast (1-3%)**

- ductal carcinoma that invades nipple with scaling, ulceration, erythema, and eczematous lesion

**Inflammatory Carcinoma (1-3%)**

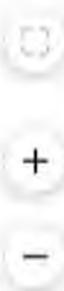

- most aggressive form of breast cancer
- ductal carcinoma that grows in nests (vs. solid tumour); invades and blocks dermal lymphatics
- clinical features: erythema, skin edema, warm, swollen, and tender breast ± lump, nipple changes
- peau d'orange indicates advanced disease (IIIb-IV)

**Sarcomas: rare**

- most commonly phyllodes tumour, a variant of fibroadenoma with potential for malignancy
- can also be angiosarcomas – after previous radiation

**Lymphoma: rare****Other**

- papillary, medullary, mucinous, and tubular cancers
- generally better prognosis

## Treatment

Table 31. Breast Cancer Treatment by Stage

Stage	Primary Treatment Options	Adjuvant Systemic Therapy
<b>0</b> ( <i>in situ</i> ) Tis, N0, M0	BCS + radiotherapy BCS alone if margins >1 cm and low nuclear grade Mastectomy* + SLNB	Consider postoperative tamoxifen for ER+, trastuzumab for HER2+
<b>I</b> IA: T1, N0, M0 IB: T1, N1mi, M0	BCS + axillary node dissection + radiotherapy Mastectomy* + axillary node dissection/SLNB	May not be needed; discuss risks/benefits of chemotherapy and tamoxifen
<b>II</b> A: T0, N1, M0 T1, N1, M0 T2, N0, M0 B: T2, N1, M0 T3, N0, M0	BCS + axillary node dissection + radiotherapy Mastectomy* + axillary node dissection/SLNB	Chemotherapy for premenopausal women or postmenopausal and ER negative, followed by tamoxifen if ER+
<b>III</b> A: T0, N2, M0 T1, N2, M0 T2, N2, M0 T3, N1, M0 T3, N2, M0 B: T4, N0, M0 T4, N1, M0 T4, N2, M0	Likely mastectomy + axillary node dissection + radiotherapy after chemotherapy (neoadjuvant)	Neoadjuvant therapy should be considered (i.e. preoperative) especially if not resectable chemotherapy and/or hormone therapy. Adjuvant radiation and chemotherapy may also be appropriate (i.e. postoperative)
<b>Inflammatory</b>	Mastectomy + axillary node dissection + radiotherapy	Neoadjuvant therapy
<b>IV</b> any T, any N, M1	Surgery as appropriate for local control	Primary treatment is systemic therapy (i.e. chemotherapy) and/or hormone therapy

BCS = breast conserving surgery; SLNB = sentinel lymph node biopsy

\*If no reason to select mastectomy, the choice between BCS + radiotherapy and mastectomy can be made according to patient's preference since choice of local treatment does not significantly affect survival if local control is achieved

## PRIMARY SURGICAL TREATMENT

## Breast Conservation Surgery (BCS)

- lumpectomy must be combined with radiation for survival equivalent to mastectomy
- contraindications include
  - high-risk of local recurrence (e.g. extensive malignant-type calcifications on mammogram), and multifocal primary tumours
  - failure to obtain tumour-free margins after re-excision
  - not suitable for radiation therapy (pregnancy, previous radiation, and collagen vascular disease)
  - large tumour size relative to breast

## Mastectomy

- radical mastectomy (rare): removes all breast tissue, skin, pectoralis muscle, and axillary nodes
- modified radical mastectomy (MRM): removes all breast tissue, skin, and axillary nodes
- simple mastectomy: removes all breast tissue and skin
- see [Plastic Surgery](#), PL38 for breast reconstruction

## Sentinel Lymph Node Biopsy (SLNB)

- performed in women with clinically node-negative invasive breast cancer and those with extensive DCIS who are undergoing mastectomy
- patients with clinically suspicious nodes should get U/S + FNA prior to decision to proceed with SLNB
- technetium-99 ± blue dye injected at tumour site prior to surgery to identify sentinel node(s)
- intraoperative frozen section evaluated can be considered
- proceed with ALND if >3 positive nodes, with 1-3 nodes whole breast radiation therapy may be an alternative
- 5% false negative rate

## Axillary Lymph Node Dissection (ALND)

- perform in patients with:
  - locally advanced (T4a, b, c) or inflammatory breast cancer
  - clinically node-positive axilla, confirmed by FNA or core biopsy, in a patient for whom neoadjuvant chemotherapy is not planned
  - several other specific cases (sentinel or axillary nodes, which remain positive after neoadjuvant chemotherapy, axillary recurrence following previous breast cancer treatment, among others)
- side effects: risk of arm lymphedema (10-15%), especially if getting radiation therapy, decreased arm sensation, and shoulder pain

BCS can be offered to most women with stage I/II disease

There is no survival benefit of mastectomy over lumpectomy plus radiation for stage I and II disease

**Effect of Radiotherapy after Mastectomy and Axillary Surgery on 10 Year Recurrence and 20 Year Breast Cancer Mortality: Meta-Analysis of Individual Patient Data for 8135 Women in 22 Randomised Trials**

EBCTCG (Early Breast Cancer Trialists' Collaborative Group)

Lancet 2014;383(9935):2127-2135

**Study:** Assessed the effect of radiotherapy in women with one to three positive lymph node after mastectomy and axillary dissection in a meta-analysis of 8135 women in 22 trials.

**Results:** For 700 women with axillary dissection and no positive nodes, radiotherapy had no significant effect on local/regional recurrence, overall recurrence, or breast cancer mortality. For 1314 women with axillary dissection and one to three positive nodes, radiotherapy reduced local/regional, overall recurrence, and breast cancer mortality. 1133 of these 1314 women were in trials in which systemic therapy (cyclophosphamide, methotrexate, and fluorouracil, or tamoxifen) was given in both trial groups and radiotherapy again reduced local/regional recurrence, overall recurrence, and breast cancer mortality. For 1772 women with axillary dissection and four or more positive nodes, radiotherapy reduced local/regional recurrence, overall recurrence, and breast cancer mortality.

**Conclusion:** Post mastectomy and axillary dissection, radiotherapy reduced both recurrence and breast cancer mortality in the women with one to three positive lymph nodes in these trials even when systemic therapy was given.

## ADJUVANT/NEOADJUVANT

### Radiation

- indications
  - decrease risk of local recurrence; almost always used after BCS, sometimes after mastectomy
  - inoperable locally advanced cancer
  - axillary nodal radiation may be added if nodal involvement

### Hormonal

- indications
  - ER positive plus node-positive or high-risk node-negative
  - selective estrogen receptor modulators (SERM) if premenopausal (e.g. tamoxifen) or aromatase inhibitors if postmenopausal (e.g. anastrozole); optimal duration 5-10 yr
  - other options include ovarian ablation (e.g. goserelin/GnRH agonist, oophorectomy), progestins (e.g. megestrol acetate), and androgens (e.g. fluoxymesterone)
  - palliation for metastatic disease

### Chemotherapy

- indications
  - ER negative plus node-positive or high-risk node-negative
  - triple-negative disease (ER/PR and HER2-negative) - more common in younger and African-American women
  - ER positive and young age
  - stage I disease at high-risk of recurrence (high grade, lymphovascular invasion)
  - palliation for metastatic disease
  - for HER2 positive breast cancer, add trastuzumab ± pertuzumab to the chemotherapy regimen

## FOLLOW-UP

### Post-Treatment Follow-Up

- assessment and physical exam q3-6 mo x 3 yr, q6-12 mo x 2 yr, and annually thereafter
- following BCS mammography q6-12 mo; can reduce to annual once stable, no other routine imaging unless clinically indicated
- women who receive tamoxifen should have regular gynaecologic follow-up (increased risk of endometrial cancer)

### Local/Regional Recurrence

- recurrence in treated breast or ipsilateral axilla
- 1% per yr up to maximum of 15% risk of developing contralateral malignancy
- 5x increased risk of developing metastases

### Metastasis

- bone > lungs > pleura > liver > brain
- treatment is palliative: hormone therapy, chemotherapy, radiation
- overall survival of metastatic breast cancer is 36-60 mo

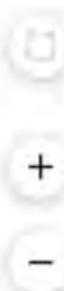

**Effect of Axillary Dissection vs. No Axillary Dissection on 10-Year Overall Survival Among Women With Invasive Breast Cancer and Sentinel Node Metastasis: The ACOSOG Z0011 (Alliance) Randomized Clinical Trial**  
JAMA 2017;318(10):918-926

**Purpose:** Assessed whether the 10 yr overall survival of patients with sentinel lymph node metastases treated with breast-conserving therapy and sentinel lymph node dissection (SLND) alone without axillary lymph node dissection (ALND) is noninferior to that of women treated with axillary dissection.

**Results:** The 10 yr overall survival was 86.3% in the SLND alone group and 83.6% in the ALND group. The 10 yr disease-free survival was 80.2% in the SLND alone group and 78.2% in the ALND group. 10 yr regional recurrence did not differ significantly between the 2 groups.

**Conclusion:** Among women with T1 or T2 invasive primary breast cancer, no palpable axillary adenopathy, and 1 or 2 sentinel lymph nodes containing metastases, 10-yr overall survival for patients treated with SLND alone was noninferior to overall survival for those treated with ALND.

## Surgical Endocrinology

### Thyroid and Parathyroid

- see [Endocrinology](#), E24

#### Thyroidectomy

- indications: some thyroid cancers or suspicious thyroid nodules, metastases to thyroid, large (substernal) or symptomatic thyroid goitre, toxic nodules, or some patients with Graves' disease (not candidates for RAI)
- preoperative workup: thyroid U/S for thyroid nodules, FNA for nodules  $\geq 1$  cm with suspicious U/S features or for most nodules  $\geq 1.5$  cm with low suspicion U/S features, and CT neck for preoperative staging when advanced disease is suspected
- complications
  - lobectomy: recurrent laryngeal nerve palsy (hoarseness or swallowing issues), neck hematoma
  - total thyroidectomy: same as above plus hypoparathyroidism/hypocalcemia, bilateral RLN palsy (requiring tracheostomy)
  - 20-75% of patients need thyroxine after lobectomy and 100% need thyroxine after total thyroidectomy

#### Parathyroidectomy

- elevated calcium found for any reason as an outpatient (but also incidental finding as inpatient) is likely primary hyperparathyroidism and should be investigated further
- indications: symptomatic primary hyperparathyroidism (osteoporosis/stones), asymptomatic primary hyperparathyroidism with specific laboratory criteria (profoundly elevated serum  $\text{Ca}^{2+}$ , hypercalciuria/asymptomatic kidney stones, Cr clearance  $< 30\%$  normal,  $< 50$  yr)
- contraindications: familial hypocalciuric hypercalcemia
- preoperative localization to find parathyroid adenoma. Localizing studies include:  $^{99\text{mTc}}$  sestamibi scanning with  $\pm$  SPECT, U/S, contrast CT
- complications: recurrent/superior laryngeal nerve injury, postoperative hypocalcemia, infection, and bleeding

### Adrenal Gland

- see [Endocrinology](#), E33 and E40
- functional anatomy
  - cortex: glomerulosa (mineralocorticoids), fasciculata (glucocorticoids), and reticularis (sex steroids)
  - medulla: catecholamines (epinephrine, norepinephrine)
- types of adrenal tumours: functional (e.g. Cushing's syndrome, Conn's syndrome, pheochromocytoma) or non-functional

#### INCIDENTALOMA

- adrenal mass discovered by investigation of unrelated symptoms/issues

#### Epidemiology

- benign adenoma (70-80%) > metastases to adrenal (22%) >> cyst carcinoma, pheochromocytoma, neuroblastoma
- metastasis to adrenal gland from: lung > breast, colon, lymphoma, melanoma, and kidney
- peak incidence of carcinoma: females ages 50-60, risk decreases with increasing age and male gender

#### Investigations

- CT: size  $> 4$ - $6$  cm is best predictor of primary adrenal carcinoma (92% are  $> 6$  cm), MRI is not as good as CT and does NOT need to be done after CT
- functional studies
  - pheochromocytoma: plasma metanephrines (highly specific and sensitive). If not available, 24 h urine catecholamines
  - Cushing's: 24 h urine cortisol or 1 mg overnight dexamethasone suppression test
  - aldosteronoma: electrolytes, AM aldosterone, AM plasma renin activity level, ARR (Aldosterone-Renin-Ratio). If inconclusive, saline suppression test if appropriate
  - not routinely - only if clinical suspicion: adrenal androgens: 17-OH progesterone and dehydroepiandrosterone (DHEAS)
- FNA biopsy: NOT APPROPRIATE in most cases. Diagnostic adrenalectomy by high volume endocrine surgeon ideal if diagnostic uncertainty

**Treatment**

- functional tumour: resect
- non-functional tumour
  - >4 cm: consider resection
  - <4 cm: follow-up imaging in 6-12 mo, resect if >1 cm enlargement
  - genetic testing important for ALL Pheochromocytoma/paragangliomas as >30% are related to genetic syndrome

**Pancreas****INSULINOMA**

- tumour that secretes insulin
- most common pancreatic endocrine neoplasm; 10% associated with MEN1 syndrome

**Clinical Features**

- Whipple's triad
- palpitations, trembling, diaphoresis, confusion, seizure, and personality changes

**Investigations**

- blood work: decreased serum glucose and increased serum insulin and C-peptide, pro-insulin
- CT, EUS, MRI: insulinomas evenly distributed throughout head, body, tail of pancreas

**Treatment**

- only 10% are malignant
- enucleation of solitary insulinomas may be done endoscopically
- tumours >2 cm located close to the pancreatic duct may require pancreatectomy or pancreaticoduodenectomy

**GASTRINOMA**

- tumour secreting gastrin; cause of Zollinger-Ellison syndrome, associated with MEN1

**Clinical Features**

- abdominal pain, PUD, severe esophagitis
- multiple ulcers in atypical locations refractory to antacid therapy

**Investigations**

- blood work: serum gastrin levels (usually >1000 pg/mL), secretin stimulation test
- endoscopy: 90% of patients develop peptic ulcers
- CT, EUS, MRI: 70-90% found in Passaro's triangle (head of pancreas medially, 2nd portion of duodenum inferiorly, and the confluence of the cystic and CBD superiorly)
- somatostatin receptor scintigraphy scan

**Treatment**

- 50% are malignant
- surgical resection of tumour dependent on location
- non-surgical treatment: high dose PPI, octreotide (somatostatin analogs)
- radiation therapy may be considered for nonsurgical candidates

**VASOACTIVE INTESTINAL PEPTIDE-SECRETING TUMOUR**

- tumour secreting VIP; commonly located in the distal pancreas and most are malignant when diagnosed

**Clinical Features**

- severe watery diarrhea causing dehydration, anorexia, weakness, and electrolyte imbalance (hypokalemia)

**Investigations**

- blood work: serum VIP levels
- CT, MRI, EUS

**Treatment**

- repletion of fluid and electrolytes
- somatostatin analogues
- surgical resection/palliative debulking

**Whipple's Triad**

- Symptomatic fasting hypoglycemia
- Serum glucose <2.8 mmol/L
- Relief of symptoms when glucose is administered

**Zollinger-Ellison Syndrome**

Characterized by gastric acid hypersecretion caused by secretion of gastrin from gastrinomas; patient experiences diarrhea and abdominal pain, as well as peptic disease and reflux disease

**Hypertrophic Pyloric Stenosis**

Non-bilious emesis in infants is the classic presentation

**Rule of 2s for Meckel's Diverticulum**

- 2% of the population
- 2:1 male-to-female ratio
- Symptomatic in 2% of cases
- Found within 2 feet (10-90 cm) of the ileocecal (IC) valve
- 2 inches in length
- 2 inches in diameter
- 2 types of tissue (ileal or ectopic gastric, pancreatic)
- Often present by 2 y/o

## Paediatric Surgery

Condition	Epidemiology and Risk Factors	Pathophysiology	Clinical Features and History	Physical Exam	Investigations	Treatment	Prognosis
<b>Hydrocele</b> (see <a href="#">urology</a> , U32)	1-2% of live births Majority resolve spontaneously by 1 yr M:F=6:1 Prematurity	Communicating hydroceles: processus vaginalis connects peritoneum with tunica vaginalis, so peritoneal fluid flows freely between the two with potential for abdominal contents to enter groin (i.e. inguinal hernia) Noncommunicating hydroceles: processus vaginalis is closed and more fluid produced than absorbed in tunica vaginalis; in older children, may be secondary to testicular pathology (e.g. reactive hydrocele)	Painless scrotal mass Communicating hydroceles increase in size with standing or valsalva, may be absent in the morning and large in the evening	Transillumination suggests hydrocele Silk glove sign: gently palpating hydrocele sac over pubic tubercle feels like rubbing silk on silk	U/S if suspect pathology	Most resolve spontaneously by 1 yr Surgical repair if: Persistence >2 yr Pain Fluctuating in size which suggests communication Cosmetic reasons Infection	<2% recurrence
<b>Hypertrophic Pyloric Stenosis</b>	0.03-1.0% of live births Can present at 1-20 wk, most commonly at 6-8 wk M:F=4:1 Early erythromycin exposure (<13 d old)	Acquired pyloric circular muscle hypertrophy results in gastric outlet obstruction Hypovolemia caused by emesis of gastric contents causes hypochloremic, hypokalemic metabolic alkalosis Electrolyte exchange based volume retention in kidneys results in paradoxical aciduria	Projectile non-bilious vomiting Vomiting 30-60 min after feeds Hungry after vomiting Dehydration (variable severity)	Smooth oblong 1-2 cm "olive" mass palpable above umbilicus in the RUQ Visible left-to-right gastric contraction "waves" after feeding	Electrolytes (assess hypochloremia, dehydration) U/S shows pyloric length 17 mm, muscle thickness >4 mm Upper GI series (necessary only when U/S is unavailable or non-diagnostic) will show "string sign"	Fluid resuscitate with NS, correct electrolyte and acid/base abnormalities with DS, 1/2NS + 20 mEq/L KCl at maintenance rate NG tube decompression unnecessary Pyloromyotomy, open (Ramstedt vs. transumbilical or laparoscopic approach) is the definitive treatment Alternative therapies such as 1FN/wait or atropine impractical due to long time course of effect	Pyloromyotomy curative
<b>Congenital Diaphragmatic Hernias</b> 3 types: Posterolateral (Bochdalek) Left-sided (85%) Right-sided (13%) Bilateral, rare, often fatal  Anterior (Morgagni)  Hiatus	1 in 2000 to 5000 live births Presents within hours of life although some cases of delayed presentation M:F >10% are associated with other congenital anomalies Prenatal diagnosis common	Combinations of small bowel, large bowel, stomach, and solid viscera (spleen, liver) may herniate into thorax  Varying degrees of pulmonary hypoplasia and pulmonary hypertension possible	Early respiratory distress Cyanosis Scaphoid abdomen Prenatal diagnosis	Decreased air entry ± bowel sounds in the chest Displaced heart sounds	Prenatal US/MRI ABG CXR (bowel loops in hemithorax, shifted heart) Echocardiography Genetic consultation if warranted	Intubate/ventilate Orogastric suction Period of respiratory stabilization due to associated pulmonary hypoplasia (may require extracorporeal membrane oxygenation) Surgical repair after stable by hernia reduction and closure of diaphragmatic defect open vs. thoracoscopic vs. laparoscopic with or without prosthetic or muscular patch depending on size of defect	Better outcomes in later presentations Neurodevelopmental impairment Hearing deficit (40%) Associated GERD MSK defects chest wall and scoliotic defects as potential complications of thoracotomy Long term surveillance for potential recurrence Failure to thrive Chronic lung disease if severe hypoplasia
<b>Meckel's Diverticulum</b> Most common remnant of vitelline duct that connects yolk sac with primitive midgut	1-3% of population M:F=3:1 Present most frequently during first 5 yr of life Symptomatic in 2% of cases	Failure of vitelline duct to regress 5-7 wk <i>in utero</i> ; 50% contain heterotopic tissue (e.g. gastric mucosa, ectopic pancreas); other associated anomalies include omphalomesenteric fistula, umbilical sinus, umbilical cyst, and fibrous band	BRBPR (heterotopic gastric mucosa in Meckel's causing mucosal ulceration and bleeding in adjacent small bowel mucosa) Abdominal sepsis (Meckel's diverticulitis ± perforation) Small bowel volvulus around fibrous band Intestinal obstruction symptoms	Tenderness and distension (lower abdomen) near umbilicus	AXR Meckel scan: scan for ectopic gastric mucosa with technetium Tc99m pertechnetate IV (sensitivity 85%, specificity 95%)	Stabilize, resection by laparotomy or laparoscopy ± incidental appendectomy	Resection curative
<b>Malrotation</b>	1:500 live births 1/3 present by 1 wk of age, 3/4 by 1 mo of age, 90% by 1 yr of age M:F=1:1 Higher incidence among patients with cardiac anomalies or heterotaxy syndromes	Failure of gut to normally rotate around SMA with associated abnormal intestinal attachments and anatomic positions Represent a spectrum of rotational abnormalities including complete non-rotation (which is not at high-risk for volvulus)	Cardinal sign: bilious emesis (especially if abdomen nondistended) If bilious emesis with distended abdomen, consider surgical exploration to rule out volvulus Rectal bleed (late/ominous signs) Intermittent symptoms	Bilious drainage from NG tube Tachycardic, pale Diaphoretic Flat abdomen Tenderness	AXR: obstruction of proximal SBO, double-bubble sign, intestinal wall thickened Immediate UGI: dilated duodenum, duodenojejunal segment (Ligament of Treitz) right of midline and not fixed posteriorly over spinal column, "corkscrew" sign indicating volvulus U/S: "whirlpool" sign, abnormal SMA/SMV relationship indicates UGI to rule out rotational anomalies	IV antibiotics Fluid resuscitation EMERGENT LAPAROTOMY Ladd procedure: counterclockwise reduction of midgut volvulus, division of Ladd's bands, division of peritoneal attachments between cecum and abdominal wall that obstruct duodenum, broadening of the mesentery (open folded mesentery like a book and divide congenital adhesions), ± appendectomy Positioning the bowel into non-rotation (SBO in right abdomen, LBO in left abdomen)	Mortality related to length of bowel loss: 10% necrosis 100% survival rate, 75% necrosis 35% survival rate Recurrence 2-6%

Condition	Epidemiology and Risk Factors	Pathophysiology	Clinical Features and History	Physical Exam	Investigations	Treatment	Prognosis
<b>Gastroschisis</b>	1:2000 live births Antenatal diagnosis common Increased risk with younger maternal age and associated with IUGR Rate slightly higher in male infants Smoking	Defect of abdominal wall near umbilicus, with free extrusion of intestine into amniotic cavity No specific environmental factor identified Defect in embryogenesis unclear	Not associated with genetic syndromes 10% with intestinal atresia Some cases associated with short bowel syndrome due to antenatal volvulus and necrosis of herniated bowel	Hollow viscera (stomach, small and large bowels) Defect lateral to cord (usually right) Bowel may be inflamed, thickened, matted, foreshortened Defect size variable	Prenatal U/S Elevated MS-AFP	NG tube decompression IV fluids IV antibiotics Keep viscera moist and protected until surgical reduction with primary abdominal closure or staged closure with silo May have bowel dysmotility requiring motility medications	>90% survival rate
<b>Omphalocele</b>	1:5000 live births Antenatal diagnosis common Lower gestational age Increased maternal age M:F=1.5:1	Defect of abdominal wall and umbilical ring, with extrusion of sac-covered viscera (amnion, Wharton's jelly, peritoneum) through the umbilical ring Duhamel's theory failure of body wall morphogenesis Commonly associated with rotational abnormalities of the intestine	30-70% associated with genetic syndromes (e.g. Pentalogy of Cantrell, congenital heart disease, Beckwith-Wiedemann syndrome, Trisomy 18) Associated pulmonary hypoplasia	Hollow viscera (stomach, small and large bowels, often liver) Sac present with cord attached	Prenatal U/S Elevated MS-AFP	NG tube decompression IV fluids, IV antibiotics Small defect (<2 cm): Primary closure Medium (2-4 cm) and large (>4 cm) defects: silver sulfadiazine coupled with compression dressing (to allow epithelialization and gradual reduction) or Silo Silo Pouch, followed by future repair ± mesh	40-70% survival rate Higher survival rates most likely related to antenatal mortality of fetuses with giant omphaloceles
<b>Umbilical Hernias</b>	Incidence 2-14% Increases with prematurity Decreases with increasing age	Incomplete closure of peritoneal and fascial layers within umbilicus by 4 yr Hernia is peritoneum-lined and skin-covered Size of fascial defect determines chances of spontaneous closure	Majority asymptomatic Majority (95%) spontaneously resolve by age 4 Incarceration prior to age 5 very rare Most symptoms occur in late adolescence or adulthood	Protrusion from umbilicus Different from less common abdominal wall hernias that do not spontaneously resolve (e.g. epigastric hernias) Most defects >1.5 cm in infancy will not close spontaneously	None if uncomplicated	Repair if not spontaneously closed by age 5 Earlier repair of large "proboscoid" hernias with extensive skin stretching may be warranted for cosmetic reasons Simple primary closure of fascial defect	Rarely become incarcerated Low risk of recurrence
<b>Intestinal Atresia</b>	Incidence 2-14% May be antenatally diagnosed by dilated bowel loops or "double-bubble" sign on x-ray for duodenal atresia Decreased with increasing age	Duodenal failure of bowel to recanalize after endodermal epithelium proliferation (wk 8-10) Jejunal/ileal acquired as a result of vascular disruption → ischemic necrosis → resorption of necrotic tissue → blind distal and proximal ends Colonic mechanism unknown, thought to be similar to small bowel atresia	Gastric distension and vomiting (usually bilious) Duodenal may be associated with other anomalies (tracheoesophageal fistula, cardiac, renal, and vertebral anomalies), 24-28% have Down syndrome Jejunal/ileal within 2 d of birth, may be associated with CF Colonic within 3 d of birth	Complete physical Special attention to abdominal exam, perineum, and anus Include evaluation of respiratory distress and signs of volume depletion Congenital anomalies Jaundice	Contrast enema ± UGI with small bowel follow through (SBFT) Group and screen INR and PTT if for surgery	NPO NG tube decompression Fluid resuscitation TPN Broad spectrum antibiotics Duodenal duodenoduodenostomy or duodenojejunostomy Jejunal/ileal primary anastomosis; or if atresia associated with short bowel then may create end stoma or defer surgery for bowel lengthening procedures Colonic primary anastomosis	Long-term survival: Duodenal 86% Jejunal/ileal 84% Colonic 100%
<b>Congenital Aganglionic Meirschprung's Disease</b>	1:5000 births M:F=3:1 to 4:1, approaches 1:1 when whole colon involved Can have aganglionosis of small bowel as well Familial Hirschsprung's in <5% of cases	Defect in migration of neurocrest cells to intestine resulting in aganglionic bowel that fails to peristaltise and internal sphincter that fails to relax (internal anal sphincter achalasia) causing functional and partial mechanical obstruction, respectively Starts in the rectum and variable involvement proximally; RET mutation	Failure to pass meconium spontaneously within 48 h of life (95% pass meconium within 24 h, 5% within 48 h) Symptoms of bowel obstruction: abdominal distension, constipation, bilious emesis Enterocolitis/sepsis Failure to thrive	± Abdominal distension Squirt/blast sign	Rectal biopsy (gold standard) look for aganglionosis and neural hypertrophy AXR Contrast enema to find narrow rectum and transition zone Anal manometry unreliable in infants classic finding is absence of rectoanal inhibitory reflex	Duhamel pull-through procedure: surgical resection of aganglionic intestinal segment and anastomosis of remaining intestine to anus Either in newborn period or staged if extensive aganglionosis	Most have normal/near-normal anorectal function Complications: fecal incontinence and constipation, postoperative enterocolitis (medical emergency if progresses to sepsis)
<b>Cryptorchidism</b>	Most common congenital abnormality of the GU tract 2-5% of term males most of these descend spontaneously by 6 mo of age 1% of males do not spontaneously descend Suspect in prematurity	Idiopathic Descent is mediated by INSL3 and testosterone Descent usually begins at 28 wk	Palpable testicle within inguinal canal or testicle which can be milked down into the scrotum (called retractile testis) Occasionally no palpable testis as it is intra-abdominal Consider other congenital abnormalities	Scrotal asymmetry Bi-annual testicular exam with palpation Distinguish truly undescended testis from retractile testis (which is "high" testis due to hyperactive cremasteric muscles)	Depends on age of presentation Older child: LH, FSH, Müllerian inhibiting substance, hCG stimulation test for gonadotropin production Infant: U/S, FSH, LH, karyotype, MIS, 17-hydroxy-progesterone If non-palpable: exam under anesthesia, exploratory laparoscopy	hCG to stimulate testosterone production and descent Orchidopexy especially if undescended by age 6 mo-2 yr	Orchidopexy Decreased risk of torsion and blunt trauma to testicle No effect on malignant potential of testicle Descent can preserve spermatogenesis if performed by 1yr

Condition	Epidemiology and Risk Factors	Pathophysiology	Clinical Features and History	Physical Exam	Investigations	Treatment	Prognosis
<b>Intussusception</b>	Most common cause of bowel obstruction between 6-36 mo 26:100,000 newborns M:F=3:2 Pathologic lead points: enlarged Peyer's patches due to viral infections of the GI tract, polyps, Meckel's diverticulum CF, lymphoma and IBD may increase risk	Usually idiopathic Usually starts at ileocecal junction Telescoping of bowel into itself causing an obstruction and vascular compromise	Acute onset abdominal pain Episodic "colicky" pain Vomiting ± bilious Abdominal mass Currant-jelly stool suggests mucosal necrosis and sloughing	Abdominal exam Palpate for masses (especially sausage shaped upper abdominal mass) and tenderness Signs of bowel obstruction: distended abdomen Look for localized peritonitis which suggests transmural ischemia	AXR for signs of bowel obstruction or perforation U/S if suspect pathology	If peritonitis, consider operative management Non-operative management involves reduction via air contrast enema Operative reduction (open or laparoscopically) Resection of involved colon if failure to reduce or bowel appears compromised	10% recurrence rate If recurrent = more likely non-idiopathic If successfully reduced by enema in older children allow 2 wk resolution of edema before performing SBFT to rule out pathologic lead points
<b>Tracheoesophageal Fistula (TEF)</b>	1:3000-1:4500 Typically occurs with esophageal atresia	Defect in the lateral septation of the foregut into the esophagus and trachea causing connection between the esophagus and trachea Associated anomalies in 50%: VACTERL association	Varies with type of fistula May have history of maternal polyhydramnios May present after several months (if no associated esophageal atresia) of non-bilious vomiting, coughing, cyanosis with feeds, respiratory distress, recurrent pneumonia, frothy bubbles of mucus in mouth, and nose that return after suctioning	Abdominal distention	X-ray: anatomic abnormalities, NG tube curled in pouch	Investigate for other congenital anomalies Early repair by surgical ligation to prevent lung damage and maintain nutrition and growth	Complications: pneumonia, sepsis, reactive airways disease Following repair: esophageal stenosis and strictures at repair site, GERD, and poor swallowing (i.e. dysphagia, regurgitation)
<b>Inguinal Hernias</b>	5% of all term newborns 2x risk and more likely bilateral if pre-term M:F=4:1 Low birth weight increases risk 1/5 inguinal hernias will become incarcerated if patient is <1yr Incarceration is more common in females Associated with other conditions: androgen insensitivity, connective tissue diseases	All infant hernias are indirect: descent of intra-abdominal contents through the internal inguinal ring through a patent tunica vaginalis inguinal hernia can be reducible, incarcerated (unreducible), or strangulated	Most common presentation: painless intermittent mass in groin, may also note extension into scrotum (scrotal mass in absence of inguinal mass is a hydrocele) If incarcerated: tender, vomiting, firm mass, erythema then cyanosis of mass may be noted	Palpate for "bag of worms" - suggests possible testicular varicocele Biannual testicular exam + palpation along inguinal canal to evaluate for any masses "Silk sign" palpable thickening of cord Mass palpated at external inguinal ring and reducible through inguinal canal into abdomen Must always try reduction to confirm that hernia is not incarcerated	Physical exam is gold standard U/S only if physical exam uncertain (e.g. in small infants where exam can be difficult)	Manual reduction in the ER to relieve acute symptoms For reducible hernia: repair within a few wk (if <1 yr) vs. elective repair (if >1 yr) For incarcerated hernia: repair immediately (emergency) Herniorrhaphy (laparoscopic or open) definitive treatment by reduction of herniated contents and high ligation of sac for indirect hernias	Risk of recurrence after surgical reduction <3%, higher if repair done in premature infants or if hernia was incarcerated/strangulated

## Skin Lesions

- see [Dermatology, D8](#); [Emergency Medicine, ER43](#); [Plastic Surgery, PL5](#)

All inguinal hernias of infancy and childhood require repair at the earliest convenience; emergent repair if incarcerated/strangulated

## Common Medications

Types	Drugs and Dosing
<b>Antiemetics</b>	<p>dimenhydrinate (Gravol<sup>®</sup>) 25-50 mg PO/IV/IM q4-6 h prn</p> <p>prochlorperazine (Stemetil<sup>®</sup>) 5-10 mg PO/IV/IM BID-TID prn</p> <p>metoclopramide (Maxeran<sup>®</sup>) 10 mg IV/IM q2-3 h prn, 10-15 mg PO QID (30 min before meals and QHS)</p> <p>ondansetron (Zofran<sup>®</sup>) 4-8 mg PO q8 h prn</p> <p>granisetron (Kytril<sup>®</sup>) 1 mg PO BID (for nausea from chemotherapy/radiation)</p>
<b>Analgesics</b>	<p>acetaminophen + codeine (Tylenol<sup>®</sup> #3/plain) 1-2 tabs q4-6 h PO/PR prn</p> <p>hydromorphone 1-2 tabs PO q4 h prn, 0.5-2 mg IV q3-4 h prn</p> <p>ibuprofen 200-400 mg PO q4-6 h prn</p> <p>morphine 2.5-10 mg IM/SC q4-6 h prn + 1-2 mg IV q1 h prn for breakthrough</p> <p>ketorolac (Toradol<sup>®</sup>) 30-60 mg IM/IV q6 h prn</p> <p>acetaminophen/oxycodone (Percocet<sup>®</sup>) 325/5 mg, 1-2 tabs PO q4-6 h prn</p>
<b>DVT Prophylaxis</b>	<p>heparin 5000 units SC BID, if cancer patient then heparin 5000 units SC TID/BID</p> <p>dalteparin (Fragmin<sup>®</sup>) 5000 units SC daily</p> <p>enoxaparin (Lovenox<sup>®</sup>) 40 mg SC daily</p>
<b>Antidiarrheals</b>	<p>loperamide (Imodium<sup>®</sup>) 4 mg PO initially, then 2 mg PO after each loose stool up to 16 mg/d</p> <p>diphenoxylate + atropine (Lomotil<sup>®</sup>) 2 tabs/10 mL PO QID</p>
<b>Laxatives</b>	<p>sennosides (Senokot<sup>®</sup>) 1-2 tabs QHS</p> <p>docusate sodium (Colace<sup>®</sup>) 100 mg PO BID</p> <p>glycerine suppository 1 tab PR prn</p> <p>lactulose 15-30 mL PO QID prn</p> <p>milk of magnesia (MOM) 30-60 mL PO QID prn</p> <p>bisacodyl (Dulcolax<sup>®</sup>) 10-15 mg PO prn</p>
<b>Sedatives</b>	<p>zopiclone (Imovane<sup>®</sup>) 5-7.5 mg PO QHS prn</p> <p>lorazepam (Ativan<sup>®</sup>) 0.5-2 mg PO/SL QHS prn</p>
<b>Antibiotics</b>	<p>cefazolin (Ancef<sup>®</sup>) 1 g IV/IM on call to OR or q8 h – GP except <i>Enterococcus</i>, GN only <i>E. coli</i>, <i>Klebsiella</i>, and <i>Proteus</i></p> <p>cefalexin (Keflex<sup>®</sup>) 250-500 mg PO QID – <i>Listeria</i>, GP except <i>Enterococcus</i>, GN only <i>E. coli</i>, <i>Klebsiella</i>, and <i>Proteus</i></p> <p>ceftriaxone 1-2 g IM/IV q24 h broad coverage including <i>Pseudomonas</i></p> <p>ampicillin 1-2 g IV q4-6 h – <i>Listeria</i>, GP (<i>Enterococcus</i>) except <i>Streptococcus</i> and <i>E. coli</i>, oral anaerobes except</p>
<b>Bacteroides</b>	<p>gentamicin 3-5 mg/kg/d IM/IV divided q8 h; monitor creatinine, gentamicin levels GN including <i>Pseudomonas</i></p> <p>ciprofloxacin 400 mg IV q12 h, 500 mg PO BID – GN including <i>Pseudomonas</i></p> <p>metronidazole (Flagyl<sup>®</sup>) 500 mg PO/IV BID (500 mg PO TID for <i>C. difficile</i>) – anaerobes</p> <p>clindamycin 600-900 mg IV q8 h, 150-400 mg PO QID – GP except <i>Enterococcus</i>, anaerobes</p> <p>piperacillin/tazobactam 3.375 g IV q6 h – GP, GN, and anaerobes</p> <p>vancomycin 1g IV q12 h – GP and MRSA</p> <p>sulfamethoxazole/trimethoprim DS (Septra<sup>®</sup>) PO BID – GP, GN including <i>Nocardia</i></p>
<b>Over-the-Counter Medications</b>	<p>bismuth subsalicylate (Pepto-Bismol<sup>®</sup>) 2 tabs or 30 mL PO q30 min-1 h up to 8 doses/d</p> <p>side effects: black stools, risk of Reye's syndrome in children</p> <p>ASA + citrate + bicarbonate (Alka-Seltzer<sup>®</sup>) 2 tabs in 4 oz water PO q4 h prn, max 8 tabs</p> <p>aluminum hydroxide + magnesium hydroxide (Maalox<sup>®</sup>) 10-20 mL or 1-4 tabs PO prn</p> <p>calcium carbonate (Tums<sup>®</sup>) 1-3 g PO q2 h prn</p> <p>calcium carbonate and magnesium hydroxide (Rolaids<sup>®</sup>) 2-4 tabs PO q1 h prn, max 12 tabs/d</p>

## Landmark General and Thoracic Surgery Trials

Trial Name	Reference	Clinical Trial Details
<b>GROIN HERNIAS</b>		
Outcomes of Laparoscopic vs. Open Repair of Primary Ventral Hernias	JAMA Surg 2013;148:1043-1048	<p><b>Title:</b> Outcomes of Laparoscopic vs. Open Repair of Primary Ventral Hernias</p> <p><b>Purpose:</b> To compare outcomes of patients undergoing laparoscopic ventral hernia repair (LVHR) vs. open ventral hernia repair (OVHR).</p> <p><b>Methods:</b> Single centre, retrospective study of 532 consecutive patients who underwent an elective PVH repair. The outcomes of the LVHR and OVHR were compared in terms of the primary outcomes of interest SSI, hernia recurrence, and bulging.</p> <p><b>Results:</b> 79 patients with LVHR matched to 79 patients with OVHR with mesh with a median follow-up of 56 mo. LVHR was associated with fewer SSIs (7.6% vs. 34.1%) but more cases of bulging (21.5% vs. 1.3%) and port-site hernia (2.5% vs. 0.0%). No differences in recurrence were observed.</p> <p><b>Conclusions:</b> LVHR is associated with fewer SSIs but more clinical cases of bulging and risk of developing a port-site hernia, compared to OVHR.</p>
<b>ACUTE CHOLECYSTITIS</b>		
CHOCOLATE	BMJ 2018;363:k3965	<p><b>Title:</b> Laparoscopic cholecystectomy versus percutaneous catheter drainage for acute cholecystitis in high risk patients (CHOCOLATE): multicentre randomised clinical trial</p> <p><b>Purpose:</b> To assess whether laparoscopic cholecystectomy is superior to percutaneous catheter drainage in high risk patients with acute calculous cholecystitis.</p> <p><b>Methods:</b> 142 patients were randomized to either the laparoscopic cholecystectomy group or to the percutaneous catheter drainage group.</p> <p><b>Results:</b> Although rate of death did not differ significantly between the laparoscopic cholecystectomy and percutaneous catheter drainage group, the complication rate in the laparoscopic cholecystectomy was significantly lower than that of the percutaneous catheter drainage (12% vs. 65%). The drainage group compared to the cholecystectomy group required reintervention at a higher rate, had recurrent biliary disease more frequently, and had longer lengths of stay.</p> <p><b>Conclusions:</b> Laparoscopic cholecystectomy compared with percutaneous catheter drainage reduced the rate of major complications in high risk patients with acute cholecystitis.</p>
<b>BREAST CANCER</b>		
10 Year Survival after Breast-Conserving Surgery Plus Radiotherapy Compared with Mastectomy in Early Breast Cancer in The Netherlands: A Population-Based Study	Lancet Oncol 2016;17(8):1158	<p><b>Title:</b> 10 Year Survival after Breast-Conserving Surgery Plus Radiotherapy Compared with Mastectomy in Early Breast Cancer in The Netherlands: A Population-Based Study</p> <p><b>Purpose:</b> To evaluate 10 yr overall and breast cancer-specific survival after breast-conserving surgery plus radiotherapy compared with mastectomy in Dutch women with early breast cancer.</p> <p><b>Methods:</b> Population study of women from the Netherlands Cancer Registry diagnosed with primary, invasive, stage T1-2, N0-1, M0 breast cancer, undergoing either breast-conserving surgery plus radiotherapy or undergoing mastectomy.</p> <p><b>Results:</b> Breast-conserving surgery plus radiotherapy showed improved 10 yr overall and relative survival compared with mastectomy in early breast cancer, but 10 yr distant metastasis-free survival was improved with breast-conserving surgery plus radiotherapy compared with mastectomy in the T1N0 subgroup only, indicating a possible role of confounding by severity.</p> <p><b>Conclusions:</b> Breast-conserving surgery plus radiotherapy is at least equivalent to mastectomy with respect to survival and may influence treatment decisions for patients.</p>

# Acronyms

ACEI	angiotensin converting enzyme inhibitor	ESAS	Edmonton Symptom Assessment Scale	MMSE	Mini Mental Status Examination	PPS	Palliative Performance Scale
ADL	activities of daily living	ESR	erythrocyte sedimentation rate	MS	multiple sclerosis	PR	per rectal
ADR	adverse drug reaction	GABA	gamma-aminobutyric acid	MSK	musculoskeletal	PTH	parathyroid hormone
BPH	benign prostatic hypertrophy	GCA	giant cell arteritis	NE	norepinephrine	PSW	personal support worker
BUN	blood urea nitrogen	GERD	gastroesophageal reflux disease	NP	nurse practitioner	PUD	peptic ulcer disease
CBT	cognitive behavioural therapy	GFR	glomerular filtration rate	NPIAP	National Pressure Injury Advisory Panel	PVD	peripheral vascular disease
CGA	comprehensive geriatric assessment	IADL	instrumental activities of daily living	NSTEMI	non-ST elevation myocardial infarction	RA	rheumatoid arthritis
CKD	chronic kidney disease	IBD	inflammatory bowel disease	NYD	not yet diagnosed	SNRI	serotonin-norepinephrine reuptake inhibitor
CNS	central nervous system	IBS	irritable bowel syndrome	OTC	over the counter	SSRI	selective serotonin reuptake inhibitor
CO	cardiac output	INR	international normalized ratio	PCI	percutaneous coronary intervention	TIA	transient ischemic attack
CrCl	creatinine clearance	LOC	level of consciousness	POA	power of attorney	TCA	tricyclic antidepressant
		LV	left ventricle			UI	urinary incontinence

# Physiology and Pathology of Aging

## Holistic Considerations for Aging

- aging is a loss of homeostasis relating to a breakdown in maintenance of specific molecular and cellular structures and pathways
- some of these changes are specific to the tissues of certain organs, whereas others occur over a number of organ systems
- normal age-related changes represent biologic processes common to everyone as they age; however, the rate and extent is extremely heterogeneous; thus, for the same chronological age, individuals may present with a different biological age or frailty level
- major categories of impairment develop with old age and affect the physical, mental, and social domains of older adults, usually due to many predisposing and precipitating factors rather than a single cause

The table below outlines the physiological changes that occur with aging and their organ specific impacts. In addition, it outlines pathological conditions occurring in greater frequency in older adults. Physiological changes may predispose older adults to pathological conditions; however, unlike normal changes of aging, not all older adults will develop pathological changes associated with aging

**Table 1. A Systems-Based Analysis of Potential Changes That Can Occur with Aging**

System	Physiological Changes	Impact of Physiologic Changes	Pathological Changes Occurring Frequently with Older Adults
<b>Neurologic</b>	Decreased brain mass and cerebral blood flow Increased white matter changes Reduced number of neurons Reduced action potential speed	Mild impact on working memory and processing speed Reduced sleep time Reduced fine-motor control Reduced reflex response	Increased insomnia, neurodegenerative disease (e.g. Vascular dementia, Alzheimer's disease), stroke
<b>Senses</b>	Eyes: thickened lenses, reduced pupil diameter, increased lipid infiltrates, decreased lacrimal gland secretion ENT: reduced saliva, atrophied hair cells, reduced cochlear and inner ear neurons, reduced ossicular articulation	Eyes: reduced visual acuity, dark adaptation ENT: reduced sense of smell and taste, reduced detection of higher frequency sounds, reduced vestibular function	Increased glaucoma, cataracts, macular degeneration, presbycusis, presbyopia, tinnitus, vertigo, oral dryness
<b>Cardiovascular</b>	Increased left ventricular thickness and stiffness Increased vascular resistance Reduced pacemaker cells Decreased baroreflex and autonomic reflexes Decreased vessel elasticity, cardiac myocyte size and number, $\beta$ -adrenergic responsiveness	Increased sBP, decreased dBp, HR, CO, wide pulse pressure Heart and blood vessels less responsive to physiological stress	Increased atherosclerosis, CAD, MI, CHF, HTN, arrhythmias, orthostatic hypotension
<b>Respiratory</b>	Increased tracheal cartilage calcification, mucous gland hypertrophy Decreased elastic recoil, increased residual volume, reduced vital capacity, forced expiratory volume Reduced chest wall compliance	Decreased arterial partial pressure of oxygen, decreased exercise tolerance, decreased pulmonary reserve	Increased COPD, pneumonia, pulmonary embolism
<b>Gastrointestinal</b>	Increased intestinal villous atrophy Decreased esophageal peristalsis, gastric acid secretion, liver mass, hepatic blood flow, calcium, and iron absorption	Reduced B12, calcium and iron absorption	Increased dysphagia, cancer, diverticulitis, constipation, fecal incontinence, hemorrhoids, intestinal obstruction, malnutrition, weight loss

## Functional Assessment (ADLs and IADLs)

ADLs: ABCDE-TT	IADLs: SHAFT-TT
Ambulating	Shopping
Bathing	Housework
Continence	Accounting/Managing finances
Dressing	Food preparation
Eating	Transportation
Transferring	Telephone
Toileting	Taking medications

Can use formal assessment tools such as the Lawton-Brody Instrumental Activities of Daily Living Scale to assess functioning

## Comprehensive Geriatric Assessment for Older Adults Admitted to Hospital

Cochrane DB Syst Rev 2017;CD006211  
**Purpose:** To determine whether CGA can improve care provided to older adults admitted to hospital.  
**Results/Conclusions:** Inpatient CGA increases likelihood that patients will be alive in their own homes at 3-12 mo follow-up (risk ratio (RR) 1.06, 95% CI 1.01-1.10), decreases the likelihood that patients will be admitted to a nursing home at 3-12 mo (RR 0.80, 95% CI 0.72-0.89), and results in little or no difference in dependence (RR 0.97, 95% CI 0.89-1.04). Evidence for cost-effectiveness of performing a CGA in older adults admitted to hospital is inconclusive due to imprecision and inconsistency among studies.

## Comprehensive Geriatric Assessment for Community-Dwelling, High-Risk, and Frail Older People

Cochrane DB Syst Rev 2022;CD0012705  
**Purpose:** Appraisal of the effectiveness of using the CGA for community-dwelling, high-risk, and frail older adults.  
**Results/Conclusions:** CGA resulted in no difference in mortality during median follow-up at 12 months (RR 0.88 95% CI 0.76-1.02), and concurrently no difference in nursing home admission (RR 0.93, 95% CI 0.76 to 1.14). CGA may decrease the risk of unplanned hospital admission over 14 months of follow-up (RR 0.83 95% CI 0.70 to 0.99).

**Table 1. A Systems-Based Analysis of Potential Changes That Can Occur with Aging**

System	Physiological Changes	Impact of Physiologic Changes	Pathological Changes Occurring Frequently with Older Adults
<b>Renal and Urologic</b>	Decreased renal mass and number of renal tubules and glomeruli, reduced renal blood flow Reduce nerve density and diminished detrusor function in bladder Reduced diurnal antidiuretic hormone	Decreased eGFR and concentration ability of kidney Increased urine pH Reduced hydroxylation of vitamin D Proteinuria Urinary frequency and urgency Nocturia	Increased urinary incontinence and urgency, nocturia, BPH, prostate cancer, pyelonephritis, nephrolithiasis, UTI, testicular atrophy, prostate enlargement
<b>Reproductive</b>	Decreased androgen, estrogen, sperm count, vaginal secretion Decreased ovary, uterus, vagina, and breast size		Increased breast and endometrial cancer, cystocele, rectocele, atrophic vaginitis
<b>Endocrine</b>	Increased NE, PTH, insulin, vasopressin Decreased thyroid and adrenal corticosteroid secretion	Impaired stress response	Increased DM, hypothyroidism
<b>MSK</b>	Increased calcium loss from bone Decreased muscle mass/sarcopenia, cartilage, synovial fluid lubrication	Decreased strength (note: reduced motor strength on neurological examination is not expected) Joint stiffness and reduced joint capsule flexibility	Increased arthritis, bursitis, osteoporosis, muscle weakness with gait abnormalities, polymyalgia rheumatica
<b>Integumentary</b>	Atrophy of sebaceous and sweat glands Decreased epidermal and dermal thickness, dermal vascularity, melanocytes, collagen synthesis, elastin synthesis Increased skin laxity, wrinkles, and skin stiffness	Increased skin laxity, wrinkles, and skin stiffness, and easy bruising	Increased lentigo, cherry hemangiomas, pruritus, seborrheic keratosis, herpes zoster, decubitus ulcers, skin cancer, easy bruising, onychomycosis, senile purpura, aerosis cutis
<b>Immunologic</b>	Decreased antigen-antibody affinity, decreased efficacy of neutrophils and macrophages, decreased numbers of B and T cells (excluding memory B and memory T cells)	Reduced response to new pathogens, reduced response to immunizations and need for boosters Blunted fever response and atypical presentation of infections which may lead to delayed care	Increased susceptibility to malignancies, infections, and autoimmune conditions
<b>Psychiatric</b>	Decreased processing speed, cognitive flexibility, visuospatial perception, working memory, and divided attention Loss of synaptic plasticity		Increased depression, dementia, delirium, suicidality, anxiety, sleep disruption

## Framework for the Approach to the Older Adult

### History: A Brief Geriatric Screen Using "The 5 M's Framework"

- **mind:** consider mentation, dementia, delirium, and depression
  - consider more validated screening when concerns are raised from family members
  - consider asking if patients suffer from chronic pain
- **mobility:** observe for impaired gait and balance and consider fall injury prevention strategies
  - consider evidenced-based ways to reduce injuries: exercise, vision evaluation and treatment, home safety assessment, occupational therapy support, calcium and vitamin D supplementation
- **medications:** monitor for polypharmacy, consider de-prescribing where possible, check adherence, check medication understanding from patient perspective, be cautious of adverse medication effects
- **multimorbidity:** use a bio-psycho-social approach to assess a patient's comorbidities
- **matters most:** explore values and priorities (maintaining independence, preventing adverse events, optimizing comfort, prioritizing prolonged life)

### Focused Geriatric Physical Exam

- **general and vital signs:** weight (signs of cachexia, unintentional weight loss), height (reduction may indicate vertebral compression fractures or osteoporosis), blood pressure, and orthostatic vitals
- **head and neck:** test visual acuity, in-office hearing screen (whisper test), dentition, denture fit, lymphadenopathy, and neck masses
- **cardiac:** auscultate for arrhythmias, murmurs, extra heart sounds
- **respiratory:** auscultate, observe for SOB
- **peripheral vascular exam:** assess for arterial or venous insufficiency, inspect for edema and ulcers, palpate for diminished peripheral pulses
- **dermatologic:** look for premalignant/malignant lesions especially on sun-exposed areas, examine for pressure sores in patients with diabetes, especially those who are immobile, examine for unexplained bruises or signs of elder abuse
- **MSK:** determine range of motion of all joints, based on history and focused joint exam for arthritic features
- **gait:** check footwear and fit of gait aids, assess gait, Romberg for balance, and 30 s sit-to-stand test
- **neurologic:** examine cranial nerves, examine tone, reflexes, sensation, upper motor signs, and power in upper and lower extremities

# Presentations in Older Adults

## Constipation

- see [Gastroenterology, G27](#)

### Definition

- Rome IV Diagnostic Criteria ( $\geq 2$  must be present in  $\geq 1/4$  of bowel movements for  $\geq 3$  mo with symptom onset  $\geq 6$  mo prior):
  - straining
  - hard stools
  - sensation of incomplete evacuation
  - use of manual maneuvers to facilitate defecation
  - sensation of anorectal obstruction/blockage
  - $< 3$  bowel movements per wk
  - patients must meet both of the following criteria:
    - loose stool rarely present without the use of laxatives
    - does not meet Rome IV criteria for IBS

### Epidemiology

- chronic constipation increases with age (up to 1/3 of patients  $> 65$  yr experience constipation and 1/2 of patients  $> 80$  yr)
- in the elderly, chronic constipation may present as fecal impaction and overflow diarrhea

### Etiology

- neurological: dementia
- metabolic: hypercalcemia, hypothyroidism, hypokalemia
- nutritional: low dietary fibre, dehydration
- drugs association with constipation:
  - OTC
  - opioids
  - psychotropics (e.g. antipsychotics, TCAs)
  - anticholinergics (e.g. dimenhydrinate, diphenhydramine, TCAs, antimuscarinics for urinary incontinence)
  - calcium channel blockers
  - diuretics
  - supplements (e.g. iron, calcium)

### Pathophysiology

- impaired rectal sensation (increased rectal distention required to stimulate the urge to defecate)
- colorectal dysmotility

### Alarm Symptoms

- fever
- blood in stool
- severe nausea/vomiting, severe abdominal pain
- abdominal/rectal mass
- unintentional weight loss
- obstipation
- new changes in bowel habits when age  $> 50$  yr
- unexplained anemia or iron deficiency on blood work

### Treatment

- non-pharmacological
  - bowel training
  - increase fibre intake (note: bulking agents, e.g. psyllium, Metamucil®, may worsen constipation in some)
  - ensure adequate fluid intake
  - increase physical activity
- pharmacological
  - see Figure 1
  - discourage chronic laxative use
  - review medication regime, reduce dosages or substitute
- see [Common Medications, GM17](#)

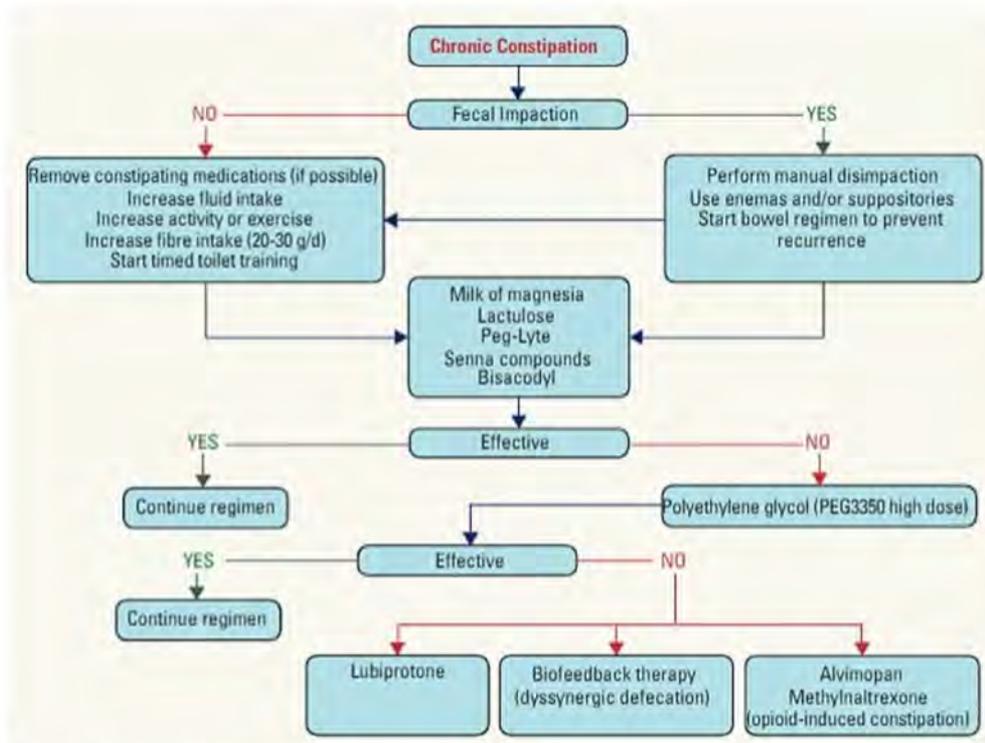

Figure 1. Treatment algorithm for the management of chronic constipation in older adults

Adapted from: Clin Interv Aging 2010;5:163-171

**A Double-Blind, Placebo-Controlled Study of Prucalopride in Elderly Patients with Chronic Constipation**

Neurogastroenterol Motil 2010;22(9):991-98  
**Purpose:** To assess the efficacy, safety, and tolerability of prucalopride in chronically constipated elderly patients.  
**Results/Conclusions:** The prucalopride dose range tested (1-4 mg daily) is effective at promoting bowel movements, minimizing constipation-associated symptoms, and improving quality of life. It is safe and well-tolerated in elderly patients with chronic constipation.

**The Effect of Probiotics as a Treatment for Constipation in the Elderly: A Systematic Review**

Arch Gerontol Geriatr 2017;71:142-49  
**Purpose:** Evaluate the effectiveness of probiotics in treating elderly constipation, as an alternative to traditional drug-based treatments.  
**Results/Conclusions:** Analysis of placebo-controlled RCTs suggested that administration of probiotics significantly improved constipation in the elderly by 10-40% compared to placebo. Further trials are required to elucidate optimal protocols of probiotic treatment regimens.

**Delirium in Older Persons: Advances in Diagnosis and Treatment**

JAMA 2017;318(12):1161-74  
**Purpose:** To provide overview of current state of diagnosis and treatment of delirium and identify promising areas for future research  
**Methods:** Controlled vocabulary and keyword terms were searched in Ovid MEDLINE, Embase and the Cochrane Library with focus on studies conducted in elderly populations.  
**Results:** 127 articles met inclusion criteria. High sensitivity and specificity brief screening tools and measures of delirium severity contribute to ability to diagnose, treat, risk stratify, and prognosticate patients. Nonpharmacologic approaches are effective for delirium prevention and recommended for delirium treatment. Pharmacologic treatment (antipsychotics, other sedatives) for agitation should only be used if the patient is at safety risk to themselves or others or is impeding medical treatment of the underlying cause.  
**Conclusion:** Better screening and diagnosis of delirium leads to better risk stratification. Nonpharmacologic approaches of delirium prevention are effective, whereas pharmacological management of delirium is controversial.

**Delirium**

• see [Psychiatry](#), PS23 and [Neurology](#), N21

**Definition**

• acute and potentially reversible disturbance in cognition, attention, or level of consciousness

**Epidemiology**

- delirium is especially common among patients in the ICU setting, postsurgical setting, and general medical setting
  - up to 25% of patients after elective surgery
  - 50% of patients after high-risk procedures (e.g. cardiac surgery, hip-fracture repair)
  - up to 75% of mechanically ventilated patients in the ICU
- can affect all ages but is especially common in hospitalized older adults
  - one-third of general medical patients >70 yr have delirium

**Screening/Diagnostic Tools**

- screened using the Confusion Assessment Method: delirium likely if 1 + 2 and either 3 or 4 are present
  1. acute onset and fluctuating course
  2. inattention
  3. disorganized thinking
  4. altered level of consciousness
- classified as: hyperactive, hypoactive, or mixed

**Differential Diagnosis**

• 3Ds (dementia, delirium, depression) can present with overlapping cognitive changes

**An Approach to Delirium: "DIMS-R"**

- **D:** drugs (consider prescribed, over the counter, overdose, intoxication, and withdrawal)
- **I:** infection (consider urinary tract, lungs, skin, bacteremia)
- **M:** metabolic disturbances (consider fluid imbalances, electrolyte abnormalities, nutritional deficiencies)
- **S:** structural insults (cardiovascular, CNS, pulmonary, GI)
- **R:** retention (urinary retention, constipation)

**Work-Up**

- work-up is not universal and depends on possible causes based on history and physical exam:
  - drugs, toxins, withdrawal: medication review, substance use history
  - infection, infarction, inflammation: CBC, urinalysis, urine culture, blood culture, CXR, ECG, troponin, creatinine kinase

- metabolic: basic and extended electrolytes, vitamin B12, TSH, LFT, toxicology screen, glucose, arterial blood gas/venous blood gas, creatinine
- structural: neurologic exam, CT head

**Delirium Prevention in Older Adults**

- ensure optimal vision and hearing to support orientation (e.g. appropriate eyewear and hearing aids)
- frequent reorientation techniques
- family visitation
- maintaining a routine in prolonged hospital stays
- ensure adequate dentition
- adequate pain management
- provide adequate nutrition and hydration (up in chair to eat and drink whenever feasible)
- encourage regular mobilization to build and maintain strength, balance, and endurance
- avoid unnecessary medications and monitor for drug interactions
- avoid bladder catheterization
- ensure adequate sleep at night and wakefulness during the day

**Table 2. Differentiating the Three Ds of Cognitive Impairment**

	Dementia	Delirium	Depression
Onset	Gradual or step-wise decline	Acute (hours to days)	Subacute (weeks to months)
Duration	Months to years	Days to weeks	Variable
Natural History	Progressive, usually irreversible	Fluctuating, reversible High morbidity/mortality in very old	Recurrent, usually reversible
Level of Consciousness	Normal	Fluctuating	Normal
Attention	Intact initially	Impaired, difficulty concentrating	
Orientation	Intact initially	Impaired, fluctuating	Intact
Behaviour	Disinhibition, loss of ADL/IADLs, personality change	Severe agitation/retardation	Importuning, self-harm/suicide
Psychomotor	Normal	Fluctuates between extremes	Slowing
Sleep-Wake Cycle	Fragmented sleep at night	Reversed sleep-wake cycle	Early morning awakening
Mood and Affect	Labile, flattened, apathetic	Anxious, irritable, fluctuating	Depressed, stable
Cognition	Chronic, gradually progressive decline in cognition Domains impacted depend on dementia subtype	Fluctuation preceded by mood changes Inattention	Impaired concentration
Memory Loss	Short term memory impairment is predominate in Alzheimer's dementia	May have impaired short-term memory	Possible impairment in episodic memory

**Evidence on Management of Delirium:**

- see "Antipsychotics for Treating Delirium in Hospitalized Adults: A Systematic Review"
- see "Delirium in Older Persons: Advances in Diagnosis and Treatment"

**Elder Abuse**

**Definition**

- includes physical abuse, sexual abuse, emotional/psychological abuse, financial exploitation, and neglect
- elder abuse is a criminal offence under the Criminal Code of Canada and in most U.S. states

**Epidemiology**

- in Canada in 2019, almost 4518 seniors were victims of police-reported family violence
- the perpetrators of family violence against seniors were identified to be their grown child (34% of cases) and their spouses (26% of the cases)
- in older adults ≥60 yr, elder abuse is estimated to occur in 10% of patients
- insufficient evidence to include/exclude screening in the Periodic Health Exam

**Risk Factors**

**Table 3. Risk Factors for Elder Abuse**

Situational Factors	Social
Victim Characteristics	Physical or emotional dependence on caregiver Lack of close family ties History of family violence Dementia or recent deterioration in health
Perpetrator Characteristics	Related to victim Dependency on older adult (e.g. financial dependency)

**Antipsychotics for Treating Delirium in Hospitalized Adults: A Systematic Review**  
A m Intern Med 2019;171:485-95

**Purpose:** Evaluate with current literature the risks and benefits of antipsychotics in delirium management for hospitalized adults.  
**Study Selection:** RCTs of antipsychotic vs. placebo or another antipsychotic, as well as prospective observational studies that report harms, are selected through searches on PubMed, Embase, CENTRAL, CINAHL, and PsycINFO from inception to July 2019. The review selected 16 RCTs and 10 observational studies of hospitalized adults.  
**Data Synthesis:** No significant difference in sedation, delirium, hospital length-of-stay, or mortality between haloperidol and second-generation antipsychotics vs. placebo. No difference in mortality in direct comparisons between second-generation antipsychotics. While short term use of antipsychotics for delirium management does not appear to pose neurological harm, it poses a risk of QT prolongation.  
**Conclusion:** The current evidence does not support the routine use of haloperidol or second-generation antipsychotics in delirium management for adult inpatients.

**Elder Abuse Prevalence in Community Settings: A Systematic Review and Meta-Analysis**  
Lancet Glob Health 2017;5:147-56

**Purpose:** Since quantitative syntheses of elder abuse prevalence are rare, the study aimed to quantify and understand prevalence variation at global and regional levels.  
**Methods:** A comprehensive search strategy from 14 databases was employed to identify elder abuse prevalence studies in the community, published from inception to June 2015. Subgroup analysis and meta-regression were used to explore heterogeneity.  
**Results:** 52 of the 38544 initially identified studies were eligible for inclusion, all of which were geographically diverse (28 countries). The pooled prevalence estimates were 11.6% for psychological abuse, 6.8% for financial abuse, 4.2% for neglect, 2.6% for physical abuse, and 0.9% for sexual abuse. Significant heterogeneity was found in associations with overall prevalence estimates, including sample size, income classification, and method of data collection, but not with gender.  
**Conclusion:** Elder abuse is a neglected public health priority, especially compared with other types of violence. Elder abuse seems to affect 1 in 6 older adults worldwide, a figure totaling 141 million people.

**Elder Abuse Screening Tools: A Systematic Review**  
J Adult Prot 2017;19:368-79

**Context and Purpose:** With high rates of morbidity and mortality, along with deleterious psychological harms, elder abuse is often difficult to detect. This study seeks to review currently available elder abuse screening tools.  
**Results:** 11 of 34 full text studies met inclusion criteria and were included in the final analysis. Of these, three studies reported sensitivity and specificity while the remainder reported validity and reliability testing. Ultimately, the clinical environment will dictate the choice of screening tool.  
**Limitations:** Variations in tool qualities and characteristics led to challenges in data synthesis. A further challenge was the lack of a gold standard screening tool for elder abuse, for evaluation of heterogeneity.  
**Conclusion:** Research on screening tools remains hard-pressed in distinguishing those assessing suspected or actual elder abuse and those assessing risk factors for abuse. Although screening tools carry inherent limitations, they can be used to guide further assessments for an objective diagnosis.

### Screening Tools

- Elder Abuse Suspicion Index® (EASI®): a six-item questionnaire to raise a physician's level of suspicion for elder abuse and promote referral of possible victims for further assessment by social services

### Management

- assess patient's decision-making capacity regarding any proposed intervention
- address imminent safety
- consider referral to local resources (home care, respite agencies, shelters, legal services, police services, government-supported elder abuse consultants)
- create emergency safety plan
- offer assistance with reporting abuse
- in Ontario, reporting elder abuse is mandatory when an older adult resides in a Long-term Care Home or a Retirement Home

## Falls

### Definition

- an event resulting in a person coming to rest inadvertently on a lower level, other than as a consequence of sudden paralysis, epileptic seizure, or overwhelming external force

### Epidemiology

- approximately 20-30% of older adults  $\geq 65$  yr fall each year in Canada, prevalence increases with age
  - falls resulting in injury (e.g. broken/fractured bones, sprain/strain, concussion) were more likely to occur in women than men
  - 25% associated with serious and 1/3 of hospitalizations were associated with hip fractures
  - more than 1/3 of older adults are admitted to long-term care after hospitalization

### Etiology

- intrinsic factors
  - age-related changes and diseases associated with aging: MSK (arthritis, muscle weakness), sensory (visual, proprioceptive, vestibular), cognitive (depression, dementia, delirium, anxiety), cardiovascular (CAD, arrhythmia, MI, low BP), neurologic (stroke, decreased LOC, gait disturbances/ataxia), and metabolic (glucose, electrolytes)
  - orthostatic/syncopal
  - acute illness, exacerbation of chronic illness
- extrinsic factors
  - environmental (e.g. home layout, slippery surfaces, overcrowding, new environments)
  - side effects of medications, polypharmacy (>4 medications), and substance misuse (e.g. alcohol misuse)
- situational factors
  - activities (e.g. rushing to the toilet, walking while distracted)

### History and Physical Exam

- falls history: pre-fall symptoms (chest pain, syncope, presyncope, palpitations), infectious symptoms, mechanisms, loss of consciousness, head trauma, neck/cervical spine trauma, post-fall (how long were they on the ground, who helped them up, post-fall confusion or amnesia)
- extended history: previous falls and/or gait instability, intrinsic, extrinsic and situational factors, associated symptoms, medication and alcohol use, change in medications
- have a witness present, if possible, for interview
- physical exam: orthostatic BP, injury screen, cardiac, visual acuity, examination of feet and footwear, gait assessment, Timed Up-and-Go Test, MSK, neurologic

### Investigations

- CGA to identify potential causes
- investigations should be tailored based on history and physical examination. They might consist of:
  - CBC, electrolytes, BUN, creatinine, glucose, Ca<sup>2+</sup>, TSH, vitamin B12, urinalysis, cardiac enzymes, ECG, CT head (as directed by history and physical), coagulation profile
- bone densitometry (dual-energy X-ray absorptiometry) for osteoporosis screening in all women and men >65 yr

### Interventions

- interventions depend on the identified intrinsic and extrinsic risk factors. First address any acute illness that precipitated the fall and treat any injuries or complications
- muscle strengthening, balance retraining (e.g. Tai Chi) with appropriate assistive devices, and group exercise programs
- hip protectors
- fitted gait aid
- multidisciplinary, multifactorial, health and environmental risk factor assessment, and intervention programs in the community

#### EASI

For each of the 6 items below, indicate "yes," "no," or "did not answer." A response of "yes" on 1+ of questions 2-6 is concerning for elder abuse  
Q.1-Q.5 asked of patient; Q.6 answered by doctor (Within the last 12 months)

- Have you relied on people for any of the following: bathing, dressing, shopping, banking, or meals?
- Has anyone prevented you from getting food, clothes, medication, glasses, hearing aids or medical care, or from being with people you wanted to be with?
- Have you been upset because someone talked to you in a way that made you feel shamed or threatened?
- Has anyone tried to force you to sign papers or to use your money against your will?
- Has anyone made you afraid, touched you in ways that you did not want, or hurt you physically?
- Doctor: Elder abuse may be associated with findings such as: poor eye contact, withdrawn nature, malnourishment, hygiene issues, cuts, bruises, inappropriate clothing, or medication compliance issues. Did you notice any of these today or in the last 12 months?

Vaile MJ, Wolfson C, Litwick M, et al. Development and validation of a tool to assist physicians' identification of elder abuse: The Elder Abuse Suspicion Index (EASI). *J Elder Abuse Negl* 2008;20(3):276-300.

#### Key Clinical History Findings in Falls Evaluation

##### SPLAT

Symptoms  
Previous falls  
Location of falls  
Activity at the time of fall  
Time of fall  
Trauma

#### Impact of Medication Classes on Falls Risk in Geriatrics (Odds Ratios)

- Antidepressants (1.68)
- Neuroleptics/antipsychotics (1.59)
- Benzodiazepines (1.57)
- Sedatives/hypnotics (1.47)
- Antihypertensive agents (1.24)
- NSAIDs (1.21)
- Diuretics (1.07)
- $\beta$ -blockers (1.01)

Meta-analysis of the impact of 9 medication classes on falls in elderly persons. *Arch Intern Med* 2009;169(21):1952-1960

- home hazard assessment and modification with potential for collaboration with occupational therapy (e.g. remove loose rugs and tripping hazards, add shower bars and stair railing, improve lighting)
- prescription of vitamin D 1000 IU daily if vitamin D stores are low
- optimization of calcium in diet with 1200 mg of supplemental calcium advised if osteoporosis is a risk
- tapering or gradual discontinuation of psychotropic medication
- postural hypotension, heart rate, and rhythm abnormalities management
- eyesight (cataract surgery) and footwear optimization
- compression socks if venous stasis edema

**Will My Patient Fall?**

JAMA 2007;297:77-86

**Purpose:** To identify the prognostic value of risk factors for future falls among older patients.  
**Study Selection:** Meta-analysis of prospective cohort studies of risk factors for falls.

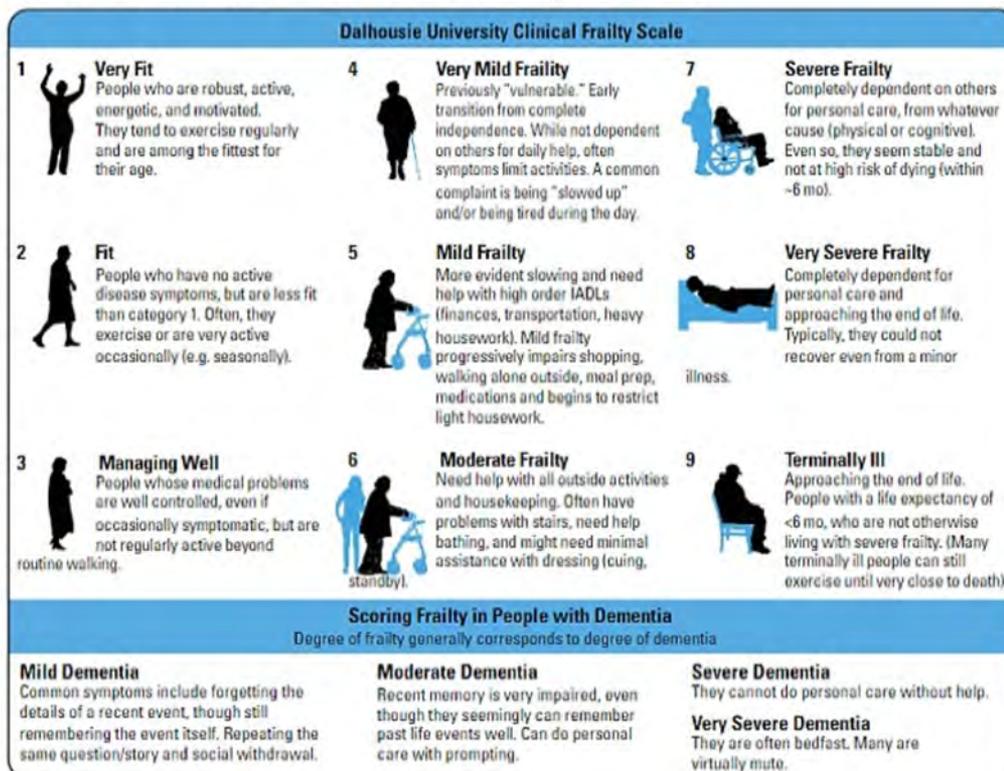

**Results:** 18 studies were included. Clinically identifiable risk factors were identified across 6 domains: orthostatic hypotension, visual impairment, impairment of gait or balance, medication use, limitations in ADLs or IADLs, and cognitive impairment. The estimated pretest probability of falling at least once in any given yr for individuals >65 yr was 27% (95% CI 19-36%). Patients who have fallen in the past year are more likely to fall again (LR 2.3-2.8). Best predictors of future falls were disturbances in gait or balance (LR 1.7-2.4), while visual impairment, impaired cognition, and medication were not reliable predictors.

**Conclusions:** Screening for risk of falling during the clinical examination begins with determining if the patient has fallen in the past yr. For patients who have not previously fallen, screening consists of an assessment of gait and balance. Patients who have fallen or who have a gait or balance problem are at higher risk of future falls.

**Frailty**

**Definition**

- frailty: clinically-recognizable state of decreased reserve in older adults with increased vulnerability to acute stressors resulting from functional decline across multiple physiologic systems
- functional decline: progressive limitation in the ability to carry out basic functional activities
- frailty is associated with higher risk of in-hospital death, adverse events, length of stay, hospital re-admission, and newly dependent at discharge following critical illness

**Figure 2. Rockwood Clinical Frailty Scale**

Adapted from and reprinted with permission: Geriatric Medicine Research, Dalhousie University, Halifax, Canada. ©2005-2020 Version 2.0. All rights reserved.

**MODELS OF FRAILTY**

**Physical Frailty (PF) Phenotype (Fried et al.)**

- Frail: ≥3 criteria; at-risk or pre-frail = 1 or 2 criteria
  1. shrinking: unintentional weight loss (baseline: >10 lbs or 5% total body weight lost in prior yr)
  2. weakness: grip strength in lowest 20% (by gender, BMI)
  3. poor endurance: as indicated by self-report of exhaustion
  4. slowness: walking time/15 feet in slowest 20% (by gender, height)
  5. low activity: kcals/wk in lowest 20% (males: <383 kcals/wk, females: <270 kcals/wk)

**Cumulative Deficit Approach (Rockwood et al.)**

- balance between assets (e.g. health, attitudes, resources, caregiver) and deficits (e.g. illness, disability, dependence, caregiver burden) that determines whether a person can maintain independence in the community
- frailty index: number of deficits present/number of deficits possible

**Etiology**

- multifactorial: dysregulated immune, endocrine, stress, and energy response systems lead to development of clinical frailty

**Table 4. Etiologies of Frailty**

Etiology	Mechanism
Physiologic Changes with Aging	Sarcopenia (age-related loss of skeletal muscle and strength), decreased mass and increased stiffness of organs, decreased reserve capacity of systems
Immune System	Elevated levels of circulating interleukin-6, C-reactive protein, white blood cells, and monocytes associated with skeletal muscle decline Elevated clotting markers (factor VIII, fibrinogen, D-dimer) upregulates clotting cascade Chronic inflammation
Endocrine System	Sarcopenia via: Decreased growth hormone and IGF-1 Increased cortisol levels Decreased DHEA-S Decreased 25 (OH) vitamin D
Stress dysregulation of autonomic nervous system	
Age-related changes in renin-angiotensin system and mitochondria likely impact sarcopenia and inflammation	

**Evidence-based Approach to the Frail Older Patient**

- CGA
  - includes: past medical history, medications, allergies, social history, function, and geriatric review of systems (cognition, mood, sleep, pain, nutrition, falls, continence, vision/hearing, skin, and safety)
  - physical exam
  - investigations: CBC, electrolytes, TSH, vitamin B<sub>12</sub>, vitamin D, LFTs, extended electrolytes
- management
  - CGA to tailor management of geriatric syndromes (e.g. falls, cognitive impairment, incontinence)
  - physical activity programs, nutritional optimization, multicomponent interventions
  - interdisciplinary primary care
  - referral to Acute Care for Elders (ACE) unit for inpatients who are living with frailty
  - medication optimization
  - caregiver support

**Immobility****Definition**

- limitation in independent and voluntary physical movement of the body or one or more lower extremities
- associated with disability, increased frailty and risk of falls, decreased quality of life

**Etiology and Risk Factors**

- multifactorial; functional assessment in addition to comprehensive history-taking and interdisciplinary approach to care is crucial
- psychological
  - fear of falling, motivation, depression
- physical changes
  - MSK disorders: history of hip or leg fractures, osteoporosis, arthritis
  - neurologic disorders: stroke, Parkinson's disease, severe dementia, neuropathies
  - cardiovascular: CHF, angina secondary to CAD, claudication secondary to PVD
  - sensory: poor vision, decreased peripheral sensation/proprioception
- interpersonal/social factors
- environmental changes
  - iatrogenic (healthcare facilities)
  - deconditioning secondary to prolonged bed rest
  - inadequate mobility aids
  - poorly controlled chronic and acute pain

**Complications**

- cardiovascular: orthostatic hypotension, venous thrombosis, embolism
- respiratory: decreased ventilation, atelectasis, pneumonia
- gastrointestinal: anorexia, constipation, incontinence, dehydration, malnutrition
- genitourinary: infection, urinary retention, bladder calculi, incontinence
- MSK: atrophy, contractures, bone loss
- skin: pressure injuries
- psychological: sensory deprivation, delirium, depression

## Incontinence

### Fecal Incontinence

#### Definition

- involuntary or inappropriate passing of feces that impacts social functioning or hygiene
- severity can range from unintentional flatus to the complete evacuation of bowel contents
- there are three subtypes:
  1. passive incontinence: involuntary discharge of stool or gas without awareness
  2. urge incontinence: discharge of fecal matter in spite of active attempts to retain bowel contents
  3. fecal seepage: leakage of stool following otherwise normal evacuation

#### Epidemiology

- the incidence of fecal incontinence differs by setting: community (17-36%), hospital (16%), and nursing home (33-65%)
- risk factors: constipation, age >80 yr, female sex, UI, impaired mobility, dementia, neurologic disease

#### Etiology

- physiological changes with age >80 yr (e.g. decreased external sphincter strength, decreased resting tone of internal sphincter, weakened anal squeeze, increased rectal compliance, and impaired anal sensation)
- trauma (e.g. vaginal delivery, pudendal nerve damage, cauda equina)
- iatrogenic
  - surgical (e.g. anorectal surgery, lateral internal sphincterotomy, hemorrhoidectomy, colorectal resection)
  - radiation (e.g. pelvic radiation)
- neurogenic (e.g. neuropathy, stroke, MS, diabetic neuropathy)
- anorectal/colorectal diseases (e.g. rectal prolapse, hemorrhoids, IBD, rectocele, cancer)
- medication (e.g. laxative, anticholinergics, antidepressants, caffeine, muscle relaxants)
- cognitive (e.g. dementia, willful soiling with psychosis)
- constipation/fecal impaction

#### Investigations (if cause not apparent from history and physical)

- differentiate true incontinence from frequency and urgency
- stool studies
- endorectal ultrasound
- colonoscopy, sigmoidoscopy, anoscopy
- anorectal manometry/functional testing

#### Management

- physiological changes with age: medication management (antimotility agents (e.g. loperamide), diet/bulking agents for loose stool), increase fluid intake, biofeedback, retraining of pelvic floor muscles, surgery
- trauma: direct surgical repair or augmentation of the sphincters
- iatrogenic: surgical repair, artificial sphincters
- neurogenic: medication management, abdominal massage, digital stimulation for dysfunction, biofeedback and behavioural training, prevent autonomic dysreflexia in spinal injury
- anorectal/colorectal diseases: treat underlying cause (optimize IBD medications), surgical (e.g. mass removal, prolapse repair, hemorrhoid removal, colostomy)
- medication-related causes: stop laxatives, lower dose, or discontinue any other offending agents
- cognitive: regular defecation program in patients with dementia, psychiatric consult (optimize medications and cognitive function)
- constipation/fecal impaction: disimpaction, prevent impaction, enema, or rectal irrigation
- safety assessment: assess bathroom distance, fall prevention strategies, need for a bedside commode, liaison with occupational therapy if necessary

### Urinary Incontinence

- see [Urology](#), U6

#### Definition

- complaint of any involuntary loss of urine
- there are 4 subtypes:
  1. stress incontinence: leakage associated with physical strain
  2. urge incontinence: leakage associated with strong urge to urinate
  3. overflow incontinence: leakage associated with poor bladder emptying
  4. functional incontinence: leakage due to illness or disability not related to the urinary tract

#### Epidemiology

- 15-30% prevalence dwelling in community and at least 50% of institutionalized older adults
- morbidity: cellulitis, pressure injuries, urinary tract infections, falls with fractures, sleep deprivation, social withdrawal, depression, sexual dysfunction

#### Transient Causes of Incontinence

##### DIAPERS

De lirim  
Infection  
Atrophic urethritis/vaginitis  
Pharmaceuticals  
Excessive urine output  
Restricted mobility  
Stool impaction

- not associated with increased mortality
- risk factors: impaired mobility, falls, medications, depression, TIA/stroke, dementia, CHF, obesity

### Etiology

- physiologic changes with age: (e.g. decreased bladder capacity)
- genitourinary diseases (e.g. cystitis, urethritis, BPH)
- neurogenic (e.g. cauda equina syndrome, stroke, MS)
- iatrogenic: (e.g. prostate surgery)
- trauma: (e.g. pelvic trauma, traumatic spinal cord injury)
- drugs (e.g. alcohol, loop diuretics, sedative hypnotics, GABAergic agents)
- cognitive (e.g. dementia, depression)
- functional impairment (e.g. arthritis, poor vision)

### Investigations

- laboratory tests: urinalysis and urine culture, serum creatinine, BUN
- imaging: post-void residual, renal ultrasound
- other: voiding diary, pad test

### Management

- lifestyle modification: avoid excessive fluid intake and alcohol
- pharmacologic:  $\beta$ -adrenergic agonists to reduce involuntary bladder contractions
- physiologic changes with age: pelvic muscle exercises, bladder training, biofeedback
- genitourinary diseases: treat underlying cause (empiric antimicrobial treatment for cystitis,  $\alpha$  blockers/5- $\alpha$  reductase inhibitors for BPH)
- functional impairment: incontinence pads, environmental modification, personal assistance
- cognitive: referral to incontinence program if needed
- safety assessment: assess bathroom distance, fall prevention strategies, need for a bedside commode, liaise with occupational therapy if necessary

## Malnutrition

### Definition

- no uniformly accepted definition of malnutrition in older adults. One definition provided by the 2018 Global Leadership Initiative on Malnutrition requires a combination of one phenotypic and one etiologic finding:
  - phenotype
    - involuntary weight loss (community:  $\geq 2\%$  over 1 mo,  $>10$  lbs over 6 mo, or  $\geq 4\%$  over 1 yr; nursing home:  $\geq 5\%$  over 1 mo,  $\geq 10\%$  over 180 d)
    - loss of muscle mass
    - low BMI
  - etiology
    - decreased food intake/absorption
    - inflammation
    - chronic disease
- other definitions include: hypocholesterolemia ( $<4.1$  mmol/L), hypoalbuminemia (community:  $\leq 38$  g/L; hospital:  $\leq 35$  g/L), insufficient energy intake, fluid accumulation (e.g. edema), loss of subcutaneous fat, decreased hand-grip function

### Etiology

- nutritional
  - decreased assimilation: impaired transit, maldigestion, malabsorption
  - decreased intake: financial, psychiatric (depression), cognitive deficits, anorexia associated with chronic disease, functional deficits (e.g. difficulty shopping, preparing meals, or feeding oneself due to functional impairment), substance use
- stress: acute or chronic illness/infection, chronic inflammation, abdominal pain
- mechanical: dental problems, dysphagia
- age-related changes: appetite dysregulation, decreased thirst, decreased smell and taste
- mixed: increased energy demands (e.g. hyperthyroidism), abnormal metabolism, protein-losing enteropathy

### Clinical Features

- history
  - weight loss in 6 mo prior to examination
  - recent or chronic illness
  - constitutional symptoms (e.g. recent weight loss)
  - dietary intake in relation to usual pattern
  - depression, GI symptoms (e.g. anorexia, nausea, vomiting, diarrhea)
  - functional disability: impaired ADLs and IADLs
  - social factors: economic barriers, dental problems, and living situation (e.g. living alone)
  - substance use (e.g. alcohol, smoking, IV or recreational drug use)

### Etiology of Malnutrition in Older Adults

#### MEALS ON WHEELS

Medications  
Emotional problems  
Anorexia  
Late-life paranoia  
Swallowing disorders  
Oral problems  
Nosocomial infections  
Wandering/dementia related activity  
Hyperthyroid/hypercalcemia/  
hypoadrenalism  
Enteric disorders  
Eating problems  
Low-salt/low-fat diet  
Stones

- physical exam
  - BMI <23.5 in males and <22.0 in females should raise concern
  - muscle wasting, temporal wasting, presence of triceps skin fold
  - loss of subcutaneous fat
  - ankle or sacral edema, ascites
  - assess cognition

**Investigations**

- CBC, electrolytes, Ca<sup>2+</sup>/albumin, Mg<sup>2+</sup>, PO<sub>4</sub><sup>3-</sup>, creatinine, LFTs (INR, bilirubin), vitamin B12, folate, TSH, lipid profile
- if indicated by assessment, can consider urinalysis, ESR, CXR

**Treatment**

- direct treatment of underlying causes
- dietary modification: high calorie foods, oral nutritional supplementation: patient specific meal replacement products (e.g. Ensure™, Glucerna™, Nepro™), vitamins/minerals (e.g. vitamin B12, calcium, vitamin D, thiamine)
- referral: speech language pathologist, nutritionist

**Presbycusis**

- see [Otolaryngology](#), OT19

**Presbyopia**

- see [Ophthalmology](#), OP8

**Pressure Injuries**

- see [Plastic Surgery](#), [Pressure Ulcers](#), PL18

**Definition**

- previously termed pressure ulcers, also termed decubitus ulcers
- any lesion caused by unrelieved pressure resulting in damage of underlying tissue; usually develops over bony prominences

**Risk Factors**

- extrinsic: friction, pressure, shear force, moisture
- intrinsic: immobility, malnutrition, comorbidities (e.g. DM, PVD, vasculitis, immunodeficiency), sensory loss
- geriatric: age-related skin changes, bedbound, cognitive impairment, chronic illness

**Table 5. NPIAP Staging System for Pressure Injuries**

<b>Stage 1</b>	Localized area of nonblanchable erythema of intact skin (appearance may vary in darkly pigmented skin) Changes in sensation, temperature, or firmness may precede visual changes Colour changes do not include purple or maroon discoloration (may indicate deep tissue penetration injury)
<b>Stage 2</b>	Partial thickness loss of skin with exposed dermis Wound bed is viable, pink or red, moist, and may present as a serum-filled blister Adipose and deeper tissue not visible
<b>Stage 3</b>	Full thickness loss of skin; adipose tissue visible Granulation tissue and epibole (rolled wound edges) often present
<b>Stage 4</b>	Full thickness skin and tissue loss Exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone Epibole, undermining, and/or tunneling often present
<b>Unstageable Pressure Injury</b>	Full-thickness skin and tissue loss; extent of tissue damage cannot be determined due to obstruction by slough or eschar
<b>Deep Tissue Pressure Injury</b>	Intact or nonintact skin with localized nonblanchable maroon or purple discoloration, or epidermal separation revealing dark wound bed or blood-filled blister Pain and temperature changes may precede skin colour changes Injury results from intense and/or prolonged pressure and shear forces at the bone-muscle interface

Source: Edsberg LE, Black JM, Goldberg M, et al. Revised National Pressure Ulcer Advisory Panel Pressure Injury Staging System: Revised Pressure Injury Staging System. *J Wound Ostomy Continence Nurs* 2016;43(6):585-597.

**Complications**

- noninfectious: amyloidosis, heterotopic bone formation, perineal urethral fistula, pseudoaneurysm, Marjolin ulcer, systemic complications of topical treatment, complications of oral/IV treatments
- infectious: bacteremia/sepsis, cellulitis, osteomyelitis, septic arthritis, sinus tracts, abscess, endocarditis, meningitis

**Risk Assessment and Prevention of Pressure Ulcers**

*Ann Intern Med* 2015;162:359-369  
The American College of Physicians (ACP) strongly recommends advanced static mattresses or advanced static overlays for patients who are at an increased risk of developing pressure injuries. The ACP also recommends against using alternating air mattresses or alternating air overlays.

**Prevention**

- pressure reduction
  - frequent repositioning (q2 h)
  - pressure-reducing devices (static, dynamic)
- maintaining nutrition, encouraging mobility, and managing incontinence
- use validated pressure injury risk assessment tools on admission for those identified to be at risk for skin breakdown

**Treatment**

- optimize nutritional status
- minimize pressure on wound
- analgesia
- all ulcers with necrosis warrant debridement (mechanical, enzymatic, and autolytic are non-urgent forms of debridement, whereas sharp debridement is performed urgently due to risk of sepsis or cellulitis)
- dressing application (exudate absorbing, barrier products to reduce friction)
- maintain moist wound environment to enable re-epithelialization
- treatment of wound infections (topical gentamicin, silver sulfadiazine, mupirocin)
- swab wounds not demonstrating clinical improvement for C&S; biopsy chronic wounds to rule out malignancy
- referral to Wound Care or Plastic Surgery
- consider other treatment options:
  - negative pressure wound therapy/vacuum-assisted closure
  - biological agents: application of fibroblast growth factor or platelet-derived growth factor to wound
  - non-contact normothermic wound therapy
  - electrotherapy

**Driving Competency**

**Reporting Requirements**

- physician-reporting to the Ministry of Transportation is mandatory in all provinces and territories except in Quebec, Nova Scotia, and Alberta, where it is discretionary
- British Columbia, Ontario: must refer for re-test at ≥80 yr
- in the U.S., varies by state

**Conditions That May Impair Driving**

**Table 6. Conditions That Impair Driving**

<b>Alcohol</b>	<p>Patients with history of impaired driving and those with a high probability of future impaired driving should not drive until further assessed</p> <p>Alcohol dependence or alcohol use disorder: if suspected, should be advised not to drive</p> <p>Alcohol withdrawal seizure: must (1) receive favourable report from addictions counsellor post-treatment and (2) be in remission and/or remained abstinent for 12 mo</p>
<b>Blood Pressure Abnormalities</b>	<p>HTN: sustained BP &gt;170/110 should be evaluated carefully</p> <p>Hypotension: sustained BP &lt;90/60; if syncopal, discontinue driving until syncope is treated and preventable</p>
<b>Cardiovascular Disease</b>	<p>Suspected asymptomatic CAD or stable angina: no restrictions</p> <p>STEMI, NSTEMI with significant LV damage, coronary artery bypass surgery: no driving for 1 mo following hospital discharge</p> <p>NSTEMI with minor LV damage, unstable angina: no driving for 48 h if PCI or 7 d if no PCI performed</p>
<b>Cerebrovascular Conditions</b>	<p>TIA: should not be allowed to drive until a medical assessment is completed</p> <p>Stroke: should not drive for at least 1 mo; may resume driving if functionally able; no clinically significant motor, cognitive, perceptual, or vision deficits; no obvious risk of sudden recurrence; underlying cause appropriately treated; no post-stroke seizure</p>
<b>COPD</b>	<p>Mild/moderate impairment: no restrictions</p> <p>Moderate or severe impairment requiring supplemental oxygen: road test with supplemental oxygen</p>

N.B. guidelines included refer specifically to private driving; please see CMA guidelines for commercial driving

**Key Factors to Consider in Older Drivers**

- SAFEDRIVE**
- Safety record
  - Attention (e.g. concentration lapses, episodes of disorientation)
  - Family observations
  - Ethanol use
  - Drugs
  - Reaction time
  - Intellectual impairment
  - Vision/Visuospatial function
  - Executive functions (e.g. planning, decision-making, self-monitoring behaviours)
- Geriatrics 1996;51:36-45

**Cognitive Tests and Determining Fitness to Drive in Dementia: A Systematic Review**

J Am Geriatr Soc 2016;64(9):1904-1917

**Purpose:** To examine the relationship between cognitive tests and driving to determine whether a cognitive assessment can be implemented as a tool to examine driver safety.

**Methods:** Systematic review of 28 studies investigating the relationship between cognitive functioning and driving in individuals with dementia.

**Results:** Composite batteries comprising multiple individual tests from different cognitive domains consistently predicted driving performance for individuals with dementia. Scores on individual tests or tests of a single cognitive domain did not predict driver safety.

**Conclusions:** While studies consistently found composite batteries predicted driving performance, these tests were not clinically usable as they lacked the ability to discriminate between safe and unsafe drivers. Need development of a reliable, valid composite battery that can correctly determine driver safety in patients with dementia.

**Table 6. Conditions That Impair Driving**

<b>Cognitive Impairment/Dementia</b>	Moderate to severe dementia is a contraindication to driving, defined as the "inability to independently perform 2 or more IADLs or any basic ADL" Patients with mild dementia should be assessed; if indicated, refer to specialized driving testing centre; if deemed fit to drive, re-evaluate patient every 6-12 mo Poor performance on MMSE, clock drawing, or Trails B suggests a need to investigate driving ability further MMSE score alone (whether normal or low) is insufficient to determine fitness to drive
<b>Diabetes</b>	Diet controlled or oral hypoglycemic agents: no restrictions in absence of diabetes complications that may impair ability to drive (e.g. retinopathy, nephropathy, neuropathy, cardiovascular, or cerebrovascular disease) Insulin use: may drive if no complications (as above) and no severe hypoglycemic episode in the last 6 mo
<b>Drugs</b>	Be aware of: analgesics, anticholinergics, anticonvulsants, antidepressants, antipsychotics, opiates, sedatives, stimulants Degree of impairment varies; patients should be warned of the medication/withdrawal effect on driving
<b>Hearing Loss</b>	Effect of impaired hearing on ability to drive safely is controversial Acute labyrinthitis, positional vertigo with horizontal head movement, recurrent vertigo: advise not to drive until condition resolves
<b>Musculoskeletal Disorders</b>	Physician's role is to report etiology, prognosis, and extent of disability (pain, range of motion, coordination, muscle strength)
<b>Postoperative</b>	Outpatient, conscious sedation: no driving for 24 h Outpatient, general anesthesia: no driving for ≥24 h
<b>Seizures</b>	First, single, unprovoked: no driving for 3 mo until complete neurologic assessment, EEG, CT head Epilepsy: can drive if seizure-free for 6 mo, on medication that does not impair ability to drive, and physician has insight into patient compliance (Ontario guideline)
<b>Sleep Disorders</b>	If patient is believed to be at risk due to a symptomatic sleep disorder but refuses investigation with a sleep study or refuses appropriate treatment, the patient should not drive
<b>Visual Impairment</b>	Visual acuity: contraindicated to drive if <20/50 with both eyes examined simultaneously Visual field: contraindicated to drive if <120° along horizontal meridian and 15° continuous above and below fixation with both eyes examined simultaneously

N.B. guidelines included refer specifically to private driving; please see CMA guidelines for commercial driving

## Hazards of Hospitalization

**Table 7. Recommendations for Sequelae of Hospitalization in Older Patients**

Sequelae	Recommendations
<b>Malnutrition</b>	No dietary restrictions (except diabetes and salt restriction if applicable), assistance, dentures if necessary, sitting in a chair to eat
<b>Urinary Incontinence</b>	Medication review, remove environmental barriers, discontinue use of catheter
<b>Depression</b>	Routine screening
<b>Adverse Drug Event</b>	Medication review
<b>Confusion/Delirium</b>	Orientation, visual and hearing aids, volume repletion, noise reduction, early mobilization, medication review, remove restraints
<b>Pressure Injuries</b>	Low-resistance mattress, daily inspection, repositioning every 2 h, nutrition
<b>Infection</b>	Early mobilization, remove unnecessary IV lines, catheters, NG tubes
<b>Falls</b>	Appropriate footwear, assistive devices, early mobilization, remove restraints, medication review
<b>Hypotension/Dehydration</b>	Early recognition and repletion (ideally oral rehydration, if possible), access to water
<b>Diminished Aerobic Capacity/Loss of Muscle Strength/Contractures</b>	Early mobilization
<b>Decreased Respiratory Function</b>	Incentive spirometry, physiotherapy
<b>Functional Decline</b>	Structured exercise, progressive resistance training, walking programs

Bell SP, Vasilevskis EE, Soraf AA, et al. Geriatric Syndromes in Hospitalized Older Adults Discharged to Skilled Nursing Facilities. *J Am Geriatr Soc* 2016;64(4):715-722.

## Healthcare Institutions

**Table 8. Classification of Healthcare Services and Institutions**

Institution/Service	Description
<b>Home and Community Support Services</b>	At-home support services offered to patients living at home independently or under the care of family members. These include professional healthcare services, personal care and support (ADL assistance), homemaking (IADL assistance), community support services (e.g. transportation, meal delivery, day programs, caregiver relief, security checks)
<b>Rehabilitation</b>	Healthcare services offered in an institution to optimize patients' function, independence, and quality of life
<b>Residential</b>	Divided into short (~60-90 d/yr) and long (indefinite) stay
a) Older adults Affordable Housing	Seniors who live independently and manage their own care, but prefer to live near other older adults; usually has accessibility features; rent is adjusted based on income
b) Retirement Home	Residents are fairly independent and require minimal support with ADLs and IADLs; often privately owned
c) Supportive Housing	Residents require minimal to moderate assistance with daily activities while living independently; often rental units in an apartment; may offer physiotherapy and rehabilitation services
d) Long-term Care/Skilled Nursing Facility	Around the clock nursing care and on-call physician coverage; often offers occupational therapy, physiotherapy, respiratory therapy, and rehabilitation services; may be used short-term for caregiver respite or for supportive patient care to regain strength and confidence after leaving the hospital
e) Hospice	Free-standing facility or designated floor in a hospital or nursing home for care of terminally ill patients and their families; focus is on quality of life and often requires prognosis $\leq 3$ mo

- names of community healthcare institutions, types of facilities, and services offered vary between geographical locations
- factors to consider when referring to community services and institutions: level and type of support required, income/socioeconomic status, social supports and/or degree of social isolation, other social determinants of health creating potential barriers to care

## Geriatric Pharmacology

### Pharmacokinetics

**Table 9. Age-Associated Pharmacokinetics**

Parameter	Age Effect	Implications
<b>Absorption (less significant)</b>	Increased gastric pH, decreased splanchnic blood flow, GI absorptive surface and dermal vascularity, delayed gastric emptying. However, appropriate absorption of most oral drugs is seen in healthy older-aged patients; reduced absorption may be related to patient comorbidities	Comorbidities, drug-drug, and drug-food interactions are more likely to affect absorption
<b>Distribution</b>	Increased total body fat Increased $\alpha_1$ -glycoprotein Decreased lean body mass and total body water Decreased albumin	Lipophilic drugs have a larger volume of distribution Increased binding of basic drugs Decreased volume of distribution of hydrophilic drugs Decreased binding of acidic drugs
<b>Metabolism (less significant)</b>	Decreased hepatic mass and hepatic blood flow; impaired phase I reactions (oxidative system)	Lower doses may be therapeutic
<b>Elimination</b>	Decreased renal blood flow, glomerular filtration rate, tubular secretion Overall reduction in renal function by 30-50%	Lower doses may be therapeutic

### Pharmacodynamics

#### Drug Sensitivity

- changes in pharmacokinetics as well as intrinsic sensitivity lead to altered drug responses
- increased sensitivity to warfarin, sedatives, antipsychotics, anticholinergics, digoxin, and narcotics
- decreased sensitivity to  $\beta$ -blockers and  $\beta$ -adrenergic stimulants, though may have increased sensitivity

**Decreased Homeostasis**

- poorer compensatory mechanisms leading to more adverse reactions (e.g. bleeding with NSAIDs/anticoagulants, altered mental status with anticholinergic/sympathomimetic/anti-Parkinsonian drugs)

**Polypharmacy****Definition**

- prescription, administration, or use of more medications than are clinically indicated

**Epidemiology**

- in Canada, >60% of older adults reported using  $\geq 5$  medications
- hospitalized older adults are given an average of 10 medications during admission

**Risk Factors for Polypharmacy**

- patient-level risk factors: age, female sex, cognitive impairment, frailty, mental health conditions, multiple chronic conditions, lack of primary care physician, residing in LTC, multiple pharmacies
- systems-level risk factors: multiple prescribers, poor documentation systems, automated refill systems, lack of systematic medication review

**Risk Factors for Non-Compliance**

- greater number of medications (compliance with 1 medication is 80%, but drops to 25% with  $\geq 6$  medications)
- increased dosing frequency, complicated container design, financial constraints, and cognitive impairment

**Adverse Drug Reactions (ADRs)**

- any noxious or unintended response to a drug that occurs at doses used for prophylaxis or therapy
- risk factors in older adults
  - intrinsic: comorbidities ( $>5$ ), age  $>85$ , low BMI, age-related changes in pharmacokinetics and pharmacodynamics, CrCl  $<50$  mL/min
  - extrinsic: number of medications ( $>9$  medications,  $>12$  doses/d), multiple prescribers, unreliable drug history, prior ADR
- prescribing cascade: process whereby an ADR is misinterpreted as a new medical condition, and a subsequent drug is prescribed to treat the initial drug-induced event. Providers should ask themselves:
  - is the new drug being prescribed to address an adverse event from a previously prescribed drug therapy?
  - is the initial drug therapy really needed, especially if leading to a drug cascade?
  - do the benefits of the initial drug therapy outweigh the harms?

**Preventing Polypharmacy**

- consider drug: safer side effect profiles, convenient dosing schedules, convenient route, efficacy
- consider patient: other medications, clinical indications, medical comorbidities
- consider patient-drug interaction risk factors for ADRs
- review drug list regularly to eliminate medications with no clinical indication or with evidence of toxicity
- avoid treating an ADR with another medication

**Inappropriate Prescribing in Older Adults****Epidemiology**

- the estimated prevalence of potentially inappropriate prescribing ranges from 12-40%

**Beers Criteria**

- a list of medications to avoid in adults  $\geq 65$  yr due to safety concerns
- 2019 update lists drugs that are inappropriate in most older adults, those that should typically be avoided with certain conditions, drugs to use with caution, drug-drug interactions, and drug dose adjustment based on kidney function
- examples include long-acting benzodiazepines, strong anticholinergics, high-dose sedatives
- older adults are often under-treated (ACEI, ASA,  $\beta$ -blockers, thrombolytics, oral anticoagulants)

**STOPP/START Criteria**

- another screening tool for potentially inappropriate prescribing in older adults
- STOPP: Screening Tool of Older Person's Prescriptions
  - systems-based list of medications contraindicated in adults  $\geq 65$  yr in the context of their diagnoses
- START: Screening Tool to Alert physicians to Right Treatment
  - systems-based list of medications indicated in adults  $\geq 65$  yr in the context of their diagnoses

New medications: Start Low, Go Slow!  
Avoid starting 2 drugs at the same time.

Adverse drug reactions in older adults may present as delirium, falls, fractures, urinary incontinence/retention, or fecal incontinence/impaction.

Principles for Prescribing in Older Adults

**CARED**

Caution/Compliance  
Age (adjust dosage for age)  
Review regimen regularly  
Educate

Discontinue unnecessary medications  
Geriatric Pearls. Philadelphia: FA Davis Company, 1999

Inappropriate prescribing in older persons: A systematic review of medications available in different criteria

Arch Gerontol Geriatr 2017;68:55-61

**Purpose:** Comprehensive review of all potentially inappropriate medications for older persons, included in prescribing criteria of the last decade.

**Results:** From 778 articles, 14 criteria were included in the final analysis, including a total of 729 medication classes among all analyzed criteria. Diazepam was included in all 14 criteria, followed by amitriptyline in 13 criteria and doxepin in 12 criteria. Benzodiazepines, antihistamines, and antipsychotics were the most common drugs reported as potentially inappropriate for older adults, among final criteria.

**Conclusion:** Benzodiazepines, NSAIDs, antihistamines, and antipsychotics were the most common drugs reported as potentially inappropriate for older persons.

## Common Medications

Table 10. Common Medications

Drug Name	Brand Name	Dosing Schedule	Indications	Contraindications	Side Effects	Mechanism of Action
<b>Cognitive Enhancers</b>						
donepezil	Aricept <sup>®</sup>	5-10 mg PO once daily	Moderate to severe dementia of Alzheimer's type	Known hypersensitivity, caution in untreated obstructive airway disease, cardiac conduction abnormalities, active PUD or occult GI bleed, seizure disorder, syncope NYD	N/V, diarrhea, anorexia, insomnia, fatigue, muscle cramps, syncope, bradycardia (uncommon), heart block (uncommon)	Reversible inhibition of acetylcholinesterase
galantamine	Reminyl <sup>®</sup>	8-12 mg PO BID	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, caution in untreated obstructive airway disease, cardiac conduction abnormalities, active PUD or occult GI bleed, seizure disorder, syncope NYD	N/V, diarrhea, anorexia, weight loss, headache, dizziness, syncope, heart block (rare), seizure (rare), delirium (rare)	Reversible inhibition of acetylcholinesterase
rivastigmine	Exelon <sup>®</sup>	1.5 mg PO BID (starting) up to 6-12 mg PO BID	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, severe hepatic disease, caution in untreated obstructive airway disease, cardiac conduction abnormalities, active PUD or occult GI bleed, seizure disorder, syncope NYD	N/V, diarrhea, headache, dizziness, anorexia, insomnia, weight loss, delirium, heart block (rare)	Acetylcholinesterase inhibition (reversible but very slow)
memantine	Ebixa <sup>®</sup> /Namenda <sup>®</sup> (Can)/(U.S.)	5 mg PO once daily (starting) up to 10 mg PO BID	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, conditions that alkalinize urine, caution in renal failure, seizures	Dizziness, headache, hypertension, constipation, confusion, hallucinations	NMDA-receptor antagonist
<b>Laxatives</b>						
bran	All-Bran <sup>®</sup>	1 cup PO once daily	Constipation		Bloating, flatus	Bulk-forming laxative
psyllium	Metamucil <sup>®</sup> Prodiem <sup>®</sup> Plain <sup>®</sup>	3.4 g PO once daily to TID	Constipation, hypercholesterolemia	N/V, abdominal pain, obstruction if another medication is taken within 2 h	Bloating, flatus	Bulk-forming laxative
lactulose	Chronulac <sup>®</sup> Cephulac <sup>®</sup> Kristalose <sup>®</sup> (U.S.) Acilac <sup>®</sup> ; Apo-Lactulose <sup>®</sup> ; Laxilose <sup>®</sup> ; PMS-Lactulose <sup>®</sup> (Can)	15-30 cc PO once daily/BID and 5-10 mL PO BID for 2-4 wk for bowel evacuation after barium exam	Constipation, hepatic encephalopathy, bowel evacuation following barium exam	Patients on low galactose diets, abdominal pain, N/V	Flatus, cramps, nausea, diarrhea	Osmotic laxative
PEG 3350 (polyethylene glycol)	Lax-A-Day <sup>®</sup> ; RestoraLAX <sup>®</sup> ; Pegalax <sup>®</sup> (Can) Gavilax <sup>®</sup> ; HealthyLax <sup>®</sup> (U.S.)	17 g PO once daily (~1 heaping tablespoon) dissolved in 1 cup (250 mL) of beverage	Constipation, bowel prep (different dosing schedule)	Known/suspected bowel obstruction, known hypersensitivity, renal impairment	Abdominal cramps, bloating of the stomach, diarrhea, flatulence, nausea	Osmotic laxative
senna	Senokot <sup>®</sup> /Ex-lax <sup>®</sup>	2-4 tablets PO once daily or 10-15 mL syrup once daily/BID. Dosing should be the smallest required to pass soft stool	Constipation	Known/suspected bowel obstruction or abnormal constriction, atonic bowel, IBD, abdominal pain NYD, rectal bleeding NYD, severe dehydration	Abdominal cramps, N/V, diarrhea, urine and/or fecal discoloration	Stimulant laxative
bisacodyl	Dulcolax <sup>®</sup>	5-15 mg PO (10 mg PR)	Constipation	Acute GI diseases (e.g. appendicitis, diarrhea), ileus, obstruction, abdominal pain, N/V, severe dehydration, and ulcerative proctitis and/or anal fissures if PR	Abdominal cramps, pain, diarrhea, dehydration, dizziness, N/V	Stimulant laxative

Parkinsonian Agents – see *Neurology*, Table 26, N57

Note: Docusate has been shown to be ineffective for the prevention/treatment of constipation in older adults

## Landmark Geriatric Medicine Trials

Trial Name	Reference	Clinical Trial Details
<b>FRAILITY</b>		
Gait Speed and Survival in Older Adults, Studenski et al. 2011	JAMA 2011;305:50-58	<p><b>Title:</b> Gait Speed and Survival in Older Adults  <b>Purpose:</b> Evaluate the relationship between gait speed and survival.  <b>Methods:</b> Pooled analysis of 9 cohort studies of adults &gt;65 yr with baseline gait speed data, followed up for 6-21 yr. The main outcomes were survival and life expectancy.  <b>Results:</b> The overall 5-yr survival was 84.8% and 10-yr survival was 59.7%. Gait speed was associated with survival in all studies (pooled hazard ratio per 0.1 m/s, 0.88; 95% CI 0.87 to 0.90; P&lt;0.001). Survival increased across the range of gait speeds with significant increments at 0.1 m/s.  <b>Conclusions:</b> Gait speed was associated with 10-yr survival in all studies, with considerable variability in predicted 10-yr survival across the range of gait speeds, at 75 yr.</p>
Frailty in Older Adults: Evidence for a Phenotype, Fried et al. 2001	J Gerontol A Biol Sci Med Sci 2001;56(3): M146-56	<p><b>Title:</b> Frailty in Older Adults: Evidence for a Phenotype  <b>Purpose:</b> Develop phenotype of frailty as a clinical syndrome.  <b>Methods:</b> Baseline and annual follow-up for outcomes of incident disease, hospitalization, falls, disability, and mortality in an original cohort of 4735 participants and later-recruited cohort of 582 African American participants. All participant data from the prospective observational Cardiovascular Health Study.  <b>Results:</b> Frailty may be defined as the presence of three or more of: unintentional weight loss (10 lbs in past yr), self-reported exhaustion, weakness (grip strength), slow walking speed, low physical activity. Frailty is associated with increased risk of comorbidity and disability.  <b>Conclusions:</b> Frailty in community-dwelling older adults may be defined as above. While comorbidity is a risk factor for frailty and disability is an outcome of frailty, frailty itself does not equal comorbidity or disability. Assessment for frailty is vital in identifying patients at increased risk for comorbidity and disability.</p>
REHAB-AF	NEJM 2021;385:203-216	<p><b>Title:</b> Physical Rehabilitation for Older Patients Hospitalized for Heart Failure  <b>Purpose:</b> Investigate interventions to address physical frailty in older patients hospitalized for acute decompensated heart failure.  <b>Methods:</b> Multicenter, randomized, controlled trial to evaluate transitional, tailored, progressive rehabilitation intervention, including four physical-function domains initiated during or soon after heart failure hospitalization and continued post-discharge for 36 sessions. Primary outcome was Short Physical Performance Battery score, and secondary outcome was 6 month rehospitalization rate.  <b>Results:</b> Older adults hospitalized for acute decompensated heart failure produce improved clinical outcomes when treated with this rehabilitation intervention program.</p>
<b>DELIRIUM</b>		
Delirium is a Strong Risk Factor for Dementia in the Oldest-Old: A Population-Based Cohort Study, Davis et al. 2012	Brain 2012;135(9):2809-16	<p><b>Title:</b> Delirium is a Strong Risk Factor for Dementia in the Oldest-Old: A Population-Based Cohort Study  <b>Purpose:</b> Use a true population sample to determine if delirium is an incident risk factor for incident dementia and cognitive decline.  <b>Methods:</b> 553 individuals aged &gt;85 yr were used to assess associations between delirium and incident dementia, as well as decline in MMSE scores. The relationship between dementia common neuropathological markers was modelled and stratified.  <b>Results:</b> Delirium increased the risk of incident dementia (OR 8.7; 95% CI 2.1 to 35), worsened dementia severity (OR 3.1; 95% CI 1.5 to 6.3) and deterioration in global function score (OR 2.8; 95% CI 1.4 to 5.5). Delirium was associated with a loss of 1.0 more MMSE points per yr (95% CI 0.11 to 1.89) than those with no history of delirium.  <b>Conclusions:</b> Delirium is a strong risk factor for incident dementia and cognitive decline in elderly patients</p>
A Multicomponent Intervention to Prevent Delirium in Hospitalized Older Patients, Inouye et al. 1999	NEJM 1999;340:669-676	<p><b>Title:</b> A Multicomponent Intervention to Prevent Delirium in Hospitalized Older Patients  <b>Purpose:</b> Evaluate the effectiveness of a multicomponent strategy for delirium prevention among older inpatients.  <b>Methods:</b> A total of 852 inpatients ≥70 yr were included in the study. In lieu of randomization, prospective individual matching was used to compare patients admitted to an intervention unit vs. one of two usual care units. In the intervention unit, the multicomponent approach sought to address cognitive impairment, sleep deprivation, immobility, visual impairment, hearing impairment, and dehydration.  <b>Results:</b> Delirium developed in 9.9% of patients in the intervention unit, vs. 15% in the usual care unit (95% CI 0.39 to 0.92). Total number of days with delirium (105 d vs. 161 d, P=0.02) and total number of delirium episodes (62 vs. 90, P=0.03) were both lower in the intervention unit.  <b>Conclusions:</b> A multicomponent intervention model aimed at addressing risk factors for delirium in hospitalized older adults is effective at reducing delirium incidence and delirium duration.</p>
<b>FALLS</b>		
PROFET	Lancet 1999;353:93-97	<p><b>Title:</b> Prevention of Falls in the Elderly Trial (Profet): A Randomised Controlled Trial  <b>Purpose:</b> Assess the benefit of a structured interdisciplinary assessment of people who have fallen.  <b>Methods:</b> Patients &gt;65 yr presenting to ED with a fall were randomized to the intervention group (detailed medical and OT-therapy assessment with referral if indicated) or to a control group (usual care only).  <b>Results:</b> The risk of falling was significantly lower in the intervention group compared to the control group (OR 0.39; 95% CI 0.23 to 0.66) as was the risk of fall recurrence (OR 0.33; 95% CI 0.16 to 0.68).  <b>Conclusions:</b> Demonstrates that an interdisciplinary approach to elderly adults with a previous history of falls can significantly decrease the risk of further falls and limit functional impairment.</p>
<b>NEUROCOGNITIVE DISORDERS</b>		
Donepezil and Memantine for Moderate-to-Severe Alzheimer's Disease, Howard et al. 2012	NEJM 2012;366:893-903	<p><b>Title:</b> Donepezil and Memantine for Moderate-to-Severe Alzheimer's Disease  <b>Purpose:</b> Assess the benefits of cholinesterase inhibitors for the long-term treatment of moderate-severe Alzheimer's disease.  <b>Methods:</b> 295 community-dwelling patients with moderate-severe Alzheimer's disease treated with donepezil were randomized to either continue donepezil, discontinue donepezil and start memantine, or continue donepezil and start memantine. The primary outcomes were SMMSE scores and Bristol Activities of Daily Living (BADLS) scores.  <b>Results:</b> Patients assigned to continue donepezil, compared to those who discontinued, had a 1.9 higher average SMMSE score (95% CI 1.3 to 2.5). The score on the BADLS was lower (less impairment) by 3.0 points (95% CI 1.8 to 4.3) (P&lt;0.001 for both comparisons). Patients who received memantine, compared with placebo, had a 1.2 higher average SMMSE score (95% CI 0.6 to 1.8, P&lt;0.001) and BADLS score that was 1.5 points lower (95% CI 0.3 to 2.8; P=0.02).  <b>Conclusions:</b> Continued treatment with donepezil was associated with cognitive benefits over the course of 12 mo in patients with moderate or severe Alzheimer's disease.</p>

Trial Name	Reference	Clinical Trial Details
<b>HYPERTENSION IN THE ELDERLY</b>		
Syst-Eur	Lancet 1997;350:757-64	<b>Title:</b> Randomised Double-blind Comparison of Placebo and Active Treatment for Older Patients with Isolated Systolic Hypertension. The Systolic Hypertension in Europe (Syst- eur) Trial Investigators <b>Purpose:</b> Investigate whether active treatment could reduce CV complications of isolated systolic HTN. <b>Methods:</b> Patients >60 yr were randomly assigned to nitrendipine 10-40 mg daily with the possible addition of enalapril 5-20 mg daily and hydrochlorothiazide 12.5-25 mg daily, or to matching placebos. Combined fatal and nonfatal stroke was the primary endpoint. <b>Results:</b> Active treatment reduced the total rate of stroke from 13.7 to 7.9 endpoints per 1000 patient-years (43% reduction; P=0.003). Nonfatal stroke reduced by 44% (P=0.007) and nonfatal cardiac endpoints decreased by 33% (P=0.03). All-cause mortality was not influenced. <b>Conclusions:</b> Among elderly patients with isolated systolic hypertension, antihypertensive drug treatment starting with nitrendipine reduces the rate of cardiovascular complications.
HYVET	NEJM 2008;358:1887-98	<b>Title:</b> Treatment of Hypertension in Patients 80 Years of Age or Older <b>Purpose:</b> Determine whether treatment of hypertension is beneficial in patients >80 yr. <b>Methods:</b> 3845 patients >80 yr and a sustained sBP >160 mmHg were randomized to receive indapamide SR 1.5 mg or matching placebo. The ACEI perindopril 2 or 4 mg was added if necessary, to achieve the target BP of 150/80 mmHg. The primary endpoint was fatal or nonfatal stroke. <b>Results:</b> The mean BP at 2 yr was 15.0/6.1 mmHg lower in the active-treatment group than in the placebo group. Active treatment was associated with a 30% reduction in the rate of death from stroke (95% CI 1 to 62; P=0.05), a 21% reduction in all-cause mortality (95% CI; 4 to 35; P=0.02). Fewer adverse events were reported in the active-treatment group. <b>Conclusions:</b> Antihypertensive treatment with indapamide (sustained release), with or without perindopril, in adults >80 yr is beneficial.
<b>INAPPROPRIATE PRESCRIBING IN THE ELDERLY</b>		
EMPOWER	JAMA Intern Med 2014;174:890-98	<b>Title:</b> Reduction of Inappropriate Benzodiazepine Prescriptions Among Older Adults Through Direct Patient Education: The Empower Cluster Randomized Trial <b>Purpose:</b> Compare the effect of direct-to-consumer education against usual care on benzodiazepine discontinuation in older adults. <b>Methods:</b> 303 long-term users of benzodiazepines aged 65-95 were randomized to the educational intervention (deprescribing patient empowerment intervention explaining risks of benzodiazepine use and a stepwise taper protocol) or the 'wait list' control. Primary outcomes were benzodiazepine discontinuation after 6 mo. <b>Results:</b> At 6 mo, 27% of patients in the intervention group had discontinued benzodiazepines, compared with 5% in the control group (risk difference 23%; 95% CI 14% to 32%). <b>Conclusions:</b> Direct-to-consumer education describing the risks of benzodiazepine use and a stepwise tapering protocol effectively elicits shared decision making and discontinuation of medications that increase the risk of harm in older adults.
STOPP and START	Int J Clin Pharmacol Ther 2008;46:72-83	<b>Title:</b> STOPP (Screening Tool of Older Person's Prescriptions) and START (Screening Tool to Alert doctors to Right Treatment). Consensus validation <b>Purpose:</b> Validate a new screening tool of older persons' prescriptions, incorporating criteria for potentially inaccurate prescriptions (called STOPP), and criteria for appropriate prescriptions (called START). <b>Methods:</b> A Delphi consensus technique was used to obtain validity from an 18-member expert panel. Inter-rater reliability was assessed by determining the kappa-statistic on 100 datasets. <b>Results:</b> STOPP consists of 65 clinically significant criteria for potentially inappropriate prescriptions; START consists of 22 evidence-based prescribing indicators. <b>Conclusions:</b> STOPP/START is a valid, reliable, and comprehensive screening tool that enables the prescribing physician to appraise an older patient's prescription drugs in the context of his/her concurrent diagnoses.

## Acronyms

ACEI	angiotensin converting enzyme inhibitors	GA	gestational age	IVM	in vitro maturation		quantification
AFP	$\alpha$ -fetoprotein	GIFT	gamete intrafallopian transfer	JRA	juvenile rheumatoid arthritis	PV	per the vagina administration
AIS	androgen insensitivity syndrome	GnRH	gonadotropin-releasing hormone	LEEP	loop electrosurgical excision procedure	RPR	rapid plasma reagin
AMH	anti-mullerian hormone	GTD	gestational trophoblastic disease	LHRH	luteinizing hormone-releasing hormone	RR	risk ratio
ARB	angiotensin II receptor blockers	GTN	gestational trophoblastic neoplasia	LMP	last menstrual period	SCC	squamous cell carcinoma
ASCUS	atypical squamous cells of undetermined significance	HERS	heart and estrogen/progestin replacement study	LN	lymph node	SERM	selective estrogen receptor modulator
AUB	abnormal uterine bleeding	HMG	human menopausal gonadotropin	LNMP	last normal menstrual period	SHBG	sex hormone binding globulin
BMD	bone mineral density	HPO	hypothalamic-pituitary-ovarian	LSIL	low grade squamous intraepithelial lesion	SHG	sonohysterography
BSO	bilateral salpingo-oophorectomy	HPV	human papillomavirus	LVSI	lymphovascular space involvement	SPRM	selective progesterone receptor modulator
BUC	buccal administration	HRT	hormone replacement therapy	MHT	menopause hormone therapy	SSRIs	selective serotonin reuptake inhibitor
BV	bacterial vaginosis	HSG	hysterosalpingography	MRKH	Mayer-Rokitansky-Küster-Hauser	TAH	total abdominal hysterectomy
CA-125	cancer antigen 125	HSIL	high grade squamous intraepithelial lesion	MTX	methotrexate	TET	tubal embryo transfer
CAH	congenital adrenal hyperplasia	HSV	herpes simplex virus	NK	natural killer	TH	total hysterectomy
CHC	combined hormonal contraception	IBD	inflammatory bowel disease	OC	oral contraceptive pill	TOT	tension-free transobturator tape
CMV	cytomegalovirus	ICSI	intracytoplasmic sperm injection	OGTT	oral glucose tolerance test	TVT	tension-free vaginal tape
CRP	C-reactive protein	ITP	immune thrombocytopenic purpura	PCOS	polycystic ovarian syndrome	TZ	transformation zone
DES	diethylstilbestrol	IUD	intrauterine device	PG	prostaglandin	UAE	uterine artery embolization
DHEA	dehydroepiandrosterone	IUI	intrauterine insemination	PID	pelvic inflammatory disease	VIN	vulvar intraepithelial neoplasia
DMPA	depot medroxyprogesterone acetate or Depo-Provera <sup>®</sup>	IUS	intrauterine system	PMB	postmenopausal bleeding	VTE	venous thromboembolism
DUB	dysfunctional uterine bleeding	IVDU	intravenous drug use	PMDD	premenstrual dysphoric disorder	VWD	von Willebrand disease
DVT	deep venous thrombosis	IVF	in vitro fertilization	PMN	polymorphonuclear neutrophils	W/D	withdrawal
EPC	emergency postcoital contraception			PMS	premenstrual syndrome	WHI	Women's Health Initiative
ESR	erythrocyte sedimentation rate			POP-Q	pelvic organ prolapse	ZIFT	zygote intrafallopian transfer

## Basic Anatomy Review

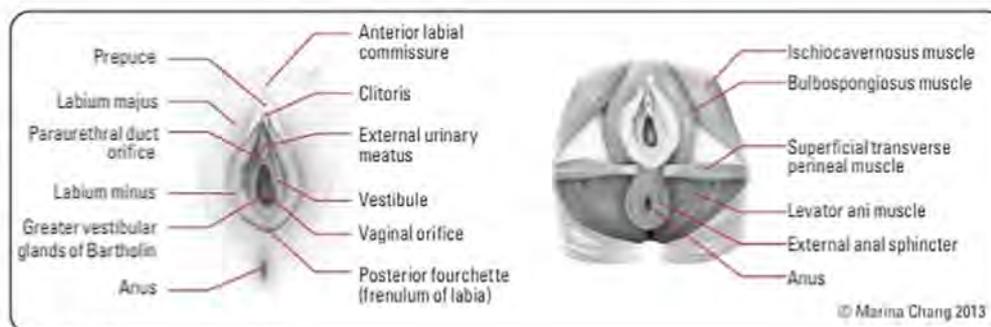

Figure 1. Vulva and perineum

### A. External Genitalia

- blood supply: internal pudendal artery, superficial external pudendal artery (labia majora)
- sensory innervation: pudendal nerve
- lymphatic drainage: superficial inguinal lymph nodes, deep inguinal lymph nodes (clitoris)

### B. Vagina

- muscular canal extending from cervix to vulva, anterior to rectum, and posterior to bladder
- lined by rugated, stratified squamous epithelium
- upper vagina separated by cervix into anterior, posterior, and lateral fornices
- blood supply: vaginal branch of internal pudendal artery with anastomoses from uterine, inferior vesical, and middle rectal arteries

### C. Uterus

- thick walled, muscular organ between bladder and rectum, consisting of two major parts:
  - uterine corpus, made up of the isthmus, fundus, and body
    - blood supply: uterine artery (branch of the internal iliac artery, anterior division)
  - cervix
    - blood supply: cervical branch of uterine artery
- supported by the pelvic diaphragm, the pelvic organs, and four paired sets of ligaments
  - round ligaments: travel from anterior surface of uterus, through broad ligaments, and inguinal canals (canal of Nuck) then terminate in the labia majora
    - function: anteversion/suspension
    - blood supply: Sampson's artery (branch of uterine artery running through round ligament)
  - uterosacral ligaments: arise from sacral fascia and insert into posterior inferior uterus
    - function: mechanical support for uterus, prevent prolapse, and contain autonomic nerve fibres

- cardinal ligaments: extend from lateral pelvic walls and insert into lateral cervix and vagina
  - function: mechanical support, prevent prolapse
- broad ligaments: pass from lateral pelvic wall to sides of uterus; contain fallopian tube, round ligament, ovarian ligament, nerves, vessels, and lymphatics. Within the broad ligament, the uterine artery anastomoses with the ovarian artery
- infundibulopelvic ligament (suspensory ligament of the ovary): continuous tissue that connects ovary to pelvic wall
  - contains the ovarian artery, ovarian vein, ovarian plexus, and lymphatic vessels
- position of the uterus
  - anteverted (majority), retroverted, neutral
  - anteflexed (more common), retroflexed

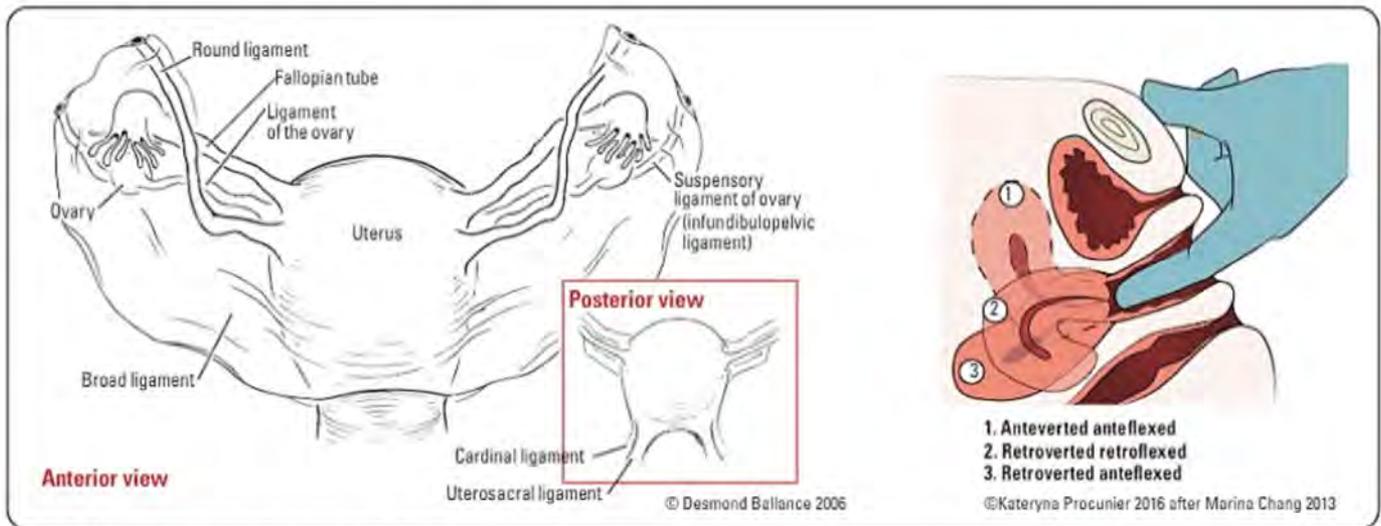

Figure 2. Genital organs and positioning of the uterus

**D. Fallopian Tubes**

- 8-14 cm muscular tubes extending laterally from the uterus to the ovary
- interstitial, isthmic, ampullary, and infundibular segments; terminates at fimbriae
- mesosalpinx: peritoneal fold that attaches fallopian tube to broad ligament
- blood supply: uterine and ovarian arteries

**E. Ovaries**

- consist of cortex with ova and medulla with blood supply
- supported by infundibulopelvic ligament (suspensory ligament of ovary)
- mesovarium: peritoneal fold that attaches ovary to broad ligament
- blood supply: ovarian arteries (branches off of aorta), left ovarian vein (drains into left renal vein), right ovarian vein (drains into inferior vena cava)

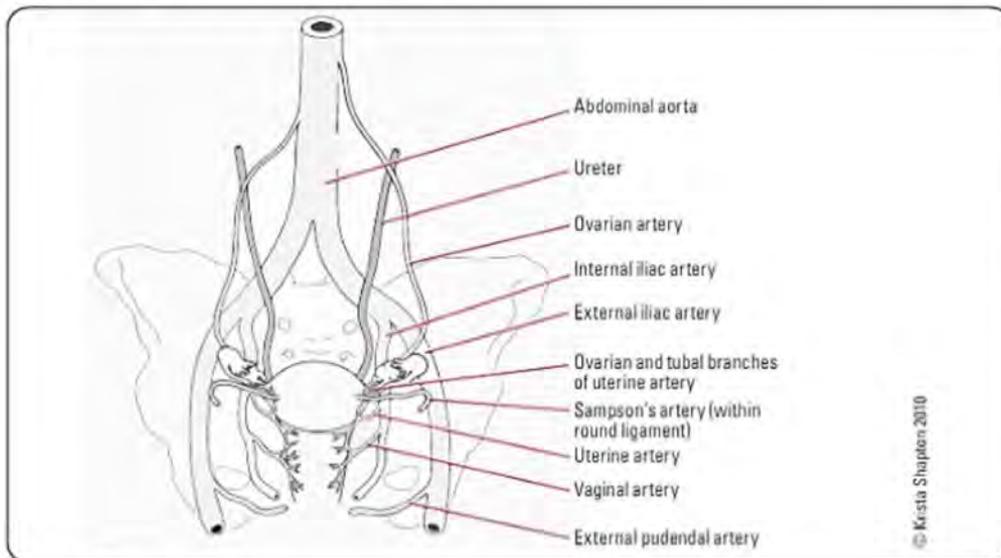

Figure 3. Vascular supply

**Determination of Uterine Position by Clinical Exam**

- If cervix faces anteriorly (under the urethra and less easily accessible), i.e. toward vaginal orifice, more likely **RETROVERTED UTERUS**
- If cervix faces posteriorly (easily accessible), i.e. toward sacrum or rectum, more likely **ANTEVERTED UTERUS**
- If uterus palpable on bimanual exam, more likely **ANTEVERTED UTERUS**
- If uterus palpable behind the cervix in the posterior fornix, more likely **RETROVERTED UTERUS**

**"Water Under the Bridge"**  
The ureters run posterior to the uterine arteries

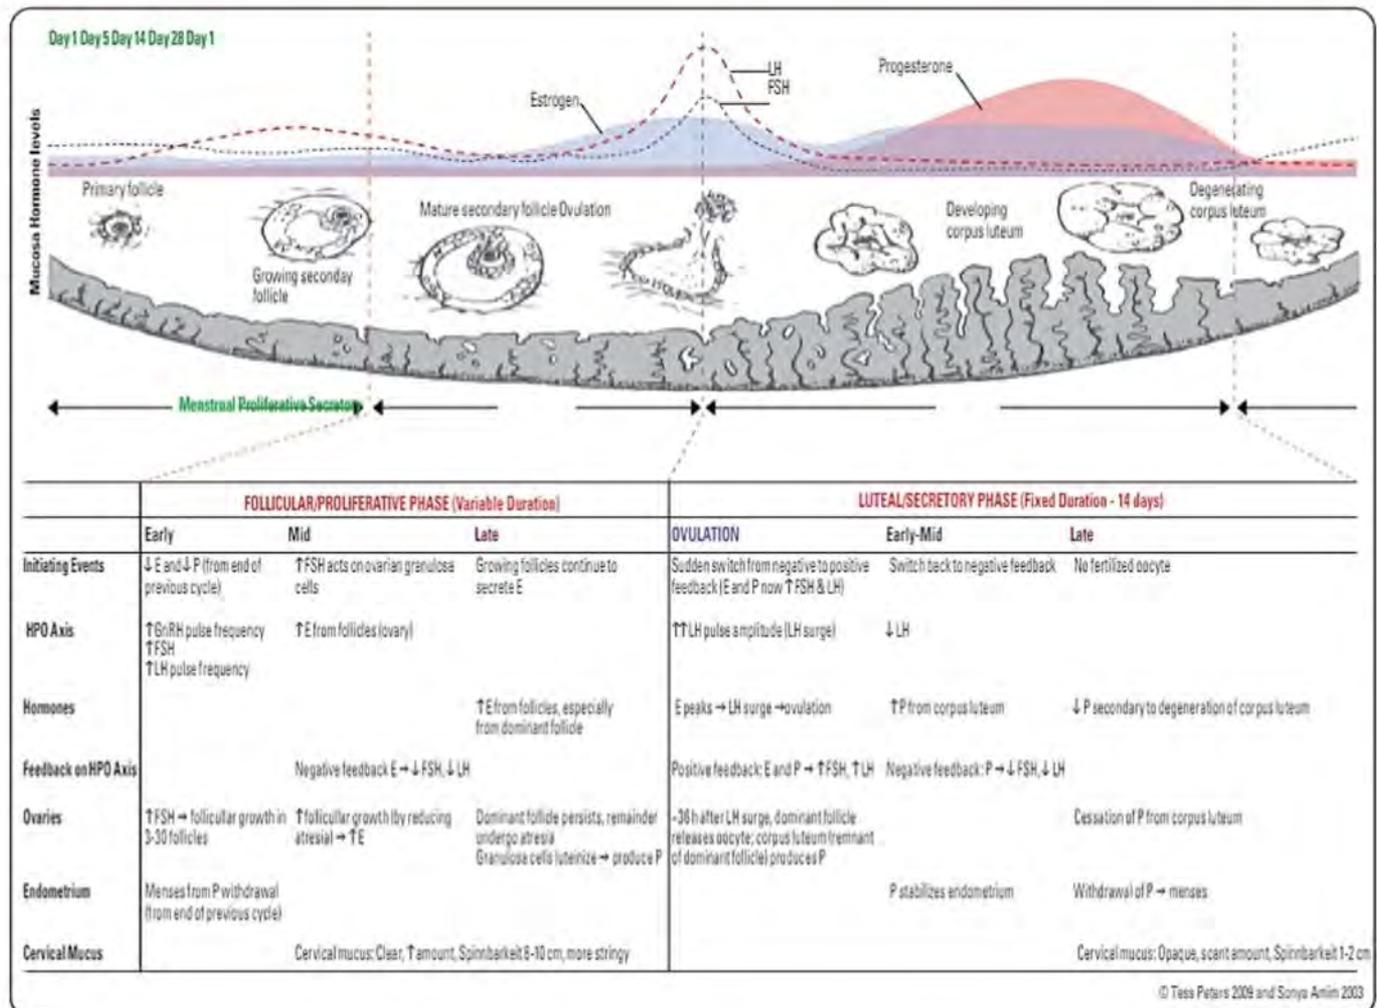

**Common Anatomy Questions in the OR**

- What is the origin of the left and right ovarian arteries?**  
Descending aorta
- What are the drainage sites for the left and right ovarian veins?**  
Left to left renal vein, right to inferior vena cava
- What is the most common place to locate the ureter?**  
In the pelvic brim, the ureter passes over the iliac vessels. The ureter can also be found near the medial leaf of the broad ligament where the ureter runs under the uterine artery
- Which artery runs under the round ligament?**  
Sampson's artery

# Menstruation

## Menstrual Cycle

### CHARACTERISTICS

- Menarche 10-15 yr
- Average 12.2 yr
- Entire cycle 28 ± 7 d with bleeding for 1-6 d
- 25-80 mL blood loss per cycle

### ESTROGEN

ESTROGEN is the main hormone in the follicular/proliferative phase and is stimulated by FSH. As the level increases it acts negatively on FSH. The majority of estrogen is secreted by the dominant follicle

#### Estrogen effects

- On the follicles in the ovaries: reduces atresia
- On the endometrium: proliferation of glandular and stromal tissue
- On all target tissues: decreases estrogen receptors

### PROGESTERONE

PROGESTERONE is the main hormone in the luteal/secretory phase and is stimulated by LH. Increased progesterone acts negatively on LH and is secreted by the corpus luteum (remnant of dominant follicle)

#### Progesterone effects

- On the endometrium: cessation of mitoses (stops building endometrium up), "organization" of glands (initiates secretions from glands), inhibits macrophages, interleukin-8, and enzymes from degrading endometrium
- On all target tissues: decrease estrogen receptors (the "anti-estrogen" effect), decrease progesterone receptors

Figure 4. Events of the normal menstrual cycle

E = estrogen; FSH = follicle-stimulating hormone; GnRH = gonadotropin-releasing hormone; HPO = hypothalamic-pituitary-ovarian; LH = luteinizing hormone; P = progesterone

## Stages of Puberty

- see [Paediatrics, P36](#)
- adrenarche: increased secretion of adrenal androgens; usually precedes gonadarche by 2 yr
- gonadarche: increased secretion of gonadal sex steroids; ~age 8 yr
- thelarche: breast development
- pubarche: pubic and axillary hair development
- menarche: onset of menses, usually following peak height velocity and/or 2 yr following breast budding

### Stages of Puberty

"Boobs, Pubes, Grow, Flow"  
Thelarche, Pubarche, Growth spurt, Menarche

### Tanner Stage

#### Thelarche

1. None
2. Breast bud
3. Further enlargement of areolae and breasts with no separation of contours
4. 2° mound of areolae and papilla
5. Areolae recessed to general contour of breast

#### Pubarche

1. None
2. Downy hair along labia only
3. Darker/coarse hair extends over pubis
4. Adult-type hair with no thigh involvement
5. Adult hair in distribution and type; extends over thighs. Not all patients achieve Tanner Stage 5. For image see [Paediatrics, P37](#)

## Premenstrual Syndrome

- physiological and emotional disturbances that occur 1-2 wk prior to menses and last until a few days after onset of menses; common symptoms include depression, irritability, tearfulness, and mood swings
- synonyms: "ovarian cycle syndrome," "menstrual molimina" (moodiness)

### Etiology

- multifactorial: not completely understood; genetics likely play a role
- CNS-mediated neurotransmitter (serotonin, dopamine, GABA) interactions with sex steroids (progesterone, estrogen, and testosterone)
- serotonergic dysregulation – currently most plausible theory

### Diagnostic Criteria for Premenstrual Syndrome

- at least one affective and one somatic symptom during the 5 d before menses in each of the three prior menstrual cycles
  - affective: depression, angry outbursts, irritability, anxiety, confusion, social withdrawal
  - somatic: breast tenderness or swelling, abdominal bloating, headache, swelling of extremities, joint or muscle pain, weight gain, fatigue
- symptoms relieved within 4 d of onset of menses and do not recur until at least day 13 of cycle
- symptoms present in the absence of any pharmacologic therapy, hormone ingestion, drug, or alcohol use
- symptoms occur reproducibly during 2 cycles of prospective recording
- patient suffers from identifiable dysfunction in social or occupational performance
- consider a PRISM (Prospective Record of the Impact and Severity of Menstrual symptoms) calendar to monitor symptoms and confirm diagnosis particularly with 3rd line treatment

### Premenstrual Syndrome Treatment

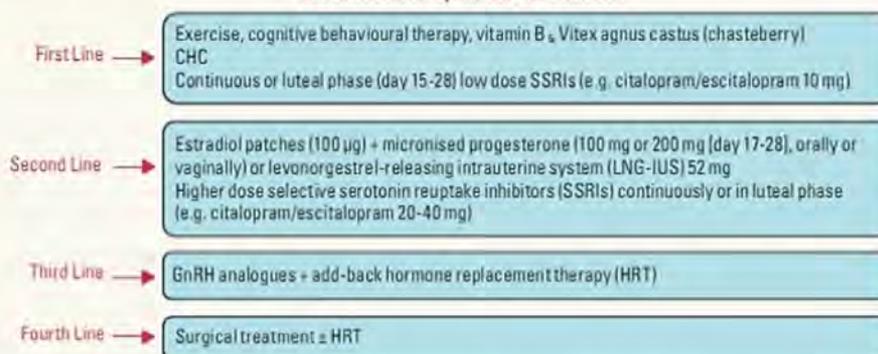

Figure 5. Royal College of Obstetricians and Gynaecologists (RCOG) guidelines for treatment of premenstrual syndrome

Adapted from source: Management of Premenstrual Syndrome. *Brit J Obstet Gynaec* 2016;48:1-33.

## Premenstrual Dysphoric Disorder

### Definition

- PMDD is similar to PMS but causes more severe symptoms and impairment of functioning

### Clinical Features

- irritability and depressed mood
- breast pain and abdominal bloating

### Diagnostic Criteria for Premenstrual Dysphoric Disorder

- at least 5 of the following 11 symptoms during most menstrual cycles of the last year (with at least 1 of the first 4)
  - depressed mood or hopelessness
  - anxiety or tension
  - affective instability

- anger or irritability
- decreased interest in activities
- difficulty concentrating
- lethargy
- change in appetite
- hypersomnia or insomnia
- feeling overwhelmed
- physical symptoms: breast tenderness/swelling, headaches, joint/muscle pain, bloating, or weight gain
- symptoms cause significant distress and/or interfere with social or occupational functioning
- symptoms must be present during the week prior to menses and resolve within a few days after onset of menses
- may be superimposed on other psychiatric disorders, provided it is not merely an exacerbation of another disorder

## Common Investigations and Procedures

### Imaging

#### Ultrasound

- transabdominal or transvaginal U/S is the imaging modality of choice for pelvic structures
- transvaginal U/S provides better resolution of uterus and adnexal structures
  - detects early pregnancy if  $\beta$ -hCG  $\geq 1500$  ( $\beta$ -hCG must be  $\geq 6500$  for transabdominal U/S)
- may be used to identify pelvic pathology
  - identify ectopic pregnancy, intrauterine pregnancy
  - assess uterine, adnexal, cul-de-sac, and ovarian masses (e.g. solid or cystic)
  - determine endometrial thickness, locate/characterize fibroids
  - detection of deep infiltrating endometriosis
  - monitor follicles during assisted reproduction
  - assess endometrial lining in postmenopausal women

### Endometrial Biopsy

- performed in the office using an endometrial suction curette (pipelle) guided through the cervix to aspirate fragments of endometrium
- pre-treatment with misoprostol (Cytotec\*) is optional (works better in premenopausal patients)
- more invasive procedure (i.e. D&C) may be done in the office or operating room  $\pm$  hysteroscopy (this may be required if endometrial biopsy is not possible in the office setting or if there is suspicion for an endometrial polyp)
- indications
  - AUB/PMB
    - age  $>40$
    - risk factors for or history of endometrial cancer
    - failure of medical treatment
    - significant intermenstrual bleeding
    - consider in women with infrequent menses suggesting anovulatory cycles

### Hysterectomy

#### Indications

- uterine fibroids
- endometriosis, adenomyosis
- uterine prolapse
- pelvic pain
- AUB
- cancer (endometrium, ovaries, fallopian tubes, cervix)

#### Complications

- general anesthetic
- bleeding
- infection
- injury to other organs (ureter, bladder, rectum)
- loss of ovarian function (if ovaries removed, iatrogenic menopause)
- venous thromboembolism

#### No. 377 - Hysterectomy for Benign

##### Gynaecological Indications

J Obstet Gynaecol Can 2019;41(4):543-557

##### Summary:

1. Hysterectomy should be approached by either vaginal, laparoscopic, or open routes.
2. Correction of preoperative anemia (hemoglobin (Hb)  $<120$  g/L), preoperative antibiotic prophylaxis, and measures to decrease risk of venous thromboembolism are recommended.
3. In patients with endometriosis, full excision of local endometriosis should be performed concurrently.
4. Opportunistic salpingectomy can be considered at the time of hysterectomy, but the planned surgical approach should not be changed for this sole purpose.
5. Urinary tract injury is a known complication of hysterectomy and there should be a low threshold for further investigation in cases where injury is suspected – consider routine cystoscopy.
6. Women should be counselled about the benefits and risks of removing the ovaries, the risk of ovarian cancer vs. the long-term health implications of earlier menopause.

### Approaches

1. open (abdominal approach): uterus removed via transverse (Pfannenstiel) or midline laparotomy
2. minimally invasive approaches
  - vaginal hysterectomy: entire procedure performed through the vagina; no abdominal incisions
  - laparoscopic-assisted vaginal hysterectomy: vascular pedicles are divided by a combination of laparoscopic and vaginal approaches
  - total laparoscopic hysterectomy: all vascular pedicles including the colpotomy approached laparoscopically and removed through the vagina
  - robotic: a type of laparoscopic approach; may be advantageous in patients with a high BMI, but more costly

**Table 1. Classification of Hysterectomy**

Classification	Tissues Removed	Indications
Subtotal Hysterectomy	Uterus	Inaccessible cervix (e.g. adhesions) Patient choice/preference
Total Hysterectomy (TH) (extrafascial simple hysterectomy/type 1)	Uterus, cervix, uterine artery ligated at uterus	Uterine fibroids Endometriosis Adenomyosis Heavy menstrual bleeding DUB
Total Hysterectomy (TH) (extrafascial simple hysterectomy/type 1) and Bilateral Salpingo-Oophorectomy (BSO)	Uterus, cervix, uterine artery ligated at uterus, fallopian tubes, ovaries	Endometrial cancer Malignant adnexal masses Consider for endometriosis
Modified Radical Hysterectomy (type 2)	Uterus, cervix, proximal 1/3 parametria, uterine artery ligated medial to the ureter, midpoint of uterosacral ligaments, and upper 1-2 cm vagina	Cervical cancer (up to stage 1B1)
Radical Hysterectomy (type 3)	Uterus, cervix, entire parametria, uterine artery ligated at its origin from internal iliac artery, uterosacral ligament at most distal attachment (rectum), and upper 1/3-1/2 vagina	Cervical cancer

## Disorders of Menstruation

### Amenorrhea

#### Differential Diagnosis of Amenorrhea

**Table 2. Differential Diagnosis of Primary Amenorrhea**

With Secondary Sexual Development		Without Secondary Sexual Development	
Normal Breast and Pelvic Development	Normal Breast, Abnormal Uterine Development	High FSH (Hypergonadotropic Hypogonadism)	Low FSH (Hypogonadotropic Hypogonadism)
Hypothyroidism	Androgen insensitivity	Gonadal dysgenesis	Constitutional delay (rare in girls)
Hyperprolactinemia	Anatomic abnormalities	Abnormal sex chromosomes (Turner's XO)	Congenital abnormalities
PCOS	Müllerian agenesis, uterovaginal septum, imperforate hymen	Normal sex chromosomes (46XX, 46XY)	Isolated GnRH deficiency
Hypothalamic dysfunction			Pituitary failure (Kallmann syndrome, head injury, pituitary adenoma, etc.)
			Acquired endocrine disorders (type 1 DM)
			Pituitary tumours
			Systemic disorders (IBD, JRA, chronic infections, etc.)
			Functional hypothalamic amenorrhea
			Asherman's Syndrome/uterine defect

#### Primary Amenorrhea

No menses by age 13 in absence of 2° sexual characteristics, or no menses by age 15 with 2° sexual characteristics, or no menses 2 yr after thelarche

#### Secondary Amenorrhea

No menses for >6 mo or 3 cycles after documented menarche

#### Most Common Causes of Primary Amenorrhea

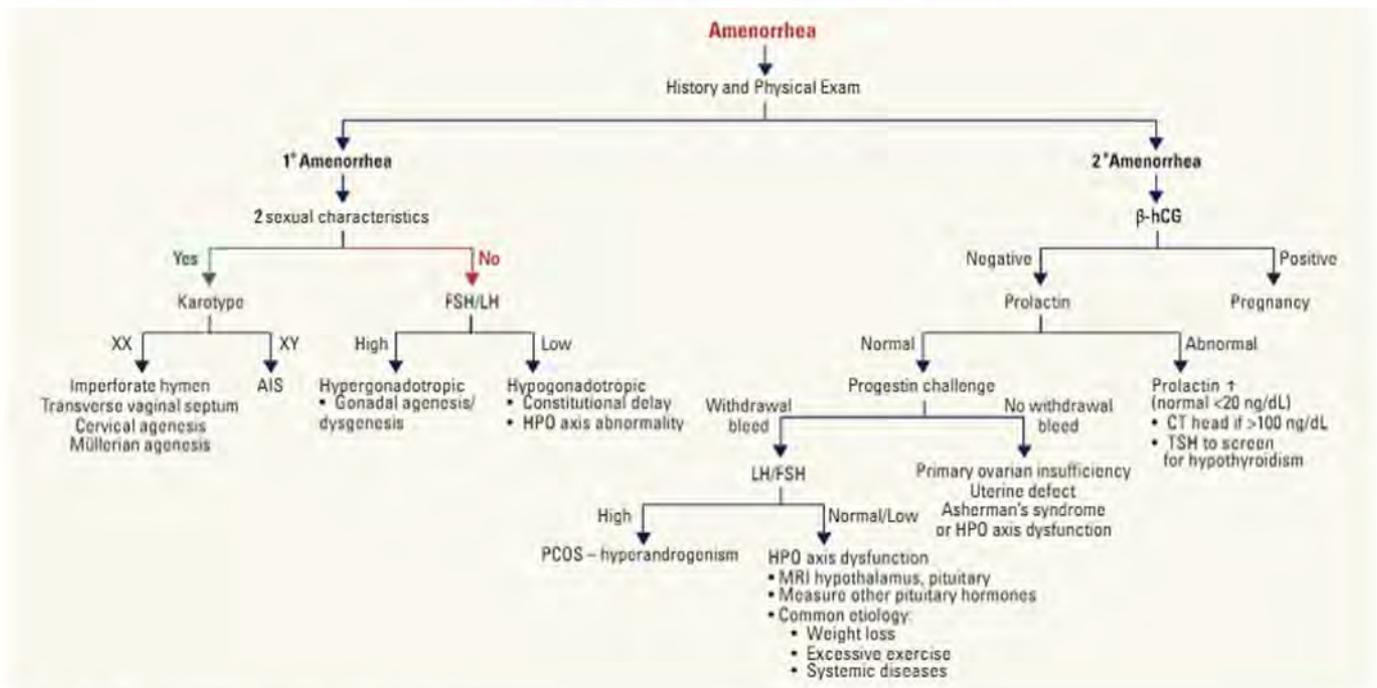

1. Gonadal dysgenesis (e.g. Turner's Syndrome)
2. Functional hypothalamic amenorrhea
3. Müllerian agenesis

**Table 3. Differential Diagnosis of Secondary Amenorrhea**

With Hyperandrogenism	Without Hyperandrogenism
<p>PCOS</p> <p>Autonomous hyperandrogenism (androgen secretion independent of the HPO axis)</p> <p>Ovarian: tumour, hyperthecosis</p> <p>Adrenal androgen-secreting tumour</p> <p>Late onset or mild congenital adrenal hyperplasia (rare)</p>	<p>Pregnancy</p> <p>Hypergonadotropic hypogonadism (i.e. primary ovarian insufficiency: high FSH, low estradiol)</p> <p>Idiopathic</p> <p>Autoimmune: type 1 DM, autoimmune thyroid disease, Addison's disease, celiac disease</p> <p>Iatrogenic: cyclophosphamide drugs, radiation</p> <p>Hyperprolactinemia</p> <p>Endocrinopathies: most commonly hyper or hypothyroidism</p> <p>Hypogonadotropic hypogonadism (low FSH):</p> <p>Pituitary compression or destruction: pituitary adenoma, craniopharyngioma, lymphocytic hypophysitis, infiltration (sarcoidosis), head injury, Sheehan's syndrome</p> <p>Functional hypothalamic amenorrhea (often related to stress, excessive exercise and/or anorexia)</p>

Functional hypothalamic amenorrhea is the most common cause of secondary amenorrhea

**Figure 6. Diagnostic approach to amenorrhea**

**Investigations**

- β-hCG, hormonal workup (TSH, prolactin, FSH, LH, androgens, estradiol)
- progesterone challenge to assess estrogen status
  - medroxyprogesterone acetate (Provera®) 10 mg PO once daily for 10-14 d
  - any uterine bleed within 2-7 d after completion of Provera® is considered to be a positive W/D test
    - W/D bleed suggests presence of adequate estrogen to thicken the endometrium; thus W/D of progesterone results in bleeding
    - if no bleeding occurs, this may be secondary to inadequate estrogen (hypoestrogenism), excessive androgens or progesterones (decidualization), pregnancy, obstructive causes (e.g. cervical stenosis), or structural causes (e.g. uterine adhesions)
- karyotype: indicated if primary ovarian insufficiency or absent puberty
- U/S to confirm normal anatomy, identify PCOS (in adult population only)

**Prolactinoma Symptoms**  
Galactorrhea, visual changes, headache

Treatment

Table 4. Management of Amenorrhea

Etiology	Management
<b>1° AMENORRHEA</b>	
AIS	Gonadal resection after puberty Psychological counselling Creation of neo-vagina with dilation
Anatomical	
Imperforate hymen	Surgical management
Transverse vaginal septum	Surgical management
Cervical agenesis	Suppression and ultimately hysterectomy
Müllerian dysgenesis (MRKH syndrome)	Psychological counselling Creation of neo-vagina with dilation Diagnostic study to confirm normal urinary system and spine
<b>2° AMENORRHEA</b>	
HPO axis dysfunction	Identify modifiable underlying cause Combined OCP to decrease risk of osteoporosis, maintain normal vaginal and breast development (NOT proven to work)
Hyperprolactinemia	MRI/CT head to rule out lesion If no demonstrable lesions by MRI: Bromocriptine, cabergoline if fertility desired Combined OCPs if no fertility desired Demonstrable lesions by MRI: surgical management
Polycystic ovarian syndrome	See <i>Polycystic Ovarian Syndrome, GY24</i>
Premature ovarian failure	Screen for DM, hypothyroidism, hypoparathyroidism, hypocortisolism Hormonal therapy with estrogen and progestin to decrease risk of osteoporosis; can use OCP after induction of puberty
Uterine defect	Evaluation with hysterosalpingography or sonohysterography
Asherman's syndrome	Hysteroscopy: excision of synechiae

2° amenorrhea is pregnancy until proven otherwise

Abnormal Uterine Bleeding

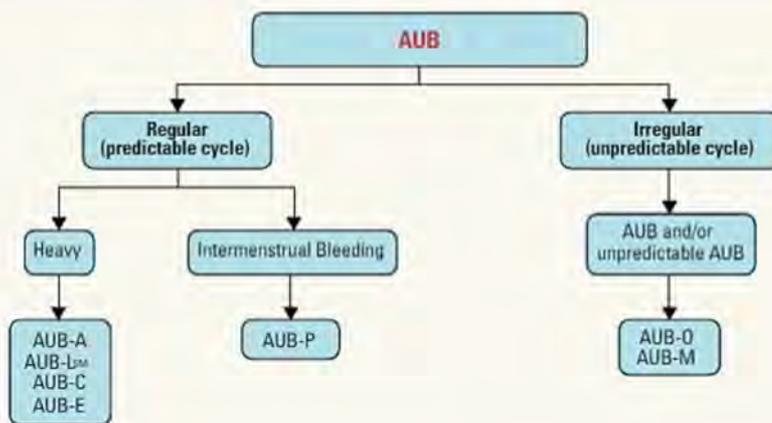

Figure 7. Diagnostic approach to abnormal uterine bleeding

Approach

- menstrual bleeding should be evaluated by ascertaining: frequency/regularity of menses, duration, volume of flow, impact on quality of life, and timing (inter- or premenstrual, or breakthrough)
- is it regular?
  - regular: cycle to cycle variability of <20 d – “Can you predict your menses within 20 days?”
  - irregular: cycle to cycle variability of ≥20 d
- is it heavy?
  - questions: How frequently do pads/tampons need to be changed? How saturated? Any clots?
  - ≥80 cc of blood loss per cycle or
  - ≥8 d of bleeding per cycle or
  - bleeding that significantly affects quality of life

Postmenopausal bleeding is endometrial cancer until proven otherwise

**Abnormal Uterine Bleeding**  
Change in frequency, duration, or amount of menstrual flow that affects quality of life

- is it structural?
  - PALM (see *Table 5*)
- is it non-structural?
  - COEIN (see *Table 5*)

**Table 5. Abnormal Uterine Bleeding – Etiologies, Investigations, and Management**

Etiology	Investigations	Management
<b>STRUCTURAL</b>		
Polyps (AUB-P)	Transvaginal sonography Saline infusion sonohysterography	Polypectomy (triage based on symptoms, polyp size, histopathology, and patient age)
Adenomyosis (AUB-A)	Transvaginal sonography MRI	See <i>Adenomyosis, GY13</i>
Leiomyoma (AUB-L) Submucosal (AUB-Lsm) Other (AUB-Lo)	Transvaginal sonography Saline infusion sonohysterography Diagnostic hysteroscopy MRI	See <i>Fibroids, GY14</i>
Malignancy and Hyperplasia (AUB-M)	Transvaginal sonography Endometrial biopsy for all women >40 yr with AUB, for women <40 yr with persistent AUB, or endometrial cancer risk factors	Dependent on diagnosis
<b>NON-STRUCTURAL</b>		
Coagulopathy (AUB-C)	CBC, coagulation profile (especially in adolescents), VWF, Ristocetin cofactor, factor VII	Dependent on diagnosis (hormonal modulation (e.g. OCP), Mirena IUS, endometrial ablation)
Ovulatory Dysfunction (AUB-O)	Bloodwork: $\beta$ -hCG, ferritin, prolactin, FSH, LH, serum androgens (free testosterone, DHEA), progesterone, 17-hydroxy progesterone, TSH, free T4 Pelvic ultrasound	See <i>Infertility, GY23</i>
Endometrial (AUB-E)	Endometrial biopsy	Tranexamic acid Hormonal modulation (e.g. OCP) Mirena IUS Endometrial ablation
Iatrogenic (AUB-I)	Transvaginal sonography (rule out forgotten IUD) Review OCP/HRT use Review medications (especially neuroleptic use)	Remove offending agent
Not Yet Classified (AUB-N)	—	—

**Treatment**

- resuscitate patient if hemodynamically unstable
- treat underlying disorders
  - if anatomic lesions and systemic disease have been ruled out, consider AUB
- medical
  - mild AUB
    - NSAIDs
    - anti-fibrinolytic (e.g. Cyklokapron<sup>®</sup>) at time of menses
    - combined hormonal contraceptive
    - progestins (Provera<sup>®</sup>) on first 10-14 d of each month or every 3 mo if AUB-O
    - Mirena<sup>®</sup> IUD
    - correct anemia - iron
  - acute, severe AUB
    - replace fluid losses, consider admission
      - a) estrogen (Premarin<sup>®</sup>) 25 mg IV q4 h x 24 h with Gravol<sup>®</sup> 50 mg IV/PO q4 h or anti-fibrinolytic (e.g. Cyklokapron<sup>®</sup>) 10 mg/kg IV q8 h (rarely used)
      - b) tapering OCP regimen, 35  $\mu$ g pill TID x 7 d then taper to 1 pill/d for 3 wk with Gravol<sup>®</sup> 50  $\mu$ g IV/PO q4 h
        - or taper to 1 tab TID x 2 d  $\rightarrow$  BID x 2 d  $\rightarrow$  once daily (more commonly used)
    - after (a) or (b), maintain patient on monophasic OCP for next several months or consider alternative medical treatment
      - medical (can also consider):
        - high dose progestins
        - danazol (Danocrine<sup>®</sup>)
        - GnRH agonists (e.g. Lupron<sup>®</sup>) with add-back if taken for >6 mo
        - ulipristal acetate
- surgical
  - polypectomy
  - myomectomy
  - uterine artery embolization
  - endometrial ablation
    - if finished childbearing
    - repeat procedure may be required if symptoms recur, especially if <40 yr
  - hysterectomy: definitive treatment

## Dysmenorrhea

### Etiology

- primary/idiopathic
- secondary (acquired)
  - endometriosis
  - adenomyosis
  - uterine polyps
  - uterine anomalies (e.g. non-communicating uterine horn)
  - leiomyoma
  - intrauterine synechiae
  - ovarian cysts
  - cervical stenosis
  - imperforate hymen, transverse vaginal septum
  - PID
  - IUD (copper)
  - foreign body

### Primary Dysmenorrhea

Recurrent, crampy lower abdominal pain during menses in the absence of demonstrable disease

### Secondary Dysmenorrhea

Pain during menses that can be attributed to an underlying disorder (i.e. endometriosis, adenomyosis, fibroids)

**Table 6. Comparison of Primary and Secondary Dysmenorrhea**

	Primary Dysmenorrhea	Secondary Dysmenorrhea
<b>Features</b>	Recurrent, crampy lower abdominal pain that occurs during menses in the absence of demonstrable disease	Similar features as primary dysmenorrhea but with an underlying disorder that can account for the symptoms, such as endometriosis, adenomyosis, or uterine fibroids
<b>Signs and Symptoms</b>	Colicky pain in abdomen, radiating to the lower back, labia, and inner thighs beginning hours before onset of bleeding and persisting for hours or days (48-72 h) Associated symptoms: N/V, altered bowel habits, headaches, fatigue (prostaglandin-associated)	Same symptoms as primary dysmenorrhea Associated symptoms: dyspareunia, abnormal bleeding, infertility
<b>Diagnosis</b>	Assess for associated dyspareunia, abnormal bleeding, infertility (signs of 2 <sup>o</sup> dysmenorrhea) Rule out underlying pelvic pathology and confirm cyclic nature of pain Pelvic examination not required; indicated for patients not responding to therapy or with signs of organic pathology	Bimanual exam: uterine or adnexal tenderness, fixed uterine retroflexion, uterosacral nodularity, pelvic mass, or enlarged irregular uterus (findings are rare in women <20 yr) U/S, laparoscopy, and hysteroscopy may be necessary to establish the diagnosis Vaginal and cervical cultures may be required
<b>Treatment</b>	Regular exercise, local heat NSAIDs: should be started before onset of pain CHCs with continuous or extended use: suppress ovulation/reduce menstrual flow	Treat underlying cause

## Endometriosis

### Definition

- the presence of endometrial tissue (glands and stroma) outside of the uterine cavity
- chronic condition, resolving only with menopause

### Etiology

- not fully understood; proposed mechanisms include (combination likely involved):
  - retrograde menstruation (Sampson's theory)
  - immunologic: decreased NK cell activity limiting clearance of transplanted endometrial cells from pelvic cavity (may be due to decreased NK cell activity)
  - metaplasia of coelomic epithelium
  - extra-pelvic disease may be due to aberrant vascular or lymphatic dissemination of cells
    - e.g. ovarian endometriosis may be due to direct lymphatic flow from uterus to ovaries

### Epidemiology

- incidence: 15-30% of premenopausal women
- mean age at presentation: 25-30 yr
- regresses after menopause

### Risk Factors

- family history (7-10x increased risk if affected 1st degree relative)
- obstructive anomalies of the genital tract (earlier onset) – resolves with treatment of anomaly
- nulliparity
- age >25 yr
- early menarche (<11-13 years old), shorter menstrual cycles (defined as ≤27 days)

### Differential Diagnoses

- Chronic PID, recurrent acute salpingitis
- Hemorrhagic corpus luteum
- Benign/malignant ovarian neoplasm
- Ectopic pregnancy

### 4 "Dys" of Endometriosis

- Dysmenorrhea
- Dyspareunia (cul-de-sac, uterosacral ligament)
- Dyschezia (uterosacral ligament, cul-de-sac, rectosigmoid attachment)
- Dysuria (bladder involvement)

### Sites of Occurrence

- ovaries: 60% of patients have ovarian involvement
- broad ligament, vesicoperitoneal fold
- peritoneal surface of the cul-de-sac, uterosacral ligaments
- rectosigmoid colon, appendix
- rarely may occur in sites outside abdomen/pelvis, including lungs and diaphragm

### Clinical Features

- may be asymptomatic and can occur with one of 3 presentations

#### 1. pain (80%)

- menstrual symptoms
  - cyclic symptoms due to growth and bleeding of ectopic endometrium, usually precede menses (24-48 h) and continue throughout and after flow
  - secondary dysmenorrhea
  - sacral backache with menses
  - pain may eventually become chronic, worsening perimenstrually
  - deep dyspareunia
- bowel and bladder symptoms
  - frequency, dysuria, hematuria
  - cyclic diarrhea/constipation, hematochezia, dyschezia (suggestive of deeply infiltrating disease)

#### 2. infertility (25%)

- 30-40% of patients with endometriosis will be infertile
- 15-30% of those who are infertile will have endometriosis

#### 3. mass (endometrioma) (20%)

- endometrioma: an endometriotic cyst encompassing ovary
- ovarian mass can present with any of above symptoms or be asymptomatic
- physical examination:
  - tender nodularity of uterine ligaments and cul-de-sac felt on rectovaginal exam
  - fixed retroversion of uterus
  - firm, fixed adnexal mass

### Investigations

- definitive diagnosis can be made based on:
  - direct visualization of lesions typical of endometriosis at laparoscopy (gold standard)
  - biopsy and histologic exam of specimens 2 or more of: endometrial epithelium, glands, stroma, hemosiderin-laden macrophages
- laparoscopy
  - mulberry spots: dark blue or brownish-black implants on the uterosacral ligaments, cul-de-sac, or anywhere in the pelvis
  - endometrioma: "chocolate" cysts on the ovaries
  - "powder-burn" lesions on the peritoneal surface
  - early white lesions and clear blebs
  - peritoneal "pockets"
- CA-125
  - may be elevated in patients with endometriosis but should NOT be used as a diagnostic test

#### Long-Term Outcomes of Elagolix in Women with Endometriosis: Results from Two Extension Studies

Obstet Gynecol 2018;132:147-160

**Purpose:** An evaluation of the safety and efficacy of elagolix (a GnRH agonist) over 12 mo in women with endometriosis-associated pain.

**Methods:** A report of 2, double-blind, Phase III, placebo-controlled RCTs to evaluate two doses of elagolix over 12 mo of continuous treatment in patients with moderate to severe endometriosis-associated pain.

**Results:** In the first trial, 52.1% of women receiving 150 mg elagolix once daily had a clinical response with regards to dysmenorrhea and 67.8% had a response with regards to non-menstrual pelvic pain. In the higher dose group (200 mg q12 h), the response rate was 78.1% and 69.1%, respectively. These response rates were comparable in the second trial. Women who received elagolix had higher rates of hot flashes, higher serum lipids, and decreases in bone mineral density.

**Conclusion:** Both high and low doses of elagolix were effective in improving dysmenorrhea and non-menstrual pelvic pain in women with endometriosis-associated pain.

#### Endometriosis – Take Home Points

- Suggestive history even with a negative exam should be considered adequate for a presumptive diagnosis
- Pelvic pain that is not primary dysmenorrhea should be considered endometriosis until proven otherwise
- Medical management is the mainstay of endometriosis

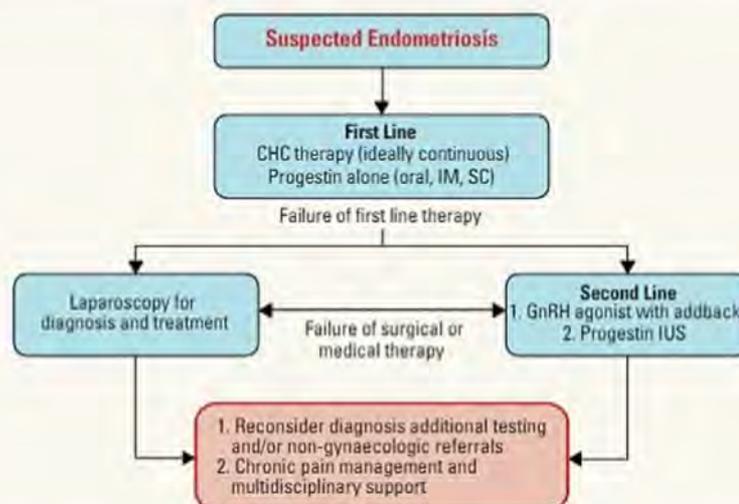

Figure 8. Society of Obstetricians and Gynaecologists of Canada (SOGC) guidelines for treatment of endometriosis

### Treatment

- surgical confirmation of disease is NOT required prior to starting medical management. Asymptomatic endometriosis does not require treatment. Management depends on certainty of the diagnosis, severity of symptoms, extent of disease, desire for future fertility, and impact to GI/GU systems (e.g. intestinal obstruction)
- medical
  - NSAIDs (e.g. naproxen sodium – Anaprox®). Avoid selective COX-2 inhibitors (celecoxib, rofecoxib, valdecoxib) in those who are attempting conception as some studies indicate these drugs can prevent or delay ovulation
  - 1st line
    - cyclic/continuous estrogen-progestin (OCP)
    - progestin (1M medroxyprogesterone (Depo-Provera®) or oral dienogest (Visanne®))
    - Mirena® IUS
  - 2nd line
    - GnRH agonist (e.g. leuprolide (Lupron®)): suppresses pituitary glands
      - side effects: hot flashes, vaginal dryness, reduced libido
      - use >6 mo: include add-back progestin or estrogen to prevent decreased BMD, reduce vasomotor side effects
    - danazol (Danocrine®): weak androgen
      - side effects: weight gain, fluid retention, acne, hirsutism, voice change (not commonly used due to side effects)
- surgical
  - conservative laparoscopy using laser, electrocautery ± laparotomy
    - ablation/resection of implants, lysis of adhesions, ovarian cystectomy of endometriomas
  - definitive: hysterectomy ± bilateral salpingo-oophorectomy
  - best time to become pregnant is immediately after conservative surgery
  - if patient is not planning to become pregnant postoperatively, suppress ovulation medically to prevent recurrence (not proven)
- above treatments are for the pain, not for the infertility associated with endometriosis, which usually involves surgery + assisted reproductive technologies. Also, management for endometriomas is surgical for symptomatic and expanding masses, but this can decrease ovarian reserve, so if it is asymptomatic and small (<5 cm), then no surgery is necessary

## Adenomyosis

- synonym: "endometriosis interna" (uterine wall may be diffusely involved)

### Epidemiology

- 15% of females >35 y/o; found in 20-40% of hysterectomy specimens
- mean age at presentation: 40-50 y/o (older age group than seen in endometriosis)
- adenomyosis is a common histologic finding in asymptomatic patients

### Clinical Features

- often asymptomatic
- heavy menstrual bleeding, secondary dysmenorrhea, pelvic discomfort
- dyspareunia, dyschezia
- uterus symmetrically bulky, usually <14 cm
- Halban's sign: tender, softened uterus on premenstrual bimanual exam

### Investigations

- clinical diagnosis
- U/S or MRI can be helpful
- endometrial sampling to rule out other pathology

### Treatment

- medical
  - iron supplements for anemia
  - analgesics, NSAIDs
  - Mirena® IUS
  - CHC, medroxyprogesterone (Depo-Provera®) – limited evidence for efficacy
  - GnRH agonists (e.g. leuprolide (Lupron®))
  - danazol 100-200 mg PO once daily (trial x 4 mo)
- surgical
  - definitive: hysterectomy – treatment of choice in women who have completed childbearing

**Adenomyosis**  
Extension of areas of endometrial glands and stroma into the myometrium

Final diagnosis of adenomyosis is based on pathologic findings, but predictably identified on MRI

## Fibroids

### Epidemiology

- diagnosed in approximately 40-50% of premenopausal women >35 yr
- more common in Black women, where they are also larger and occur at earlier age
- common indication for major surgery in females
- minimal malignant potential (1 in 1000)
- typically regress after menopause

### Pathogenesis

- estrogen stimulates monoclonal smooth muscle proliferation
- progesterone stimulates production of proteins that inhibit apoptosis
- degenerative changes (occur when tumour outgrows blood supply)
  - fibroids can painfully degenerate, become calcified, develop sarcomatous component, or obtain parasitic blood supply

### Classification

- intramural: most common, grow within the muscular wall of the uterus
- submucosal: grow within myometrium, can grow into endometrial cavity
- subserosal: grow from the serosa
- fibroids can also grow in the cervix and vagina

### Clinical Features

- majority asymptomatic (60%), often discovered as incidental finding on pelvic exam or U/S (occur in 50% of ALL women)
- abnormal uterine bleeding (30%): dysmenorrhea, heavy menstrual bleeding
- pressure/bulk symptoms (20-50%)
  - pelvic pressure/heaviness
  - increased abdominal girth
  - urinary frequency and urgency
  - constipation, bloating (rare)
  - acute urinary retention (extremely rare, but surgical emergency!)
- acute pelvic pain
  - fibroid degeneration
  - fibroid torsion (if pedunculated subserosal)
- infertility, recurrent pregnancy loss
- pregnancy complications (potential enlargement and increased pain, obstructed labour, malpresentation, difficult cesarean delivery)

### Investigations

- bimanual exam: uterus asymmetrically enlarged, usually mobile
- CBC: anemia (only found if associated with AUB/heavy menstrual bleeding)
- pelvic and/or transvaginal U/S: to confirm diagnosis and assess location of fibroids
- sonohysterogram: useful for differentiating endometrial polyps from submucosal fibroids, for assessing intracavitary growth or for assessing potential risks with fertility associated with the fibroid (submucosal only)
- endometrial biopsy to rule out uterine cancer for abnormal uterine bleeding (especially if age >40 yr)
- occasionally MRI is used for preoperative planning (e.g. before myomectomy)

### Treatment

- only if symptomatic (heavy menstrual bleeding, bulk symptoms), rapidly enlarging or intracavitary
- treat anemia if present
- conservative approach (watch and wait) if:
  - symptoms absent or minimal
  - fibroids <6-8 cm or stable in size
  - not submucosal (submucosal fibroids are more likely to be symptomatic)
  - currently pregnant due to increased risk of bleeding (follow-up U/S if symptoms progress)
- medical approach to treat AUB-L
  - antiprogesterins (ibuprofen, other NSAIDs)
  - tranexamic acid (Cyclokapron<sup>®</sup>)
  - CHC, IUS, or Depo-Provera<sup>®</sup>
  - GnRH agonist: leuprolide (Lupron<sup>®</sup>)
    - often used for 3 mo preoperatively to increase Hb and reduce fibroid size
    - reduces bleeding, shrinks fibroids, and corrects anemia
    - can be used long-term to bridge to menopause in combination with add-back progestin or estrogen
- interventional radiology approach: UAE occludes both uterine arteries, shrinks fibroids by 50% at 6 mo; improves heavy bleeding in 90% of patients within 1-2 mo; not an option in women considering childbearing
  - higher risk of surgical re-intervention than with surgical approaches

#### Leiomyomata/Fibroids

Benign smooth muscle tumour of the uterus (most common gynaecological tumour)

Submucosal leiomyomata are most symptomatic (bleeding, infertility)

Large fibroids can cause distressing bulk symptoms

The effect of pregnancy on fibroid size is variable

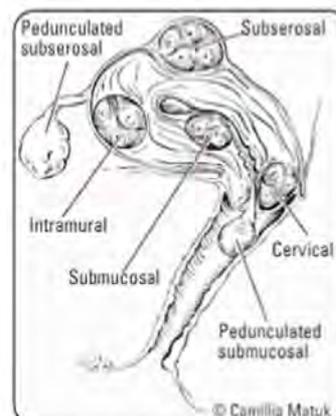

Figure 9. Possible anatomic locations of uterine leiomyomata

#### Uterine Artery Embolization for Symptomatic Uterine Fibroids

Cochrane DB Syst Rev 2014;12:CD005073

**Purpose:** To compare outcomes of UAE to other medical or surgical therapies for symptomatic uterine fibroids. Primary outcomes were patient satisfaction and live birth rate

**Results:** Seven RCTs with 793 women were included. There was no evidence of a difference in the primary outcomes or risk of major complications between the interventions. UAE was associated with a higher risk of minor complications and the need for additional surgical intervention within 2 yr

**Conclusions:** No significant differences in patient satisfaction or major complications in UAE compared to surgical intervention. UAE is associated with an increased risk of surgical re-intervention

- surgical approach
  - myomectomy (hysteroscopic, transabdominal, or laparoscopic)
  - hysteroscopic resection of fibroid and endometrial ablation for AUB-Lsm
  - hysterectomy (see *Hysterectomy*, GY6)
  - note: avoid operating on fibroids during pregnancy (due to vascularity and potential pregnancy loss); expectant management is usually best

## Contraception

- see [Family Medicine](#), FM23

**Table 7. Classification of Contraceptive Methods**

Type	Effectiveness (Perfect Use, Typical Use*)
<b>Physiological</b>	
Withdrawal/coitus interruptus	96%, 77%
Rhythm	76%
Method/calendar/mucus/symptothermal	98% (first 6 mo postpartum)
Lactational amenorrhea	15%
Abstinence of all sexual activity	100%
<b>Barrier Methods</b>	
Condom alone	98%, 82%
Spermicide alone	82%, 72%
Sponge	
Parous	80%, 76%
Nulliparous	91%, 88%
Diaphragm with spermicide	94%, 88%
Female condom	95%, 79%
Cervical cap	
Parous	74%, 68%
Nulliparous	91%, 84%
<b>Hormonal</b>	
<b>Combined (Estrogen and Progesterone)</b>	
OCP	99.7%, 92%
NuvaRing <sup>®</sup>	99.7%, 92%
Transdermal (Ortho Evra <sup>®</sup> )	99.7%, 92%
<b>Progesterone-Only</b>	
Progestin-only injection (Depo-Provera <sup>®</sup> )	99.7%, 97%
Mirena <sup>®</sup> IUS	99.9%
Etonogestrel implant (NEXPLANON <sup>®</sup> )	99%
<b>Copper IUD</b>	99.3%
<b>Surgical</b>	
Tubal ligation	99.65%
Vasectomy	99.9%
<b>Emergency Postcoital Contraception (EPC)</b>	
Yuzpe <sup>®</sup> method	98% (within 24 h), decreases by 30% at 72 h
"Plan B" levonorgestrel only	98% (within 24 h), decreases by 70% at 72 h
Postcoital IUD	99.9% (within 7 d)
Ella	99.9% (within 7 d)

\*Effectiveness: percentage of women reporting no pregnancy after 1 yr of use

### Counselling the Adolescent about Contraception

More than 90% of adolescent pregnancies are unintended, and ~50% of all pregnancies occur within the first 6 mo of initiating sexual activity; in addition, 85% of sexually active women become pregnant within 1 yr if no contraception is used and even some of the least effective contraceptive methods markedly decrease the risk of pregnancy

## Hormonal Methods

### Combined Oral Contraceptive Pills

- daily pill with a 4-7 d placebo or pill free break to allow for menstruation
- estrogen: suppresses FSH and follicular development
- progestin: prevents LH surge, suppresses ovulation, thickens cervical mucus, decreases tubal motility, decidualizes endometrium
- most contain low dose ethinyl estradiol (20-35 µg) plus progestin (norethindrone, norgestrel, levonorgestrel, desogestrel, norgestimate, drospirenone)
- failure rate (0.3-8.0%) depending on compliance
- monophasic formulations have the same amount of progestin throughout cycle while triphasic formulations have a varying amount of progestin throughout cycle

### Transdermal (Ortho Evra®)

- patch that is changed every week for 3 consecutive weeks then left off for a week to allow for menstruation
- continuous release of 6 mg norelgestromin and 0.60 mg ethinyl estradiol into bloodstream
- applied to lower abdomen, back, upper arm, buttocks, NOT breasts
- as effective as OCP in preventing pregnancy (>99% with perfect use)
- may be less effective in women >90 kg

### Contraceptive Ring (Nuva Ring®)

- thin flexible plastic ring that is inserted into the vagina by the patient and left there for 3 wk then removed for a week to allow for menstruation; releases etonogestrel 120 µg/d and estradiol 15 µg/d
- as effective as OCP in preventing pregnancy (98%)
- side effects: vaginal infections/irritation, vaginal discharge
- associated with less breakthrough bleeding than other methods

### Starting Hormonal Contraceptives

- thorough history and BP measurement (post-pandemic SOGC guidelines do not require BP reading anymore to allow for virtual appointments)
- pelvic exam not required as STI screening can be done by urine, and pap smear screening does not start until >25 yr
- can start at any time during cycle but ideally within 5 d of LMP
- follow-up visit 3 mo after hormonal contraceptives prescribed
- generally recommended to use back-up contraception for 7 days, particularly if initiated >5 days from LMP

**Table 8. Combined Estrogen and Progestin Contraceptive Methods**

Advantages	Side Effects	Contraindications
Highly effective	<b>Estrogen-related</b>	<b>Absolute</b>
Reversible	Nausea	4 wk postpartum (breastfeeding) or <21 d postpartum (not breastfeeding)
Cycle regulation	Breast changes (tenderness, enlargement)	Major surgery with prolonged immobilization
Decreased dysmenorrhea and heavy menstrual bleeding (less anemia)	Fluid retention/bloating/edema	Known/suspected pregnancy
Decreased benign breast disease and ovarian cyst development	Weight gain (rare)	Undiagnosed abnormal vaginal bleeding
Decreased risk of ovarian and endometrial cancer	Migraine, headaches	Prior thromboembolic events, thromboembolic disorders (Factor V Leiden mutation; protein C or S, or antithrombin III deficiency), active thrombophlebitis
Increased cervical mucus which may lower risk of STIs	Thromboembolic events	Cerebrovascular or coronary artery disease
Decreased PMS symptoms	Liver adenoma (rare)	Estrogen-dependent tumours (breast, uterus)
Less acne	Breakthrough bleeding (low estradiol levels)	Impaired liver function associated with acute liver disease
Osteoporosis protection (possibly)	<b>Progestin-related</b>	Congenital hypertriglyceridemia
Patient controlled	Amenorrhea/breakthrough bleeding	Smoker age >35 yr
	Headaches	Migraines with focal neurological symptoms (excluding aura)
	Breast tenderness	Uncontrolled HTN
	Increased appetite	
	Decreased libido	<b>Relative</b>
	Mood changes	Migraines (non-focal with aura <1 h)
	HTN	DM complicated by vascular disease
	Acne/oily skin*	SLE
	Hirsutism*	Controlled HTN
		Hyperlipidemia
		Sickle cell anemia
		Gallbladder disease
	*Androgenic side effects may be minimized by prescribing formulations containing desogestrel, norgestimate, drospirenone, or cyproterone acetate	<b>Drug Interactions/Risks</b>
		Rifampin, phenobarbital, phenytoin, griseofulvin, primidone, and St. John's wort can decrease efficacy of CHC requiring use of back-up method
		No evidence of fetal abnormalities if conceived on OCP
		No evidence that OCP is harmful to nursing infant but may decrease milk production

**Table 9. Selected Examples of OCPs**

Type	Active Compounds (estradiol and progestin derivative)	Advantages	Disadvantages
Alesse <sup>®</sup>	20 µg ethinyl estradiol and 0.5 mg levonorgestrel	Low dose (20 µg) OCP Less estrogen side effects	Low-dose pills can often result in breakthrough bleeding If this persists for longer than 3 mo, patient should be switched to an OCP with higher estrogen content
Tri-cyclen <sup>®</sup>	35 µg ethinyl estradiol and 0.180/0.215/0.250 mg norgestimate Triphasic oral contraceptive (graduated levels of progesterone)	Low androgenic activity can help with acne	Unlike monophasic OCP, triphasic OCPs can not be used for continuous menstrual suppression
Yasmin <sup>®</sup> and Yaz <sup>®</sup>	Yasmin <sup>®</sup> : 30 µg ethinyl estradiol + 3 mg drospirenone (a new progestin) Yaz <sup>®</sup> : 20 µg ethinyl estradiol + 3 mg drospirenone – 24/4-d pill (4 d pill free interval) Drospirenone has antiminerlocorticoid activity and antiandrogenic effects	Decreased perception of cyclic weight gain/bloating Fewer PMS symptoms Improved acne	Hyperkalemia (rare, contraindicated in renal and adrenal insufficiency) Check potassium if patient also on ACEI, ARB, K <sup>+</sup> -sparing diuretic, heparin

**PROGESTIN-ONLY METHOD**

**Progestin-Only Pill**

- progesterone-only pill taken daily with no pill free interval
- advantages: patient controlled, does not impact breast milk supply
- disadvantages: must take at exactly the same time every day so compliance can be challenging

**Progesterone Intrauterine System (IUS)**

- small device left inside uterus for a maximum of 5 yr
- Mirena IUS: 52 µg levonorgestrel - better for women with very heavy or painful periods, 20% amenorrhea rate
- Kyleena IUS: 19.5 µg levonorgestrel - best for people who want a light period every mo and are mainly looking for birth control
- advantages: convenient, low hormone dose, minimal side effects, no effect on breast milk, quick return to fertility once removed
- disadvantages: uncomfortable to put in, must be inserted and removed by a doctor, rarely can have uterine perforation or IUS expulsion
- very effective reversible contraception; more likely to be an ectopic pregnancy if conception occurs. Lower absolute risk of ectopic pregnancy compared to other contraceptive methods

**Depo-Provera<sup>®</sup>**

- injectable depot medroxyprogesterone acetate 150 mg IM every 12 wk (convenient dosing)
- advantages: suppresses ovulation, complete amenorrhea in 70% of women after 1-2 yr of use, does not affect breast milk, effective for dysmenorrhea
- disadvantages: breakthrough bleeding, weight gain, decreased bone density (may be reversible), restoration of fertility may take up to 1-2 yr

**Nexplanon<sup>®</sup>**

- 4 cm long 60 mg etonogestrel implant that is placed in the inner arm and lasts for a maximum of 3 yr
- advantages: does not affect breast milk, do not have to put something in uterus, good bleeding and pain control, no change in bone density, quick return to fertility once removed
- disadvantages: breakthrough bleeding, weight gain

**Table 10. Progestin-Only Contraceptive Methods**

Indications	Mechanism of Action	Side Effects	Contraindications
Does not affect breast milk supply Women with contraindications to combined OCP (e.g. thromboembolic or myocardial disease) Women intolerant of estrogenic side effects of combined OCPs	Progestin prevents LH surge Thickening of cervical mucus Decreases tubal motility Endometrial decidualization Ovulation suppression – oral progestins do not consistently suppress ovulation compared to combined OCPs	Irregular menstrual bleeding Weight gain Headache Breast tenderness Mood changes Functional ovarian cysts Acneloily skin Hirsutism	<b>Absolute</b> Current breast cancer Known/suspected pregnancy Undiagnosed vaginal bleeding Benign or malignant liver tumours, severe cirrhosis, or acute liver disease

**Missed Combined OCPs**

- Miss 1 pill in <24 h**
- Take 1 pill ASAP, and the next pill at the usual time
- Miss ≥1 pill in a row in 1st wk**
- Take 1 pill ASAP, and continue taking 1 pill daily until the end of the pack
  - Use back-up contraception for 7 d; EPC may be necessary
- Miss <3 pills in 2nd or 3rd wk of cycle**
- Take 1 pill ASAP, and continue taking 1 pill daily until the end of the pack
  - Do not take placebo (28-d packs) or do not take a hormone free interval (21-d packs)
  - Start the next pack immediately after finishing the previous one
  - No need for back-up contraception
- Miss ≥3 pills during the 2nd or 3rd wk**
- Take 1 pill ASAP, and continue taking 1 pill daily until the end of the pack
  - Do not take placebo (28-d packs) or do not take a hormone free interval (21-d packs)
  - Start the next pack immediately after finishing the previous one
  - Use back-up contraception for 7 d; EPC may be necessary

SOGC Committee Opinion on Missed Hormonal Contraceptives: New Recommendations. JGOC 2008;30:1050-1062.

Irregular breakthrough bleeding often occurs in the first few mo after starting OCP; usually resolves after three cycles

Progestin-only contraceptives must be taken at the same time every day

**Continuous or Extended Cycle vs. Cyclic Use of Combined Hormonal Contraceptives for Contraception**

Cochrane DB Syst Rev 2014;7  
**Purpose:** Systematic review of RCTs assessing the efficacy and side effects of cyclic administration vs. extended use (longer periods of active pills and/or shorter periods placebo) or continuous use (uninterrupted active pill administration) of combination oral contraceptives (COC).  
**Results:** The initial review published in 2012 identified 12 RCTs that ultimately showed no difference between groups with regards to efficacy (pregnancy rates), safety, and compliance rates. Continuous or extended COCs were shown to reduce menstrual symptoms (headaches, tiredness, bloating, and menstrual pain). In addition, 11 of 12 studies reported similar or improved bleeding patterns with continuous or extended cycles.  
**Conclusions:** This recently published updated systematic review identified a further 4 RCTs, however, results did not change.

## Intrauterine Device

Table 11. IUS Contraceptive Methods

Mechanism of Action	Benefits of all IUS	Risks of all IUS	Side Effects	Contraindications
<p><b>Copper-Containing IUS (Nova-T®):</b> mild foreign body reaction in endometrium, toxic to sperm and alters sperm motility</p> <p><b>Progesterone-Releasing IUS (Mirena®, Kyleena®):</b> decidualization of endometrium and thickening of cervical mucus; minimal effect on ovulation</p>	<p>Return to baseline fertility after removal is very fast</p> <p>No estrogen (doesn't affect breastfeeding, can use if smoker, hypertension, previous VTE)</p> <p>Lasts 5 yr but can be removed before that if desired</p> <p>Can insert immediately after placental delivery and post-abortion</p>	<p>Insertion is uncomfortable</p> <p>Must be inserted and removed by a doctor</p> <p>Infection (especially if multiple partners and within first 10 d of insertion)</p> <p>Uterine wall perforation on insertion (1/10000)</p> <p>Expulsion (5% in the 1st yr, greatest in the 1st mo)</p> <p>Chance of pregnancy very low, but if pregnant, higher relative risk of an ectopic pregnancy or miscarriage</p> <p>IUS do not protect against STIs*</p>	<p><b>Copper IUS:</b> increased blood loss and duration of menses, dysmenorrhea, increased vaginal discharge</p> <p><b>Progesterone IUS:</b> spotting, bloating, headache, acne, breast tenderness, nausea, headaches, ovarian cyst formation, vaginal discharge, and/or mood changes. Usually very mild.</p>	<p><b>Absolute</b></p> <p><b>Both Copper and Progesterone IUS</b></p> <p>Known or suspected pregnancy</p> <p>Undiagnosed genital tract bleeding</p> <p>Acute or chronic PID</p> <p>Lifestyle risk for STIs</p> <p>Known distorted uterine cavity</p> <p>Immediately post-septic abortion</p> <p><b>Copper IUS</b></p> <p>Known allergy to copper or Wilson's disease</p> <p><b>Relative:</b></p> <p><b>Both Copper and Progesterone IUS</b></p> <p>Valvular heart disease</p> <p>PMHx of PID or ectopic pregnancy</p> <p>Presence of prosthesis</p> <p>Abnormalities of uterine cavity</p> <p>Intracavitary fibroids</p> <p>Cervical stenosis</p> <p>Immunosuppressed individuals (e.g. HIV)</p> <p>Abnormalities of uterine cavity (excluding distorted uterine cavity)</p> <p>Copper IUS – Severe dysmenorrhea or heavy menstrual bleeding</p>

\*Cervical swabs for gonorrhoea and chlamydia should be done prior to insertion

## Emergency Postcoital Contraception

Table 12. Emergency Postcoital Contraceptive (EPC) Methods

Method	Mechanism of Action	Side Effects	Contraindications
<b>HORMONAL</b>			
<p><b>Yuzpe Method</b></p> <p>Øvral® 2 tablets then repeat in 12 h (100 µg ethinyl estradiol 500 µg levonorgestrel)</p> <p>Can substitute with any OCP as long as it contains 100 µg ethinyl estradiol</p> <p>2% overall risk of pregnancy</p> <p>Used within 72 h of unprotected intercourse, limited evidence of benefit up to 5 d</p> <p>Efficacy decreased with time (e.g. less effective at 72 h than 24 h)</p>	<p>Unknown; theories include:</p> <p>Suppresses ovulation or causes deficient luteal phase</p> <p>Alters endometrium to prevent implantation</p> <p>Affects sperm/ova transport</p>	<p>Nausea (due to estrogen; treat with Gravol®)</p> <p>Irregular spotting</p>	<p>Pre-existing pregnancy (although not teratogenic)</p> <p>Caution in women with contraindications to OCP (although no absolute contraindications)</p>
<p><b>"Plan B"</b></p> <p>Use within 72 h of unprotected intercourse, can use up to 5 d after</p> <p>750 µg levonorgestrel q12 h for 2 doses (can also take 2 doses together)</p> <p>Greater efficacy (75-95% if used within 24 h) and better side effect profile than Yuzpe method</p> <p>No estrogen thus very few contraindications/side effects (less nausea)</p> <p>Less effective if &gt;75 kg, not recommended if &gt;80 kg</p>	<p>Same as above</p>	<p>Same as above</p>	<p>Same as above but no caution in women with contraindications to OCP</p>
<p><b>Ulipristal (Ella™)</b></p> <p>30 mg PO within 5 d of unprotected intercourse</p>	<p>Selective Progesterone Receptor Modulator (SPRM) with primarily antiprogesterin activity; may delay ovulation by up to 5 d</p>	<p>Headache, hot flashes, constipation, vertigo, endometrial thickening</p>	<p>Same as above but no caution in women with contraindications to OCP</p>
<b>NON-HORMONAL</b>			
<p><b>Postcoital IUD (Copper)</b></p> <p>Insert up to 7 d postcoitus</p> <p>Prevents implantation</p> <p>1% failure rate</p> <p>Can use for short duration in higher risk individuals</p>	<p>See Table 11</p>	<p>See Table 11</p>	<p>See Table 11</p>

### Follow-up

- 3-4 wk post treatment to confirm efficacy (confirmed by spontaneous menses or pregnancy test)
- contraception counselling

## Termination of Pregnancy

### Indications

- patient desires an end to pregnancy
- may be for medical reasons (health of mother or fetal anomaly) or social reasons, including patient request

### Legal Considerations

- no current law in Canada concerning abortion, therefore considered legal at any GA, however GA limits and access vary significantly by region
- CPSO: a physician must provide a referral for abortion services regardless of personal beliefs, but not compelled to personally perform procedure

### Rates

- 13.1 abortions in 1000 women 15-44 yr in Canada (2017 CIHI data)
- worldwide: 56 million induced abortions per yr; half are unsafe (WHO data)
- maternal mortality almost zero where induced abortion is safe and legal; rises to 100 maternal deaths in 100000 live births in sub-Saharan Africa and other countries where abortion is illegal and unsafe
- in Canada, 91% of induced abortions occur <12 wk GA; much less common after 24 wk GA (usually only for maternal/fetal reasons)

### Methods of Induced Abortion

- medical
  - gold standard up to 9 wk GA
  - mifepristone and misoprostol 95-98% effective up to 49 d after LMP
  - mifepristone (200 mg PO on 1st d) blocks the progesterone receptor (progesterone required in early pregnancy), alters the endometrium, induces bleeding and causes the cervix to soften
  - misoprostol (800 mg PV/BUC on 2nd or 3rd d) is a synthetic prostaglandin that stimulates uterine contractions and expulsion of the products of conception
  - can also use misoprostol alone or methotrexate and misoprostol (with lower success rates of 90-95%)
  - good follow-up and back-up access to D&C required if medical abortion fails
  - side effects: bleeding (self-limited) and pain (while tissue passes) are expected side effects, as well as nausea, diarrhea, and chills/fever due to prostaglandin effects
  - contraindications:
    - absolute: ectopic pregnancy, chronic adrenal failure, ambivalence
    - relative: unconfirmed GA, IUD in situ, long term steroid therapy, bleeding disorder/anticoagulation, porphyria
  - between 14-24 wk GA medical induction of labour (misoprostol followed by oxytocin) is an option, whereas after 24 wk GA induction of labour is the only option
- surgical
  - <14 wk GA:
    - manual vacuum aspiration – up to 12 wk GA with handheld aspiration device
    - suction dilatation + aspiration ± curettage – may involve presurgical preparation of cervix with laminaria tents and/or misoprostol
  - 14-24 wk GA: dilatation and evacuation; presurgical preparation of cervix required with laminaria tents
  - pain or discomfort during procedure mitigated by use of appropriate analgesia/sedation/anesthesia (including paracervical blocks)
  - rare complications (1-5%): laceration of cervix, infection/endometritis, retained products of conception, ongoing pregnancy
  - very rare complications (0.1-2%): hemorrhage, perforation of uterus, Asherman's syndrome (adhesions within the endometrial cavity causing amenorrhea/infertility), future preterm birth (controversial and likely only with repeated abortion)
- counselling
  - counselling options always provided including possibility of carrying pregnancy with/without adoption
  - offer future contraception (most effective way to prevent unintended pregnancies) and family planning services
  - ensure follow-up

# Pregnancy-Related Complications

## First and Second Trimester Bleeding

### Approach to the Patient with Bleeding in First Trimester (T1)/ Second Trimester (T2)

#### History

- risk factors for ectopic pregnancy (see *Ectopic Pregnancy, GY21*)
- previous spontaneous abortion
- recent trauma
- characteristics of the bleeding (including any tissue passed)
- characteristics of the pain (cramping pain suggests spontaneous abortion)
- history of coagulopathy
- gynaecological/obstetric history
- fatigue, dizziness, syncopal episodes due to hypovolemia, fever (may be associated with septic abortion)

#### Physical

- vitals (including orthostatic changes)
- abdomen (symphysis fundal height, tenderness, presence of contractions)
- perineum (signs of trauma, genital lesions)
- speculum exam (cervical os open or closed, presence of active bleeding/clots/tissue)
- pelvic exam (uterine size, adnexal mass, uterine/adnexal tenderness, cervical motion tenderness)

#### Investigations

- $\beta$ -hCG
- U/S (confirm intrauterine pregnancy and fetal viability)
- CBC
- group and screen

#### Treatment

- IV resuscitation for hemorrhagic shock
- treat the underlying cause

## Spontaneous Abortions

- see *Termination of Pregnancy, GY19* for therapeutic abortions

**Table 13. Classification of Spontaneous Abortions**

Type	History	Clinical and Ultrasound Findings	Management ( $\pm$ Rhogam <sup>®</sup> )
<b>Threatened</b>	Bleeding $\pm$ cramping	Live fetus on ultrasound Cervix closed	Watch and wait ~5% will go on to abort
<b>Inevitable</b>	Bleeding and cramping $\pm$ rupture of membranes	Fetus low in uterus on ultrasound Cervix open	a) Watch and wait b) Misoprostol 800 $\mu$ g PV now and 800 $\mu$ g PV 24 h later c) D&C
<b>Incomplete</b>	Bleeding and cramps $\pm$ passage of tissue noticed	Residual tissue in uterus on ultrasound Cervix open	a) Watch and wait b) Misoprostol 800 $\mu$ g PV now and 800 $\mu$ g PV 24 h later c) D&C
<b>Complete</b>	Bleeding and complete passage of sac and placental tissue	Empty uterus on ultrasound Cervix closed, no bleeding	No management needed
<b>Missed</b>	No bleeding (fetal death in utero)	No fetal heart rate on ultrasound, fetus and sac still in uterus Cervix closed, no bleeding	a) Watch and wait b) Mifepristone 200 mg PO followed by misoprostol 800 $\mu$ g PV 24 h later c) D&C
<b>Recurrent</b>	$\geq 3$ consecutive spontaneous abortions		Evaluate mechanical, genetic, environmental, and other risk factors
<b>Septic</b>	Contents of uterus infected – very rare	Tissue in uterus on ultrasound Foul discharge	a) IV broad spectrum antibiotics b) D&C 24 h after antibiotics c) Misoprostol 800 $\mu$ g PV 24 h later

#### Bleeding in Pregnancy Definitions

- First trimester bleeding: vaginal bleeding within the first 12 wk
- Second trimester bleeding: 12-20 wk

#### Differential Diagnosis

- Physiologic bleeding: spotting, due to implantation of placenta – reassure and check serial  $\beta$ -hCGs
- Abortion (threatened, inevitable, incomplete, complete)
- Abnormal pregnancy (ectopic, molar) (see *Hydatidiform Mole, GY53*)
- Trauma (post-coital or after pelvic exam)
- Genital lesion (e.g. cervical polyp, neoplasms)
- Subchorionic hematoma
- Non-OB/GYN related cause of bleeding (e.g. hemorrhoids)

Every woman of childbearing age presenting to ER with abdominal or pelvic pain should have  $\beta$ -hCG measured

#### Management of Abortions

- Always rule out an ectopic pregnancy
- Always check Rh; if negative, give Rhogam<sup>®</sup>
- Always ensure patient is hemodynamically stable

Embryonic demise can be diagnosed by ultrasound based on an intrauterine gestational sac, embryonic crown-rump length  $\geq 7$  mm, and no cardiac activity

# Ectopic Pregnancy

## Definition

- embryo implants outside of the endometrial cavity

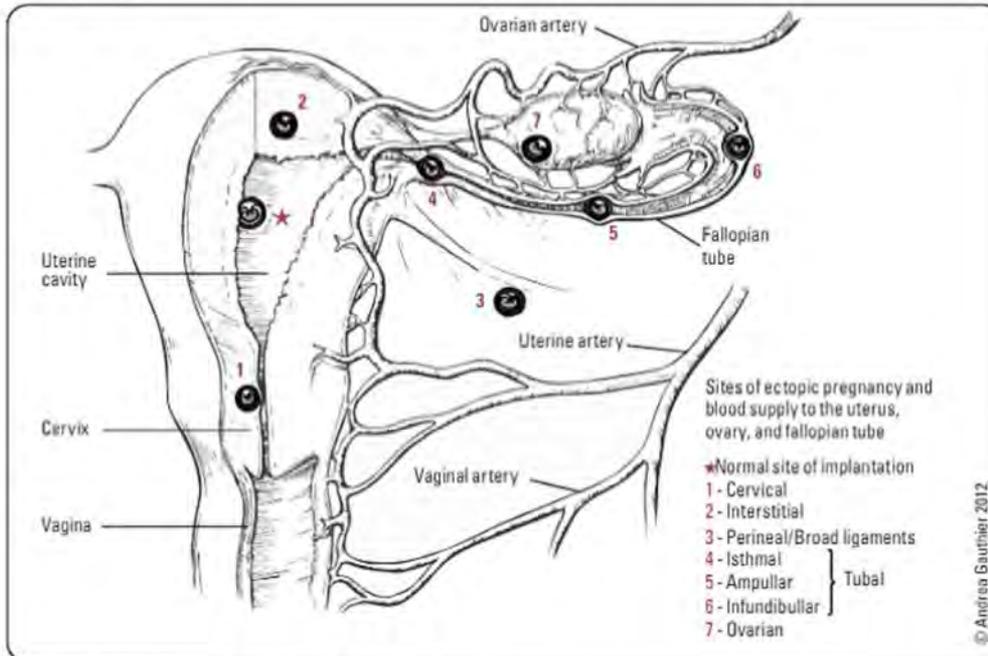

Figure 10. Sites of ectopic pregnancy implantation

ampullary (70%) >> isthmal (12%) > fimbrial (11%) > ovarian (3%) > interstitial (2%) > abdominal (1%)

## Epidemiology

- 1/100 pregnancies
- fourth leading cause of maternal mortality, leading cause of maternal death in first trimester
- increase in incidence over the last 3 decades
- three commonest locations for ectopic pregnancy: ampullary (70%), isthmic (12%), fimbrial (11%)

## Etiology

- 50% due to damage of fallopian tube cilia following PID
- intrinsic abnormality of the fertilized ovum
- conception late in cycle
- transmigration of fertilized ovum to contralateral tube

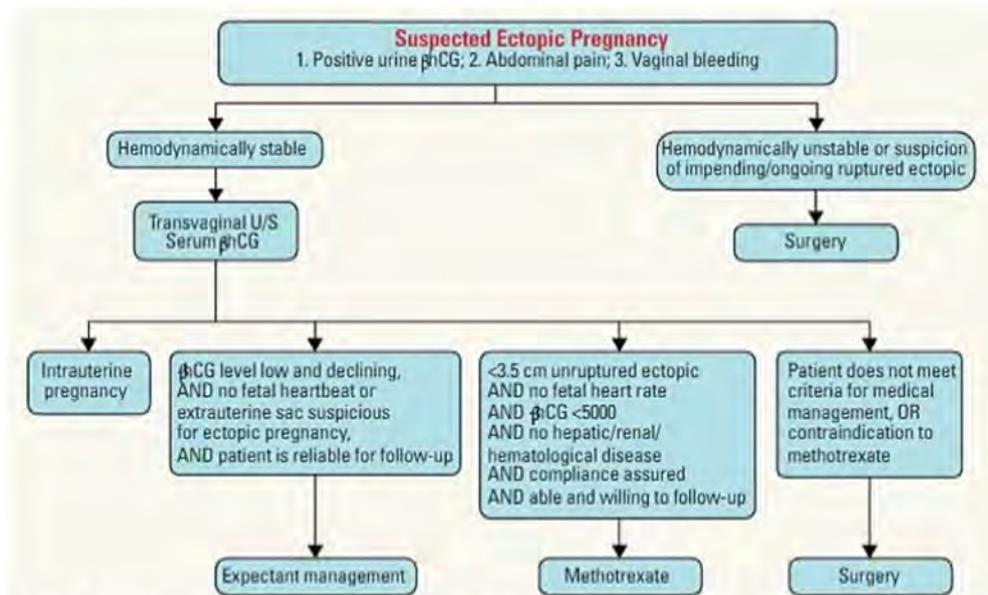

Figure 11. Algorithm for suspected ectopic pregnancy

### Contraindications to Methotrexate Therapy for Ectopic Pregnancy

- Hemodynamic instability
- Abnormalities in hematologic, hepatic, or renal function
- Immunodeficiency
- Active pulmonary disease
- Peptic ulcer disease
- Hypersensitivity to methotrexate
- Heterotopic pregnancy with coexisting viable intrauterine pregnancy
- Breastfeeding
- Unwilling or unable to adhere to methotrexate protocol

### Risk Factors

- previous ectopic pregnancy
- gynaecologic
  - current IUD use – overall risk of pregnancy very low, but increased risk of ectopic pregnancy if pregnancy occurs
  - history of PID (especially infection with *C. trachomatis*), salpingitis
  - infertility
- infertility treatment (IVF pregnancies following ovulation induction (7% ectopic rate))
- previous procedures
  - any surgery on fallopian tube (for previous ectopic pregnancy, tubal ligation, etc.)
  - abdominal surgery for ruptured appendix, etc.
- smoking
- structural
  - uterine leiomyomas
  - adhesions

### Investigations

- serial  $\beta$ -hCG levels; normal doubling time with intrauterine pregnancy is every 48 h in the first 8 wk
  - rise in  $\beta$ -hCG <35% every two days across 3 measurements is consistent with a non-viable pregnancy
  - prolonged doubling time, plateau, or decreasing levels before 8 wk implies nonviable gestation but does not provide information on location of implantation
  - 85% of ectopic pregnancies demonstrate abnormal  $\beta$ -hCG doubling
- ultrasound
  - extra-uterine gestational sac with a yolk sac or embryo, regardless of cardiac activity, is diagnostic
  - specific suggestive, but not diagnostic, finding on transvaginal U/S is a tubal ring
- suspect ectopic pregnancy in case of empty uterus by transvaginal U/S with  $\beta$ -hCG >2000-3000 mIU/mL
- laparoscopy (sometimes used for definitive diagnosis)

### Treatment

- goals of treatment: conservative (preserve tube if possible), maintain hemodynamic stability
- surgical = laparoscopy
  - linear salpingostomy an option if tube salvageable, however, patient must be reliable to follow-up with weekly  $\beta$ -hCG
  - 15% risk of persistent trophoblast if salpingostomy, must monitor  $\beta$ -hCG titres weekly until they reach non-detectable levels
  - salpingectomy if tube damaged or ectopic is ipsilateral recurrence
  - consider Rhogam® if Rh-negative
  - patient may require laparotomy if unstable, extensive abdominal surgical history, etc.
- medical = methotrexate
  - folic acid reductase inhibitor affecting rapidly dividing cells
  - use 50 mg/m<sup>2</sup> body surface area; given as a one time IM dose
  - this is 1/5 to 1/6 chemotherapy dose, therefore minimal side effects (reversible hepatic dysfunction, diarrhea, gastritis, dermatitis)
  - follow  $\beta$ -hCG levels on days 4 and 7 after injection, and then weekly until  $\beta$ -hCG is non-detectable
  - plateaued or rising levels suggest persistent trophoblastic tissue requiring further treatment
  - 82-95% success rate, but up to 25% will require a second dose
  - administer a second dose if  $\beta$ -hCG does not decrease by at least 15%
  - tubal patency following methotrexate treatment approaches 80%
  - stop prenatal vitamins as folic acid will decrease efficacy of methotrexate
- expectant management is an option for patients who are clinically stable, reliable for follow-up, understand the risk of tubal rupture, and have  $\beta$ -hCG levels that are low and declining

### Prognosis

- 9% of maternal deaths during pregnancy attributed to ectopic pregnancy
- 40-60% of patients will become pregnant again after surgery
- 10-20% will have subsequent ectopic pregnancy

#### DDx of Lower Abdominal Pain

- Urinary tract: UTI, kidney stones
- GI: diverticulitis, appendicitis
- Gynaecological: endometriosis, PID, fibroid (degenerating, infarcted, torsion), ovarian torsion, ovarian neoplasm, ovarian cyst, pregnancy-related

Any woman presenting with abdominal pain, vaginal bleeding, and amenorrhea is an ectopic pregnancy until proven otherwise

More than half of patients with ectopic pregnancy have no risk factors

#### Presentation of Ectopic Pregnancy Ruptures

- Acute abdomen with increasing pain
- Abdominal distention
- Shock

# Infertility

## Epidemiology

- 10-15% of couples, must investigate both members of the couple

## Female Factors

### Etiology

- increasing age
- chemotherapy
- ovulatory dysfunction (15-20%)
  - hypothalamic (hypothalamic amenorrhea)
    - stress, poor nutrition, excessive exercise (even with presence of menstruation), history of eating disorders
  - pituitary (prolactinoma, hypopituitarism)
  - ovarian
    - PCOS
    - primary ovarian insufficiency
    - luteal phase defect (poor follicle production, premature corpus luteum failure, failed uterine lining response to progesterone), poorly understood
  - systemic diseases (thyroid, diabetes, Cushing's syndrome, renal/hepatic failure)
  - congenital (Turner's syndrome, gonadal dysgenesis, gonadotropin deficiency)
- outflow tract abnormality (15-20%)
  - tubal factors (20-30%)
    - PID
    - adhesions (previous surgery, peritonitis, endometriosis)
    - ligation/occlusion (previous ectopic pregnancy)
  - uterine factors (<5%)
    - congenital anomalies, bicornuate uterus, septate uterus, prenatal DES exposure, intrauterine adhesions (e.g. Asherman's syndrome), submucosal fibroids/polyps
    - infection (endometritis, pelvic tuberculosis)
  - cervical factors (5%)
    - hostile or acidic cervical mucus, anti-sperm antibodies
    - structural defects (cone biopsies, laser or cryotherapy)
- endometriosis (15-30%)
- multiple factors (30%)
- unknown factors (10-15%)

### Investigations

- ovarian factors
  - day 3: FSH, LH, estradiol, TSH, prolactin, free and total testosterone, androstenedione, DHEAS, free testosterone
  - day 21-23: high serum progesterone levels confirm ovulation
  - general health: CBC, Fe, HbA1c
- tubal factors
  - hysterosalpingogram (HSG) – dye insufflated into uterus and x-ray taken
    - shows uterine cavity shape and if tubes are patent
    - can be therapeutic – opens fallopian tube
  - sonohysterogram (SHG) – saline insufflated into uterus and ultrasound done
    - shows uterine cavity shape and if tubes are patent
    - can be therapeutic and opens the tubes
  - laparoscopy with dye insufflation (or tubal dye test) rarely done as diagnostic
- peritoneal/uterine factors
  - HSG/SHG, hysteroscopy
- other
  - karyotype
  - anti-mullerian hormone (AMH) – a test of ovarian reserve, the higher the number the better

**Infertility:** inability to conceive or carry to term a pregnancy after 1 yr of regular, unprotected intercourse

**Primary infertility:** infertility in the context of no prior pregnancies

**Secondary infertility:** infertility in the context of a prior conception  
Generally, 75% of couples achieve pregnancy within 6 mo, 85% within 1 yr, 90% within 2 yr

### When Should Investigations Begin?

- <35 yr: after 1 yr of regular unprotected intercourse
  - 35-40 yr: after >6 mo of regular unprotected intercourse
  - >40 yr: immediately
- Earlier if:**
- History of PID
  - History of infertility in previous relationship
  - Prior pelvic surgery
  - Chemotherapy/radiation in either partner
  - Recurrent pregnancy loss
  - Moderate-severe endometriosis

### Ethical Considerations in Infertility Treatment

- Infertility demands non-judgmental discussion
- Ethical issues surrounding surrogacy, donor gametes, and other advanced reproductive technologies are still evolving and remain controversial
- If the physician finds that certain treatment options lie outside of their moral boundaries, the infertile couple should be referred to another physician

**Treatment**

- lifestyle modifications (quit smoking/cannabis, reduce caffeine/alcohol intake, healthy diet, exercise, etc.)
    - education: time intercourse relative to ovulation (have sex every other day from 2 d prior to 3 d following presumed ovulation)
  - medical
    - ovulation induction
      - clomiphene citrate (Clomid\*): estrogen antagonist used in anovulatory patients
        - blocks brain's perception of circulating estrogen, resulting in increased release of FSH and LH which can help to induce ovulation (better results if anovulatory)
        - followed by  $\beta$ -hCG for stimulation of ovum release
      - letrozole: aromatase inhibitor; may be associated with a higher rate of live births in patients with PCOS
    - may add:
      - bromocriptine (dopamine agonist) or carbamazepine (anticonvulsant) if elevated prolactin
      - metformin (for PCOS)
      - luteal phase progesterone supplementation for luteal phase defect (mechanism not completely understood)
      - anticoagulation and ASA (81 mg PO once daily) for women with a history of recurrent spontaneous abortions (for antiphospholipid antibody syndrome)
      - thyroid replacement to keep TSH <2.5
  - surgical/procedural
    - tubuloplasty
    - lysis of adhesions
    - artificial insemination: intracervical insemination (ICI), intrauterine insemination (IUI), intrauterine tuboperitoneal insemination (IUTPI), intratubal insemination (ITI)
    - sperm washing
    - IVF
    - intrafallopian transfer (IFT)
    - GIFT\*: immediate transfer with sperm after oocyte retrieval
    - ZIFT\*: transfer after 24 h culture of oocyte and sperm
    - TET\*: transfer after >24 h culture
    - ICSI
    - IVM
    - $\pm$  oocyte or sperm donors
    - $\pm$  pre-genetic screening for single gene defects in karyotype of zygote
- \*not performed in Canada

**Male Factors**

- see [Urology, U37](#)

**Etiology**

- varicocele (>40%)
- idiopathic (>20%)
- obstruction (~15%)
- cryptorchidism (~8%)
- immunologic (~3%)
- exogenous androgens

**Investigations**

- semen analysis and culture

**Normal Semen Analysis (WHO lower reference limits)**

- Must be obtained after 2-7 d of abstinence
- Volume 1.5 cc
- Count 15 million/cc
- Vitality 58% live
- Motility 32% progressive, 40% total (progressive + non-progressive)
- Morphology 4.0% normal

**Polycystic Ovarian Syndrome**

**Etiology**

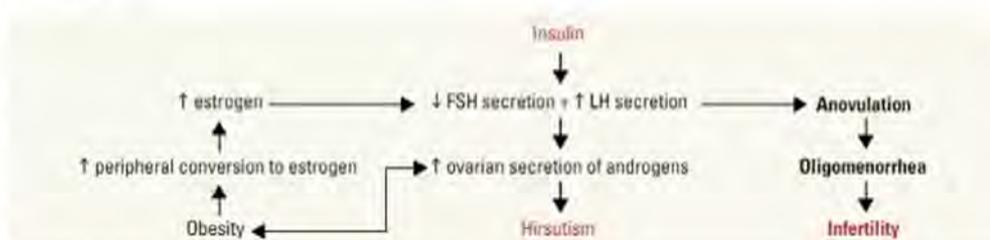

Figure 12. Pathophysiology of polycystic ovarian syndrome

**Polycystic Ovarian Syndrome – HAIR-AN**  
 Hirsutism, Hyper Androgenism, Infertility, Insulin Resistance, Acanthosis Nigricans

### Diagnosis

- Rotterdam diagnostic criteria: 2 of 3 required
  - oligomenorrhea/irregular menses for 6 mo
  - hyperandrogenism
    - clinical evidence – hirsutism or acne
    - biochemical evidence – raised free testosterone
  - polycystic ovaries on U/S (not appropriate in adolescents)

### Clinical Features

- average age 15-35 yr at presentation
- in adolescents, wait at least 1-2 yr to make diagnosis as adolescence resembles PCOS
- abnormal/irregular uterine bleeding, hirsutism, infertility, obesity, virilization
- acanthosis nigricans: darkening of skin folds in intertriginous zones (indicative of insulin resistance)
- insulin resistance occurs in both lean and obese patients
- FMHx of DM

### Investigations

- assess BMI, BP, and fasting lipid profile at presentation
  - goal: identify hyperandrogenism or chronic anovulation and rule out specific pituitary or adrenal disease as the cause
- laboratory
  - prolactin, TSH, free T4
  - 17-hydroxyprogesterone, LH:FSH >2:1 (LH is chronically high with FSH mid-range or low (low sensitivity and specificity))
  - increased DHEAS, androstenedione, and free testosterone (most sensitive)
- transvaginal or transabdominal U/S: polycystic-appearing ovaries
  - “string of pearls” – 12 small follicles 2-9 mm or increased ovarian volume (>10 cc)
- tests for insulin resistance or glucose tolerance
  - 75 g OGTT yearly (particularly if obese)
- consider endometrial biopsy if long-standing abnormal uterine bleeding to rule out hyperplasia
- rule out other causes of abnormal bleeding

### Treatment

- cycle control
  - lifestyle modification (decrease BMI, increase exercise) to decrease peripheral estrone formation
  - hormonal IUS, combined hormonal contraception or cyclic Provera® to prevent endometrial hyperplasia due to unopposed estrogen
  - oral hypoglycemic (e.g. metformin) if T2DM or if trying to become pregnant
  - tranexamic acid (Cyklokapron®) for menorrhagia only
- infertility
  - medical induction of ovulation: letrozole, clomiphene citrate, human menopausal gonadotropins (HMG (Pergonal®)), LHRH, recombinant FSH, and metformin
    - metformin may be used in conjunction with clomiphene citrate for ovulation induction
  - ovarian drilling (perforate the stroma), wedge resection of the ovary - rarely done
  - bromocriptine (if hyperprolactinemia)
- hirsutism
  - any OCP can be used
    - Diane 35® (cyproterone acetate): antiandrogenic
    - Yasmin® (drospirenone and ethinyl estradiol): spironolactone analogue (inhibits steroid receptors)
  - mechanical removal of hair
  - finasteride (5- $\alpha$  reductase inhibitor)
  - flutamide (androgen reuptake inhibitor)
  - spironolactone (androgen receptor inhibitor)

#### PCOS may be confused with

- Late onset CAH (21-hydroxylase deficiency)
- Cushing's syndrome
- Ovarian and adrenal neoplasms
- Hyperprolactinemia
- Hypothyroidism

#### Clinical Signs of Endocrine Imbalance

- Menstrual disorder/amenorrhea (80%)
- Infertility (74%)
- Hirsutism (69%)
- Obesity (49%)
- Impaired glucose tolerance (35%)
- DM (10%)

#### Long-Term Health Consequences

- Hyperlipidemia
- Adult-onset DM
- Endometrial hyperplasia
- Subfertility
- Obesity
- Sleep apnea

#### Diagnostic Criteria for Polycystic Ovary Syndrome: Pitfalls and Controversies

DOC 2008;8:671-679

At present, there is no clear-cut definition of biochemical hyperandrogenemia, particularly since there is dependence on poor laboratory standards for measuring androgens in women. Clinical signs of hyperandrogenism are ill-defined in women with PCOS, and diagnosis of both hirsutism and polycystic ovarian morphology remains subjective. There is also the inappropriate tendency to assign ovulatory status solely on the basis of menstrual cycle history or poorly timed endocrine measurements. Therefore it is important as clinicians to recognize the multifactorial and complex nature of PCOS and place this in the context of our present diagnostic limitations.

# Gynaecological Infections

## Physiologic Discharge

- clear, white, flocculent, odourless discharge; pH 3.8-4.2
- smear contains epithelial cells, Lactobacilli
- increases with increased estrogen states: pregnancy, OCP, mid-cycle, PCOS, or premenarchal
- if increased in perimenopausal/postmenopausal woman, consider investigation for other effects of excess estrogen (e.g. endometrial cancer)

## Non-Physiologic Discharge

- etiology
  - genital tract infection
  - vulvovaginitis: candidiasis, trichomoniasis, BV, polymicrobial superficial infection
  - chlamydia, gonorrhoea
  - pyosalpinx, salpingitis
  - genital tract inflammation (non-infectious)
  - local: chemical irritants, douches, sprays, foreign body, trauma, atrophic vaginitis, desquamative inflammatory vaginitis, focal vulvitis
  - neoplasia: vulvar, vaginal, cervical, endometrial
  - systemic: toxic shock syndrome, Crohn's disease, collagen vascular disease, dermatologic (e.g. lichen sclerosis)
  - IUD, OCP (secondary to progesterone)

## Vulvovaginitis

### PREPUBERTAL VULVOVAGINITIS

- clinical features: irritation, pruritus, discharge, vulvar erythema, vaginal bleeding (can be due to Group A *Streptococcus* and *Shigella*)
- etiology
  - non-specific vulvovaginitis is responsible for 25-75% of vulvovaginitis in prepubertal girls
  - there are a number of potential factors in children that increase the risk of vulvovaginitis:
    - lack of labial development
    - non-estrogenized, thin mucosa
    - more alkaline pH (pH 7) than postmenarchal girls/women
    - obesity
    - poor hygiene (proximity of anus to vagina)
    - foreign bodies (most commonly toilet paper)
    - irritation by bubble baths, shampoos, perfumed soaps, and chemicals
  - localized skin disorders: lichen sclerosis, condyloma acuminata
  - trauma: accidental straddle injury, sexual abuse
  - infectious
    - pinworms
    - *Candida* (if using diapers or chronic antibiotics)
    - Group A *Streptococcus*, *S. aureus*, and *Shigella*
    - discovery of STI should raise suspicion of sexual abuse
  - other
    - polyps, tumour (ovarian malignancy)
    - psychosomatic vaginal complaints (specific to vaginal discharge)
    - endocrine abnormalities (specific to vaginal bleeding)
    - blood dyscrasia (specific to vaginal bleeding)
    - other systemic diseases: measles, chickenpox, scarlet fever, Epstein-Barr Virus, *Mycoplasma pneumoniae*-induced rash and mucositis, Stevens-Johnson syndrome, Crohn's disease, and Kawasaki disease have all been associated with vulvovaginal signs and symptom
- investigations
  - vaginal swab for culture (specifically state that it is a pre-pubertal specimen)
  - pH, wet-mount, and KOH smear in prepubertal adults only
- treatment
  - enhanced hygiene and local measures (handwashing, white cotton underwear, use sitz baths, use mild detergent, urinate with legs spread apart, no nylon tights, no tight-fitting clothes, no sleeper pajamas, avoid bubble baths, eliminate fabric softener, avoid prolonged exposure to wet bathing suits) to protect vulvar skin
  - infectious: treat with antibiotics for organism identified

### Vulvovaginitis

Vulvar and vaginal inflammation

### Vulvar Hygiene

Recommend wipe front to back, wash vulva only with water, avoid daily pantyliners, avoid douching, no need for "feminine cleansers/sprays/powders", use gentle laundry detergents for underwear, cotton underwear, no underwear at night

### Prepubertal and Adolescent Gynaecological Infections: Legal Aspects of Confidentiality

- Clinicians who treat adolescents must be aware of federal, state, and provincial laws related to adolescent consent and confidentiality
- Clinicians must be aware of guidelines governing funding sources for particular services and be familiar with the consent and confidentiality policies of the facility in which they practice

Most common gynaecological problem in prepubertal girls is non-specific vulvovaginitis, not yeast

Table 14. Other Common Causes of Vulvovaginitis in Prepubertal Girls

	Pinworms	Lichen Sclerosus	Foreign Body
Diagnosis	Cellophane tape test	Area of white patches and thinning of skin (figure of 8)	Careful examination with or without sedation
Treatment	Empirical treatment with mebendazole (anthelmintic)	Topical steroid creams	Irrigation of vagina with saline, may require local anesthesia or an exam under anesthesia

## INFECTIOUS VULVOVAGINITIS

Table 15. Infectious Vulvovaginitis

	Candidiasis	Bacterial Vaginosis (BV)	Trichomoniasis
Organisms	<i>Candida albicans</i> (90%) <i>Candida glabrata</i> (~5%) <i>Candida tropicalis</i> (<5%)	Replacement of vaginal Lactobacillus with: <i>Gardnerella vaginalis</i> <i>Mycoplasma hominis</i> Anaerobes: <i>Prevotella</i> , <i>Mobiluncus</i> , <i>Bacteroides</i>	<i>Trichomonas vaginalis</i> (flagellated protozoan)
Risk Factors	Immunosuppression (DM, AIDS, etc.) Recent antibiotic use Increased estrogen levels (e.g. pregnancy, OCP)	High frequency of vaginal intercourse Smoking Douching	Sexual transmission
Discharge	Whitish, "cottage cheese," minimal	Grey, thin, diffuse, fishy smelling	Yellow-green, malodorous, diffuse, frothy
% asymptomatic	20% asymptomatic	50-75% asymptomatic	25% asymptomatic
Signs/Symptoms	Intense pruritus Swollen, inflamed genitals Vulvar burning, dysuria, dyspareunia	Fishy odour, especially after coitus Absence of vulvar/vaginal irritation	Petechiae on vagina and cervix Occasionally irritated, tender vulva Dysuria, frequency, dyspareunia
pH	≤4.5	≤4.5	≤4.5
Saline Wet Mount	KOH wet mount reveals hyphae and spores	>20% clue cells = squamous epithelial cells dotted with coccobacilli ( <i>Gardnerella</i> ) Paucity of WBC Paucity of Lactobacilli Positive whiff test: fishy odour with addition of KOH to slide (due to formation of amines)	Motile flagellated organisms Many WBC Inflammatory cells (PMNs) Can have positive whiff test
Treatment	Clotrimazole, butoconazole, miconazole, terconazole suppositories, and/or creams for 1, 3, or 7 d treatments Only vaginal treatment in pregnancy Fluconazole 150 mg PO in single dose	No treatment if non-pregnant and asymptomatic, unless scheduled for pelvic surgery or procedure <b>Oral</b> Metronidazole 500 mg PO BID x 7 d* Oral treatment is best in pregnancy <b>Vaginal</b> Metronidazole 0.75% gel x 5 d once daily Clindamycin 2% 5 g intravaginally at bedtime for 7 d Probiotics ( <i>Lactobacillus</i> sp.): oral or topical alone or as adjuvant	Treat even if asymptomatic Metronidazole 2 g PO single dose or metronidazole 500 mg BID x 7 d (alternative) Symptomatic pregnant women should be treated with metronidazole 2 g once
Other	Prophylaxis for recurrent infection includes boric acid, vaginal suppositories, luteal phase fluconazole Routine treatment of partner(s) not recommended (not sexually transmitted)	Associated with recurrent preterm labour, preterm birth, and postpartum endometritis Routine treatment of partner(s) not recommended (not sexually transmitted)	Treat partner(s) (sexually transmitted)

\* Need to warn patients on metronidazole not to consume alcohol (disulfiram-like action)

## Sexually Transmitted Infections

• see [Family Medicine, FM46](#)

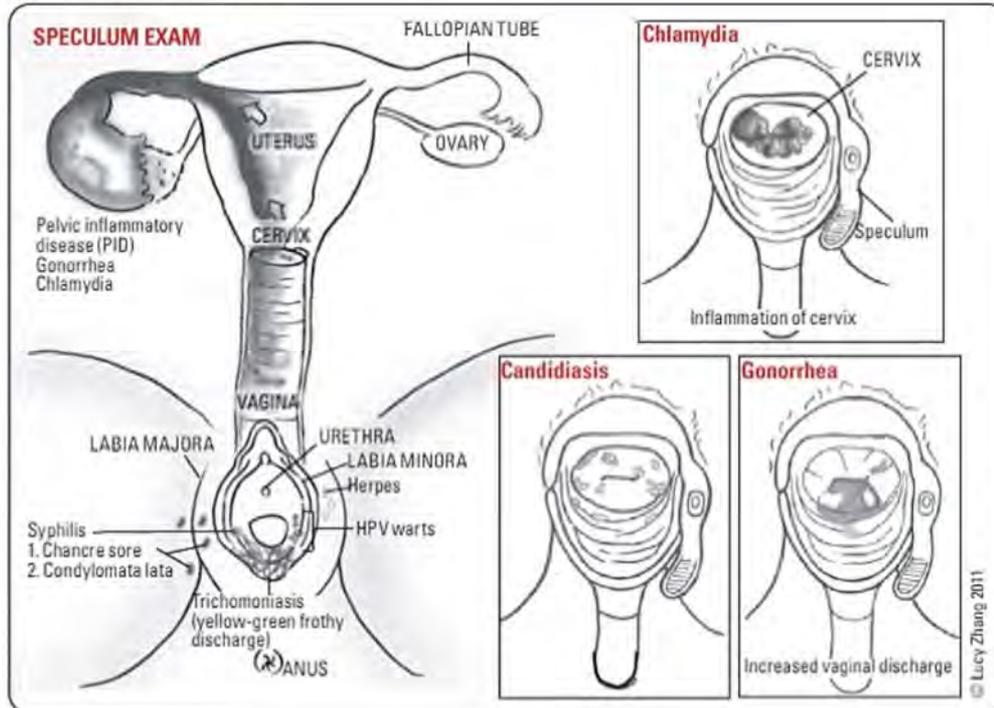

Figure 13. Speculum exam

### TRICHOMONIASIS

• see [Infectious Vulvovaginitis, GY27](#)

### CHLAMYDIA

#### Etiology

• *Chlamydia trachomatis*

#### Epidemiology

- most common bacterial STI in Canada
- often associated with *N. gonorrhoeae* (patients with chlamydia should also be tested for gonorrhoea)

#### Clinical Features

- asymptomatic (80% of women)
- muco-purulent endocervical discharge
- urethral syndrome: dysuria, frequency, pyuria, no bacteria on culture
- pelvic pain
- postcoital bleeding or intermenstrual bleeding (particularly if on OCP and prior history of good cycle control)
- symptomatic sexual partner

#### Investigations

- cervical culture or nucleic acid amplification test (can present in pharynx, rectum)
- obligate intracellular parasite: tissue culture is the definitive standard
- urine and self vaginal tests now available, which are equally or more effective than cervical culture

#### Treatment

- doxycycline 100 mg PO BID for 7 d or azithromycin 1 g PO in a single dose
  - Doxycycline is contra-indicated in the 2nd and 3rd trimesters of pregnancy
- reportable disease, test and provide empiric treatment to all sexual partners of the index case within 60 d prior to symptom onset or date of specimen collection (if the index case is asymptomatic)
- test of cure is recommended 3 wk after completion of treatment when compliance to treatment is suboptimal, an alternative treatment regimen is used, experiencing persistent symptoms, or the person is prepubertal or pregnant

#### Screening

- during pregnancy
- asymptomatic sexually active people under 25 yr
- neonates born to mothers with chlamydia
- any other people with risk factors for sexually transmitted and blood-borne infections

#### CDC Notifiable Diseases

- Chancroid
- Chlamydia
- Gonorrhoea
- Hepatitis A, B, C
- HIV
- Syphilis

#### Risk Factors for STIs

- History of previous STI
- Contact with infected person
- Sexually active individual <25 yr
- Multiple partners
- New partner in last 3 mo
- Lack of barrier protection use
- Social factors (homelessness, drug use)

#### STI Testing

- Vaginal swab
- Tests for bacterial vaginosis, trichomoniasis, *Candida*
- Cervical swab
- Tests for gonorrhoea and chlamydia

Test of cure for *C. trachomatis* and *N. gonorrhoeae* is not routinely indicated. Repeat testing if symptomatic, if compliance with treatment is uncertain, or if pregnant.

**Complications**

- PID: low-grade salpingitis and adhesions resulting in tubal obstruction
- infertility
- ectopic pregnancy
- chronic pelvic pain
- Fitz-Hugh-Curtis syndrome (liver capsule inflammation)
- reactive arthritis (male predominance, HLA-B27 associated), conjunctivitis, urethritis
- perinatal infection: conjunctivitis, pneumonia

**GONORRHEA****Etiology**

- *Neisseria gonorrhoeae*
- symptoms and risk factors same as chlamydia

**Investigations**

- Gram stain shows Gram-negative intracellular diplococci
- cervical, rectal, and throat culture (if clinically indicated)

**Treatment**

- single dose of ceftriaxone 250 mg IM plus azithromycin 1 g PO
  - if pregnant: above regimen or spectinomycin 2 g IM plus azithromycin 1 g PO (avoid quinolones)
  - also treat chlamydia, due to high rate of co-infection
- treat partners
  - reportable disease
  - screening as with chlamydia

**HUMAN PAPILLOMAVIRUS****Etiology**

- most common viral STI in Canada
- >200 subtypes, of which >30 are genital subtypes
- HPV types 6 and 11 are classically associated with anogenital warts/condylomata acuminata
- HPV types 16 and 18 are the most oncogenic (classically associated with cervical HSIL)
- types 16, 18, 31, 33, 35, 36, 45 (and others) associated with increased incidence of cervical and vulvar intraepithelial hyperplasia and carcinoma
  - HPV is readily transmissible between opposite and same-sex partners through receptive and penetrative vaginal, anal and oral sex, and non-penetrative sex (digital-vaginal sex and skin-to-skin contact)
  - infection with one HPV type does not appear to provide protection against infection with related HPV types

**Clinical Features**

- latent infection
  - no visible lesions, asymptomatic
  - only detected by DNA hybridization tests
- subclinical infection
  - visible lesion found during colposcopy or on Pap test
- clinical infection
  - visible wart-like lesion without magnification (check pharynx too)
  - hyperkeratotic, verrucous or flat, macular lesions
  - vulvar edema

**Investigations**

- cervical cytology by Pap test
  - koilocytosis: nuclear enlargement and atypia with perinuclear halo
- biopsy of lesions at colposcopy
- detection of HPV DNA subtype using nucleic acid probes (not routinely done but can be done in presence of abnormal Pap test to guide treatment)

**Treatment**

- anogenital warts
  - patient administered
    - podofilox 0.5% solution or gel BID x 3 d in a row (4 d off) then repeat x 4 wk
    - imiquimod (Aldara®) 5% cream 3x/wk nightly x 16 wk
    - sinecatechins 10% ointment 0.5 cm strand TID x up to 16 wk, daily dose ≤ 250 mg (need not be washed off)

**Genital Warts During Pregnancy**

- Condyloma tend to get larger in pregnancy and should be treated early (consider excision)
- Removal only if obstructing birth canal or risk of extensive bleeding
- Do not use imiquimod, podophyllin, or podofilox in pregnancy
- Baby at risk for juvenile respiratory papillomatosis, but cone dissection does not significantly reduce the risk

**Human Rights in Health Equity: Cervical Cancer and HPV Vaccines**

Am J Law Med 2009;35:365-387

- While cervical cancer rates have drastically fallen in developed countries due to effective prevention and treatment, socially disadvantaged women within these countries remain disproportionately more likely to develop and die of cervical cancer.
- In most developing countries cervical cancer rates have risen or remained unchanged.
- It must be recognized that cervical cancer disparities between race groups, urban and rural residence, and high and low socioeconomic status are attributed to disparate screening and vaccination coverage.
- Programs are implemented without sufficient attention to conditions that render screening less effective or inaccessible to disadvantaged social groups including: lack of information, undervaluing of preventive care, opportunistic delivery in limited healthcare settings, sexual health stigma, and related privacy concerns.

**A9-Valent HPV Vaccine Against Infection and Intraepithelial Neoplasia in Women**

NEJM 2015;372:711-723

**Purpose:** To determine the efficacy and immunogenicity of the 9HPV (types 6, 11, 16, 18) vs. 9vHPV (five additional types 31, 33, 45, 52, 58) vaccines.

**Method:** International randomized, double-blinded phase 2B-3 study of 9vHPV vaccine in 14215 women between ages of 16-26. Participants were randomized to the 9vHPV vaccine group or the 9HPV vaccine group and each received a series of three IM injections (d 1, 2 mo, and 6 mo). Swabs of labial, vulvar, perineal, perianal, endocervical, and ectocervical tissue was obtained and used for HPV DNA testing/Pap smear.

**Results:** Rate of high-grade cervical, vulvar, or vaginal disease was 14.0 per 1000 person-yr in both vaccine groups. The rate of high-grade cervical, vulvar, or vaginal disease related to HPV-31, 33, 45, 52, and 58 was 0.1 per 1000 person-yr in the 9vHPV group and 1.6 per 1000 person-yr in the 9HPV group (95% CI=0.9-99.8). Antibody responses to HPV-6, 11, 16, and 18 were not significantly different between the two vaccine groups although adverse events related to injection sites were more common in the 9vHPV group.

**Conclusions:** The 9vHPV vaccine was non-inferior to 9HPV vaccine in preventing infection and disease related to HPV-6, 11, 16, and 18 and also covered additional oncogenic types HPV-31, 33, 45, 52, and 58 in a susceptible population.

- provider administered
  - cryotherapy with liquid nitrogen: repeat q1-2 wk
  - podophyllin resin in tincture of benzoin: weekly
  - trichloroacetic acid (TCA) (80-90%) or bichloroacetic acid weekly x 4-6 wk; safe in pregnancy
  - surgical removal/laser
- intraepithelial lesions and cancers (See *Gynaecological Oncology, GY42*)

### Prevention

- vaccination: Gardasil<sup>9</sup>, Gardasil<sup>9</sup>, Cervarix<sup>9</sup> (see *Table 28, GY49*)
- condoms may not fully protect (areas not covered, must be used every time throughout entire sexual act)

## HERPES SIMPLEX VIRUS OF VULVA

### Etiology

- 90% are HSV-2, 10% are HSV-1

### Clinical Features

- may be asymptomatic
- initial symptoms: average incubation is 4 d after exposure (range 2-12 d)
- prodromal symptoms: tingling, burning, and pruritus
- multiple, painful, shallow ulcerations with small vesicles appear 7-10 d after initial infection (absent in many infected persons); lesions are infectious
- inguinal lymphadenopathy, malaise, and fever often with first infection
- dysuria and urinary retention if urethral mucosa affected
- recurrent infections: common but less severe, less frequent, and shorter in duration (usually only HSV-2)

### Investigations

- viral culture preferred in patients with ulcer present; however, decreased sensitivity as lesions heal
- HSV DNA PCR
- cytologic smear (Tzanck smear) shows multinucleated giant cells, limited use due to low sensitivity and specificity
- type specific serologic tests for antibodies to HSV-1 and HSV-2 (not routinely available in Canada)

### Treatment

- first episode: acyclovir 200 mg PO five times daily x 7-10 d, famciclovir 250 mg PO TID x 7-10 d, or valacyclovir 1 g PO BID x 7-10 d
- recurrent episode: acyclovir 400 mg PO TID x 5 d, famciclovir 125 mg PO BID x 5 d, or valacyclovir 1 g PO once daily x 5 d
- daily suppressive therapy
  - consider for >6 recurrences per yr or recurrence every 2 mo
  - acyclovir 400 mg PO BID, famciclovir 250 mg PO BID, valacyclovir 500 mg PO once daily, or valacyclovir 1 g PO once daily
- severe disease: IV acyclovir 5-10 mg/kg IV q8 h x 2-7 d or until clinical improvement observed followed by oral antiviral therapy to complete 10 d of total therapy
- education regarding transmission: avoid sexual contact from onset of prodrome until lesions have cleared, use barrier contraception

## SYPHILIS

### Etiology

- *Treponema pallidum*

### Classifications

- primary syphilis
  - 3-4 wk after exposure (median incubation 21 d)
  - painless chancre on vulva, vagina, or cervix
  - painless inguinal lymphadenopathy
  - serological tests usually negative, local infection only
- secondary syphilis (can resolve spontaneously)
  - 2-6 mo after initial infection, in 25% of patients with untreated primary syphilis
  - nonspecific symptoms: malaise, anorexia, headache, and diffuse lymphadenopathy
  - generalized maculopapular rash: palms, soles, trunk, and limbs
  - condylomata lata: anogenital, broad-based, fleshy, grey lesions
  - serological tests usually positive
- latent syphilis
  - no clinical manifestations; detected by serology only

### Epidemiology of Genital Ulcers

HSV	70-80%
1 <sup>o</sup> Syphilis	5%
Chancroid ( <i>Haemophilus ducreyi</i> )	<1%

- tertiary syphilis
  - may involve any organ system
  - neurological: tabes dorsalis, and general paresis
  - cardiovascular: aortic aneurysm and dilated aortic root
  - vulvar gumma: nodules that enlarge, ulcerate, and become necrotic (rare)
- congenital syphilis
  - may cause fetal anomalies, stillbirths, or neonatal death

### Investigations

- aspiration of ulcer serum or node
- dark field microscopy (most sensitive and specific diagnostic test for syphilis): look for spirochetes
- non-treponemal screening tests (VDRL, RPR); non-reactive after treatment, can be positive with other conditions
- specific anti-treponemal antibody tests (FTA-ABS, MHA-TP, TP-PA)
  - confirmatory tests; remain reactive for life (even after adequate treatment)

### Treatment

- reportable disease, partners should be referred for treatment
- treatment of primary, secondary, latent syphilis of <1 yr duration
  - benzathine penicillin G 2.4 million units IM single dose
- treatment of latent syphilis of >1 yr duration
  - benzathine penicillin G 2.4 million units IM q1 wk x 3 wk
- treatment of neurosyphilis
  - IV aqueous penicillin G 3-4 million units q4 h x 10-14 d
- screening
  - high-risk groups (partner with syphilis, HIV-infected individuals, high risk sexual behaviour, history of incarceration)
  - in pregnancy (see [Obstetrics, Infections During Pregnancy, OB31](#))

### Complications

- if untreated, 25-40% will experience late complications

### HIV

- see [Infectious Diseases, ID27](#)

## Bartholin Gland Abscess

### Etiology

- follows the infection of an obstructed Bartholin duct
- most commonly *E. coli*, polymicrobial, *S. aureus*, and Group B *Strep*

### Clinical Features

- unilateral swelling and pain in inferior lateral opening of vagina
- sitting and walking may become difficult and/or painful

### Treatment

- large mass >3 cm
  - 1st or 2nd episode: I&D under local anesthesia with placement of Word catheter (10 French latex catheter) for 2-3 wk
  - recurrence after two failed attempts with Word catheter: marsupialization in OR
- small mass <3 cm
  - I&D with Word catheter, sitz baths, warm compresses
- antibiotics: reserved for patients with recurrence, high risk of complicated infection, culture-positive MRSA, systemic infection

Figure 14. Bartholin gland abscess

## Pelvic Inflammatory Disease

- up to 20% of all gynaecology-related hospital admissions
- infection of the upper genital tract (above the cervix) including endometrium, fallopian tubes, ovaries, pelvic peritoneum ± contiguous structures that primarily affects young, sexually active women

### Etiology

- microbial etiology unknown in most cases, often considered a polymicrobial infection
- causative organisms (in order of frequency)
  - *C. trachomatis*
  - *N. gonorrhoeae*
    - gonorrhea and chlamydia often co-exist
  - *M. genitalium*
  - *E. coli* and colonic anaerobes found in rare cases of PID in postmenopausal women
  - very rare pathogens: *M. tuberculosis*, *H. influenzae*, *S. pneumoniae*, and the agents of actinomycosis

### Risk Factors

- age 15-25 yr
- multiple partners, STI in partner
- previous PID
- IUD (extremely rare, occurs within first 3 wk after insertion)

### Clinical Features

- wide spectrum of clinical presentation: time course typically acute although many women will have subclinical PID that does not prompt a patient to present for medical care but severe enough to cause significant sequelae (fertility issues)
- clinical diagnosis of PID: fever >38.3°C, lower abdominal pain and tenderness, and abnormal discharge (cervical or vaginal)
- uncommon: N/V, dysuria, and AUB
- chronic disease (often due to chlamydia)
  - constant pelvic pain
  - dyspareunia
  - palpable mass
  - very difficult to treat, may require surgery

### Investigations

- blood work
  - β-hCG (must rule out ectopic pregnancy), CBC, blood cultures if suspect septicemia
- urine routine and microscopy (R&M)
- speculum exam, bimanual exam
  - vaginal swab for Gram stain, C&S
  - nucleic acid amplification tests (NAAT) for *N. gonorrhoeae*, *C. trachomatis*, *M. genitalium*
  - HIV testing and serologic testing for syphilis
- ultrasound
  - may be normal
  - free fluid in cul-de-sac
  - pelvic or tubo-ovarian abscess
  - hydrosalpinx (dilated fallopian tube)
- laparoscopy
  - only done in patients that have failed outpatient treatment, symptoms not improving after 72 h of inpatient treatment, or unclear diagnosis
  - surgery has high specificity but low sensitivity

### Treatment

- must treat with polymicrobial coverage
- percutaneous drainage of abscess under U/S guidance
- laparoscopic drainage when no response to treatment, surgical (salpingectomy, TAH/BSO) if failure
- consider removing IUD after a minimum of 24 h of treatment
- reportable disease, treat partners
- consider re-testing for *C. trachomatis* and *N. gonorrhoeae* 4-6 wk after treatment if documented infection

PID accounts for up to 20% of all gynaecological hospital admissions

### PID Diagnosis

#### Minimum diagnostic criteria

- Cervical motion tenderness
- Uterine tenderness
- Adnexal tenderness

#### Additional diagnostic criteria

- Oral temperature >38.3°C
- Leukocytosis on saline microscopy of vaginal secretions/wet mount
- Elevated ESR or CRP
- Laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis*

#### Definitive diagnostic criteria

- Endometrial biopsy with histopathologic evidence of endometritis
- Transvaginal sonography or MRI showing thickened fluid-filled tubes, free fluid or tubo-ovarian complex
- Gold standard: laparoscopy demonstrating abnormalities consistent with PID

**Table 16. Inpatient and Outpatient Management Options for Pelvic Inflammatory Disease**

	Inpatient	Outpatient
<b>Indications</b>	Moderate to severe illness Atypical infection Adnexal mass, tubo-ovarian mass, or pelvic abscess Failed or cannot tolerate oral therapy Immunocompromised Pregnant Adolescent (first episode) Surgical emergency cannot be excluded (e.g. ovarian torsion) PID is secondary to instrumentation	Typical findings Mild to moderate illness Oral antibiotics tolerated Compliance ensured Follow up within 48-72 h (to ensure symptoms not worsening)
<b>Antibiotic Regimen</b>	Cefoxitin 2 g IV q6 h + doxycycline 100 mg PO/IV q12 h or Clindamycin 900 mg IV q8 h + gentamycin 2 mg/kg IV/IM loading dose then gentamycin 1.5 mg/kg q8 h maintenance dose Continue IV antibiotics for 24 h after symptoms have improved then doxycycline 100 mg PO BID to complete 14 d (add metronidazole 500 mg PO BID x 14 d in patients with tubo-ovarian abscess)	1st line: ceftriaxone 500 mg IM x 1 dose + doxycycline 100 mg PO BID x 14 d or cefoxitin 2 g IM x 1 dose + probenecid 1 g PO + doxycycline 100 mg PO BID ± metronidazole 500 mg PO BID x 14 d 2nd line: ofloxacin 400 mg PO BID x 14 d or levofloxacin 500 mg PO once daily x 14 d ± metronidazole 500 mg PO BID x 14 d

**Complications of Untreated Pelvic Inflammatory Disease**

- chronic pelvic pain
- persistent hydrosalpinx
- abscess, peritonitis
- adhesion formation
- ectopic pregnancy
- infertility
  - 1 episode of PID: 13% infertility
  - 2 episodes of PID: 36% infertility
- bacteremia
- septic arthritis, endocarditis

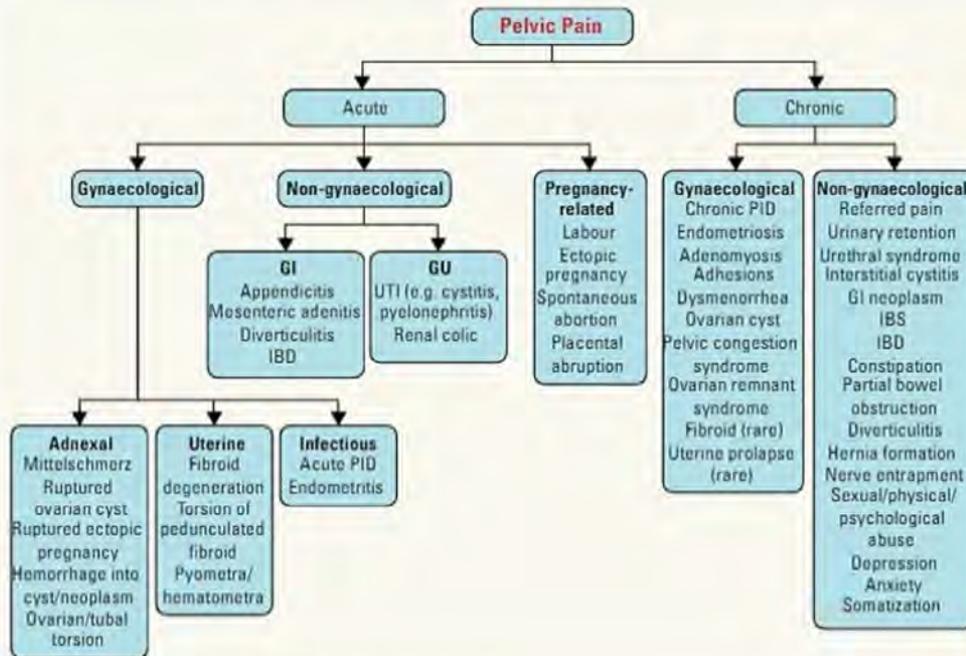

Figure 15. Approach to pelvic pain

**Toxic Shock Syndrome (TSS)**

- see Infectious Diseases, ID22
- Staphylococcal toxic shock syndrome (TSS) is a clinical illness characterized by rapid onset of fever, rash, hypotension, and multiorgan system involvement

**Risk Factors**

- menstrual TSS
  - significantly decreased as a result of the withdrawal of highly-absorbent tampons and polyacrylate rayon-containing products from the market; however, tampon use remains a risk factor for TSS (high absorbency, tampons used continuously for more days of their cycle, and keeping a single tampon in place for a longer period of time)

**Toxic Shock Syndrome**  
Multiple organ system failure due to *S. aureus* exotoxin (rare condition)

- non-menstrual TSS (gynaecologic)
  - diaphragm, cervical cap, or sponge use (prolonged use, i.e. >24 h)
  - surgical and postpartum wound infections, mastitis, sinusitis, osteomyelitis, arthritis, burns, cutaneous lesions, etc.

#### Clinical Features

- sudden high fever/chills
- sore throat, headache, and diarrhea
- macular erythroderma followed by desquamation 1-2 wk later
- signs of multisystem organ failure
- refractory hypotension

#### Treatment

- treatment of shock
- remove potential sources of infection (foreign objects)
- surgical debridement (if warranted)
- adequate hydration
- empiric antibiotic therapy with vancomycin (load 20-35 mg/kg and maintenance 15-20 mg/kg q8-12 h) + clindamycin 900 mg IV q8 h + piperacillin-tazobactam 4.5 g IV q6 h
- continue combination therapy until patient is hemodynamically stable for at least 48-72 h

## Surgical Infections

#### Postoperative Infections in Gynaecological Surgery

- pelvic cellulitis
  - common post hysterectomy, affects vaginal vault
  - erythema, induration, tenderness, and discharge involving vaginal cuff
  - if fever and leukocytosis, treat with broad-spectrum ABx (i.e. clindamycin and gentamicin)
  - drain if excessive purulence or large mass
  - can result in intra-abdominal and pelvic abscess
- see [General and Thoracic Surgery, Postoperative Fever, G58](#)

## Sexual Abuse

- see [Emergency Medicine, ER27](#) and [Family Medicine, FM29](#)

## Sexuality and Sexual Dysfunction

#### SEXUAL RESPONSE

1. desire: energy that allows an individual to initiate or respond to sexual stimulation (libido)
2. arousal: physical and emotional stimulation leading to breast and genital vasodilation and clitoral engorgement (excitement)
3. orgasm: physical and emotional stimulation is maximized, allowing the individual to relinquish their sense of control
4. resolution: most of the congestion and tension resolves within seconds, complete resolution may take up to 60 min

**Note:** this framework cannot be applied consistently to women's sexual response. For many women, the phases may vary in sequence, overlap, repeat, or be absent during some or all sexual encounters

#### SEXUAL DYSFUNCTION

##### Classification

- lack of desire (most common)
- lack of arousal
- anorgasmia
  - primary anorgasmia: never achieved orgasm under any circumstances
  - secondary anorgasmia: was able to achieve orgasms before but unable to achieve orgasms presently
- dyspareunia: painful intercourse, can be superficial or deep

##### Etiology

- biological:
  - gynaecological (e.g. pregnancy, childbirth, menopausal atrophy, endometriosis, prolapse, urinary incontinence)
  - urological (e.g. recurrent UTI, chronic renal failure)
  - vascular (e.g. peripheral vascular disease, CAD)
  - neurological dysfunction (e.g. nerve entrapment syndrome, spinal cord injury, multiple sclerosis, Parkinson's)

- musculoskeletal (e.g. arthritis, mechanical back pain)
- systemic health disorders (e.g. DM, thyroid disorders)
- medication side effects (e.g.  $\beta$ -blockers, benzodiazepines, SSRIs, antipsychotics, oral contraceptives)
- behavioural or lifestyle (e.g. smoking, alcohol consumption, opioids, obesity)
- psychological:
  - early events: history of sexual violence, unpleasant early sexual experiences, or growing up in a family or society that communicates no information or negative messages about women's sexuality
  - current events: depression, anxiety, psychosis, fatigue, stress, or other mental health disorders
- relationship:
  - abuse
  - relationship distress
  - failure to engage in effective sexual stimulation

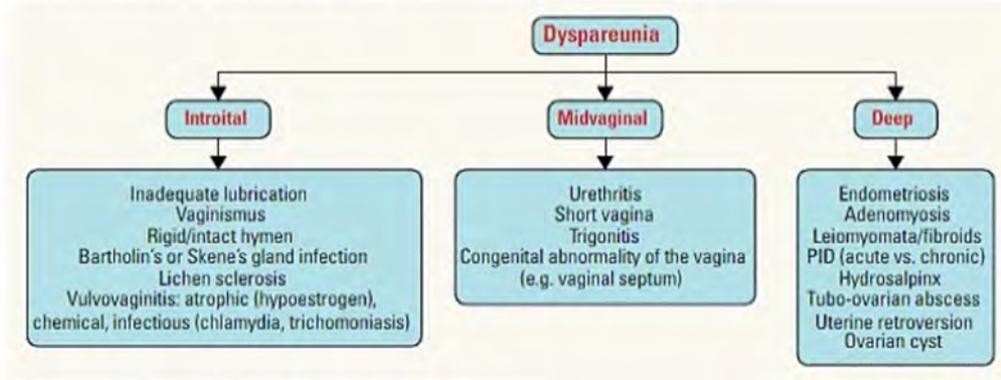

Figure 16. Approach to dyspareunia

**Treatment**

- general:
  - assess patient goals and construct a safety plan as needed
  - counseling
  - lifestyle changes
  - improve body image
- lack of desire:
  - biological: rule out other conditions/medication side effects; consider sildenafil for SSRI side effects; consider androgens (testosterone, DHEA), estrogens, tibolone in postmenopausal women; consider serotonergic and dopaminergic agents: flibanserin, bupropion, buspirone; consider bremelanotide
  - psychological: rule out/treat depression, other mental health issues
  - relationship: assess couple interaction and partner sexual function; treat partner and relationship conflict
- concerns with arousal/lubrication:
  - biological: non-hormonal, water-based lubricants; consider estrogen (topical cream, tablet, or ring)
  - psychological: address sexual anxieties
  - relationship: education regarding slowing of sexual response with aging
- anorgasmia:
  - biological: augment stimulation  $\pm$  vibrator; consider androgens
  - psychological: sex education, anxiety reduction, and use of erotica
  - relationship: stimulation needs and helping patient teach partner what they need
- sexual pain disorders:
  - biological: rule out other conditions; topical estrogen if atrophy; consider nerve modulators (amitriptyline, gabapentin, or pregabalin); pelvic floor physiotherapy
  - psychological: sex therapy if vaginismus
  - relationship: rule out abuse (with patient alone)

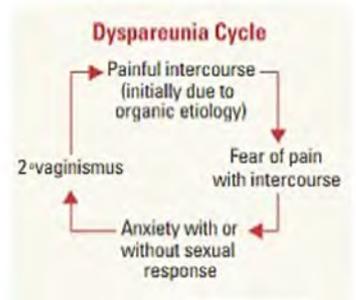

Figure 17. Dyspareunia cycle

**Kegel Exercises**  
Regular contraction and relaxation to strengthen pelvic floor muscles

**Reverse Kegel Exercises**  
1 s contraction then 5 s of relaxation

# Menopause

• see [Family Medicine, FM43](#)

## Definitions

- lack of menses for 1 yr
- timing of menopause
  - physiological; average age 51 yr (follicular atresia)
  - premature ovarian insufficiency; before age 40 (autoimmune disorder, infection, Turner's syndrome)
  - iatrogenic (surgical/radiation/chemotherapy)

## Clinical Features

- associated with estrogen deficiency
  - vasomotor instability (tends to dissipate with time)
    - hot flushes/flashes, night sweats, sleep disturbances, formication, nausea, and palpitations
  - urogenital atrophy involving vagina, urethra, and bladder (genitourinary syndrome of menopause (GUSM))
    - dyspareunia, pruritus, vaginal dryness, bleeding, post-coital bleeding, urinary frequency, urgency, and incontinence
    - inspection may reveal: thinning of tissues, erythema, petechiae, abrasions, and dryness on speculum exam
  - skeletal
    - osteoporosis, joint and muscle pain, and back pain
  - skin and soft tissue
    - decreased breast size, and skin thinning/loss of elasticity
  - psychological
    - increased anxiety, depression, irritability, fatigue, decreased libido, and memory loss

## Investigations

- for women with irregular cycles and menopausal symptoms:
  - >45 yr: no testing necessary
  - 40-45 yr:  $\beta$ -hCG, prolactin, TSH
  - <40 yr:  $\beta$ -hCG, FSH, prolactin, TSH
- increased levels of FSH (>35 IU/L) on day 3 of cycle (if still cycling) and LH (FSH>LH)
- FSH level not always predictive due to monthly variation; use absence of menses for 1 yr to diagnose
- decreased levels of estradiol (later)

## Treatment

- goal is for individual symptom management

**Table 17. Treatment of Menopause**

Vasomotor Instability	Vaginal Atrophy	Urogenital Health	Osteoporosis	Decreased Libido	CVD*	Mood and Memory
Menopause hormonal therapy (MHT) as first line, SSRIs, venlafaxine, gabapentin, propranolol, clonidine, acupuncture, behavioural modifications	Local estrogen: cream (Premarin®) or Estragyn Vaginal Cream®, vaginal suppository (VagFem®), ring (Estring®), lubricants (Replens®), intravaginal laser	Lifestyle changes (weight loss, bladder training), pelvic floor exercises, local estrogen replacement, surgery	Calcium 1000-1500 mg once daily, vitamin D 800-1000 IU, weight-bearing exercise, smoking cessation, bisphosphonates (e.g. alendronate), SERMs (e.g. raloxifene (Evista®)), HRT (second-line treatment)	Vaginal lubricants, counselling, androgen-replacement testosterone cream or the oral form (Andriol®)	Manage CVD risk factors	Anti-depressants (first line), MHT (augments effect), CBT

\*CVD (cardiovascular disease)

### Menopause

Occurrence of last spontaneous menstrual period, resulting from loss of ovarian function (loss of oocyte response to gonadotropins)

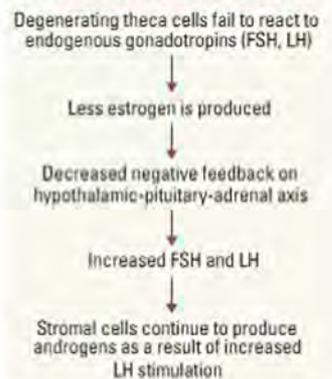

### "Being in menopause"

Lack of menses for 1 yr

### Perimenopause

Period of time surrounding menopause (2-8 yr preceding + 1 yr after last menses) characterized by fluctuating hormone levels, irregular menstrual cycles, and symptom onset

### Menopause Pathophysiology

**Figure 18. Menopause pathophysiology**

- 85% of women experience hot flashes
- 20-30% seek medical attention
- 10% are unable to work

# Menopause Hormone Therapy

• see [Family Medicine, FM43](#)

## Treatment Guidelines

- primary indication is treatment of menopausal symptoms (vasomotor instability)
  - should not be prescribed if the only objective is the prevention of chronic disease
- before starting, review the benefits and risk (see Table 18) and contraindications with the patient
- use the lowest effective dose; patients with standard dose should be advised to lower dose after a few years
- patients receiving MHT must be evaluated annually
- decisions around duration of treatment should be individualized, but recommended to avoid treatment >5 yr with combination estrogen and progesterone treatment due to the duration-dependent risk of breast cancer
  - tapering and abruptly discontinuing MHT have similar impact on symptom recurrence, but for patients with a history of severe baseline vasomotor symptom, gradual tapering is probably preferable

**Table 18. MHT Benefits vs. Risks**

Benefits	Risks
Reduction of vasomotor symptoms	Thromboembolic events
Reduction of sleep problems	Stroke
Reduction of mood or anxiety problems	Breast cancer (increased risk after 4-5 yr with estrogen-progesterone regimens, no increased risk for at least 8 yr with estrogen-alone regimens)
Reduction of aches and pains	Coronary heart disease (for women age >60 and those who are >10 yr after menopause)
Osteoporosis prevention and treatment	Endometrial hyperplasia and cancer (with estrogen-only regimens)
Reversal of vulvar and vaginal atrophy (local estrogen therapy recommended if such atrophy is the only indication for therapy)	

## MHT Components

- estrogen
  - oral or transdermal (e.g. patch, gel)
  - transdermal preferred for women overall, especially with hypertriglyceridemia or impaired hepatic function, smokers, and women who suffer from headaches associated with oral MHT, due to decrease risk of VTE
  - low-dose (preferred dose: Premarin® 0.3 mg/Estradot® patch 25 µg, can increase if necessary)
- progestin
  - given in combination with estrogen for women with an intact uterus to prevent development of endometrial hyperplasia/cancer

### Long-Term Hormone Therapy for Perimenopausal and Postmenopausal Women

Cochrane DB Syst Rev 2017;1:CD004143

**Purpose:** To determine the effect of long-term HT (hormone therapy) on mortality, cardiovascular outcomes, cancer, gallbladder disease, fractures, cognition, and quality of life (QoL) in perimenopausal and postmenopausal women, during HT use, and after cessation of HT.

**Results:** 22 studies with 43637 women included. Most studies included postmenopausal American women with at least some degree of comorbidity, with a mean participant age over 60 yr. Combined continuous HT: increased risk of coronary event after 1 yr (from 2/1000 to 3-7/1000), venous thromboembolism after 1 yr (2/1000 to 4-11/1000), stroke after 3 yr (6/1000 to 6-12/1000), breast cancer after 5.6 yr (19/1000 to 20-30/1000), gallbladder disease after 5.6 yr (27/1000 to 38-60/1000), and death from lung cancer after 5.6 yr use plus 2.4 yr additional follow up (5/1000 to 6-13/1000). Estrogen only HT: increased risk of venous thromboembolism after 1-2 yr use (2/1000 to 2-10/1000; after 7 yr, 16/1000 to 16-28/1000), stroke after 7 yr (24/1000 to 25-40/1000), and gallbladder disease after 7 yr use (27/1000 to 38-60/1000) but reduced the risk of breast cancer after 7 yr (25/1000 to 15-25/1000 and clinical fracture after 7 yr (141/1000 to 92-113/1000). Women >65 yr of age taking combined HT had shown an increase in the incidence of dementia after 4 yr use (9/1000 to 11-30/1000). For women with cardiovascular disease, use of combined continuous HT significantly increased the risk of venous thromboembolism at 1 yr (3/1000 to 3-29/1000).

**Conclusions:** HT may be contraindicated for some women with increased risk of cardiovascular disease, thromboembolic disease, and certain cancers such as breast cancer in women with a uterus. HT is not indicated for primary or secondary prevention of cardiovascular disease, dementia, or deterioration of cognitive function.

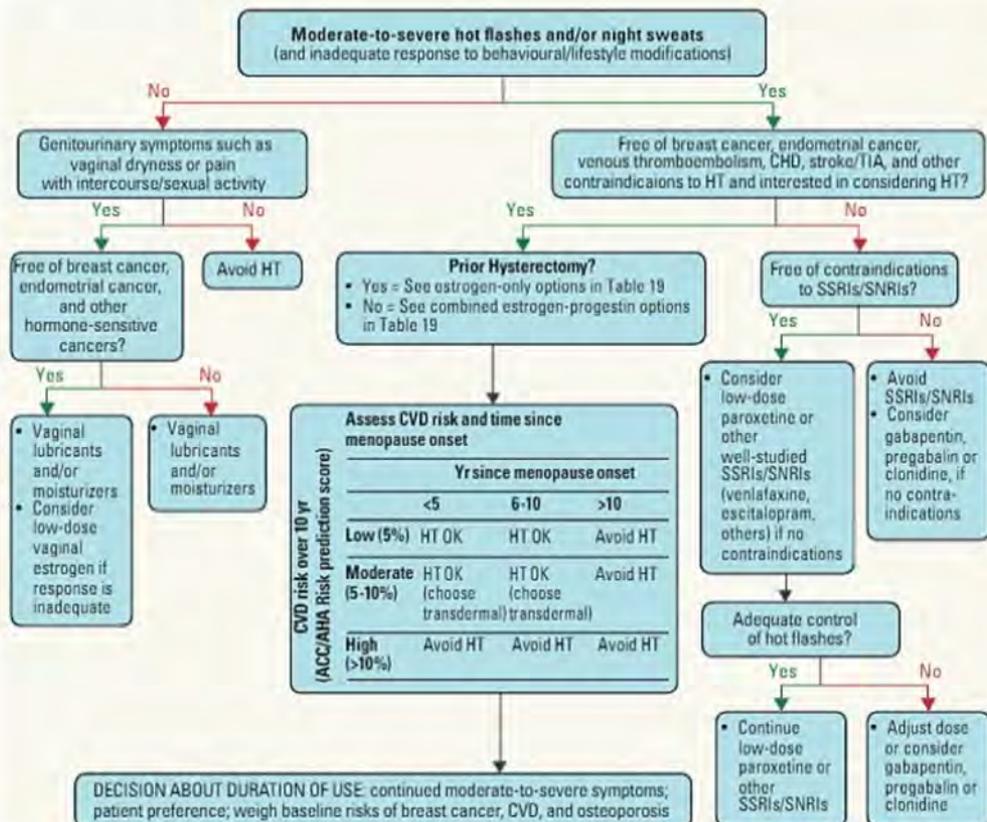

Osteoporosis is the single most important health hazard associated with menopause

Cardiovascular disease is the leading cause of death post-menopause

Increased risk of breast cancer (RR 1.3) is associated with estrogen+progesterone HRT, but not with estrogen-only HRT

All women taking HRT should have periodic surveillance and counselling regarding its benefits and risks

**Figure 19. Hormone therapy in menopause**

**Table 19. Examples of MHT Regimens**

MHT Regimen	Trade Names	Standard Doses
Estrogen-only – oral	Estrace <sup>®</sup>	17 β-estradiol 0.5-1 mg tablet daily
	Premarin <sup>®</sup>	CE 0.3-0.625 mg tablet daily
	Estragyn <sup>®</sup>	Esterified estrogens 0.3-0.625 mg cyclic
Estrogen-only – transdermal	Patches:	
	Estradot <sup>®</sup> , Sandoz Estradiol Derm <sup>®</sup> , Oesclim <sup>®</sup> , Climara <sup>®</sup>	17 β-estradiol 25-100 µg 1-2x/wk
	Gel:	
	EstroGel <sup>®</sup> , Divigel <sup>®</sup>	1-2 metered doses/actuation daily 0.25-1mg packets daily
Estrogen-only – vaginal	Cream:	
	Premarin <sup>®</sup>	CE 0.625 mg/g
	Estragyn <sup>®</sup>	Estrone 1 mg/g
	Inserts: Vagifem <sup>®</sup>	17 β-estradiol 10 µg
Combined E-P – oral	Ring: Estring <sup>®</sup>	17 β-estradiol 2 mg
	Activelle <sup>®</sup>	1 mg 17 β-estradiol/0.5 mg NEA
	Angeliq <sup>®</sup>	1 mg 17 β-estradiol/1 mg drospirenone
Combined E-P – transdermal	Patch: Estalis <sup>®</sup> (2 doses available)	17 β-estradiol/NEA: 50/140 µg continuous 2x/wk 50/140 µg or 50/250 µg cyclic 2x/wk

CE = conjugated estrogen; E-P = estrogen-progestin; NEA = norethindrone acetate  
Current common practice includes using the Mirena<sup>®</sup> IUD as the progesterone component (levonorgestrel 52 mg over 5 yr, approximately 20 µg/d)

**Side Effects of MHT**

- estrogen
  - breast tenderness
  - nausea
  - headache
  - bloating
- progestins
  - mood alterations
  - breast tenderness
  - bloating
  - sedation (micronized progesterone)

**Contraindications to MHT**

- absolute
  - acute liver disease
  - undiagnosed vaginal bleeding
  - history of breast cancer
  - known or suspected uterine cancer/breast cancer
  - acute vascular thrombosis, or history of severe thrombophlebitis or thromboembolic disease
  - cardiovascular disease
- relative
  - pre-existing uncontrolled HTN
  - uterine fibroids and endometriosis
  - familial hyperlipidemias
  - migraine headaches
  - family history of estrogen-dependent cancer
  - chronic thrombophlebitis
  - DM (with vascular disease)
  - gallbladder disease, hypertriglyceridemia, and impaired liver function (consider transdermal estrogen)
  - fibrocystic disease of the breasts

**Menopausal Hormone Therapy and Health Outcomes During the Intervention and Extended Poststopping Phases of the Women's Health Initiative Randomized Trials**

**Purpose:** To report comprehensive findings from the 2 Women's Health Initiative (WHI) hormone therapy trials with extended post-intervention follow-up.  
**Methods:** A total of 27347 postmenopausal women ages 50-79 were enrolled at 40 US centers. In the CEE+MPA trial, 16608 women, with intact uterus, received either continuous combined HRT (CEE 0.625 mg + MPA 2.5 mg once daily) or placebo. In the CEE-only trial, 10739 women, with prior hysterectomy, received either CEE 0.625 mg once daily or placebo.  
**Results:** Results all reported as cases per 10000 person-yr, stratified for age (50-59, 60-69, 70-79):

- CEE+MPA CHD: 6 additional cases (50-59), 0 additional cases (60-69), 19 additional cases (70-79)
- CEE+MPA Invasive breast cancer: 6 additional cases (50-59), 7 additional cases (60-69), 15 additional cases (70-79)
- CEE+MPA Stroke: 5 additional cases (50-59), 11 additional cases (60-69), 13 additional cases (70-79)
- CEE+MPA PE: 6 additional cases (50-59), 8 additional cases (60-69), 18 additional cases (70-79)
- CEE+MPA Colorectal cancer: 1 fewer case (50-59), 8 fewer cases (60-69), 12 fewer cases (70-79)
- CEE+MPA Hip fractures: 2 fewer cases (50-59), 3 fewer cases (60-69), 14 fewer cases (70-79)
- CEE-only CHD: 11 fewer cases (50-59), 2 fewer cases (60-69), 7 additional cases (70-79)
- CEE-only Invasive breast cancer: 5 fewer cases (50-59), 11 fewer cases (60-69), 5 fewer cases (70-79)
- CEE-only Stroke: 1 fewer case (50-59), 18 additional cases (60-69), 18 additional cases (70-79)
- CEE-only PE: 4 additional cases (50-59), 7 additional cases (60-69), 2 fewer cases (70-79)
- CEE-only Colorectal cancer: 3 fewer cases (50-59), 3 fewer cases (60-69), 18 additional cases (70-79)
- CEE-only Hip fractures: 3 additional cases (50-59), 7 fewer cases (60-69), 21 fewer cases (70-79)

**Absolute Contraindications to MHT**

- ABCD**  
 Acute liver disease  
 Undiagnosed vaginal Bleeding  
 Cancer (breast/uterine), Cardiovascular disease  
 DVT (thromboembolic disease)

## Urogynaecology

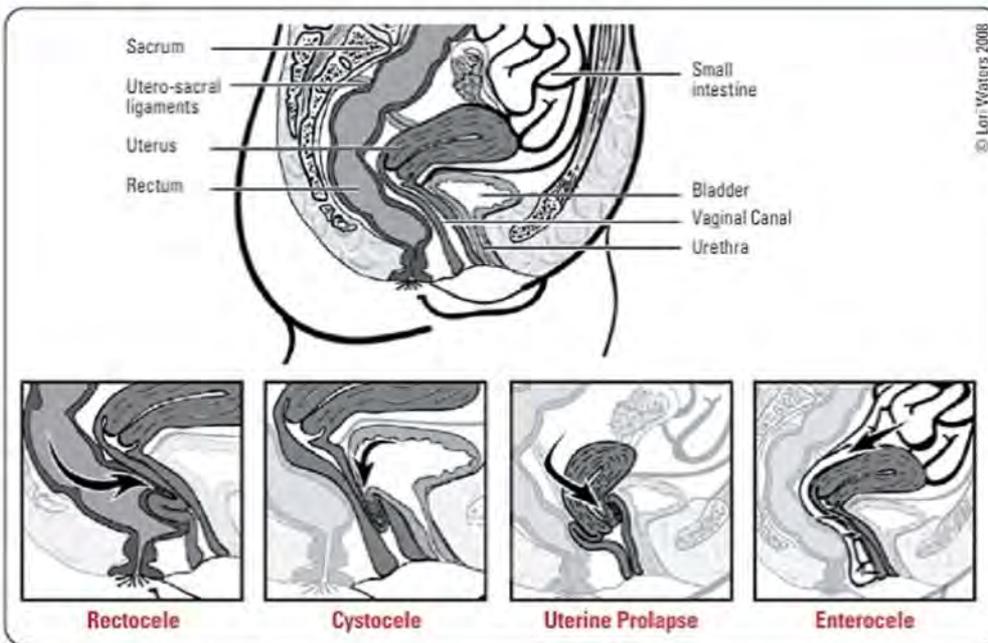

Figure 20. Pelvic anatomy

## Pelvic Organ Prolapse

### Etiology

- related to:
  - vaginal childbirth
  - aging
  - decreased estrogen (post-menopause)
  - increased intra-abdominal pressure (obesity, chronic cough, constipation, ascites, heavy lifting)
  - ethnicity (greater incidence in White women > Asian or African women)
  - connective tissue disorders

### Diagnosis

- medical history
  - assess symptoms specific to prolapse: pressure, bulge
  - assess urinary, defecatory, and sexual concerns, which are often associated with pelvic organ prolapse
- physical exam (each component with patient relaxed and then while straining)
  - inspection in the dorsal lithotomy position
  - evaluate for apical prolapse with a bivalve speculum exam, then evaluate for anterior and posterior prolapse with the posterior blade of the bivalve speculum
  - use the POP-Q staging system to quantify stage of prolapse
  - evaluate for any coexisting pelvic abnormalities with a bimanual exam
  - test the strength of pelvic floor muscles with voluntary Kegel contractions
- ancillary studies
  - if continent with apical prolapse, consider clinical or urodynamic testing with and without reduction of prolapse to investigate for occult stress urinary incontinence
  - if voiding symptoms, consider post-void residual volume to evaluate urinary retention
  - if urgency or other UTI symptoms, consider urine microscopy and culture to test for UTI

### GENERAL CONSERVATIVE TREATMENT

- weight loss
- pelvic floor muscle training (e.g. Kegel exercises, pelvic physiotherapy)
- local vaginal estrogen therapy
- vaginal pessary (intravaginal devices that are either supportive or space-occupying)

The primary clinical features of pelvic organ prolapse are vaginal bulge and pressure

#### Pelvic Organ Prolapse

A weakening in the structures of the pelvic floor resulting in descent of one or more of the pelvic structures (bladder/rectum/small intestine/uterus) into the vagina

#### POP-Q Staging of Pelvic Organ Prolapse

- 0 = no prolapse
- 1 = most distal portion of prolapse >1 cm above level of hymen
- 2 = most distal portion of prolapse is between 1 cm above or below the hymen
- 3 = most distal portion of prolapse >1 cm below level of hymen but no further than 2 cm less than the total vaginal length
- 4 = complete procidentia (uterus present with complete herniation of anterior, posterior, and apical compartments) or vault eversion (no uterus present with complete eversion of the anterior, posterior, and apical compartments), most distal prolapse protrudes 2 cm of total vaginal length

**Table 20. Types and Management of Pelvic Organ Prolapse**

Type	Clinical Features	Treatment
<b>Anterior Vaginal Wall Prolapse (previously "cystocele")</b> (protrusion of bladder into the anterior vaginal wall)	Frequency, urgency, nocturia Stress incontinence Incomplete bladder emptying ± associated increased incidence of UTIs (may lead to renal impairment)	General conservative treatment (see above) Anterior colporrhaphy ("anterior repair") Consider additional/alternative surgical procedure if documented urinary stress incontinence
<b>Posterior Vaginal Wall Prolapse (previously "rectocele")</b> (protrusion of rectum into posterior vaginal wall)	Straining/digitalation to evacuate stool Constipation	General conservative treatment (see above) Also laxatives and stool softeners Posterior colporrhaphy ("posterior repair"), plication of endopelvic fascia and perineal muscles approximated in midline to support rectum and perineum (can result in dyspareunia)
<b>Uterine Prolapse</b> (protrusion of cervix and uterus into vagina)	A type of apical prolapse Groin/back pain (stretching of uterosacral ligaments) Feeling of heaviness/pressure in the pelvis Worse with standing, lifting Worse at the end of the day Relieved by lying down Ulceration/bleeding (particularly if hypoestrogenic) ± urinary incontinence	General conservative treatment (see above) Vaginal hysterectomy ± surgical prevention of vault prolapse Consider additional surgical procedures if urinary incontinence, cystocele, rectocele, and/or enterocele are present
<b>Vault Prolapse</b> (previously "enterocele", protrusion of apex of vaginal vault into vagina, post-hysterectomy, often containing small bowel)	A type of apical prolapse Same as uterine prolapse	General conservative treatment (see above) Sacralcolpopexy (vaginal vault suspension), sacrospinous fixation, or uterosacral ligament suspension

Surgery: native tissue repair vs. mesh reconstruction (usually reserved for severe, recurrent prolapse)

The only true hernia of the pelvis is an ENTEROCELE because peritoneum herniates with the small bowel

## Urinary Incontinence

- see [Urology, U6](#)

### STRESS INCONTINENCE

#### Definition

- involuntary loss of urine with increased intra-abdominal pressure (cough, laugh, sneeze, walk, run)
- affects 4-35% of all women

#### Risk Factors for Stress Incontinence in Women

- increased age
- obesity
- pregnancy/vaginal delivery
- hypoestrogenic state (post-menopause)
- smoking/chronic cough
- neurological
- genetics
- high impact exercise

#### Diagnosis

- history
  - onset, frequency, severity, and pattern of urinary incontinence
  - frequency, dysuria, urgency, and nocturia
  - pads used per 24 h
  - obstructive urinary symptoms (incomplete voiding, hesitancy, straining, post-void dribbling, and recurrent UTI)
  - pelvic organ prolapse symptoms
  - neurological conditions/symptoms
  - obstetric history, and current menopause/hormone therapy status
  - medications (sedatives, diuretics, anticholinergic medications, and OTCs)
  - lifestyle risk factors (caffeine, smoking, weight, exercise, and occupation)
  - urinary diary
- physical exam
  - height, weight, and BMI
  - abdominal exam: scars, abdominal mass, and presence of a full bladder
  - neurological exam: S2-S4 sacral nerves (motor, sensory, and reflexes)
  - elderly: mini mental status exam, and observe mobility
  - pelvic exam: inspect vulva and urogenital epithelium, assess for signs of pelvic organ prolapse, and digital rectal exam to assess for anal sphincter tone and perineal sensation
  - standing stress test

- studies

- urinalysis: hematuria, pyuria, glucosuria, proteinuria
  - hematuria/irritative voiding symptoms: cytology
  - pyuria/bacteria: urine culture
- post-void residual
  - normal:  $\leq 1/3$  total volume
  - abnormal:  $>1/3$  total volume (poor bladder contractility or bladder outlet obstruction)
- urodynamic testing
  - Society of Obstetricians and Gynaecologists of Canada (SOGC): uncertain diagnosis, fails to improve with treatment, clinical trials, or surgical intervention is planned

### Treatment

- for conservative management, see *Pelvic Organ Prolapse, GY39*
- procedures: vaginal laser, urethral bulking
- surgical
  - midurethral sling (TVT, TOT)
  - urethropexy (Burch procedure)
  - pubovaginal sling
  - urethral bulking

## OVERACTIVE BLADDER

### Definition

- symptom syndrome defined as "urgency, with or without urge urinary incontinence (UUI), usually with frequency and nocturia"
- 16% of all women
- UUI: involuntary leakage with or immediately preceded by a strong desire to void
  - involuntary bladder contraction that overcomes the urethral sphincter mechanism OR
  - poor bladder compliance

### Etiology

- idiopathic: congenital and aging
- medical: CHF, DM, and diuretics
- neurogenic: multiple sclerosis, Parkinson's, CVD, dementia, and spinal cord injury
- bladder outlet obstruction: previous bladder neck surgery and pelvic organ prolapse
- gynaecologic: UTI, pregnancy, pelvic mass, and urethral diverticulum
- psychosomatic: habits, anxiety, and high fluid consumption

### Diagnosis

- see *Stress Incontinence, GY40* for diagnosis

### Treatment

- behaviour modification (reduce bladder irritants (caffeine, smoking, alcohol, acidic, spicy); adequate water intake; regular voiding schedule)
- bladder training with pelvic physiotherapist
- medications
  - anticholinergics
    - oxybutynin (oral: Ditropan<sup>®</sup>; patch: Oxytrol<sup>®</sup>; transdermal gel: Gelnique<sup>®</sup>)
    - tolterodine (Detrol<sup>®</sup>)
    - fesoterodine (Toviaz<sup>®</sup>)
    - solifenacin (Vesicare<sup>®</sup>)
    - trospium (Trosec<sup>®</sup>)
    - darifenacin (Enablex<sup>®</sup>)
  - $\beta$ -adrenergic agonist: mirabegron (Myrbetriq<sup>®</sup>)
- procedures: sacral neuromodulation, detrusor botox injection

# Gynaecological Oncology

## Pelvic Mass

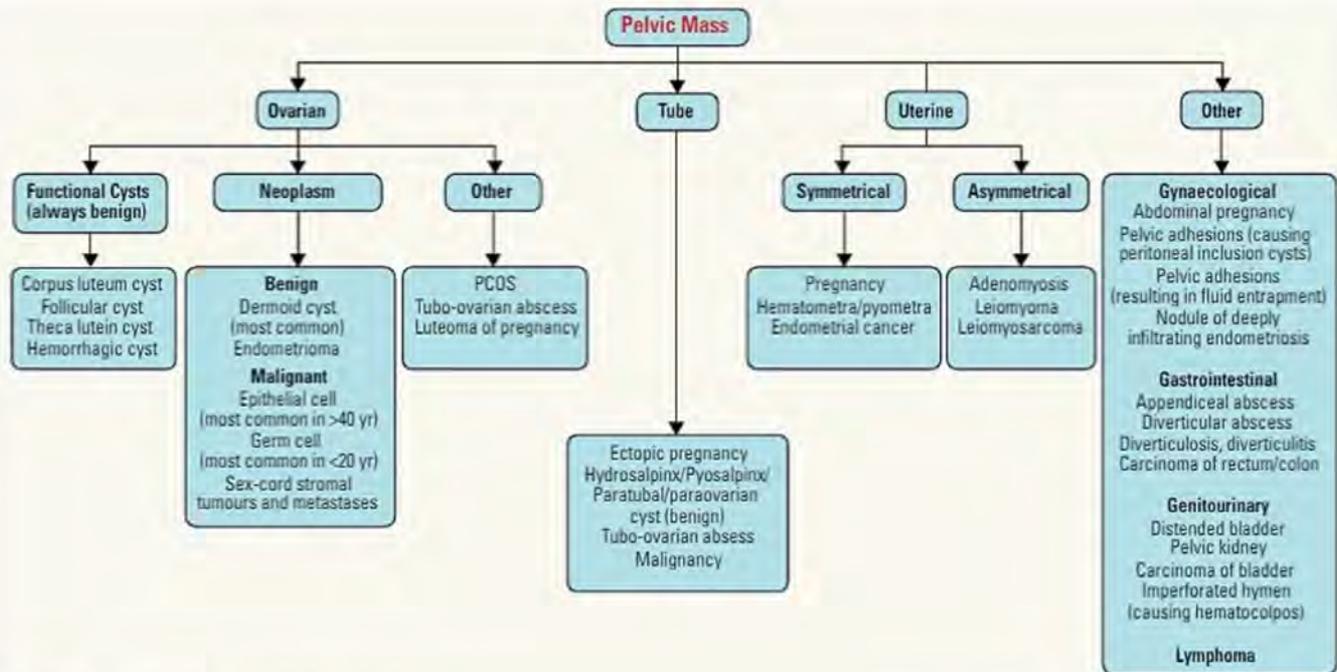

Figure 21. Differential diagnosis of pelvic mass

## Uterus

### ENDOMETRIAL CARCINOMA

#### Epidemiology

- most common gynaecological malignancy in North America (40%); 4th most common cancer in women
- 2-3% of women develop endometrial carcinoma during lifetime
- mean age is 60 yr
- majority are diagnosed in early stage due to detection of symptoms
- 85-90% 5 yr survival for stage I disease
- 70-80% 5 yr survival for all stages

Table 21. Features of Type I and Type II Endometrial Cancer

	Type I	Type II
<b>Description</b>	Estrogen-related (i.e. excess/unopposed estrogen): Endometrioid Includes well-differentiated (grade 1 and 2) endometrioid adenocarcinoma 80% of cases	Non-estrogen related: Non-endometrioid Includes serous, clear cell, grade 4 endometrioid and undifferentiated carcinomas, carcinosarcoma 20% of cases, poorer prognosis
<b>Risk Factors</b> (Increasing age and family history are risk factors for both types)	PCOS Diabetes mellitus Unbalanced HRT (balanced HRT is protective) Nulliparity or history of infertility related to anovulation Late menopause (>55 yr), early menarche Estrogen-producing ovarian tumours (e.g. granulosa cell tumours) HNPCC/Lynch II syndrome Tamoxifen Prior pelvic radiation	Parous women More likely in Black women Associated with p53 mutation, HER2 overexpression
<b>Clinical Features</b>	Postmenopausal bleeding AUB in premenopausal women (menorrhagia, intermenstrual bleeding)	AUB

\*HNPCC = Hereditary non-polyposis colorectal cancer

**Incidence of Malignant Gynaecological Lesions in North America**  
endometrium > ovary > cervix > vulva > vagina > fallopian tube

#### Risk Factors for Endometrial Cancer

##### COLD NUT

- Ca ncer (ovarian, breast, colon)
- Obesity
- Late menopause
- Diabetes mellitus
- Nulliparity
- Unopposed estrogen: PCOS, anovulation, HRT
- Tamoxifen (chronic use)
- (Genetic syndromes: Hereditary Nonpolyposis Colorectal Cancer (HNPCC) - Lynch II syndrome, Cowden syndrome)

Postmenopausal bleeding = endometrial cancer until proven otherwise (95% present with vaginal bleeding)

An endometrial thickness of 5 mm or more is considered abnormal in a postmenopausal woman with vaginal bleeding and a thickness of more than 11 mm is considered abnormal in a postmenopausal woman without vaginal bleeding

**Screening**

- no known benefit for mass screening
- annual endometrial sampling starting at age 30-35 only for women at high-risk (HNPCC/Lynch II syndrome)
- routine pelvic ultrasound should not be used as screening test (high false positive rates)

**Investigations**

- endometrial sampling in all suspected patients (office endometrial biopsy most commonly)
- hysteroscopy considered in patients with persistent uterine bleeding with benign sampling or inadequate sampling
- additional tumour markers, CT, MRI only in specific cases such as high-grade tumours, suspected extrauterine spread

**Prognostic Factors**

- FIGO stage (most important factor)
- Age
- Grade
- Histologic subtype
- Depth of myometrial invasion
- Presence of LVSI

**Complications of Therapy**

**Surgical Complications**

- Surgical site infection
- Lymphedema
- VTE
- Urinary retention
- UTI
- Pelvic lymphocyst
- Leg weakness
- Vaginal dryness

**Radiation Complications**

- Radiation fibrosis
- Cystitis
- Proctitis
- Long-term increase in other types of malignancy

**Table 22. FIGO Staging of Endometrial Cancer (2009)**

Stage	Description	Stage	Description
I	Confined to corpus uteri including endocervical glandular involvement	IIIC	Metastasis to pelvic ± para-aortic LNs
IA	Less than 50% myometrial invasion	IIIC1	Positive pelvic LN
IB	More than 50% myometrial invasion	IIIC2	Positive para-aortic LN ± positive pelvic LNs
II	Involves cervical stroma, but does not extend beyond uterus	IV	Involves bladder ± bowel mucosa ± distant metastases (note: omental disease is stage IV)
III	Involves serosa, adnexa, vagina, or parametrium	IVA	Involves bladder ± bowel mucosa
IIIA	Invasion of serosa ± adnexae	IVB	Distant metastases, including intra-abdominal and intraperitoneal metastases, ± inguinal LNs
IIIB	Vaginal ± parametrial involvement		

FIGO: International Federation of Gynaecology and Obstetrics

**Treatment**

- surgical: total hysterectomy + BSO
  - pelvic washings ± pelvic and para-aortic node dissection ± omentectomy in more advanced cases
  - goals: treatment, staging, determining need for adjuvant treatment
- adjuvant therapy: includes radiation and chemotherapy, depends on clinical and histological features
- hormone therapy: can be used in fertility-sparing treatments (e.g. progesterone IUD or oral progestins)

**Uterine Sarcoma – Presentation**  
Bleeding, abdominal distention, pelvic pressure

CA-125 is indicated for monitoring response to treatment

**UTERINE SARCOMA**

- rare; 3-9% of all uterine malignancies
- arise from stromal components (endometrial stroma, mesenchymal, or myometrial tissues)
- behave more aggressively and are associated with worse prognosis than endometrial carcinoma; 5 yr survival is 35%
- vaginal bleeding is most common presenting symptom

**Table 23. Summary of Uterine Sarcoma Subtypes and Features**

Type	Epidemiology	Features	Diagnosis	Treatment
<b>PURE TYPE</b>				
1. Leiomyosarcoma	Most common type of uterine sarcoma Average age of presentation is 55 yr, but may present in premenopausal women Often coexists with benign leiomyomata (fibroids)	Histologic distinction from leiomyoma: 1. Increased mitotic count (>10 mitoses/10 high-power fields) 2. Tumour necrosis 3. Cellular atypia Rapidly enlarging fibroids in a premenopausal woman Enlarging fibroids in a postmenopausal woman	Often postoperatively after uterus removed for presumed fibroids Stage using FIGO 2009 staging for leiomyosarcomas and ESS	Hysterectomy ± BSO usually No routine pelvic lymphadenectomy Chemotherapy is used in cases of metastatic disease Radiation therapy does not improve local control or survival Poor outcomes overall, even for early-stage disease
2. Endometrial Stromal Sarcoma (ESS)	Usually presents in perimenopausal or postmenopausal women with abnormal uterine bleeding	Abnormal uterine bleeding Good prognosis	Diagnosed by histology of endometrial biopsy or D&C Stage using FIGO 2009 staging for leiomyosarcomas and ESS	Hysterectomy & BSO (remove ovaries as ovarian hormones may stimulate growth) No routine pelvic lymphadenectomy Adjuvant therapy based on stage and histologic features (hormones and/or radiation) Hormonal therapy (progestins) may be used for metastatic disease
3. Undifferentiated Sarcoma	Rare; less common than leiomyosarcoma and ESS	Severe nuclear pleomorphism, high mitotic activity, tumour cell necrosis, and lack of smooth muscle or endometrial stromal differentiation Poor prognosis	Often found incidentally postoperatively for abnormal bleeding	Treatment primarily surgical Radiation and/or chemotherapy for advanced disease or unresectable disease
<b>MIXED TYPE</b>				
4. Adenosarcoma	The rarest of the uterine sarcoma Mixed tumour of low malignancy potential	Present with abnormal vaginal bleeding Polypoid mass in uterine cavity	Mixture of benign epithelium with malignant low-grade sarcoma Often found incidentally at time of hysterectomy for PMB Stage using FIGO 2009 staging for adenosarcoma	Treatment is surgical with hysterectomy & BSO

Table 24. FIGO Staging of Uterine Sarcoma (2009)

Stage	Description	Stage	Description
I	Tumour limited to uterus	III	Tumour invades abdominal tissues
IA	<5 cm	IIIA	One site
IB	>5 cm	IIIB	More than one site
II	Tumour extends beyond uterus	IIIC	Metastasis to pelvic and/or para-aortic lymph nodes
IIA	To the pelvis, adnexal involvement	IV	Distant spread
IIB	To extra-uterine pelvic tissue	IVA	Tumour invades bladder and/or rectum
		IVB	Distant metastasis

## Ovary

### BENIGN OVARIAN TUMOURS

- see Table 25
- many are asymptomatic
- usually enlarge slowly, if at all
- may rupture or undergo torsion, causing pain
  - pain associated with torsion of an adnexal mass usually originates in the iliac fossa and radiates to the flank
- peritoneal irritation may result from an infarcted tumour (rare)

### MALIGNANT OVARIAN TUMOURS

- see Table 25

### Epidemiology

- lifetime risk 1.4%
- majority of ovarian cancer cases are detected in women >50 yr
- causes more deaths in North America than all other gynaecologic malignancies combined
- 4th leading cause of cancer death in women
- 85% epithelial; 15% non-epithelial
- 10-15% of epithelial ovarian cancers are related to hereditary predisposition

### Risk Factors (for epithelial ovarian cancers)

- early menarche and/or late menopause
- personal history of breast, colon, or endometrial cancer
- family history of breast, colon, endometrial, or ovarian cancer
- advanced age
- BRCA mutation (serous) and Lynch syndrome (non-serous, non-mucinous)
- use of fertility drugs (limited evidence)

### Protective Factors (for epithelial ovarian cancers)

- OCP: likely due to ovulation suppression (significant reduction in risk even after 1 yr of use, 50% after 5 yr)
- pregnancy/breastfeeding

### Prophylactic Measures

- prophylactic BSO in high-risk women (i.e. BRCA mutation carriers)
- prophylactic salpingectomy in high-risk women (i.e. BRCA mutation carriers who do not want oophorectomy yet)

### Screening

- no effective method
- routine CA-125 or U/S not recommended

### Clinical Features

- most women with epithelial ovarian cancer present with advanced stage disease (i.e. stage IIIC high grade serous histology)
- symptoms:
  - abdominal symptoms (nausea, bloating, pain, dyspepsia, anorexia, early satiety)
  - symptoms of mass effect
  - increased abdominal girth (from ascites or tumour itself)
  - urinary urgency and frequency
  - constipation

### Ovaries are like GEMS

Germ cell  
Epithelial  
Metastatic  
Sex cord stromal

Most (70%) epithelial ovarian cancers present at stage III disease

### Ovarian Tumour Markers

**Epithelial cell:**

- CA-125 (serous and endometrioid)

**Sex-cord stromal cell:**

- Granulosa cell: inhibin
- Sertoli-Leydig: androgens

**Germ cell:**

- Dysgerminoma: LDH
- Yolk sac: AFP
- Choriocarcinoma:  $\beta$ -hCG
- Immature teratoma: none
- Embryonal cell: AFP +  $\beta$ -hCG

Diagnosis of ovarian tumours requires surgical pathology

Any adnexal mass in postmenopausal women should be considered malignant until proven otherwise

**Omental Cake:** a term for ascites plus a fixed upper abdominal and pelvic mass; almost always signifies ovarian cancer

**Screening for Ovarian Cancer: Updated Evidence Report and Systematic Review for the US Preventive Services Task Force**  
JAMA 2018;319(6):595-606

**Purpose:** To systematically review evidence on benefits and harms of ovarian cancer screening among average-risk, asymptomatic women.  
**Methods:** Systematic review of RCTs of ovarian cancer screening in average-risk women that reported mortality or quality-of-life outcomes. Interventions included transvaginal US and/or CA-125 testing. Comparators were usual care or no screening.

**Results:** Four trials (n = 293587) were included. No trial found a significant difference in ovarian cancer mortality with screening. In two trials, screening led to surgery for suspected ovarian cancer in 1% of women without cancer and for transvaginal US with or without CA-125 screening in 3%, with major complications occurring in 3% to 15% of surgeries. Evidence of psychological harms was found in cases of repeat follow-up scans and tests.

**Conclusions:** Ovarian cancer mortality did not significantly differ between screened women and those with no screening or in usual care.

**Treatment**

- debulking surgery including total hysterectomy, BSO, omentectomy, removal of all visible disease
- many epithelial ovarian cancers (i.e. serous ovarian carcinoma) are chemosensitive: treat with platinum-based chemotherapy + taxol
- neo-adjuvant chemotherapy (if needed) to shrink down tumours prior to debulking
- adjuvant chemotherapy to treat microscopic disease

**Low Malignant Potential (also called "Borderline") Tumours**

- a subcategory of epithelial ovarian cancer (~15% of all epithelial ovarian tumours)
- approximately one-third of tumours are identified in women <40 yr
- pregnancy and breastfeeding are protective factors
- tumour cells with histologically malignant characteristics arise from the ovarian surface, but do not invade ovarian stroma
- able to metastasize, but uncommon
- treated primarily with surgery (BSO/omental biopsy ± hysterectomy)
  - chemotherapy has limited benefit: can be treated with hormonal manipulation (letrozole)
  - young patients can be treated with fertility-sparing options such as cystectomy or unilateral salpingo-oophorectomy
- generally slow growing, excellent prognosis
  - 5 yr survival >99%
  - recurrences tend to occur late, may be associated with low-grade serous carcinoma

**Malignant Ovarian Tumour Prognosis**

5 Yr Survival	
Stage I	75-95%
Stage II	60-75%
Stage III	23-41%
Stage IV	11%

**Table 25. Ovarian Tumours**

Type	Description	Presentation	Ultrasound/Cytology	Treatment
<b>FUNCTIONAL TUMOURS (all benign)</b>				
Follicular Cyst	Follicle fails to rupture during ovulation	Usually asymptomatic May rupture, bleed, tort, infarct, causing pain ± signs of peritoneal irritation	4-8 cm mass, unilocular, lined with granulosa cells	Symptomatic or suspicious masses warrant surgical exploration Otherwise if <6 cm, wait 6 wk then re-examine as cyst usually regresses with next cycle OCP (ovarian suppression): will prevent development of new cysts Treatment usually laparoscopic (cystectomy vs. oophorectomy, based on fertility choice)
Corpus Luteum Cyst	Corpus luteum fails to regress after 14 d, becoming cystic or hemorrhagic	More likely to cause pain than follicular cyst May delay onset of next period	Larger (10-15 cm) and firmer than follicular cysts	Same as for follicular cysts
Theca-Lutein Cyst	Due to atretic follicles stimulated by abnormal β-hCG levels	Associated with molar pregnancy, ovulation induction with clomiphene		Conservative Cyst will regress as β-hCG levels fall
Endometrioma	See <i>Endometriosis, GY11</i>			
Polycystic Ovaries	See <i>Polycystic Ovarian Syndrome, GY24</i>			
<b>BENIGN GERM CELL TUMOURS</b>				
Benign Cystic Teratoma (dermoid)	Single most common ovarian germ cell neoplasm Elements of all 3 cell lines; contains dermal appendages (sweat and sebaceous glands, hair follicles, teeth)	May rupture, twist, infarct 20% bilateral 20% occur outside of reproductive yr	Smooth-walled, mobile, unilocular U/S may show calcification which is pathognomonic	Treatment usually laparoscopic cystectomy; may recur
<b>MALIGNANT GERM CELL TUMOURS</b>				
General Information	Rapidly growing, 2-3% of all ovarian cancers	Usually children and young women (<30 yr)		Surgical resection (often conservative unilateral salpingo-oophorectomy ± nodes) ± chemotherapy
Dysgerminoma	Produces LDH	10-15% bilateral		When diagnosed at stage IA, no adjuvant treatment is indicated If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure
Immature Teratoma	No tumour marker identified	Almost always unilateral		When diagnosed at stage IA Grade 1, no adjuvant treatment is indicated When diagnosed at Grade 2-3, either adjuvant chemotherapy or surgical staging is indicated If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure
Yolk Sac Tumour	Produces AFP	Abdominal pain and pelvic mass		High grade tumour can be treated with adjuvant chemotherapy or monitor AFP levels
Ovarian Choriocarcinoma	Produces β-hCG	Precocious puberty and irregular vaginal bleeding		High grade tumour usually treated with adjuvant chemotherapy

Table 25. Ovarian Tumours

Type	Description	Presentation	Ultrasound/Cytology	Treatment
<b>EPITHELIAL OVARIAN TUMOURS (malignant or borderline)</b>				
General Information	Derived from mesothelial cells lining peritoneal cavity Classified based on histologic type 80-85% of all ovarian neoplasms (including malignant tumours)		Varies depending on subtype	<b>Borderline</b> Cystectomy vs. unilateral salpingo-oophorectomy <b>Malignant</b> 1. Early stage (stage I): Hysterectomy/BSO/staging (omentectomy, peritoneal biopsies, washings, pelvic and para-aortic lymphadenectomy). Depending on histology, may require adjuvant chemotherapy 2. Advanced stage: Upfront cytoreductive (debulking) followed by adjuvant chemotherapy consisting of IV carboplatin/paclitaxel vs. intraperitoneal chemotherapy (stage III) neoadjuvant chemotherapy with IV carboplatin/paclitaxel, followed by delayed debulking with further adjuvant IV chemotherapy
Serous	Most common ovarian tumour histology 50% of all ovarian cancers 75% of epithelial tumours 70% benign	20-30% bilateral	Lining similar to fallopian tube epithelium Often multilocular Histologically contain psammoma bodies (calcified concentric concretions)	See above
Mucinous	20% of epithelial tumours	Rarely complicated by Pseudomyxoma peritonei: implants seed abdominal cavity and produce large quantities of mucin	Resembles endocervical epithelium Often multilocular May reach enormous size	Poor response to chemotherapy If mucinous, remove appendix as well to rule out possible source of primary disease
Clear Cell	10% of epithelial tumours Can be found adjacent to endometriosis More common in the Asian population	More likely to be detected at an early stage	Contains glycogen-rich cells with clear cytoplasm and hobnail cells	Poor response to chemotherapy
Endometrioid	10% of epithelial tumours Can be found adjacent to endometriosis	Can be associated with endometrial neoplasm	Typically cystic or solid, unilateral, and confined to the ovary	Tend to respond well to chemotherapy
<b>SEX CORD STROMAL OVARIAN TUMOURS</b>				
Fibroma/Thecoma (benign)	From mature fibroblasts in ovarian stroma	Non-functioning Occasionally associated with Meig's syndrome (triad of benign ovarian tumour, ascites, and pleural effusion)		
Granulosa-Theca Cell Tumours (benign or malignant)	Tumour marker is inhibin	Estrogen-producing: feminizing effects (precocious puberty, menorrhagia, postmenopausal bleeding) Risk of endometrial cancer due to estrogen	Histologic hallmark of cancer is small groups of cells known as Call-Exner bodies	Surgical resection of tumour Chemotherapy may be used for unresectable metastatic disease
Sertoli-Leydig Cell Tumour (benign or malignant)	Can measure elevated androgens as tumour markers	Androgen-producing: virilizing effects (hirsutism, deep voice, recession of front hairline)		Surgical resection of tumour Chemotherapy may be used for unresectable metastatic disease
<b>METASTATIC OVARIAN TUMOURS</b>				
From GI Tract, Breast, Endometrium, Lymphoma	4-8% of ovarian malignancies Krukenberg tumour: metastatic ovarian tumour (usually GI tract, commonly stomach or colon, breast primary tumour)	80% bilateral	Krukenberg tumours have "signet-ring" cells	

### Investigation of Suspicious Ovarian Mass

- women with suspected ovarian cancer based on history, physical, or investigations should be referred to a gynaecologic oncologist
  - bimanual examination
    - solid, irregular, or fixed pelvic mass is suggestive of ovarian cancer
  - RMI (Risk of Malignancy Index) is best tool available to assess likelihood of ovarian malignancy and need for preoperative gynaecologic oncology referral (see sidebar)
- physical exam findings largely dependent on stage of disease
- blood work: CBC, LFTs, electrolytes, Cr, tumour markers as appropriate (CA-125, inhibin,  $\beta$ -hCG, LDH, AFP, androgens, CEA, Ca19-9, estrogen)
- biopsy not recommended due to tumour spillage into peritoneum, if extensive disease, can get cytological diagnosis from paracentesis from ascites or tissue biopsy from peritoneal deposits or omental cake
- radiology
  - transvaginal U/S best to visualize ovaries
  - CT abdomen and pelvis to look for metastatic disease
  - bone scan or PET scan not indicated

#### Causes of Elevated CA-125

- Age influences reliability of test as a tumour marker
- 50% sensitivity in early-stage ovarian cancer (poor), therefore not good for screening
- Malignant
  - Gynaecologic: ovary, uterus
  - Non-Gynaecologic: pancreas, stomach, colon, rectum
- Non-Malignant
  - Gynaecologic: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID
  - Non-Gynaecologic: cirrhosis, pancreatitis, renal failure

- try to rule out other primary source (if suspected), based on:
  - occult blood per rectum: endoscopy ± barium enema
  - gastric symptoms: gastroscopy ± upper GI series
  - abnormal vaginal bleeding: endometrial biopsy to rule out concurrent endometrial cancer; abnormal cervix: need to biopsy cervix (not Pap smear); breast lesion identified or risk factors present: mammogram

**Table 26. FIGO Staging for Primary Carcinoma of the Ovary (Surgical Staging) (2014)**

Stage	Description
<b>I</b>	Growth limited to the ovaries
IA	1 ovary, no ascites, no tumour on external surface, capsule intact, negative washings
IB	2 ovaries, no ascites, no tumour on external surface, capsule intact
IC	1 or 2 ovaries with any of the following: surgical spill (IC1), capsule ruptured (IC2), tumour on ovarian surface (IC2), or malignant cells in ascites (IC3)
<b>II</b>	Growth involving one or both ovaries with pelvic extension or primary peritoneal cancer
IIA	Extension ± implants to uterus/tubes
IIB	Extension to other pelvic structures
<b>III</b>	Tumour involving one or both ovaries with peritoneal implants outside the pelvis and/or positive retroperitoneal nodes
IIIA	Positive retroperitoneal LNs and/or microscopic metastasis beyond pelvis
IIIA1	Positive retroperitoneal LNs
IIIA2	Microscopic, extrapelvic peritoneal involvement ± positive retroperitoneal LNs
IIB	Macroscopic peritoneal metastasis beyond pelvis ≥2 cm, ± positive retroperitoneal LNs. Includes extension to capsule of liver/spleen
IIIC	Same as above but peritoneal metastasis >2 cm
<b>IV</b>	Distant metastasis beyond peritoneal cavity
IVA	Pleural effusion with positive cytology
IVB	Hepatic and/or splenic parenchymal metastasis or metastasis to extra-abdominal organs (inguinal LNs and LNs outside of abdominal cavity included)

FIGO = International Federation of Gynaecology and Obstetrics

## Cervix

### MALIGNANT CERVICAL LESIONS

#### Epidemiology

- majority are SCC (90%); adenocarcinomas increasing (10%); rare subtypes include small cell, adenosquamous
- 8000 deaths annually in North America
- average age at presentation: 50 yr; bimodal distribution (increased frequency in 40s and 60s)

#### Etiology

- at birth, vagina is lined with squamous epithelium; columnar epithelium lines only the endocervix and the central area of the ectocervix (original squamocolumnar junction)
- during puberty, estrogen stimulates eversion of a single columnar layer (ectopy), thus exposing it to the acidic pH of the vagina, leading to metaplasia (change of exposed epithelium from columnar to squamous)
  - a new squamocolumnar junction forms as a result
- the TZ is the area located between the original and the current squamocolumnar junction
- the majority of dysplasias and cancers arise in the TZ of the cervix
- must have active metaplasia in presence of inducing agent (e.g. HPV) to get dysplasia
- dysplasia progresses to carcinoma *in situ* (CIS), which further progresses to invasion of cervical tissues
- slow process (~10 yr on average)
- growth is by local extension
- metastasis occurs late

#### Risk Factors

- HPV infection
  - see *Sexually Transmitted Infections, GY47*
  - high-risk of neoplasia associated with types 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 68, 73, and 82
  - low-risk of neoplasia associated with types 6, 11
  - >99% of cervical cancers contain one of the high-risk HPV types
- high-risk behaviours (risk factors for HPV infection)
  - multiple partners
  - other STIs (HSV, trichomonas)
  - early age at first intercourse
  - high-risk male partner

#### A Risk of Malignancy Incorporating CA-125, Ultrasound, and Menopausal Status for the Accurate Preoperative Diagnosis of Ovarian Cancer

BJOG 1990;97:922-929

RMI = U x M x CA-125

Ultrasound Findings (1 pt for each)

- Multilocular cyst
- Evidence of solid areas
- Evidence of metastases
- Presence of ascites
- Bilateral lesions

U = 1 (for US scores of 0 or 1)

U = 4 (for US scores of 2-5)

Menopausal Status

- Postmenopausal: M = 4
- Premenopausal: M = 1

Absolute Value of CA-125 Serum Level

- For RMI >200; gynaecologic oncology referral is recommended

#### Optimal Primary Surgical Treatment for Advanced Epithelial Ovarian Cancer

Cochrane DB Syst Rev 2011;(8):C0007565

**Summary:** During primary surgery for stage III or IV epithelial ovarian cancer, all attempts should be made to achieve complete cytoreduction. When this is not achievable, optimal (<1 cm) residual disease should be the goal.

**Methods:** Identified 11 retrospective studies consisting of 4735 women using comprehensive search strategy.

**Results:**

1. When suboptimal (margins >1 cm) was compared with optimal (<1 cm) cytoreduction, the survival estimates were reduced but remained statistically in favour of the lower volume disease group.
2. No significant difference in overall survival between suboptimal and optimal cytoreduction.
3. Borderline difference in progression-free survival when residual disease >2 cm and <2 cm were compared (p=0.05).

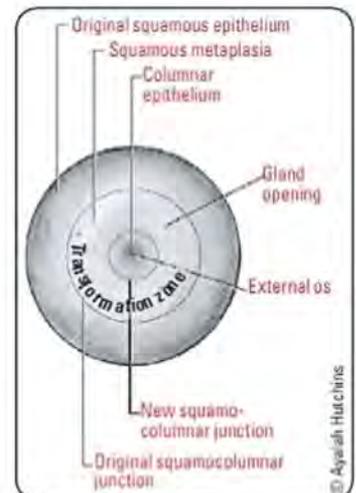

Figure 22. The cervix

Cervical cancer is most prevalent in developing countries and, therefore, is the only gynaecologic cancer that uses clinical staging; this facilitates consistent international staging with countries that do not have technologies such as CT and MRI

- smoking
- poor screening uptake is the most important risk factor for cervical cancer in Canada
- at-risk groups include:
  - immigrant Canadians
  - Indigenous peoples in Canada
  - geographically-isolated Canadians
  - sex-trade workers
  - low socioeconomic status Canadians
  - immunocompromised individuals

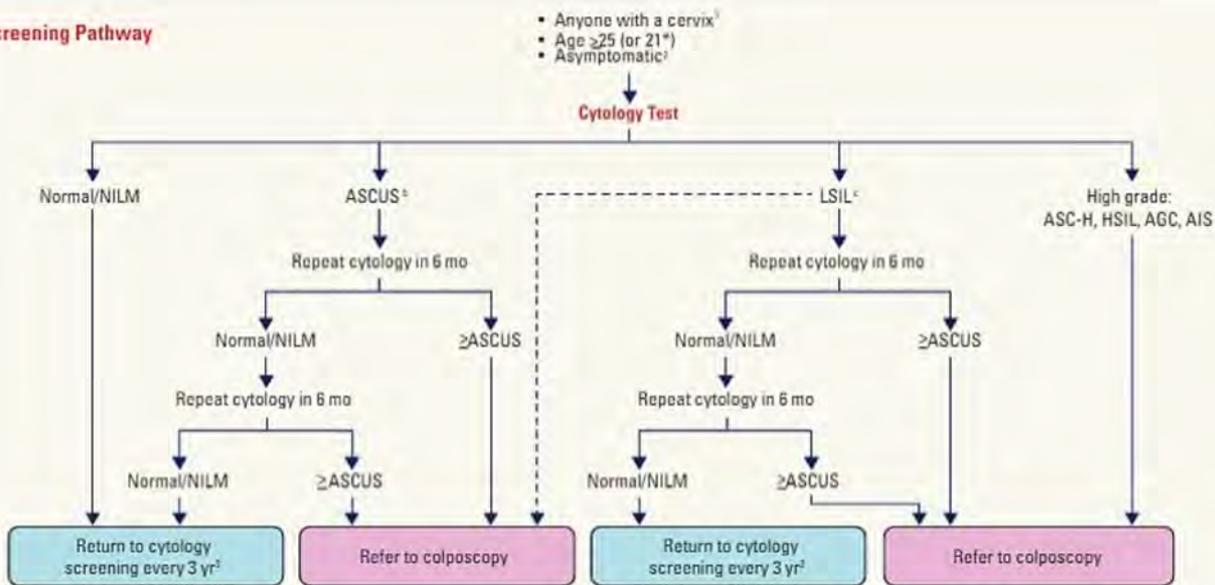

**Cervical Cancer Screening Guidelines (Pap Test)**

- see [Family Medicine, FM5](#)

**Clinical Features**

- SCC: exophytic, fungating tumour
- adenocarcinoma: endophytic or exophytic, with barrel-shaped cervix
- early
  - asymptomatic
  - discharge: initially watery, becoming brown or red
  - postcoital bleeding
- late
  - 80-90% present with bleeding: either postcoital, postmenopausal, or irregular bleeding
  - pelvic or back pain (extension of tumour to pelvic walls)
  - bladder/bowel symptoms
- signs
  - friable, raised, reddened, or ulcerated area visible on cervix

**Screening Pathway**

<sup>1</sup>These guidelines apply to anyone with a cervix including: women; pregnant people; transmen; non binary people; people who have undergone a subtotal hysterectomy; and people who have been vaccinated with the HPV vaccine

<sup>2</sup>Any visible cervical abnormalities or abnormal symptoms must be investigated. Consider referral to a specialist (e.g. colposcopist, gynaecologist, gynaecologist)

<sup>3</sup>Immunocompromised people may be at elevated risk and should receive annual screening

<sup>4</sup>Ontario Health (Cancer Care Ontario) is aware that the Screening Activity Report is not yet aligned with this guidance and will be updated with HPV implementation. Criteria for preventive care bonuses may not be updated during the interim period of changeover to HPV testing. Criteria for preventive care bonuses will be updated when HPV testing is implemented in screening

<sup>5</sup>HPV testing is not currently funded by the Ministry of Health. Primary care providers can consider HPV testing for those with ASCUS results on a patient pay basis or where available (i.e. in some hospital settings) for people ages 30 and older

<sup>6</sup>Repeat cytology or colposcopy are acceptable management options after the first LSIL result. Low grade abnormalities often regress on their own and may be best managed in surveillance, however colposcopy may be considered

**Figure 23. Decision making chart for Pap test (not applicable for adolescents)**

Adapted from: Ontario Cervical Screening Program, June 2020. Cervical screening guidelines unique to each province

**Diagnosis**

- colposcopy is a clinical procedure that facilitates identification and biopsy of suspicious cells
- in colposcopy:
  - apply acetic acid and identify acetowhite lesions, punctation, mosaicism, and abnormal blood vessels to guide cervical biopsy
  - ECC if entire lesion is not visible or no lesion visible
  - diagnostic excision (LEEP) if:
    - unsatisfactory colposcopy (poor visualization/access to transformation zone)
    - discrepancy between cytology, colposcopy, and histological findings
    - positive findings/glandular abnormalities in endocervical curettage
    - suspicious for adenocarcinoma *in situ* (consider cold-knife conization)
    - recurrence of lesion post-ablation or excision
    - inability to rule out invasive disease, i.e. large lesions (lesions extending into endocervical canal, extending widely on cervix, or onto vaginal epithelium)
- consider cold-knife conization (in OR) if glandular abnormality suspected based on cytology or colposcopic findings due to concern for margin interpretation
- any imaging modality or pathological findings are permitted for FIGO clinical staging

**Table 27. FIGO Staging Classification of Cervical Cancer (Clinical Staging) (2018)**

Stage	Description
<b>I</b>	<b>Confined to cervix</b>
IA	Diagnosed only by microscopy
IA1	Stromal invasion not >3 mm deep
IA2	3 mm to <5 mm deep
IB	Measured deepest invasion ≥5 mm (greater than stage IA), lesion limited to cervix
IB1	Stromal invasion ≥5 mm deep and <2 cm wide
IB2	Stromal invasion ≥5 mm deep and ≥2 cm and <4 cm wide
IB3	≥4 cm in width
<b>II</b>	<b>Beyond uterus but not to the pelvic wall or lower 1/3 of vagina</b>
IIA	Limited to upper 2/3 of vagina, no obvious parametrial involvement
IIA1	Clinically visible lesion <4 cm wide
IIA2	Clinically visible lesion ≥4 cm wide
IIB	Obvious parametrial involvement, but not up to pelvic wall
<b>III</b>	<b>Extends to pelvic wall, and/or involves lower 1/3 of vagina, and/or causes hydronephrosis or non-functioning kidney, and/or involves pelvic and/or para-aortic lymph nodes</b>
IIIA	Involves lower 1/3 vagina but no extension into pelvic wall
IIIB	Extension into pelvic side wall and/or hydronephrosis or non-functioning kidney
IIIC	Involvement of pelvic and/or para-aortic lymph nodes, irrespective of tumour size and extent
IIIC1	Pelvic lymph nodes metastasis only
IIIC2	Para-aortic lymph node metastasis
<b>IV</b>	<b>Carcinoma has extended beyond true pelvis or has involved (biopsy proven) the mucosa of the bladder or rectum (bullous edema does not permit a case to be allotted to stage IV)</b>
IVA	Spread of the growth to adjacent organs (bladder or rectum)
IVB	Distant metastases

**Treatment: Prevention and Management**

**Prevention: HPV Vaccine**

- two vaccines currently approved (Gardasil\*, Cervarix\*)

**Table 28. Comparison of Two Vaccines against Human Papillomavirus (HPV)**

	Gardasil®*	Cervarix®
<b>Viral Strains Covered</b>	6, 11, 16, 18, 31, 33, 45, 52, and 58	16, 18
<b>Route of Administration</b>	IM	IM
<b>Schedule of Dosing</b>	2 Dose: Second dose administered 6-12 mo after first dose 3 Dose: 0, 2, 6 mo	0, 1, 6 mo
<b>Side Effects</b>	Local: redness, pain, swelling General: headache, low grade fever, GI upset	Local: redness, pain, swelling General: headache, low grade fever, GI upset
<b>Approved Age</b>	Females ages 9-45, males ages 9-45	Females ages 9-45
<b>Contraindications</b>	Pregnant women and women who are nursing (limited data)	

\*Gardasil-9 also covers types 31, 33, 45, 52, and 58; also used to prevent genital warts

**The Bethesda Classification System** is based on cytological results of a Pap test that permits the examination of cells but not tissue structure. LSIL, HSIL, or cervical carcinoma is a histological diagnosis, requiring a tissue sample via biopsy of suspicious lesions seen during colposcopy

Stage 0	99%
Stage I	75%
Stage II	55%
Stage III	30%
Stage IV	7%
Overall	50-60%

**Final Efficacy, Immunogenicity, and Safety Analyses of a Nine-Valent Human Papillomavirus Vaccine in Women Aged 16-26 Years: A Randomised, Double-Blind Trial**  
Lancet 2017;390:2143-2159

**Purpose:** A nine-valent HPV vaccine (9vHPV) was developed which covers additional strains of HPV compared to the quadrivalent vaccine (qHPV). This study reported the efficacy of the 9vHPV vaccine.  
**Methods:** A randomized double-blind efficacy trial comparing the nine-valent HPV vaccine (9vHPV) to the quadrivalent HPV vaccine (qHPV) in 14215 women. The primary outcomes were incidence of high-grade cervical, vulvar, and vaginal diseases related to HPV-31, 33, 45, 52, and 58 and non-inferiority of anti-HPV 6, 11, 16, and 18 mean titres.  
**Results:** The incidence of high-grade cervical, vulvar, and vaginal disease was 0.5 cases per 10000 person-yr for the 9vHPV group compared to 19 cases per 10000 person-yr for the qHPV group. HPV 6, 11, 16, and 18 titres were non-inferior in the 9vHPV group compared to the qHPV group. There were no clinically meaningful differences in severe adverse effects between groups.  
**Conclusions:** The 9vHPV vaccine is effective at preventing infection, cytological abnormalities, and high-grade lesions and may offer broader protection against HPV and cervical cancer compared to the qHPV vaccine.

- should be administered before onset of sexual activity (i.e. before exposure to virus) for optimal benefit of vaccination
- may be given at the same time as hepatitis B or other vaccines using a different injection site
- not for treatment of active infections
- most women will not be infected with all four types of the virus at the same time, therefore vaccine is still indicated for sexually active females or those with a history of previous HPV infection or HPV-related disease

### Abnormal Pap Tests in Pregnancy

- incidence: 1 in 2200
- Pap test at initial prenatal visit if overdue for routine Pap test
  - if abnormal Pap or suspicious lesion, refer to colposcopy
  - if diagnostic conization required, should be deferred until T2 to minimize risk of pregnancy loss
  - if invasive cancer ruled out, management of dysplasia deferred until completion of pregnancy (may deliver vaginally)
  - if invasive cancer present, management depends on prognostic factors, degree of fetal maturity, and patient wishes
    - general recommendations in T1: consider pregnancy termination, management with either radical surgery (hysterectomy vs. trachelectomy if desires future fertility), or concurrent chemoradiation therapy
    - recommendations in T2/T3: delay of therapy until viable fetus and C-section for delivery with concurrent radical surgery or subsequent concurrent chemoradiation therapy

**Table 29. Management of Abnormal Cervical Histology and Cervical Cancer**

Histology Result from Colposcopy	Management
Normal	If histology results normal and cytology > LSIL, then repeat colposcopy in 6 mo
LSIL	<p><b>Women &lt;25 yr</b> If cytology is LSIL, ASCUS, or normal, then annual Paps by primary care provider x 3 years, followed by return to normal screening If cytology is HSIL, then consider pathology review, and/or reassessment every 6-12 mo in colposcopy</p> <p><b>Women ≥ 25 yr</b> If HPV -: routine Pap screening every 3 yr If HPV +: follow-up colposcopy with cytology and HPV test (if 30 yr or older) in 1 yr</p>
HSIL CIN II/CIN III	<p><b>Women ≥25 yr</b> Excisional procedures (e.g. cold knife, LEEP) or laser preferred Those with positive margins should have follow-up with colposcopy and directed biopsies and/or endocervical curettage</p> <p><b>Women &lt;25 yr</b> Colposcopy every 6 mo for 2 yr or treatment may be acceptable based on patient preference</p>
AIS	Repeat colposcopy + treatment (e.g. LEEP, cold-knife cone) ± endocervical curettage
Stage IA1 (no LVSI)	LEEP if future fertility desired (and lesion ≤2 cm) Simple hysterectomy if future fertility is not desired
Stage IA2, IB1, IB2	Typically treated with radical hysterectomy and pelvic lymphadenectomy (sentinel nodes or pelvic lymph node dissection) If high chance of adjuvant radiation then consider primary chemoradiation as more morbidity occurs from double-modality treatment (surgery and radiation) Equal cure rates may be obtained with primary radiation therapy; advantage of surgery: may accurately stage and grade and more targeted adjuvant therapy Advantage is that ovaries can be spared if premenopausal, better sexual functioning For fertility preservation (if tumour <2 cm), may have radical trachelectomy (removal of cervix and parametria) and nodes instead of radical hysterectomy for early-stage disease Chemoradiation therapy if adverse high-risk prognostic factors on radical surgical specimen, such as: positive pelvic lymph nodes, positive parametria, and/or positive margins or adverse cervical factors (2 or more): deep stromal invasion, size >4 cm, LVSI
Stages IB3 (>4 cm), II, III, IV	Primary chemoradiation therapy CT to assess extent of disease: evaluate pelvic and para-aortic nodes For positive nodes on PET: primary chemoradiation with extended field RT Hysterectomy generally not suggested following primary treatment with curative intent

## Fallopian Tube

- least common site for carcinoma of female reproductive system (0.3%)
- usually serous epithelial carcinoma
- new evidence shows that some serous ovarian cancers originate in the fallopian tube
- more common in fifth and sixth decade

### Clinical Features

- classic triad present in minority of cases, but very specific
  - watery discharge (most specific): "hydrops tubae profluens"
  - vaginal bleeding or discharge in 50% of patients
  - crampy lower abdominal/pelvic pain
- most patients present with a pelvic mass (see *Pelvic Mass, GY42* and *Ovary, GY44* for guidelines regarding diagnosis/investigation)

### Treatment

- same as for malignant epithelial ovarian tumours, see *Table 25, GY45*
- salpingectomy (removal of fallopian tubes to prevent ovarian cancer)

## Vulva

### BENIGN VULVAR LESIONS

#### Non-Neoplastic Disorders of Vulvar Epithelium

- biopsy is often necessary to make diagnosis and/or rule out malignancy:
  1. Lichen sclerosus
    - subepithelial fat becomes diminished; labia become thin, atrophic, with membrane-like epithelium and labial fusion
    - pruritus, dyspareunia, burning, bleeding, ulceration, excoriations
    - 'figure of 8' distribution
    - most common in postmenopausal women but can occur at any age
    - patients should be monitored for malignancy, due to increased risk of SCC
    - treatment: high-potency topical steroid (clobetasol), likely long-term treatment necessary
  2. Lichen simplex chronicus
    - surface of labia majora is thickened and hyperkeratotic, leather-like in appearance
    - pruritus and burning, often at night most common symptoms
    - typically occurs in postmenopausal women
    - treatment: medium- or high-potency steroid cream based on symptom severity + nighttime antihistamines
  3. Lichen planus
    - autoimmune disorder where T cells attack basal keratinocytes
    - peak incidence at age 30-60
    - 3 variants including erosive, papulosquamous, and hypertrophic
    - can extend into vaginal canal and cause loss of structure (desquamative vaginitis)
    - can have oral lichen planus in oral cavity
    - treatment: ultrapotent steroid cream BID until plaques resolve, vaginal suppositories, or immunosuppressive therapies (e.g. cyclosporine) are all accepted

### Tumours

- papillary hidradenoma, nevus, fibroma, hemangioma

### MALIGNANT VULVAR LESIONS

#### Epidemiology

- 5% of genital tract malignancies
- 90% SCC; remainder melanomas, basal cell carcinoma, Paget's disease, Bartholin's gland carcinoma
  - Type I disease: HPV-related (50-70%)
    - more likely in younger women
    - 90% of vulvar intraepithelial neoplasia (VIN) contain HPV DNA (usually types 16, 18)
  - Type II disease: not HPV-related, associated with current or previous vulvar dystrophy
    - usually postmenopausal women

#### Risk Factors

- HPV infection
- VIN: precancerous change which presents as multicentric white or pigmented plaques on vulva (may only be visible at colposcopy)
- progression to cancer rarely occurs with appropriate management
  - treatment: local excision (i.e. superficial vulvectomy ± split thickness skin grafting to cover defects if required) vs. ablative therapy (i.e. laser, cauterization) vs. local immunotherapy (imiquimod)

Any suspicious lesion of the vulva should be biopsied

- history of cervical cancer
- cigarette smoking
- immunodeficiency
- vulvar lichen sclerosus

### Clinical Features

- most lesions occur on the labia majora, followed by the labia minora (less commonly on the clitoris or perineum)
- localized pruritus, or white, red, or skin coloured papules, nodules, or plaques most common
- less common: ulcer, bleeding, discharge, pain, and dysuria
- patterns of spread
  - local
  - groin lymph nodes (usually inguinal, then spreading to pelvic nodes)
  - hematogenous

### Investigations

- ± vulvar biopsy
- always biopsy any suspicious lesion
  - do not remove entire lesion during biopsy (allows for site identification through sentinel LN injection if malignant)

### Prognosis

- depends on stage: particularly nodal involvement (single most important predictor followed by tumour size)
  - lesions >4 cm associated with poorer prognosis
- overall 5 yr survival rate: 79%

### Treatment

- FIGO Stage I (tumour confined to vulva; no extension to adjacent perineal structures): radical local excision
- FIGO Stage II (tumour of any size with extension to adjacent perineal structures, no nodal metastases): modified radical vulvectomy
- FIGO stage III-IV (extension to any of: proximal 2/3 of urethra, proximal 2/3 of the vagina, bladder mucosa, rectal mucosa, or fixed to pelvic bone, or large/distant nodal metastases): sentinel lymph node biopsy followed by surgical resection of residual primary and adjuvant chemotherapy or radiation

## Vagina

### BENIGN VAGINAL LESIONS

- inclusion cysts
  - cysts form at site of abnormal healing of laceration (e.g. episiotomy)
  - no treatment required
- endometriosis
  - dark lesions that tend to bleed at time of menses
  - treatment: excision
- Gartner's duct cysts
  - remnants of Wolffian duct seen along side of cervix
  - treatment: conservative unless symptomatic
- urethral diverticulum
  - can lead to recurrent urethral infection, dyspareunia
  - treatment: surgical correction if symptomatic

### MALIGNANT VAGINAL LESIONS

#### Epidemiology

- primary carcinomas of the vagina represent 2-3% of malignant neoplasms of the female genital tract
- 80-90% are SCC
- more than 50% diagnosed between 70-90 yr

#### Risk Factors

- associated with HPV infection (analogous to cervical cancer)
- increased incidence in patients with prior history of cervical and vulvar cancer

#### Investigations

- cytology
  - significant false negative rate for existing malignancy (i.e. if gross lesion present, biopsy)
- colposcopy
- Schiller test (normal squamous epithelium takes up Lugol's iodine)
- biopsy, partial vaginectomy (wide local excision for diagnosis)
- rule out disease on cervix, vulva, or anus (most vaginal cancers are metastatic from one of these sites)
- staging

## Clinical Features

**Table 30. Clinical Features of Malignant Vaginal Lesions**

Type	Clinical Features
Vaginal Intra-Epithelial Neoplasia (VAIN)	Grades: analogous to cervical dysplasia
Squamous Cell Carcinoma (SCC)	Most common site is upper 1/3 of posterior wall of vagina Asymptomatic Painless vaginal discharge (often foul-smelling) and bleeding Vaginal bleeding especially during/post-coitus Urinary and/or rectal symptom 2° to compression
Adenocarcinoma	Most are metastatic, usually from cervix, endometrium, ovary, or colon Most primaries are clear-cell adenocarcinomas Two types: non-DES and DES syndrome

## Treatment

- Stage I
  - radiation therapy: for tumours >2 cm diameter or tumour involvement of the middle or lower vagina
  - surgical excision: radical hysterectomy, upper vaginectomy, and bilateral pelvic lymphadenectomy
- Stage II-IV: primary radiation with or without chemotherapy

## Gestational Trophoblastic Disease/Neoplasia

- refers to a spectrum of proliferative abnormalities of the trophoblast
- GTD = abnormal, can be benign or lead to the malignant form, called GTN

### Epidemiology

- 1/1000 pregnancies
- marked geographic variation (as high as 1/125 in Taiwan)
- 80% benign, 15% locally invasive, 5% metastatic
- cure rate >95%

### HYDATIDIFORM MOLE (GTD)

#### Complete Mole

- most common type of hydatidiform mole
- diffuse trophoblastic hyperplasia, hydropic swelling of chorionic villi, no fetal tissues or membranes present
- 46XX or 46XY, chromosomes completely of paternal origin (90%)
- One sperm fertilizes egg with reduplication or two sperm fertilize empty egg
- 15-20% risk of progression to malignant sequelae
- risk factors
  - geographic (most common in those of South East Asian background)
  - others (maternal age >40 yr,  $\beta$ -carotene deficiency, vitamin A deficiency not proven)
  - prior molar pregnancy
- clinical features often present during apparent pregnancy with abnormal symptoms/findings
  - vaginal bleeding (97%)
  - hyperemesis gravidarum (26%)
  - excessive uterine size for LMP (51%)
  - hyperthyroidism (7%)
  - theca-lutein cysts >6 cm (50%)
  - $\beta$ -hCG >100000 IU/L
  - preeclampsia (27%)
  - no fetal heartbeat detected, due to absence of fetal parts

With development of HTN early in pregnancy (i.e. <20 wk), think gestational trophoblastic disease

#### Partial (or Incomplete) Mole

- focal trophoblastic hyperplasia and hydropic villi are associated with fetus or fetal parts
- often triploid (XXY, XYY, XXX) with chromosome complement from both parents
  - usually related to single ovum fertilized by two sperm
- low-risk of progression to malignant sequelae (<4%)
- associated with fetus, which may be growth-restricted, and/or have multiple congenital malformations
- clinical features
  - typically present similar to threatened/spontaneous/missed abortion
  - pathological diagnosis often made after D&C

**Investigations**

- quantitative  $\beta$ -hCG levels (tumour marker) abnormally high for gestational age
- U/S findings
  - if complete: no fetus (classic "snow storm" due to swelling of villi)
  - if partial: molar degeneration of placenta  $\pm$  fetal anomalies, multiple echogenic regions corresponding to hydropic villi, and focal intrauterine hemorrhage
- CXR (may show metastatic lesions)
- features of molar pregnancies at high-risk of developing persistent GTN post-evacuation
  - local uterine invasion as high as 31%
  - $\beta$ -hCG >100000 IU/L
  - excessive uterine size
  - prominent theca-lutein cysts >6 cm in diameter

**Treatment**

- for GTD: suction D&C (or rarely hysterectomy)
- Rhogam<sup>®</sup> if Rh-negative
- for GTN: single agent (i.e. methotrexate, actinomycin D) or multi-agent (i.e. EMACO, EMA-EP) chemotherapy based on WHO scoring system

**Follow-up**

- serial  $\beta$ -hCGs (as tumour marker) every week until negative x 3 (usually takes several wk), and then one month after for incomplete hydatidiform mole or monthly for 6 months if complete hydatidiform mole
- reliable contraception required to avoid pregnancy during entire follow-up period
- women who become pregnant during the follow-up period should be referred to gynaecologic oncology and maternal-fetal medicine specialists
- increase or plateau of  $\beta$ -hCG indicates GTN: single or multi-agent chemotherapy based on WHO scoring system (see Table 31)

**Table 31. WHO Prognostic Score for GTD (2011)**

Prognostic Factor	Score			
	0	1	2	4
Maternal Age	<40	$\geq$ 40		
Antecedent Pregnancy	Mole	Abortion	Term	
Interval (End of Antecedent Pregnancy to Chemotherapy in Months)	<4	4-6	7-13	>13
HCG IU/L	<10 <sup>3</sup>	10 <sup>3</sup> -10 <sup>4</sup>	10 <sup>4</sup> -10 <sup>5</sup>	>10 <sup>5</sup>
Number of Metastases	0	1-4	5-8	>8
Site of Metastases	Lung	Spleen, kidney	GI tract	Brain, liver
Largest Tumour Mass		3-5 cm	>5 cm	
Prior Chemotherapy			Single drug	Two drugs

A score of 6 or less is considered low-risk GTD. A score of 7 or more is considered high-risk GTD. A score of  $\geq$  13 is considered ultra high-risk GTD. The prognostic factor score is recorded after the FIGO score stage, separated by a colon

**GTN (MALIGNANT GTD)****GTN Diagnosis**

- $\beta$ -hCG plateau: <10% drop in  $\beta$ -hCG over four values in 3 wk (e.g. days 1, 7, 14, and 21) OR
- $\beta$ -hCG rise >20% in any two values over 2 wk or longer (e.g. measure at days 1, 7, 14) OR
- $\beta$ -hCG persistently elevated >6 mo OR
- metastases on work-up

**Invasive Mole or Persistent GTN**

- development of metastases following treatment of documented molar pregnancy
- histology: molar tissue from D&C
- metastases are rare (4%)

**Choriocarcinoma**

- often presents with symptoms from metastases
- highly anaplastic, highly vascular
- no chorionic villi, elements of syncytiotrophoblast and cytotrophoblast
- may follow molar pregnancy, miscarriage, therapeutic abortion, ectopic pregnancy, or normal pregnancy

**Placental-Site Trophoblastic Tumour**

- rare aggressive form of GTN
- abnormal growth of intermediate trophoblastic cells
- low  $\beta$ -hCG, production of human placental lactogen (hPL), relatively insensitive to chemotherapy

### Classification of GTN

- non-metastatic
  - ~15% of patients after molar evacuation
  - may present with abnormal bleeding
  - all have rising or plateau of  $\beta$ -hCG
  - negative metastases on staging investigations
- metastatic
  - 4% of patients after treatment of complete molar pregnancy
  - metastasis more common with choriocarcinoma, which tends toward early vascular invasion and widespread dissemination
  - if signs or symptoms suggest hematogenous spread, do not biopsy (they bleed)
    - lungs (80%): cough, hemoptysis, CXR lesion(s)
    - vagina (30%): vaginal bleeding, "blue lesions" on speculum exam
    - pelvis (20%): rectal bleeding (if invades bowel), U/S lesion(s)
    - liver (10%): elevated LFTs, U/S, or CT findings
    - brain (10%): headaches, dizziness, seizure (symptoms of space-occupying lesion), CT/MRI findings
  - highly vascular tumour, which is more likely to bleed and result in anemia
  - all have rising or plateau of  $\beta$ -hCG
  - classification of metastatic GTN
    - divided into good prognosis and bad prognosis
    - features of bad prognosis
      - long duration (>4 mo from antecedent pregnancy)
      - high pre-treatment  $\beta$ -hCG titre: >100000 IU/24 h urine or >40000 IU/L of blood
      - brain or liver metastases
      - prior chemotherapy
      - metastatic disease following term pregnancy
    - good prognosis characterized by the absence of each of these features

### Investigations (for Staging)

- blood work: CBC, electrolytes, creatinine,  $\beta$ -hCG, TSH, LFTs
- imaging: CXR, U/S pelvis only
- if CXR shows lung metastasis then CT abdomen/pelvis, MRI brain
- if suspect brain metastasis but CT brain negative, consider lumbar puncture for CSF  $\beta$ -hCG
- ratio of plasma  $\beta$ -hCG:CSF  $\beta$ -hCG <60 indicates metastases

Lungs are the primary site for malignant GTN metastases; when pelvic exam and CXR are negative, metastases are uncommon

**Table 32. FIGO Staging and Management of Malignant GTN**

Stage	Findings	Management
I	Disease confined to uterine corpus	Single agent chemotherapy for low-risk disease (WHO score $\leq 6$ ) 1st line: pulsed actinomycin D (Act-D) IV q2 wk Alternatives: methotrexate (MTX)-based regimen 20% of patients need to switch to alternate single-agent regimen due to failure of $\beta$ -hCG to return to normal Combination chemotherapy (EMA-CO: etoposide, MTX, ACT-D, cyclophosphamide, vincristine) if high-risk (WHO score $\geq 7$ ) or if resistant to single-agent chemotherapy Can consider hysterectomy if fertility not desired or placental-site trophoblastic tumour
II	Metastatic disease to genital structures	As above
III	Metastatic disease to lungs with or without genital tract involvement	As above
IV	Distant metastatic sites including brain, liver, kidney, GI tract	Ultra high-risk patients should have low-dose induction chemotherapy weekly for 1-3 wk, followed by multi-agent chemotherapy

### Follow-up (for GTN)

- contraception for all stages to avoid pregnancy during entire follow-up period
- stage I, II, III
  - weekly  $\beta$ -hCG until 3 consecutive normal results
  - then monthly x 6-12 mo
- stage IV
  - weekly  $\beta$ -hCG until 3 consecutive normal results
  - then monthly x 24 mo

# Common Medications

**Table 33. Common Medications**

Drug Name (Brand Name)	Action	Dosing Schedule	Indications	Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)
acyclovir (Zovirax®)	Antiviral; inhibits DNA synthesis and viral replication	<b>First Episode:</b> 400 mg PO TID x 7-10 d <b>Recurrence:</b> 400 mg PO TID x 5 d	Genital herpes	<b>S/E:</b> headache, GI upset <b>D/I:</b> zidovudine, probenecid
bromocriptine (Parlodel®)	Dopaminomimetic, agonist at D2 Receptor and antagonist at D1 Receptor; acts directly on anterior pituitary cells to inhibit synthesis and release of prolactin	<b>Initial:</b> 1.25-2.5 mg PO once daily at night with food <b>Then:</b> increase by 2.5 mg every 2-7 d as needed until optimal therapeutic response <b>Usual Range:</b> 1.5-15 mg once daily  For IVF: <b>Initial:</b> 1.25 mg/d PO between days 4-6 of follicular phase <b>Then:</b> 2.5 mg/d until 3 d after onset menstruation	Galactorrhea + amenorrhea 2° to hyperprolactinemia Prolactin-dependent menstrual disorders and infertility Prolactin-secreting adenomas (microadenomas, prior to surgery of macroadenomas) IVF	<b>S/E:</b> N/V, headache, postural hypotension, somnolence <b>C/I:</b> uncontrolled HTN, pregnancy-induced HTN, CAD, breastfeeding <b>D/I:</b> domperidone, macrolides, octreotide
clomiphene citrate (Clomid®)	Increases output of pituitary gonadotropins to induce ovulation	50 mg once daily x 5 d Try 100 mg or 160 mg once daily if ineffective 3 courses: adequate trial	Patients with persistent ovulatory dysfunction (e.g. amenorrhea, PCOS) who desire pregnancy	<b>S/E:</b> Common: hot flashes, abdominal discomfort, exaggerated cyclic ovarian enlargement, accentuation of Mittelschmerz Rare: ovarian hyperstimulation syndrome, multiple pregnancy, visual blurring, birth defects <b>C/I:</b> pregnancy, liver disease, hormone-dependent tumours, ovarian cyst, undiagnosed vaginal bleeding
clotrimazole (Canesten®)	Antifungal; disrupts fungal cell membrane	<b>Tablet:</b> 100 mg/d intravaginally x 7 d or 200 mg/d x 3 d or 500 mg x 1 dose <b>Cream (1 or 2%):</b> 1 applicator intravaginally QHS x 3-7 d <b>Topical:</b> apply BID x 7 d	Vulvovaginal candidiasis	<b>S/E:</b> vulvar/vaginal burning
combined oral contraceptive pill (OCP)	Ovulatory suppression by inhibiting LH and FSH Decidualization of endometrium Thickening of cervical mucus to prevent sperm penetration		Contraception Disorders of menstruation	See Tables 7-10, GY15-GY17 and Table 12, GY18
dienogest (Visanne®)	Synthetic progestin	2 mg PO	Pelvic pain associated with endometriosis	<b>S/E:</b> changes to menstrual pattern, VTE <b>C/I:</b> pregnancy, lactation, liver disease/malignancy, VTE disorders, cardiovascular disease, hormone-dependent tumours, undiagnosed AUB
doxycycline	Tetracycline derivative; inhibit protein synthesis	100 mg PO BID x ≈7 d	Chlamydia, gonococcal infection, syphilis	<b>S/E:</b> GI upset, hepatotoxicity <b>C/I:</b> pregnancy, severe hepatic dysfunction <b>D/I:</b> warfarin, digoxin
elagolix (Orlissa®)	Synthetic GnRH antagonist; induces reversible hypoestrogenic state	150 mg PO daily or 400 mg PO BID	Endometriosis, emerging evidence for fibroids, adenomyosis	<b>S/E:</b> hot flushing, nausea, headache <b>C/I:</b> pregnancy, osteoporosis, undiagnosed vaginal bleeding, severe hepatic dysfunction <b>D/I:</b> Organic Anion Transport Protein (OATP) 1B1 inhibitors
fluconazole (Diflucan®)	Antifungal; disrupt fungal cell membrane	150 mg PO x 1 dose	Vulvovaginal candidiasis unresponsive to clotrimazole	<b>S/E:</b> headache, rash, N/V, abdominal pain, diarrhea <b>D/I:</b> terfenadine, cisapride, astemizole, hydrochlorothiazide, phenytoin, warfarin, rifampin
intrauterine device (IUD) copper IUD (Nova-T®) progesterone-releasing IUD (Mirena®, Kyleena®)	Copper IUD: mild foreign body reaction in endometrium, which is toxic to sperm and alters sperm motility Progesterone-releasing IUD: decidualization of endometrium and thickening of cervical mucus, may suppress ovulation	Contraceptive effects last 3 yr; up to 5 yr (Copper IUD, Mirena®, Kyleena®)	Contraception Disorders of menstruation	See Tables 7-10, GY15-GY17 and Table 12, GY18
leuprolide (Lupron®)	Synthetic GnRH antagonist; induces reversible hypoestrogenic state	3.75 mg IM q1 mo or 11.25 mg IM q3 mo Usually ≤6 mo, check bone density if >6 mo Retreatment with Lupron® alone not recommended because of effects on bone density	Endometriosis Leiomyomata DUB Precocious puberty	<b>S/E:</b> hot flashes, sweats, headache, vaginitis, reduction in bone density, acne, GI upset <b>C/I:</b> pregnancy, undiagnosed vaginal bleeding, breastfeeding

Table 33. Common Medications

Drug Name (Brand Name)	Action	Dosing Schedule	Indications	Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)
menotropin (Pergonal <sup>®</sup> )	Human gonadotropin with FSH and LH effects; induce ovulation and stimulate ovarian follicle development	75-150 IU of FSH and LH IM once daily x 7-12 d, then 10000 IU HCG 1 d after last dose	Infertility	S/E: bloating, irritation at injection site, abdominal/pelvic pain, headache, N/V, multiple pregnancy C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, undiagnosed uterine bleeding
metronidazole (Flagyl <sup>®</sup> )	Bactericidal; forms toxic metabolites which damage bacterial DNA	2 g PO x 1 dose or 500 mg PO BID x 7 d	Bacterial vaginosis, Trichomonas vaginitis	S/E: headache, dizziness, N/V, diarrhea, disulfiram-like reaction (flushing, tachycardia, N/V) C/I: pregnancy (1st trimester) D/I: cisapride, warfarin, cimetidine, lithium, alcohol, amiodarone, milk thistle, carbamazepine
nexplanon (etonogestrel implant)	Releases progestin which causes decidualization of endometrium and thickening of cervical mucus, may suppress ovulation	Contraceptive effects last up to 3 yr	Contraception Disorders of menstruation	See Tables 7-10, GY15-GY17 and Table 12, GY18
oxybutynin (Ditropan <sup>®</sup> )	Anticholinergic; relaxes bladder smooth muscle, inhibits involuntary detrusor contraction	5 or 10 mg/d PO May increase doses by 5 mg weekly to a max of 30 mg/d	Overactive bladder (urge incontinence)	S/E: dry mouth/eyes, constipation, palpitations, urinary retention, dizziness, headache C/I: glaucoma, GI ileus, severe colitis, obstructive uropathy, use with caution if impaired hepatic/renal function
tolterodine (Detrol <sup>®</sup> )	Anticholinergic	1-2 mg PO BID	Overactive bladder (urge incontinence)	S/E: anaphylaxis, psychosis, tachycardia, dry mouth/eyes, headache, constipation, urinary retention, chest pain, abdominal pain C/I: glaucoma, gastric/urinary retention, use with caution if impaired hepatic/renal function
tranexamic acid (Cyklokapron <sup>®</sup> )	Anti-fibrinolytic; reversibly inhibits plasminogen activation	1-1.5 g TID-QID for first 4 d of cycle Max 4 g/d Ophthalmic check if used for several wk	Menorrhagia	S/E: N/V, diarrhea, dizziness, rare cases of thrombosis, abdominal pain, MSK pain C/I: thromboembolic disease, acquired disturbances of colour vision, subarachnoid hemorrhage, age <15 yr
ulipristal acetate (Fibristal <sup>®</sup> ) -withdrawn from market in 2020 urofollitropin (Metrodin <sup>®</sup> )	Selective progesterone receptor modulator (SPRM)	5 mg PO once daily for max 3 mo; first tablet taken anytime during first 7 d of menstruation	Leiomyoma (preoperative)	S/E: headache, hot flushes, constipation, vertigo, endometrial thickening C/I: pregnancy, undiagnosed vaginal bleeding, any gynaecological cancer
urofollitropin (Metrodin <sup>®</sup> )	FSH	75 IU/d SC x 7-12 d	Ovulation induction in PCOS	S/E: ovarian enlargement or cysts, edema and pain at injection site, arterial thromboembolism, fever, abdominal pain, headache, multiple pregnancy C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, abnormal uterine bleeding

## Landmark Gynaecology Trials

Trial Name	Reference	Clinical Trial Details
<b>Endometrial Cancer</b>		
PORTEC-3	LANCET 2019; 20(9):1273-1285	<p><b>Title:</b> Adjuvant Chemoradiotherapy versus Radiotherapy Alone in Women with High-Risk Endometrial Cancer (PORTEC-3): Patterns of Recurrence and Post-Hoc Survival Analysis of a Randomised Phase 3 Trial</p> <p><b>Purpose:</b> To investigate the benefit of combined adjuvant chemotherapy and radiotherapy vs. pelvic radiotherapy alone for women with high-risk endometrial cancer.</p> <p><b>Methods:</b> Women with high-risk endometrial cancer were randomly assigned to receive radiotherapy alone or chemoradiotherapy. The co-primary endpoints were overall survival and failure-free survival. Secondary endpoints included vaginal, pelvic, and distance recurrence.</p> <p><b>Results:</b> At a median of 72.6 mo, 5 yr overall survival was 81.4% with chemoradiotherapy vs. 76.1% with radiotherapy, and 5 yr failure-free survival was 76.5% with chemoradiotherapy vs. 69.1% with radiotherapy. Distant metastases occurred in 78/330 women in the chemoradiotherapy group vs. 98/330 in the radiotherapy group.</p> <p><b>Conclusions:</b> For women with stage 3 or serous endometrial cancers, or both, chemoradiotherapy should be recommended over radiotherapy alone.</p>
<b>Cervical Cancer</b>		
LACC	NEJM 2018; 379:1895-1904	<p><b>Title:</b> Minimally Invasive versus Abdominal Radical Hysterectomy for Cervical Cancer</p> <p><b>Purpose:</b> To investigate survival outcomes after laparoscopic or robot-assisted radical hysterectomy (minimally invasive surgery) vs. open abdominal radical hysterectomy (open surgery).</p> <p><b>Methods:</b> Patients with stage A1, IA2, or IB1 cervical cancer and a histologic subtype of squamous-cell carcinoma, adenocarcinoma, or adenosquamous carcinoma, were randomly assigned to undergo minimally invasive surgery or open surgery.</p> <p><b>Results:</b> The rate of disease-free survival at 4.5 yr was 86% with minimally invasive surgery and 96.5% with open surgery, a difference of -10.6% (95% confidence interval [CI], -16.4 to -4.7). Minimally invasive surgery was associated with a lower rate of disease-free survival than open surgery (3 yr rate, 91.2% vs. 97.1%) and a lower rate of overall survival (3 yr rate, 93.8% vs. 99.0%).</p> <p><b>Conclusions:</b> Among women with early-stage cervical cancer, minimally invasive radical hysterectomy was associated with lower rates of disease-free survival and overall survival than open abdominal radical hysterectomy.</p>

BM	bone marrow	HBV	hepatitis B virus	NHL	non-Hodgkin lymphoma	TPO	thrombopoietin
CALR	calreticulin	Hct	hematocrit	NHL	non-Hodgkin lymphoma	TT	thrombin time
CAR	chimeric antigen receptor	HCV	hepatitis C virus	OCV	oral contraceptive pill	TTP	thrombotic thrombocytopenic purpura
CLL	chronic lymphocytic leukemia	HELLP	hemolysis, elevated liver enzymes, and low platelet count	PCC	prothrombin complex concentrates	UFH	unfractionated heparin
CML	chronic myeloid leukemia	HIT	heparin-induced thrombocytopenia	PE	pulmonary embolism	UPEP	urine protein electrophoresis
CMV	cytomegalovirus	HL	Hodgkin lymphoma	PFS	progression-free survival	VTE	venous thromboembolism
CRP	C-reactive protein	HMWK	high molecular weight kininogen	Ph	Philadelphia chromosome	VWD	von Willebrand disease
DAT	direct antiglobulin test	HUS	hemolytic uremic syndrome	PI	protease inhibitors	VWF	von Willebrand factor
DDAVP	desmopressin	IBD	inflammatory bowel disease	PK	prekallikrein	WHO	World Health Organization
DIC	disseminated intravascular coagulation	IMF	idiopathic myelofibrosis	PMN	polymorphonuclear neutrophil	XRT	radiation therapy
DLBCL	diffuse large B-cell lymphoma	IMID	immunomodulatory drugs	PNH	paroxysmal nocturnal hemoglobinuria		
DOAC	direct oral anticoagulant	INR	international normalized ratio	PT	prothrombin time		
		IPC	intermittent pneumatic compression				

# Basics of Hematology

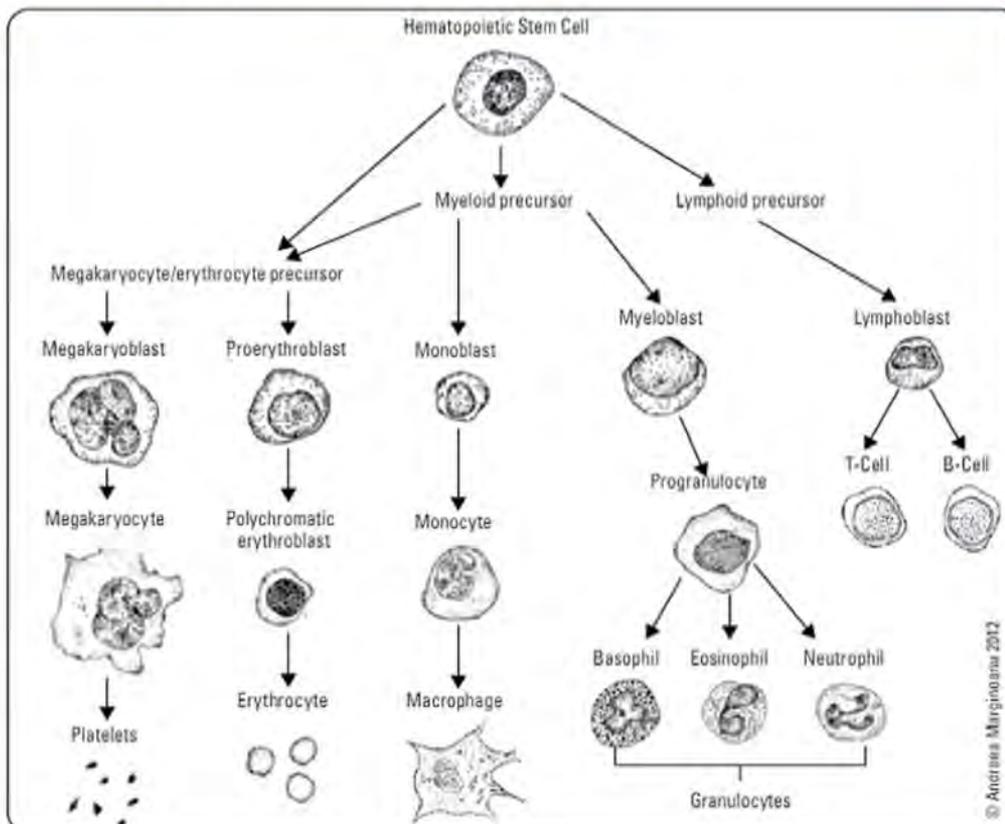

Figure 1. Hematopoiesis

- over  $10^{11}$  blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies, and cranium
- lifespan of mature cells in blood
  - erythrocytes (90-120 d), neutrophils (~1 d), platelets (7-10 d), lymphocytes (varies - memory cells persist for years)

**Erythrocyte:** carries oxygen from lungs to peripheral tissues  
**Reticulocyte:** immature erythrocyte  
**Hb:** protein contained in erythrocytes which binds oxygen  
**Neutrophil:** granulocyte integral in innate immunity; main cell in acute inflammation  
**Eosinophil:** granulocyte involved in response to parasites (especially helminths) and allergic response  
**Basophil:** granulocyte mainly involved in allergy and parasitic infection  
**Lymphocyte:** integral cell in adaptive immunity  
**Monocyte:** involved in innate immunity; can differentiate into macrophage or dendritic cell  
**Platelet:** mediator of primary hemostasis  
**Plasma:** acellular, fluid component of blood containing water and proteins (including coagulation factors and immunoglobulins)  
**Serum:** equivalent to plasma minus coagulation factors

- role of lymphoid organs
  - spleen: part of reticuloendothelial system, sequesters aged RBCs, removes opsonized cells, and site of Ab production
  - thymus: site of T-cell maturation and involutes with age
  - lymph nodes: sites of B- and T-cell activation (adaptive immune response)

## Complete Blood Count

Table 1. Common Terms Found in the CBC

Test	Definition	Normal Values*
RBC Count	Number of RBCs per volume of blood	3.5-5.0 x 10 <sup>12</sup> /L (female) 4.0-5.5 x 10 <sup>12</sup> /L (male)
Hb	Amount of Hb in the blood	115-155 g/L (female) 125-170 g/L (male)
Hct	Percentage of a given volume of whole blood occupied by packed RBCs	37-46% (female) 38-50% (male)
MCV	Average RBC size	80-100 fL
MCH	Average amount of Hb per RBCs	27-34 pg
MCHC	Average concentration of Hb inside RBCs	315-355 g/L
RDW	Percentage of variance in RBC size	11.5-15.5%
Reticulocyte Count	Number of reticulocytes per volume of blood	23-90 x 10 <sup>9</sup> /L (0.5-1.5%)
ESR	Rate at which RBCs separate from the serum, becoming sediment in the bottom of the test tube	<20 mm/h (female) <10 mm/h (male)
WBC Count	Number of WBCs per volume of blood	3.5-10.5 x 10 <sup>9</sup> /L
WBC Differential	Segmented neutrophils Band neutrophils Basophils Eosinophils Lymphocytes Monocytes	2-7 x 10 <sup>9</sup> /L <0.7 x 10 <sup>9</sup> /L <0.10 x 10 <sup>9</sup> /L <0.5 x 10 <sup>9</sup> /L 1.0-4.0 x 10 <sup>9</sup> /L 0.1-1.0 x 10 <sup>9</sup> /L
Platelet Count	Number of platelets per volume of blood	130-380 x 10 <sup>9</sup> /L
Mean Platelet Volume (MPV)	Measurement of platelet size	9.0-14.0 fL

\*All values apply to adults. Reference standards do not apply to all ethnic groups.

### Approach to Interpreting a CBC

1. consider values in the context of an individual's baseline:
  - up to 5% of population without disease may have values outside "normal" range
  - an individual may display a clinically significant change from their baseline without violating "normal" reference range
2. is one cell line affected or are several?
  - if all lines are low: pancytopenia (see *Pancytopenia, H8*)
  - if RBCs and platelets are low: consider a MAHA/TMA (see *Microangiopathic Hemolytic Anemia/Thrombotic Microangiopathy, H23*) or an autoimmune process (Evan's Syndrome)
  - if single cell line affected: see *Common Presenting Problems, H6*

To estimate Hb based on the Hct, multiply by 3

#### Clinical Use of RDW

- To distinguish the etiologies of microcytosis:
  - Iron deficiency: increased RDW (anisocytosis) as cells are of varying sizes in iron deficiency
  - $\beta$ -thalassemia minor: normal RDW (also expect a high RBC count) as cells are of similar size because the red cell abnormality is not progressive

## Blood Film Interpretation

### RED BLOOD CELLS

#### Size

- microcytic (MCV <80 fL), normocytic (MCV = 80-100 fL), macrocytic (MCV >100 fL)
- anisocytosis: RBCs with increased variability in size (increased RDW)
  - iron deficiency anemia, HAs, MF, blood transfusion, and MDS

#### Colour

- hypochromic: increase in size of central pallor (normal = less than 1/3 of RBC diameter)
  - iron deficiency anemia, anemia of chronic disease, and sideroblastic anemia
- polychromasia: suggests increased reticulocytes (pinkish-blue cells)
  - increased RBC production by BM

#### Shape

- poikilocytosis: increased proportion of RBCs of abnormal shape
  - iron deficiency anemia, hemoglobinopathies, MF, severe B<sub>12</sub> deficiency, MDS, and burns

**Table 2. Common Erythrocyte Shapes**

Shape	Definition	Associated Conditions
Discocyte	Biconcave disc	Normal RBC
		
Spherocyte	Spheroidal RBC (due to membrane defect or loss of membrane)	Hereditary spherocytosis, immune hemolytic anemia
		
Elliptocyte/Ovalocyte	Oval-shaped, elongated RBCs • Elliptocytes: the RBC long axis is $\geq 2x$ the length of the short axis • Ovalocytes: the RBC long axis is $< 2x$ the length of the short axis	Hereditary elliptocytosis, megaloblastic anemia, MF, iron-deficiency anemia (pencil forms), and MDS
		
Schistocyte (helmet cell, fragment)	Fragmented cells (due to traumatic disruption of membrane)	MAHA/TMA (HUS, aHUS, TTP, DIC), preeclampsia, HELLP, malignant HTN, vasculitis, glomerulonephritis, burns, and prosthetic heart valves
		
Sickle Cell	Sickle-shaped RBC (due to polymerization of HbS)	Sickle cell disorders: HbSC, HbSS
		
Codocyte (target cell)	"Bull's eye" (due to a surface that is disproportionately large compared to their volume)	Liver disease, HbSC, thalassemia, iron deficiency anemia, and asplenia
		
Dacryocyte (teardrop cell)	Single pointed end, looks like a teardrop	MF, MDS, $\beta$ thalassemia, megaloblastic anemia, and BM infiltration
		
Acanthocyte (spur cell)	Distorted RBC with irregularly distributed thorn-like projections (due to abnormal membrane lipid or protein composition)	Severe liver disease (spur cell anemia), starvation/anorexia, and post-splenectomy
		
Echinocyte (burr cell)	RBC with numerous regularly spaced, small, spiny projections	Uremia, HUS, burns, cardiopulmonary bypass, post-transfusion, and storage artifact
		
Rouleaux Formation	Aggregates of RBCs resembling stacks of coins (due to increased plasma concentration of high molecular weight proteins)	Pregnancy is most common cause (due to physiological increase in fibrinogen), inflammatory conditions (due to polyclonal immunoglobulins), plasma cell dyscrasias (due to monoclonal paraproteinemia, e.g. MM, macroglobulinemia), and storage artifact
		

Illustrations: Ayaluh Hutchins and Merry Shiyu Wang 2012

**Table 3. RBC Inclusions**

Inclusions	Definition	Associated Conditions
Nucleus	Present in erythroblasts (immature RBCs)	Hyperplastic erythropoiesis (seen in hypoxia, hemolytic anemia), BM infiltration disorders, and MPNs (MF)
		
Heinz Bodies	Denatured and precipitated Hb	G6PD deficiency (post-exposure to oxidant), thalassemia, and unstable Hb
		
Howell-Jolly Bodies	Small spherical nuclear remnant, typically in periphery and ordinarily removed by the spleen	Post-splenectomy, hyposplenism (SCD), neonates, and megaloblastic anemia
		
Basophilic Stippling	Deep blue granulations indicating ribosome aggregation	Thalassemia, heavy metal (Pb, Zn, Ag, Hg) poisoning, megaloblastic anemia, MDS, and hereditary (pyrimidine 5'-nucleotidase deficiency)
		
Sideroblasts	Late erythrocytes in BM with Fe-containing granules in the cytoplasm	Hereditary, idiopathic, drugs, ethanol, hypothyroidism (see Sideroblastic Anemia, HT), MDS, and toxins (Pb)
		

Illustrations: Ayaluh Hutchins and Merry Shiyu Wang 2012

**WHITE BLOOD CELLS**

**lymphocytes**

- comprise 30-40% of WBCs; great variation in "normal" lymphocyte morphology
- the major classes of lymphocytes include: T cells, B cells, and natural killer (NK) cells
- nucleus occupies ~90% of cytoplasm

**+ neutrophils**

- normally, only mature neutrophils (with 3-4 lobed nuclei) and band neutrophils (immediate precursor with horseshoe-shaped nuclei) are found in circulation
- hypersegmented neutrophil: >5 lobes suggests megaloblastic process (B12 or folate deficiency)
- left shift (increased granulocyte precursors)
  - seen in leukemoid reactions: acute infections, pregnancy, neonates, hypoxia, shock, MPNs (CML, MF), and G-CSF (growth factor that stimulates neutrophil production) use

**+ blasts**

- immature, undifferentiated precursors; associated with acute leukemia, MDS, and G-CSF use

**Left Shift**

- Refers to an increase in granulocyte precursors in the peripheral blood film (myelocytes, metamyelocytes, promyelocytes, blasts). If present, implies increased marrow production of granulocytes (e.g. inflammation, infection, G-CSF administration, CML)
- The presence of predominantly blasts in the peripheral smear without further differentiated precursor cells or mature neutrophils, suggests clonal cell disorder (MDS, acute leukemias)
- If >20% of the total WBC differential consists of blasts, this is acute leukemia and is a medical emergency

**Table 4. Abnormal WBC on Film**

Appearance	Definition	Associated Conditions
 <b>Smudge Cell</b>	Lymphocytes damaged during blood film preparation indicating cell fragility	CLL and other lymphoproliferative disorders
 <b>Auer Rod</b>	Cytoplasmic inclusions that form long needles in the cytoplasm of myeloblasts	Pathognomonic for AML
 <b>Atypical Lymphocyte</b>	Pale blue cytoplasm with pink granules. Cytoplasm is indented by RBC edges	Viruses (particularly EBV) and T-LGL leukemia

Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012 and Danielle Sayeau 2017

**PLATELETS**

- small, purple, anuclear cell fragments

**Bone Marrow Aspiration and Biopsy**

- sites: posterior iliac crest/spine, sternum (aspiration only)
- analyses: most often done together
  - aspiration: takes a fluid marrow sample for cellular morphology (includes iron stain), flow cytometry, cytogenetics, molecular studies, and microbiology (C&S, acid-fast bacilli smear and culture, and PCR)
    - note: differential diagnosis for a "dry tap": MF, hairy cell leukemia, BM infiltration
  - biopsy: takes a sample of intact BM to assess histology (architecture) and immunohistochemistry
  - only aspirates, not biopsies, can be obtained from the sternal site

**Indications**

- unexplained CBC abnormalities
- diagnosis and evaluation of infiltrating cancers: plasma cell disorders, leukemias, and solid tumours
- diagnosis and staging of lymphoma or solid tumours
- evaluate iron metabolism and stores (gold standard, but rarely done)
- evaluate suspected deposition and storage disease (e.g. amyloidosis, Gaucher's disease)
- evaluate fever of unknown origin, suspected mycobacterial, fungal, and parasitic infections, or granulomatous disease
- evaluate unexplained splenomegaly
- confirm normal BM in potential allogeneic hematopoietic cell donor

**Important Considerations**

- do not perform a BM biopsy if there is evidence of infection over the targeted skin site
- risk of procedure: 1/100 chance of bleeding, very rare infection risk

# Common Presenting Problems

## Anemia

### Definition

- a decrease in RBC mass that can be detected by Hb concentration, Hct, and RBC count
  - adult males: Hb <130 g/L or Hct <38%
  - adult females: Hb <120 g/L or Hct <37% (changes with pregnancy and trimester)

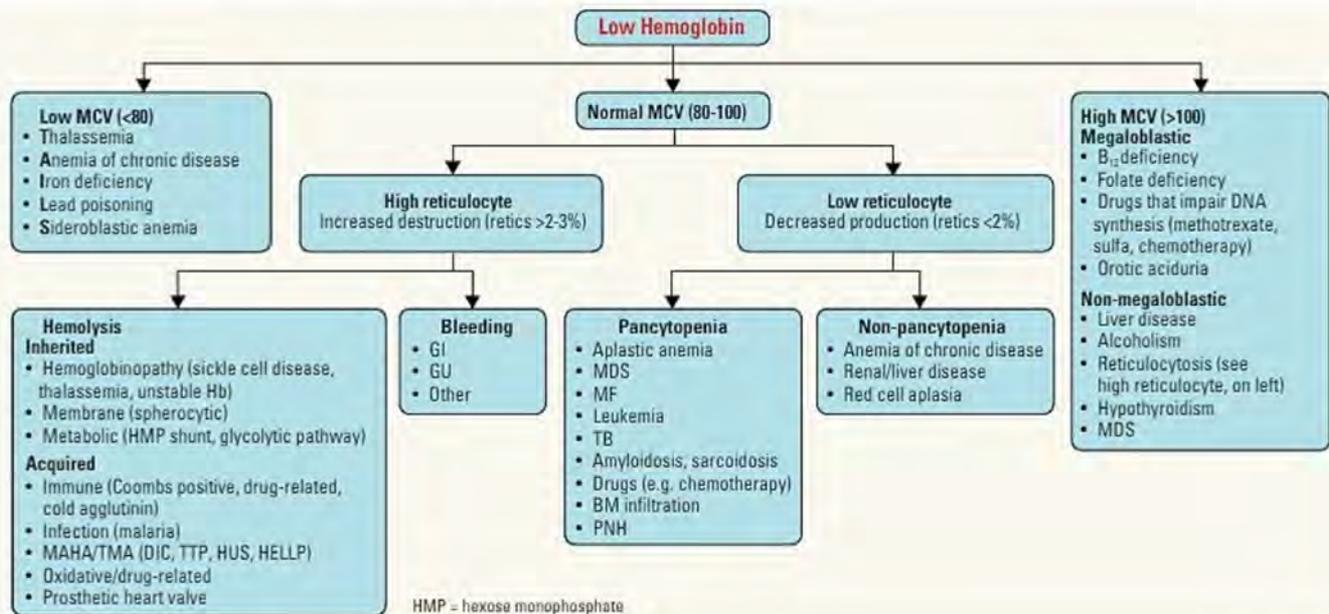

Figure 2. Approach to anemia – classification by MCV

### Clinical Features

- history
  - symptoms of anemia: fatigue, headache, light-headedness, malaise, weakness, decreased exercise tolerance, dyspnea, palpitations, dizziness, tinnitus, and syncope
  - acute vs. chronic, bleeding, systemic illness, travel, medications, diet (Fe, B12 sources), alcohol, and family history
  - menstrual history: menorrhagia, menometrorrhagia
  - rule out pancytopenia (recurrent infection, mucosal bleeding, easy bruising)
- physical signs
  - HEENT: pallor in mucous membranes and conjunctiva at Hb <90 g/L, ocular bruits at Hb <55 g/L, angular cheilitis, jaundice
  - cardiac: tachycardia, orthostatic hypotension, systolic flow murmur, wide pulse pressure, signs of CHF
  - dermatologic: ecchymosis, petechiae, pallor in palmar skin creases at Hb <75 g/L, jaundice (if due to hemolysis), nail changes (spooning), and glossitis
  - splenomegaly, lymphadenopathy

### Investigations

- rule out dilutional anemia (low Hb due to increased effective circulating volume)
- CBC with differential, reticulocyte count, and blood film
- rule out nutritional deficit, gastrointestinal and genitourinary disease in iron deficiency anemia
- additional laboratory investigations as indicated (see *Microcytic Anemia, H14, Normocytic Anemia, H17, Hemolytic Anemia, H18, and Macrocytic Anemia, H25*)
- N.B. may have a mixed picture with multiple concomitant nutritional deficiencies

### Treatment

- treat underlying cause (see *Microcytic Anemia, H14, Normocytic Anemia, H17, Hemolytic Anemia, H18, and Macrocytic Anemia, H25*)

### Reticulocytes

- Reticulocytes are immature erythrocytes and are markers of erythrocyte production (↑ colour, ↑ central pallor, ↑ size)
- The reticulocyte count should always be interpreted in the context of Hb concentration
- The reticulocyte count should normally increase in response to a decrease in RBC
- With blood loss, reticulocytes should increase 2-3x initially and then 5-7x over the next week
- A normal reticulocyte count in anemia should be interpreted as a sign of decreased production, and may result from BM infiltration, nutritional deficiency, or other causes
- Anemia with reticulocytosis suggests appropriate bone marrow response

## Erythrocytosis

### Definition

- an increase in Hb and/or Hct: Hb >165 g/L or Hct >49% (males); Hb >160 g/L or Hct >48% (females)

### Etiology

- relative/spurious erythrocytosis (decreased plasma volume): diuretics, severe dehydration, burns, and "stress" (Gaisböck's syndrome)
- absolute erythrocytosis

**Table 5. Etiology of Erythrocytosis**

Primary	Secondary	Inappropriate Production of Erythropoietin
<b>PV</b> (see <i>Polycythemia Vera, H43</i> )	Physiologic (poor tissue oxygenation/hypoxia) Carbon monoxide poisoning Heavy smoking High altitude Pulmonary Disease COPD Sleep apnea Pulmonary hypertension Cardiovascular Disease R to L shunt (Eisenmenger syndrome) Hemoglobinopathy High O <sub>2</sub> affinity Hb Methemoglobinemia	Tumours Hepatocellular carcinoma Renal cell carcinoma Cerebellar hemangioblastoma Pheochromocytoma Uterine leiomyoma Ovarian tumour Other Polycystic kidney disease Renal artery stenosis Post-kidney transplant Hydronephrosis Androgens Exogenous EPO

### Clinical Features

- secondary to high red cell mass and hyperviscosity
  - headache, dyspnea, dizziness, tinnitus, visual disturbances, hypertensive symptoms, and paresthesia
  - symptoms of angina, CHF, and aquagenic pruritus (only in MPNs)
- thrombosis (venous or arterial) or bleeding (seen with acquired VWD or acquired platelet dysfunction in MPNs)
- physical findings
  - splenomegaly ± hepatomegaly, facial plethora/ruddy complexion (70%) and/or palms, gout

### Investigations

- serum EPO: differentiates primary (low/normal) from other etiologies (elevated)
  - search for tumour as source of EPO as indicated (e.g. abdominal U/S, CT head)
  - JAK-2 mutation analysis: positive in >96% of cases of PV
    - only send if low/normal EPO level
- ferritin (iron deficiency can mask the diagnosis; if iron deficient with reticulocytosis, suggestive of PV)

### Treatment

- if primary: see *Polycythemia Vera, H43*
- if secondary: treat underlying cause
  - O<sub>2</sub> for hypoxemia, CPAP for sleep apnea, surgery for EPO-secreting tumours, counselling and education (e.g. smoking cessation, work environment), use the lowest dose possible if on androgen therapy
  - often cardiologists will be hesitant to treat high Hct in cyanotic patients

## Thrombocytopenia

### Definition

- platelet count <150 x 10<sup>9</sup>/L

### Clinical Features

- history: mucocutaneous bleeding (easy bruising, gingival bleeding), epistaxis, perioperative bleeding (including dental procedures), heavy menstrual bleeding, peripartum bleeding, and GI bleeding
- physical exam: bruising, petechiae, ecchymoses, non-palpable purpura, and wet purpura
- see *Disorders of Primary Hemostasis, H28* for complications

### Investigations

- CBC and differential
- blood film
  - rule out pseudothrombocytopenia (platelet clumping or platelet satellitism)
  - decreased production: other cell line abnormalities, blasts (suggesting myeloid malignancy), hypersegmented PMNs (suggesting megaloblastic anemia), and leukoerythroblastic changes (suggesting BM infiltration or fibrosis)
  - increased destruction: large platelets (often seen in ITP), schistocytes (seen in MAHA/TMA)
- workup for nutritional deficiencies: B12, RBC, folate
- PT/INR, aPTT, and fibrinogen if DIC suspected
- LFTs if findings of liver disease are present
- H. pylori*, HIV, and HCV serology
- abdominal ultrasound to look for splenomegaly

**Rule-of-thumb:** a deficit in all cell lines suggests decreased production, sequestration, or hemodilution. A deficit in platelets and RBCs suggests non-immune destruction or Evan's syndrome. An isolated thrombocytopenia suggests an immune-mediated process. In hospitalized patients, drugs and infection account for the majority of cases of thrombocytopenia

**Must rule out pseudothrombocytopenia:** platelet clumping secondary to EDTA Abs present in serum. This can be seen on blood film and confirmed by repeating in a citrated sample (i.e. using a sodium citrate tube to collect blood, rather than EDTA)

**Wet vs. Dry Purpura**  
**Wet purpura:** hemorrhaging of mucous membranes  
**Dry purpura:** bruising or petechiae on skin surface

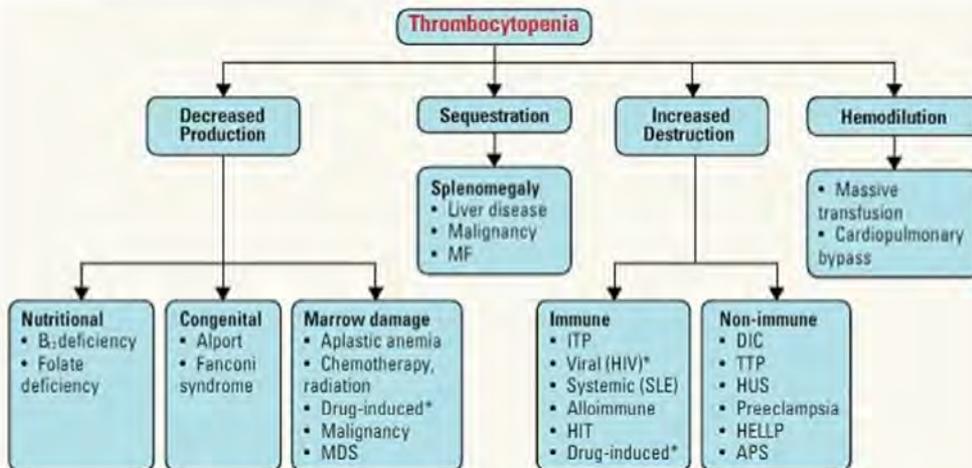

### Treatments

- life-threatening bleeding: platelet transfusion (repeat CBC 1 h post-transfusion to confirm an appropriate rise in counts)
- if secondary: treat underlying cause
- ITP: see *Immune Thrombocytopenia, H28*

### References

- APS: see *Hematology, H36*
- Aplastic Anemia: see *Hematology, H17*
- B12/Folate Deficiency: see *Hematology, H25, H26*

- ITP: see *Hematology, H28*
- Myelodysplasia: see *Hematology, H41*
- Preeclampsia: see *Obstetrics, OB26*
- SLE: see *Rheumatology, RH11*

\*In hospitalized patients most common causes of thrombocytopenia are drugs and infection

Figure 3. Approach to thrombocytopenia

Adapted from: Cecil Essentials of Medicine

## Thrombocytosis

### Definition

- platelet count  $>450 \times 10^9/L$
- primary thrombocytosis (uncommon): due to MPNs (e.g. CML, PV, primary MF, and ET; rarely associated with MDS)
- reactive/secondary thrombocytosis (common): acute phase reactant (e.g. surgery, inflammation, infection, trauma, bleeding, iron deficiency, neoplasm, ischemic injury, and hyposplenia/asplenia)

### Clinical Features

- history: trauma, surgery, splenectomy, infection, inflammation, bleeding, iron deficiency, prior diagnosis of chronic hematologic disorder, and constitutional symptoms (malignancy)
- vasomotor symptoms: headache, visual disturbances, lightheadedness, atypical chest pain, acral dysesthesia, erythromelalgia, livedo reticularis, and aquagenic pruritus
- clotting risk, bleeding risk (rare)
- physical exam: splenomegaly is a common finding among patients with MPNs

### Investigations

- CBC and differential, peripheral blood film, serum ferritin
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- if reactive process has been ruled out, BM biopsy may be required to rule out MPN/MDS

### Treatment

- primary: ASA  $\pm$  cytoreductive agents (e.g. hydroxyurea, anagrelide, interferon- $\alpha$ )
- secondary: treat underlying cause

## Pancytopenia

### Definition

- a decrease in all hematopoietic cell lines below normal reference ranges

### Clinical Features

- anemia: fatigue (see *Anemia, H6*)
- leukopenia: recurrent infections (see *Neutropenia, H9*)
- thrombocytopenia: mucocutaneous bleeding (see *Thrombocytopenia, H7*)

### Investigations

- CBC and differential, peripheral blood film, serum ferritin, reticulocyte count, PT, PTT, blood type and screen, complete metabolic panel, B12, folate
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- workup as per *Figure 4, H9* and presenting symptoms/physical exam
- if reactive process has been ruled out, BM biopsy may be required

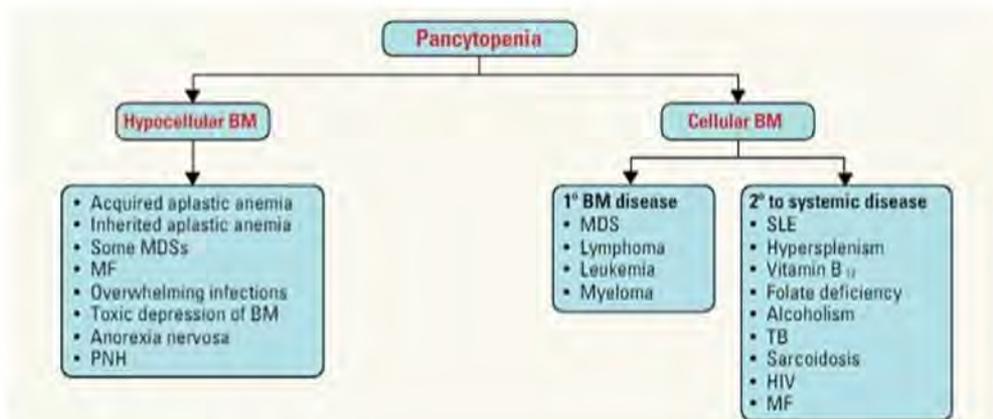

Figure 4. Approach to pancytopenia

## Neutrophilia

### Definition

- variable definition, but generally an ANC  $>7.7 \times 10^9/L$  (WHO definition)

### Etiology

- primary neutrophilia
  - CML, chronic neutrophilic leukemia
  - other MPNs: PV, ET, MF
  - hereditary neutrophilia (autosomal dominant)
  - chronic idiopathic neutrophilia in otherwise healthy patients
  - leukocyte adhesion deficiency
- secondary neutrophilia
  - stress/exercise/epinephrine: movement of neutrophils from marginated pool into circulating pool
  - obesity
  - infection
  - inflammation: e.g. rheumatoid arthritis (RA), IBD, chronic hepatitis, MI, PE, and burns
  - malignancy: hematologic (i.e. marrow invasion by tumour) and non-hematologic (especially large cell lung cancer)
  - medications: glucocorticoids,  $\beta$ -agonists, lithium, G-CSF

### Clinical Features

- signs and symptoms of fever, inflammation, malignancy to determine appropriate further investigations
  - including LAD and organomegaly
- examine oral cavity, teeth, peri-rectal area, genitals, and skin for signs of infection

### Investigations

- CBC and differential: mature neutrophils or bands  $>20\%$  of total WBC suggests infection/inflammation
- blood film: left shifted WBCs, Döhle bodies (intracytoplasmic structures composed of agglutinated ribosomes), toxic granulation, and cytoplasmic vacuoles in infection
- may require BM biopsy if MPN suspected

### Treatment

- directed at underlying cause

## Neutropenia

### Definition

- mild: ANC  $1.0-1.5 \times 10^9/L$
- moderate: ANC  $0.5-1.0 \times 10^9/L$  (risk of infection starts to increase)
- severe: ANC  $<0.5 \times 10^9/L$
- profound: ANC  $<0.1 \times 10^9/L$  for  $>7$  d

ANC = WBC count  $\times$  (%PMNs + %bands)  
Beware of fever + ANC  $<0.5 \times 10^9/L$  =  
FEBRILE NEUTROPENIA

## Etiology

**Table 6. Etiology of Neutropenia**

Decreased Production	Peripheral Destruction/Sequestration	Excessive Margination (Transient Neutropenia)
<b>Infection</b> Viral hepatitis, EBV, HIV, TB, typhoid, malaria <b>Hematological Diseases</b> Idiopathic, aplastic anemia, MF, BM infiltration, cyclic, PNH, MDS, large granular lymphocyte leukemia, hairy cell leukemia, immune-mediated <b>Drug-Induced</b> Alkylating agents, antimetabolites, anticonvulsants, antipsychotics, anti- inflammatory agents, antithyroid drugs <b>Toxins/Chemicals</b> High dose radiation, benzene, dichloro diphenyl trichloroethane (DDT) <b>Nutritional Deficiency</b> B12, folate <b>Idiopathic</b> Constitutional neutropenia, benign cyclic neutropenia	Anti-neutrophil Abs Spleen or lung trapping Autoimmune disorders: RA (Felty syndrome), SLE Granulomatosis with polyangiitis (formerly Wegener's) Drugs: haptens (e.g. $\alpha$ -methyl dopa)	Idiopathic (most common) Overwhelming bacterial infection Hemodialysis Cardiopulmonary bypass Racial variation (e.g. African or Ashkenazi Jewish descent)

### Clinical Features

- fever, chills (only if infection present)
- infection by endogenous bacteria (e.g. *S. aureus*, Gram negatives from GI and GU tract)
- painful ulceration on skin, anus, mouth, and throat following colonization by opportunistic organisms
- avoid digital rectal exam

### Investigations

- dependent on degree of neutropenia, history, and symptoms
- ranges from observation with frequent CBCs and differential with peripheral smears to BM aspiration and biopsy

### Treatment

- manage specific underlying causes and medications that contribute to neutropenia
- regular dental care: chronic gingivitis and recurrent stomatitis are major sources of morbidity
- treatment of febrile neutropenia
- in severe immune-mediated neutropenia, G-CSF may increase neutrophil counts
  - if no response to G-CSF, consider immunosuppression (e.g. steroids, cyclosporine, and methotrexate)

## Lymphocytosis

### Definition

- absolute lymphocyte count  $>4.0 \times 10^9/L$

### Etiology

- infection (reactive lymphocytosis)
  - viral infections (majority); particularly mononucleosis
  - TB, pertussis, brucellosis, toxoplasmosis
- smoking
- physiologic response to stress (e.g. trauma, status epilepticus)
- hypersensitivity (e.g. drugs, serum sickness)
- autoimmune (e.g. RA)
- neoplasm (e.g. CLL, thymoma, B-cell lymphocytosis of undetermined significance)
- asplenia (e.g. post-splenectomy)

### Investigations

- CBC and differential, peripheral smear assessing lymphocyte morphology, and in select cases, flow cytometry for assessing lineage and clonality

### Treatment

- treat underlying cause

#### Prophylactic Hematopoietic Colony-Stimulating Factors on Mortality and Infection

Ann Intern Med 2007;147:400-411

**Purpose:** To review the effects of colony-stimulating factor (CSF) on mortality, infections, and febrile neutropenia in patients undergoing chemotherapy or SCT.

**Study Selection:** 148 RCTs comparing the effects of CSFs to either placebo or no therapy were included. Prophylactic CSFs were given concurrently with or after initiation of chemotherapy.

**Results:** There were no differences in all-cause mortality or infection-related death between CSF and placebo groups. Compared to placebo or no therapy, CSFs reduced infection rate (median rate 38.9% vs. 43.7%; rate ratio 0.85), microbiologically documented infections (MR 23.5% vs. 28.6%; rate ratio 0.86), and febrile neutropenia (MR 25.3% vs. 44.2%; rate ratio 0.7).

**Conclusions:** Prophylactic CSFs decrease infection rates and episodes of febrile neutropenia in patients undergoing chemotherapy or SCT, but have no effect on mortality.

G-CSF = Neupogen<sup>®</sup> = filgrastim

Presence of atypical lymphocytes suggests viral infection

Presence of smudge cells suggests a lymphoproliferative disorder if persistently elevated above  $5.0 \times 10^9/L$  for  $>3$  mo; consider flow cytometry of peripheral blood

## Lymphopenia

### Definition

- absolute lymphocyte count  $<1.0 \times 10^9/L$

### Etiology

- older age
- idiopathic CD4+ lymphopenia
- iatrogenic (radiation, chemotherapy, immunosuppressive agents)
- HIV/AIDS, HBV, HCV
- malignancy
- malnutrition, alcoholism
- autoimmune disease (e.g. SLE)

### Clinical Features

- opportunistic infections (see [Infectious Diseases](#))

### Investigations

- CBC and differential, lymphocyte subpopulations, immunoglobulin levels

### Treatment

- treat underlying cause
- treat opportunistic infections aggressively and consider antimicrobial prophylaxis (see [Infectious Diseases](#), ID48)

## Eosinophilia

### Definition

- absolute eosinophil count  $>0.5 \times 10^9/L$

### Etiology

- primary: due to clonal BM disorder
  - if no primary etiology identified, classified as hypereosinophilic syndrome
    - 6 mo of eosinophilia (count  $>1.5 \times 10^9/L$ ) with end organ damage and no other detectable causes
    - can involve heart, BM, and CNS
- secondary
  - most common causes are parasitic (usually helminth) infections and allergic reactions
  - less common causes:
    - collagen vascular diseases (e.g. RA, polyarteritis nodosa, see [Rheumatology](#), RH21)
    - respiratory causes (asthma, eosinophilic pneumonia, and eosinophilic granulomatosis with polyangiitis (EGPA))
    - cholesterol emboli
    - hematologic malignancy, see [Chronic Myeloid Leukemia](#), H42 and [Hodgkin Lymphoma](#), H47
    - adrenocortical insufficiency, see [Endocrinology](#), E39
    - medications (penicillins)
    - atopic dermatitis

### Investigations

- CBC and differential, peripheral smear assessing eosinophil morphology
- end organ involvement: electrolytes, renal function tests, LFTs, creatine kinase (CK), troponin, ECG, pulmonary function tests (PFTs), CXR, chest and abdominal CT, consider BM biopsy

### Treatment

- treat underlying cause
- before initiating steroids, ensure strongyloides serology is collected to rule out infection for patients at risk

## Agranulocytosis

### Definition

- ANC is  $<100/\mu L$

### Etiology

- associated with medications in 70% of cases: e.g. chemotherapy, clozapine, thionamides (antithyroid drugs), sulfasalazine, and ticlopidine
  - immune-mediated destruction of circulating granulocytes by drug-induced Abs or direct toxic effects upon marrow granulocytic precursors

### Clinical Features

- abrupt onset of fever, chills, weakness, and oropharyngeal ulcers

### Prognosis

- high fatality without vigorous treatment

**Basophilia and/or Eosinophilia**  
Can be an indicator of CML or other MPNs, associated with pruritus due to excessive histamine production

**Investigations/Treatment**

- discontinue offending drug
- if patient is febrile, pan-culture and screen for infection (blood cultures x2, urine culture, and chest x-ray as minimum, initiate broad-spectrum antibiotics)
- consider BM aspirate and biopsy if cause unclear
- consider G-CSF

**Leukemoid Reaction**

**Definition**

- leukocytosis >50 x 10<sup>9</sup>/L

**Etiology**

- infection
- drugs
- asplenia
- intoxication
- malignancy
- hemorrhage
- acute hemolysis

**Investigations/Treatment**

- marked left shift (myelocytes, metamyelocytes, and bands in peripheral blood smear)
- rule out CML and chronic neutrophilic leukemia
- detect and treat underlying cause

**Approach to Lymphadenopathy**

**History**

- constitutional/B-symptoms (seen in TB, lymphoma, other malignancies)
- growth pattern: acute vs. chronic
- exposures: cats (cat scratch – *Bartonella henselae*), ticks (Lyme disease – *Borrelia burgdorferi*), and high-risk behaviours (HIV)
- joint pain/swelling, rashes (connective tissue disorder)
- pruritus (seen in Hodgkin lymphoma)
- medications (can cause serum sickness → lymphadenopathy)

**Clinical Features**

- determine if lymphadenopathy is localized or generalized
- generalized: typically features of systemic diseases (HIV, TB, EBV, SLE, medications, sarcoidosis, lymphoma)
- localized: typically reactive or neoplastic
  - cervical (bacterial/mycobacterial infections, ENT malignancies, and metastatic cancer)
  - supraclavicular (highest malignancy risk)
    - right (mediastinal, bronchogenic, esophageal cancer)
    - left (gastric, gallbladder, pancreas, renal, and testicular/ovarian cancer)
  - axillary (cat scratch fever, breast cancer, and metastatic cancer)
  - epitrochlear (infections, sarcoidosis, and lymphoma)
- check for splenomegaly, constitutional symptoms

**Investigations**

- CBC and differential, blood film
- if generalized, consider tuberculin test, HIV RNA, VDRL, Monospot<sup>®</sup>/EBV serology, antinuclear antibodies (ANA), and imaging
- if localized and no symptoms suggestive of malignancy, can observe 3-4 wk (if no resolution → excisional biopsy to preserve lymph node architecture)
- in areas difficult to access (retroperitoneal, mediastinal/hilar), multiple core biopsies may be more practical/feasible
- FNA should NOT be used for diagnostic purposes in lymphoproliferative disease (excisional biopsy is the gold standard)
  - FNA is helpful for recurrence of solid tumour malignancy

**Constitutional/B-Symptoms**

- Unexplained temperature >38°C
- Unexplained weight loss (>10% of body weight in 6 mo)
- Night sweats

**Drugs that can Cause Lymphadenopathy**

- Allopurinol
- Atenolol
- Captopril
- Carbamazepine
- Cephalosporins
- Gold
- Hydralazine
- Penicillin
- Phenytoin
- Primidone
- Pyrimethamine
- Quinidine
- Sulfonamides
- Sulindac

**Table 7. Inflammatory vs. Neoplastic Lymph Nodes**

Feature	Inflammatory	Neoplastic
Consistency	Fluctuant/soft	Firm/hard
Mobility	Mobile	Matted/immobile
Tenderness	Tender	Non-tender
Size	<1 cm*	>1 cm*

Note: these classifications are not absolute; lymphoma and CLL nodes can feel rubbery and are frequently mobile, non-tender  
 \*Note: inguinal lymph nodes can be up to 2 cm in size and non-pathologic

**Table 8. Differential Diagnosis of Generalized Lymphadenopathy**

Reactive	Inflammatory	Neoplastic
Bacterial (TB, Lyme, brucellosis, cat scratch disease, and syphilis)	Collagen disease (RA, dermatomyositis, SLE, vasculitis, and Sjögren's)	Lymphoproliferative disorder
Viral (EBV, CMV, HIV)	Drug hypersensitivity	Metastatic cancer
Parasitic (toxoplasmosis)	Sarcoidosis, amyloidosis	Histiocytosis X
Fungal (histoplasmosis)	Serum sickness	

## Approach to Splenomegaly

**Table 9. Differential Diagnosis of Splenomegaly**

Increased Demand for Splenic Function		Congestive	Infiltrative
<b>Hematological</b>	<b>Infectious</b>	<b>Inflammatory</b>	<b>Non-Malignant</b>
Nutritional anemias	Viral e.g. EBV, HIV/AIDS, CMV	SLE	Benign metaplasia
Hemoglobinopathies		Sarcoidosis	Cysts
Hemolysis	Bacterial	Felty syndrome	Amyloidosis
Spherocytosis	e.g. bacterial	Still's disease	Sarcoidosis
Sequestration crisis	endocarditis, TB		Hamartomas
Elliptocytosis	Parasitic e.g. malaria, histoplasmosis, leishmaniasis		Vascular abnormalities
	Fungal		<u>Lysosomal storage diseases</u> (Gaucher's, Niemann-Pick)
			<u>Glycogen storage diseases</u>
			<b>Malignant</b>
			<u>Leukemia (CML, CLL)</u>
			<u>Lymphoproliferative disease (CLL, NHL/HL)</u>
			<u>MPNs (CML, MF)</u>
			Metastatic tumour

The underlined conditions cause massive splenomegaly (spleen crosses midline or reaches pelvis)

### Causes of Splenomegaly

#### CHINA

Cirrhosis/Congestion (portal HTN)  
Hematological  
Infectious  
Neoplasm  
Autoimmune

### History

- constitutional/B symptoms, feeling of fullness in LUQ, and early satiety
- signs or symptoms of infection (e.g. mononucleosis) or malignancy
- history of liver disease, hemolytic anemia, or high-risk exposures

### Clinical Features

- jaundice, petechiae
- signs of chronic liver disease
- percussion (Castell's sign, Traube's space, and Nixon's method) and palpation
- associated LAD or hepatomegaly
- signs of CHF

### Investigations

- CBC and differential, blood film
- as indicated: liver enzymes (AST, ALT, ALP, and GGT) and/or LFTs (platelet, INR, albumin, and bilirubin), reticulocyte count, Monospot®/EBV, haptoglobin, LDH, infectious and autoimmune workup, and BM biopsy/aspirate when malignancy suspected
- imaging
  - ultrasound of abdomen/liver to assess for cirrhosis and portal vein thrombosis (if positive, refer to hepatology)
  - echo for cardiac function
  - CT to rule out lymphoma and assess splenic lesions

# Microcytic Anemia

- MCV <80 fL
- see Figure 2, H6

### Causes of Microcytic Anemia

#### TAILS

- Thalassemia
- Anemia of chronic disease
- Iron deficiency
- Lead poisoning
- Sideroblastic anemia

Table 10. Iron Indices and Blood Film in Microcytic Anemia

	Lab Tests				RDW	Blood Film
	Ferritin	Serum Iron	TIBC	% saturation		
Iron Deficiency Anemia	↓↓	↓	↑	↓	↑ (>15)	Hypochromic, microcytic
Anemia of Chronic Disease	N/↑	↓	↓	N	N	Normocytic/microcytic
Sideroblastic Anemia	N/↑	↑	N	N/↑	↑	Dual population Basophilic stippling
Thalassemia	N/↑	N/↑	N	N/↑	N/↑	Hypochromic, microcytic Basophilic stippling Poikilocytosis

## Iron Metabolism

### Iron Intake (Dietary)

- average North American adult diet = 10-20 mg iron daily
- steady state absorption is 5-10% (0.5-2 mg/d); enhanced by citric acid and ascorbic acid (vitamin C); reduced by polyphenols (e.g. in tea), phytate (e.g. in bran), dietary calcium, and soy protein
- males more likely to have positive iron balance; up to 20% of menstruating females have negative iron balance

### Iron Absorption and Transport

- dietary iron is absorbed in the duodenum (absorption impaired in IBD and celiac disease)
- in circulation, the majority of non-heme iron is bound to transferrin which transfers iron from enterocytes and storage pool sites (macrophages of the reticuloendothelial system and hepatocytes) to RBC precursors in the BM

### Iron Levels

- hepcidin is a hormone produced by hepatocytes that regulates systemic iron levels
  - binds to iron exporter ferroportin (on duodenal enterocytes and reticuloendothelial cells) and induces its degradation, thereby inhibiting iron export into circulation (iron trapping in reticuloendothelial system cells and diminished absorption of iron)
  - hepcidin production is:
    - increased in states of iron overload (inhibiting additional iron absorption) and inflammation (mediating anemia of chronic disease through iron trapping)
    - decreased in states where erythropoiesis is increased (e.g. hemolysis) or oxygen tension is low

### Iron Storage

- ferritin
  - ferric iron (Fe<sup>3+</sup>) complexed to a protein called apoferritin (liver, spleen, and BM are main ferritin storage sites)
  - small quantities are present in plasma in equilibrium with intracellular ferritin
  - also an acute phase reactant – can be spuriously elevated despite low iron stores in response to a stressor
- hemosiderin
  - aggregates or crystals of ferritin with the apoferritin partially removed
  - macrophage-monocyte system is the main source of hemosiderin storage

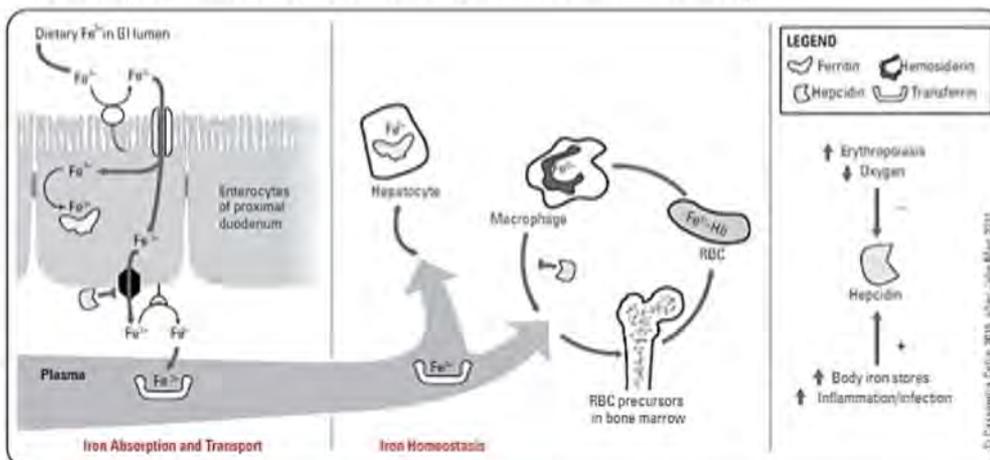

Figure 5. Iron metabolism

### Iron Indices

- BM aspirate: gold standard test for assessment of iron stores (rarely done)
- serum ferritin: most important blood test for iron stores
  - decreased in iron deficiency anemia
  - elevated in infection, inflammation, malignancy, liver disease, hyperthyroidism, and iron overload
- serum iron: measure of all non-heme iron present in blood
  - varies significantly daily
- TIBC: indirect measure of total amount of transferrin present in blood
  - normally, one third of TIBC is saturated with iron
  - increased TIBC has high specificity for decreased iron, low sensitivity
- transferrin saturation
  - serum iron divided by TIBC, expressed as a proportion or a percentage
- sTfR
  - reflects the availability of iron at the tissue level
  - transferrin receptor is expressed on the surface of erythroblasts and is responsible for iron uptake – some are cleaved off and are present in circulation as sTfR
  - in iron deficient states, more transferrin receptors are expressed on erythroblasts leading to an increase in sTfR
  - sTfR also increased during extramedullary hematopoiesis (i.e. thalassemia syndromes)
  - low in reduced erythropoiesis and iron overload
  - useful in determining iron deficiency in the setting of chronic inflammatory disorders (see *Iron Deficiency Anemia*)

## Iron Deficiency Anemia

- see [Paediatrics](#), P51
- most common cause of anemia in North America

### Etiology

- increased demand
  - increased physiological need for iron in the body (e.g. pregnancy)
- decreased supply: dietary deficiencies (rarely the only etiology in the developed world)
  - cow's milk (infant diet), "tea and toast" diet (elderly), absorption imbalances, post-gastrectomy, malabsorption (IBD of duodenum, celiac disease, autoimmune atrophic gastritis, and *H. pylori* infection)
- increased losses
  - hemorrhage
    - obvious causes: abnormal uterine bleeding, GI bleed
    - occult: peptic ulcer disease, GI cancer
  - hemolysis
    - chronic intravascular hemolysis (e.g. PNH, cardiac valve RBC fragmentation)

### Clinical Features

- iron deficiency may cause fatigue before clinical anemia develops
- signs/symptoms of anemia: see [Anemia](#), H6
- brittle hair, nail changes (brittle, koilonychia)
- pica (appetite for non-food substances, e.g. ice, paint, and dirt)
- restless leg syndrome

### Investigations

- CBC, iron indices, including sTfR
  - low ferritin (<30 µg/L) is diagnostic of iron deficiency
  - ferritin is an acute phase reactant and is elevated in the setting of inflammatory conditions and liver disease; serum ferritin <100 µg/L in these settings is suggestive of iron deficiency, necessitating further workup
- peripheral blood film
  - hypochromic microcytosis: RBCs have low Hb levels due to lack of iron
  - pencil forms, anisocytosis
  - target cells
- BM aspirate (gold standard, but rarely done)
  - iron stain (Prussian blue) shows decreased iron in macrophages and in erythroid precursors (sideroblasts)
  - intermediate and late erythroblasts show micronormoblastic maturation

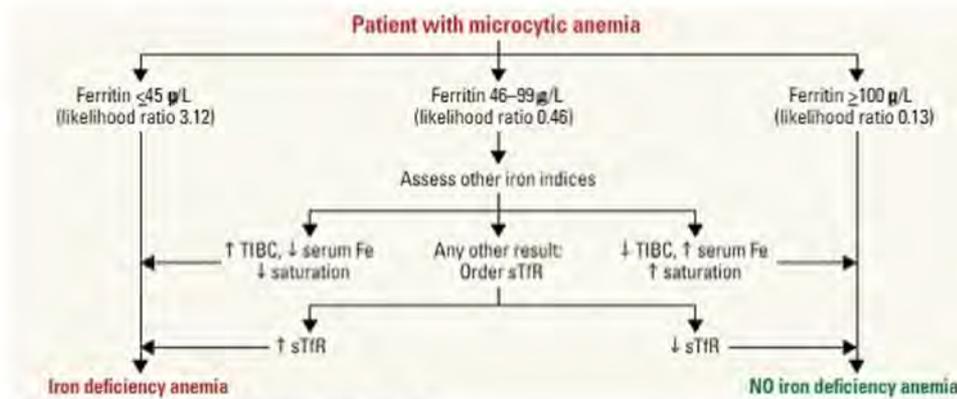

### Plummer-Vinson Syndrome

- Dysphagia (esophageal)
- Glossitis
- Iron deficiency anemia
- Stomatitis

Iron deficiency anemia is a common presentation of chronic lower GI bleeds (right-sided colorectal cancer, angiodysplasia, etc.) In males and in post-menopausal women, a GI workup is always warranted (gastroscopy, colonoscopy)

**Figure 6. Approach to interpreting iron indices**

Adapted from: *Am Fam Physician* 2007;75:671-678

### Treatment

- treat underlying cause
- iron supplementation
  - oral (capsules, syrup)
    - ferrous sulphate 325 mg once daily (65 mg elemental iron), ferrous gluconate 300 mg once daily (35 mg elemental iron), or ferrous fumarate 300 mg once daily (100 mg elemental iron), polysaccharide iron complex (150 mg elemental iron), heme iron polypeptide (11 mg elemental iron)
    - supplement until anemia corrects, then continue for 3+ mo until serum ferritin returns to normal
    - recent studies demonstrate alternate day dosing may be superior to daily or more frequent dosing, due to improved absorption, though this is still an area of investigation
  - IV iron can be considered if patient cannot tolerate or absorb oral iron, and/or if there is a need for quick recovery (e.g. chronic bleeding not manageable with oral iron)
- monitoring response
  - reticulocyte count will begin to increase after one wk
  - Hb normalizes by 10 g/L per wk (if no blood loss)

## Anemia of Chronic Disease

### Etiology

- infection, malignancy, inflammatory, and rheumatologic disease
- chronic renal and liver disease
- endocrine disorders (e.g. diabetes mellitus, hypothyroidism, hypogonadism, and hypopituitarism)

### Pathophysiology

- an anemia of underproduction due to impaired iron utilization (hepcidin is a key regulatory peptide)
  - hepatic hepcidin production is increased in inflammatory processes, trapping iron in enterocytes and macrophages (via ferroportin inhibition), see *Figure 5, H14*
  - reduced plasma iron levels make iron relatively unavailable for new Hb synthesis
  - marrow unresponsive to normal or slightly elevated EPO
- mild hemolytic component is often present i.e. RBC survival is modestly decreased

### Investigations

- diagnosis of exclusion
- associated with elevation in acute phase reactants (ESR, CRP, fibrinogen, and platelets)
- peripheral blood
  - mild: usually normocytic and normochromic
  - moderate: may be microcytic and normochromic
  - severe: may be microcytic and hypochromic
  - absolute reticulocyte count is frequently low, reflecting overall decrease in RBC production
- “classic” serum iron indices: see *Table 10, H14*
- BM
  - normal or increased iron stores
  - decreased or absent staining for iron in erythroid precursors

### Treatment

- treat underlying disease; only treat in patients who would benefit from a higher Hb
- IV iron if no benefit from PO iron (overcomes sequestration in enterocytes) or with use of ESAs in CKD
- EPO indicated in chronic renal failure; not to be used if patient has concomitant curative solid tumour malignancy; ensure Hb target <110 g/L

## Sideroblastic Anemia

- uncommon compared to iron deficiency anemia or anemia of chronic disease

### Sideroblasts

- erythrocytes with iron-containing (basophilic) granules in the cytoplasm
- "normal": granules are small and randomly spread in the cytoplasm
- "ring": iron deposits in mitochondria, forming large, abnormal granules that surround the nucleus
  - hallmark of sideroblastic anemia

### Etiology

- due to defects in heme biosynthesis in erythroid precursors
- hereditary (rare): X-linked; median survival 10 yr
- idiopathic (acquired)
  - refractory anemia with ringed sideroblasts: a subtype of MDS (see *Myelodysplastic Syndromes, H41*)
  - may be a preleukemic phenomenon (1-2% transform to AML)
- reversible
  - drugs (isoniazid, chloramphenicol), alcohol, lead, copper deficiency, zinc toxicity, and hypothyroidism

### Clinical Features

- anemia symptoms (see *Anemia, H6*)
- hepatosplenomegaly

### Investigations

- serum iron indices: see *Table 10, H14*
- CBC and blood film
  - ring sideroblasts (diagnostic hallmark)
  - RBCs are hypochromic; can be micro-, normo-, or macrocytic
  - anisocytosis, poikilocytosis, basophilic stippling
- BM biopsy

### Treatment

- depends on etiology
  - X-linked: high dose pyridoxine (vitamin B<sub>6</sub>) in some cases
  - acquired: EPO and G-CSF
  - reversible: remove precipitating cause
- supportive transfusions for severe anemia
- monitor for iron overload driven by ineffective erythropoiesis and/or transfusion

## Lead Poisoning

### Definition/Etiology

- blood lead levels >80 µg/dL, may be symptomatic at 50 µg/dL
- identify source: consider occupational history, exposures history, and utensil history

### Clinical Features

- pallor, abdominal pain, constipation, irritability, and difficulty concentrating

### Treatment

- chelation therapy: dimercaprol and EDTA are first line agents

## Normocytic Anemia

- MCV 80-100 fL
- see *Figure 2, H6*

## Aplastic Anemia

### Definition

- destruction of hematopoietic cells of the BM leading to pancytopenia and hypocellular BM

Consider lead poisoning in any child with microcytic anemia who lives in a house built before 1977

### Features of Lead Poisoning

#### LEAD

Lead lines on gingivae and epiphyses of long bones on x-ray  
Encephalopathy and Erythrocyte basophilic stippling  
Abdominal colic and microcytic Anemia (sideroblastic)  
Drops (wrist and foot drop)

### Causes of Normocytic Anemia

#### ABCD

Acute blood loss  
BM failure  
Chronic disease  
Destruction (hemolysis)

## Etiology

**Table 11. Etiology of Aplastic Anemia**

Congenital	Acquired	
Fanconi syndrome	<b>Idiopathic</b>	<b>Ionizing Radiation</b>
Shwachman-Diamond syndrome	Often T-cell mediated	<b>Post-Viral Infection</b>
Telomeropathies (dyskeratosis congenita)	<b>Drugs</b>	Parvovirus B19, EBV, HDV, HEV, HBV, HHV6, HIV
	Dose-related (i.e. chemotherapeutics)	<b>Autoimmune (rare)</b>
	Idiosyncratic (chloramphenicol, antimalarials, and phenylbutazone)	SLE, Graft-versus-host disease
	<b>Toxins</b>	Others
	Benzene/organic solvents, DDT, insecticides	PNH, pregnancy, anorexia nervosa, and thymoma

### Clinical Features

- can present acutely or insidiously
- symptoms of anemia (see *Anemia, H6*), thrombocytopenia (see *Thrombocytopenia, H7*), and/or infection
- ± splenomegaly and lymphadenopathy (depending on the cause)

### Investigations

- exclude other causes of pancytopenia (see *Figure 4, H9*), including PNH (50% of aplastic anemia patients have PNH+ stem cell clones)
- CBC
  - anemia, neutropenia, or thrombocytopenia (any combination including pancytopenia)
  - decreased reticulocytes (<1% of the total RBC count)
- blood film
  - decreased number of normal RBCs
- BM aspirate and biopsy
  - aplasia or hypoplasia of cells with adipose tissue replacement
  - no evidence of infiltration with malignant cells or fibrosis

### Treatment

- remove offending agents
- supportive care (RBC and platelet transfusions, antibiotics)
  - judicious use of blood products to decrease the risk of immune sensitization
  - iron chelation therapy for iron overload (accumulation of iron after multiple >20-unit RBC transfusions)
- immunosuppressive therapy (for idiopathic aplastic anemia)
  - horse or rabbit anti-thymocyte globulin: 40-50% of patients respond
  - cyclosporine (for improved response and survival)
- allogeneic BM transplant
- eltrombopag (TPO receptor agonist) shown to be effective; G-CSF and EPO not effective

## Hemolytic Anemia

### Definition

- anemia due to destruction and consequently shortened survival of circulating RBCs, usually defined as <100 d
- uncommon cause for anemia (<5% of cases) with many etiologies (>200)

### Classification

- hereditary
  - abnormal membrane (spherocytosis, elliptocytosis)
  - abnormal enzymes (pyruvate kinase deficiency, G6PD deficiency)
  - abnormal Hb synthesis (hemoglobinopathies)
- acquired
  - immune
    - autoimmune: warm vs. cold AIHA, see *Table 14, Classification of AIHA, H23*
    - alloimmune: hemolytic disease of the fetus/newborn and post-transfusion
  - non-immune
    - TMA (includes MAHA): thrombus in blood vessel causes RBCs to be sheared – associated with DIC, HUS, aHUS, TTP, preeclampsia/HELLP, vasculitis, and malignant hypertension
    - other causes: PNH, hypersplenism, march hemoglobinuria (exertional hemolysis), infection (e.g. malaria), snake venoms, and mechanical heart valves
- also classified as intravascular or extravascular
  - intravascular: TMA and PNH (complement mediated)
  - extravascular: RBCs are coated with Abs (AIHA) or have an abnormal membrane structure/shape or inclusions
  - infections can cause intravascular (*Clostridium*), extravascular, or both (malaria)

On blood film, schistocytes reflect an intravascular hemolysis while spherocytes usually reflect an extravascular hemolysis

Disruption of the heme biosynthetic pathway causes **porphyria**

**Porphyria**  
Inherited or acquired disorders of defective heme synthesis leading to accumulation of porphyrin precursors. Typically presents with non-specific clinical findings (abdominal pain, peripheral neuropathy, neuropsychiatric changes, and/or cutaneous photosensitivity)

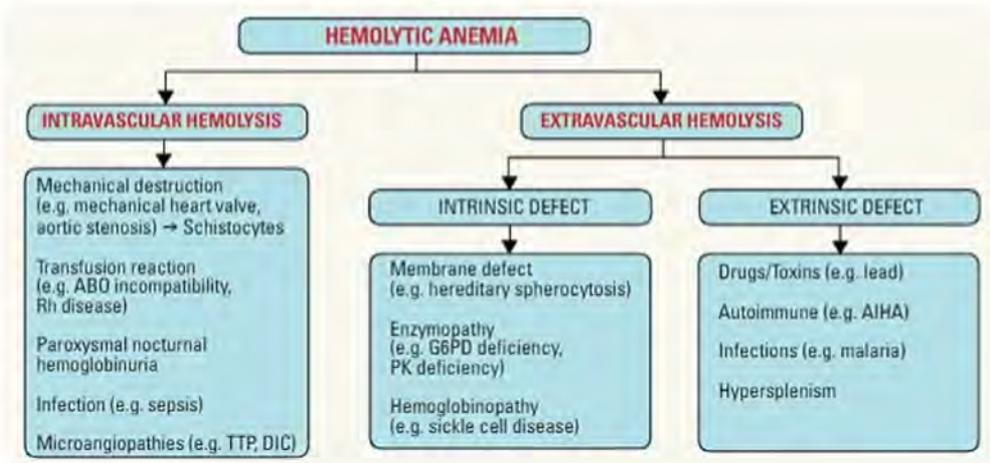

Figure 7. Hemolytic anemia

**Clinical Features**

- jaundice
- dark urine (hemoglobinuria, bilirubinuria)
- cholelithiasis (pigment stones)
- potential for an aplastic crisis (i.e. BM suppression in overwhelming infection)
- iron overload with extravascular hemolysis
- iron deficiency with intravascular hemolysis

**Investigations**

Table 12. Investigations for Hemolytic Anemia

Screening Tests	Tests Specific For Intravascular Hemolysis
Increased LDH	Schistocytes on blood film (MANA)
Decreased haptoglobin	Free Hb in serum
Increased unconjugated bilirubin	Methemalbuminemia (heme + albumin)
Increased urobilinogen	Hemoglobinuria (immediate)
Reticulocytosis	Hemosiderinuria (delayed) – most sensitive

**Tests Specific for Extravascular Hemolysis**

**Direct Antiglobulin Test (direct Coombs)**  
 Detects IgG or complement on the surface of RBC  
 Add anti-IgG or anti-complement Ab to patient's RBCs; positive if agglutination  
 Indications: hemolytic disease of newborn, AIHA, hemolytic transfusion reaction

**Indirect Antiglobulin Test (indirect Coombs)**  
 Detects Abs in serum that can recognize antigens on RBCs  
 Mix patient's serum + donor RBCs + Coombs serum (anti-human Ig Ab); positive if agglutination  
 Indications: cross-matching donor RBCs, atypical blood group, blood group Ab in pregnant women, AIHA

Haptoglobin is a circulating protein that mops up free Hb, allowing its clearance in the spleen; when free Hb is abundant, haptoglobin levels decrease

**Thalassemia**

**Definition**

- defects in production of the  $\alpha$  or  $\beta$  chains of Hb
  - resulting imbalance in globin chains leads to ineffective erythropoiesis and hemolysis in the spleen or BM
- clinical manifestations and treatment depend on specific gene and number of alleles affected
- common features
  - increasing severity with increasing number of alleles involved
  - hypochromic microcytic anemia
  - basophilic stippling, abnormally shaped RBCs on blood film
  - CBC: low MCV, low Hb, high RBC count,  $\pm$  high reticulocyte count

**Pathophysiology**

- defect may be in any of the Hb genes
  - normally 4  $\alpha$  genes in total; 2 on each copy of chromosome 16
  - normally 2  $\beta$  genes in total; 1 on each copy of chromosome 11
  - fetal Hb, HbF ( $\alpha_2\gamma_2$ ), switches to adult forms HbA ( $\alpha_2\beta_2$ ) and HbA2 ( $\alpha_2\delta_2$ ) at age 3-6 mo
  - HbA constitutes 97% of adult Hb
  - HbA2 constitutes 3% of adult Hb

**Thalas"SEA"mia**

$\beta$ -thalassemia → more prevalent in Mediterranean  
 $\alpha$ -thalassemia → more prevalent in South East Asia (SEA) and Africa ( $\alpha$  = Asia, Africa)

## $\beta$ -Thalassemia Minor (Thalassemia Trait)

### Definition

- defect in single allele of  $\beta$  gene (heterozygous for one normal  $\beta$  globin allele and one  $\beta$  globin thalassemia allele)
- common in people of Mediterranean and Asian descent

### Clinical Features

- usually asymptomatic; a palpable spleen is very rare

### Investigations

- Hb (100-140 g/L), MCV (<70 fL), Fe (normal), RBC count (normal/high)
- peripheral blood film – microcytosis, basophilic stippling
- Hb electrophoresis
  - specific: HbA<sub>2</sub> increased to 3.5-5% (normal 1.5-3.5%)
  - non-specific: 50% have slight increase in HbF

### Treatment

- no treatment required
- genetic counselling for patient and family

**Microcytosis in  $\beta$ -Thalassemia Minor**  
Microcytosis is more profound and the anemia is much milder than that of iron deficiency

## $\beta$ -Thalassemia Major

### Definition

- defect in both alleles of  $\beta$  gene (homozygous, autosomal recessive)

### Pathophysiology

- ineffective chain synthesis leading to decreased erythropoiesis, hemolysis of RBCs, and increase in HbF

### Clinical Features

- initial presentation at age 6-12 mo when HbA ( $\alpha_2\beta_2$ ) normally replaces HbF ( $\alpha_2\gamma_2$ )
  - severe anemia, jaundice
- iron overload due to compensatory gastrointestinal iron uptake progressing to hemochromatosis
  - secondary to repeated transfusions and ineffective erythropoiesis
  - leads to iron-induced organ damage
- stunted growth and development (due to hypogonadism)
- gross hepatosplenomegaly (due to extramedullary hematopoiesis)
- radiologic changes (due to expanded marrow cavity) and extramedullary hematopoietic masses (erythroid tissue tumours)
  - skull x-ray has "hair-on-end" appearance
  - pathologic fractures common
- evidence of increased Hb catabolism (e.g. pigmented gallstones)
- death can result from:
  - untreated anemia (should transfuse)
  - infection (should identify and treat early)
  - iron overload (common): late complication

### Investigations

- CBC and iron studies
- severe microcytic anemia (Hb <60 g/L)
- peripheral blood film: teardrop, target, hypochromic, microcytic
- Hb electrophoresis
  - HbA: 0-10% (normal >95%)
  - HbA<sub>2</sub> >2.5%
  - HbF: 90-100%

### Treatment

- lifelong regular transfusions to suppress endogenous erythropoiesis
- iron chelation (e.g. deferoxamine, deferasirox, and deferi-prone) to prevent iron overload in organs and the formation of free radicals (which promote tissue damage and fibrosis)
- folic acid supplementation if not transfused
- allogeneic BM transplantation (potentially curative) or cord blood transplant
- gene therapy (to encode adult Hb A) or CRISPR-Cas 9 gene editing (to allow for increased fetal Hb production) under study
- splenectomy (now performed less frequently)

**Hemochromatosis Clinical Features**

#### ABCDH

Arthralgia  
Bronze skin  
Cardiomyopathy, Cirrhosis of liver  
Diabetes (pancreatic damage)  
Hypogonadism (anterior pituitary damage)

## $\beta$ -Thalassemia Intermedia

### Definition

- clinical diagnosis in patients whose clinical manifestations are too mild to be classified as  $\beta$ -thalassemia major, but too severe to be classified as  $\beta$ -thalassemia minor

### Clinical Features

- wide variety of clinical phenotypes
- in most cases of  $\beta$ -thalassemia intermedia, both  $\beta$ -globin genes affected
- three main mechanisms account for the milder phenotype compared to  $\beta$ -thalassemia major: (1) subnormal (vs. absent)  $\beta$ -chain synthesis, (2) increased number of  $\gamma$  chains, and (3) coinheritance of  $\alpha$ -thalassemia (in some cases)
- complications more commonly seen in  $\beta$ -thalassemia intermedia than  $\beta$ -thalassemia major include extramedullary hematopoiesis, leg ulcers, gallstones, thrombosis, pulmonary hypertension, and growth retardation

### Treatment

- most patients only require periodic transfusions, although regular transfusions may eventually be necessary in adulthood (third to fourth decade of life)
- folic acid supplementation if not transfused
- iron chelation therapy is required since iron overload develops due to ineffective erythropoiesis and subsequent hepcidin downregulation

## $\alpha$ -Thalassemia

### Definition

- defect(s) in  $\alpha$  genes
- similar geographic distribution as  $\beta$ -thalassemia, but higher frequency among Asians and Africans

### Clinical Features

- 1 defective  $\alpha$  gene (aa/a-): clinically silent; normal Hb, normal MCV
- 2 defective  $\alpha$  genes (cis: aa/- or trans: a-/a-): normal Hb, decreased MCV
  - N.B. cis 2-gene deletion more common in Asia vs. trans 2-gene deletion more common in Africa – this leads to increased risk of fetal hydrops in offspring of patients from Asia vs. Africa
- 3 defective  $\alpha$  genes (a-/-): HbH ( $\beta_4$ ) disease; presents in adults, decreased Hb, decreased MCV, and splenomegaly
- 4 defective  $\alpha$  genes (-/-): Hb Barts ( $\gamma_4$ ) disease (hydrops fetalis); usually incompatible with life

### Investigations

- CBC and iron studies (for iron overload)
- peripheral blood film – screen for HbH inclusion bodies with supravital stain
- Hb electrophoresis can be used to identify HbH disease, but may miss 1- or 2-gene deletions; definitive diagnosis with DNA genotyping

### Treatment

- referral for genetic/prenatal counselling
- depends on degree of anemia
  - 1 or 2 defective  $\alpha$  genes: no treatment required
  - HbH disease: similar to  $\beta$ -thalassemia intermedia
  - Hb Barts: no definitive treatment – majority of pregnancies terminated (fetal/maternal mortality risk), intrauterine transfusion, stem cell transplants

## Sickle Cell Disease

### Definition

- autosomal recessive sickling disorders are most commonly caused by a Glu  $\rightarrow$  Val substitution at position 6 of the  $\beta$ -globin chain (chromosome 11) resulting in HbS variant, rather than HbA (normal adult Hb)
  - increased incidence of HbS allele in patients with Sub-Saharan African, Indian, Middle Eastern, or Mediterranean heritage (thought to be protective against malaria)
- SCD occurs when an individual has two HbS genes (homozygous, HbSS) or one HbS gene + another mutant  $\beta$ -globin gene (compound heterozygote) – most commonly HbS- $\beta$ -thal and HbSC disease

### Pathophysiology

- at low  $pO_2$ , deoxyHbS polymerizes leading to rigid crystal-like rods that distort membranes  $\rightarrow$  'sickles'
- the  $pO_2$  level at which sickling occurs is related to the percentage of HbS present
- sickling is aggravated by acidemia, increased  $CO_2$ , increased 2,3-DPG, fever, and increased osmolality
- fragile sickle cells then cause injury in two main ways
  - fragile sickle cells hemolyze (nitric oxide depletion)
  - occlusion of small vessels (hypoxia, ischemia-reperfusion injury)

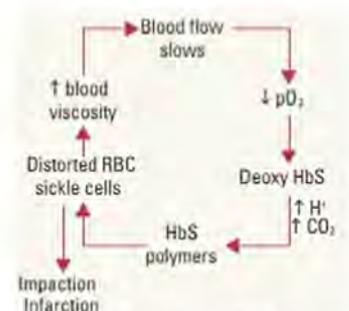

Figure 8. Pathophysiology of sickling

- Functional Asplenism:** increased susceptibility to infection by encapsulated organisms
  - S. pneumoniae*
  - N. meningitidis*
  - H. influenzae*
  - Salmonella (osteomyelitis)*

### Clinical Features

- sickle cell trait (HbAS): patient will be asymptomatic except during extreme hypoxia or infection
  - increased risk of renal medullary carcinoma
- SCD-SS (HbSS)
  - chronic hemolytic anemia
  - jaundice in the first year of life
  - retarded growth and development ± skeletal changes
  - splenomegaly in childhood; splenic atrophy in adulthood
- SCD-SS often presents with acute pain episode
  - aplastic crises
    - toxins and infections (especially parvovirus B19) transiently suppress BM
  - splenic sequestration crises
    - usually in children; significant pooling of blood in spleen resulting in acute Hb drop and shock
    - uncommon in adults due to asplenia from repeated infarction
  - vaso-occlusive crises (infarction)
    - may affect various organs causing ischemia-reperfusion injury (especially in back, chest, abdomen, and extremities), fever, and leukocytosis
    - can cause a stroke or a silent MI
    - precipitated by infections, dehydration, rapid change in temperature, pregnancy, menses, and alcohol
  - acute chest syndrome
    - acute illness characterized by fever and/or respiratory symptoms
    - new pulmonary infiltrate on chest x-ray
    - precipitated by pulmonary infection, fat embolism, and pulmonary infarction
- SCD-SC (HbSC): most common compound heterozygote
  - 1 in 833 live births in African-Americans, common in West Africa
  - milder anemia than HbSS
  - similar complications as HbSS but typically milder and less frequent (exception is proliferative sickle cell retinopathy, glomerulonephritis, and avascular necrosis)
  - spleen not always atrophic in adults

### Investigations

- sickle cell prep (detects sickling of RBCs under the microscope in response to O<sub>2</sub> lowering agent); determines the presence of a HbS allele, but does not distinguish HbAS from HbSS
- Hb electrophoresis distinguishes HbAS, HbSS, HbSC, and other variants
- all newborns in developed countries typically screened for SCD

**Table 13. Investigations for Sickle Cell Disease**

	HbAS	HbSS
<b>CBC</b>	Normal	Increased reticulocytes, decreased Hb, and decreased Hct
Peripheral Blood	Normal; possibly a few target cells	Sickled cells
Hb Electrophoresis	HbA fraction of 0.65 (65%) HbS fraction of 0.35 (35%)	No HbA, only HbS and HbF (proportions change with age); normal amount of HbA2

### Treatment

- genetic counselling
- HbAS: no treatment required
- HbSC: treatment as per HbSS, but is dictated by symptom severity
- HbSS
  - folic acid to prevent folate deficiency
  - hydroxyurea to enhance production of HbF
    - mechanism of action: stops repression of Hb-γ chains and/or initiates differentiation of stem cells expressing this gene
    - presence of HbF in the sickle cell RBCs decreases polymerization and precipitation of HbS
    - short term harms (within 6 mo): dose-related leukopenia, thrombocytopenia, anemia, and decreased reticulocyte count; decreased sperm production, mucositis, skin ulcers
    - long-term harms: birth defects in offspring of people receiving the drug, growth delays in children receiving the drug, and cancer in both children and adults who receive the drug
  - treatment of vaso-occlusive crisis
    - supportive care: oxygen, hydration (reduces viscosity), correct acidosis, analgesics/opiates
    - indication for exchange transfusion: Hb <50-60 g/L, SCD complications (acute chest syndrome, aplastic crisis, hepatic or splenic sequestration, and stroke), prevention of complications, preoperative
    - less routinely: antimicrobials for suspected infection
  - prevention of crises
    - establish diagnosis
    - avoid conditions that promote sickling (hypoxia, acidosis, dehydration, and fever)
    - vaccination in childhood (*S. pneumoniae*, *N. meningitidis*, and *H. influenzae* type b)
    - prophylactic penicillin (age 3 mo-5 yr)
    - good hygiene, nutrition, and social support

### Organs Affected by Vaso-Occlusive Crisis

Organ	Problem
Brain	Ischemic or hemorrhagic stroke, vasculopathy
Eye	Hemorrhage, blindness
Liver	Infarcts, RUQ syndrome
Lung	Acute chest syndrome, long-term pulmonary hypertension
Gallbladder	Stones
Heart	Hyperdynamic flow murmurs
Spleen	Enlarged (child); atrophic (adult)
Kidney	Hematuria, loss of renal concentrating ability, proteinuria
Intestines	Acute abdomen
Placenta	Stillbirths
Penis	Priapism
Digits	Dactylitis
Bone	Infarction, infection, avascular necrosis (femoral and humeral head)
Skin	Leg ulcers (ankle)

### Hydroxyurea (Hydroxycarbamide) for Sickle Cell Disease

Cochrane DB Syst Rev 2017;4:CD002202

**Purpose:** To assess the effects of hydroxyurea therapy in patients of any age and genotype with sickle cell disease (SCD).

**Study Selection:** Randomised and quasi-randomised controlled trials ≥1 month comparing hydroxyurea with placebo, standard therapy or other interventions.

**Results:** 8 RCTs were included, 899 total patients (both adults and children with SCD). When compared to placebo, hydroxyurea was associated with statistically significant improvements in pain alteration (pain crisis frequency, duration, intensity, hospital admissions and opioid use), measures of fetal hemoglobin and neutrophil counts and fewer occurrences of acute chest syndrome and blood transfusions. Differences in quality of life and adverse events (including serious or life-threatening events) were not statistically significant.

**Conclusion:** Evidence suggests that hydroxyurea can effectively decrease the frequency of pain episodes and other acute complications in patients with SCD. However, data on the long-term benefits and risks of hydroxyurea is still insufficient.

5. screen for complications
  - regular blood work (CBC, reticulocytes, iron indices, BUN, LFTs, and creatinine)
  - urinalysis annually (proteinuria and glomerulopathy)
  - transcranial doppler annually until 16 yr (stroke prevention)
  - retinal examinations annually from 8 yr (screen for retinopathy)
  - echocardiography once in late childhood/early adulthood (screen for pulmonary hypertension)
6. future therapies
  - gene therapy
  - voxelotor
  - crizanlizumab

**Stroke With Transfusions Changing to Hydroxyurea (SWITCH)**  
 Blood 2012;119:3925-32

**Purpose:** To compare standard treatment (transfusions/chelation) to alternative treatment (hydroxyurea/phlebotomy) for children with sickle cell anemia (SCA), stroke, and iron overload.

**Methods:** 133 pediatric patients were randomized to (1) continuation of monthly erythrocyte transfusions with oral deferasirox (28.2 ± 6.0 mg/kg/d) or (2) initiation on hydroxyurea (20 mg/kg/d escalated to maximum tolerated dose (MTD) ~26.2 ± 4.9 mg/kg/d) with discontinuation of transfusions at MTD, and monthly phlebotomy (5-10 mL/kg/mo) for iron overload.

**Primary Outcome:** Secondary stroke recurrence rate and quantitative liver iron content.

**Results:** Stroke recurrence rate was significantly lower in patients on transfusions/deferasirox as compared to those initiated on hydroxyurea/phlebotomy (0% vs. 10%, P<0.05). Differences in liver iron content between the two treatment arms were not statistically different (16.6 mg/g dry weight liver in transfusions/deferasirox vs. 15.7 mg/g in hydroxyurea/phlebotomy).

**Conclusion:** Transfusions and chelation remain the preferred management strategies for pediatric patients with SCA, stroke and iron overload.

## Autoimmune Hemolytic Anemia

Table 14. Classification of AIHA

	Warm (75-90% cases)	Cold
Ab Allotype	IgG	IgM
Agglutination Temperature	37°C	4-37°C
Direct Coombs Test (direct antiglobulin test)	Positive for IgG ± complement	Positive for complement
Etiology	Idiopathic Secondary to lymphoproliferative disorder (e.g. CLL, Hodgkin lymphoma) Secondary to autoimmune disease (e.g. SLE) Pregnancy Drug-induced (e.g. penicillin, quinine, methylidopa)	Idiopathic Secondary to infection (e.g. mycoplasma pneumoniae, EBV, HCV, syphilis) Secondary to lymphoproliferative disorder (e.g. macroglobulinemia, CLL)
Blood Film	Spherocytes	Agglutination
Management	Treat underlying cause Folic acid Corticosteroids (1st-line) Folic acid Rituximab (2nd-line to steroids) Immunosuppression Splenectomy	Treat underlying cause Folic acid Warm patient/avoid cold Rituximab regimen (1st-line) Plasma exchange (2nd-line for high IgM levels) Low dose alkylating agents (chlorambucil, cyclophosphamide) or interferon may be useful but less effective

## Microangiopathic Hemolytic Anemia/Thrombotic Microangiopathy

**Definition**

- hemolytic anemia due to intravascular fragmentation of RBCs

**Etiology**

- see *Thrombotic Thrombocytopenic Purpura and Hemolytic Uremic Syndrome, H31*
- see *Disseminated Intravascular Coagulation, H34*
- eclampsia, HELLP syndrome, AFLP
- malignant hypertension
- vasculitis
- malfunctioning heart valves
- metastatic carcinoma
- drugs (calcineurin inhibitors, quinine, simvastatin)
- infections (severe CMV or meningococcus)
- catastrophic APS

**Investigations**

- blood film: schistocytes
- hemolytic workup (CBC, reticulocyte count, LDH, haptoglobin, indirect bilirubin)
- Coombs test: negative
- urine: hemosiderinuria, hemoglobinuria

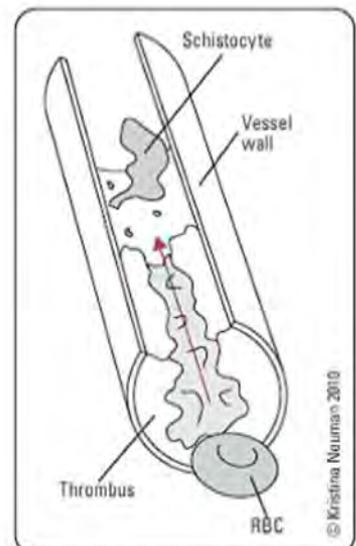

Figure 9. Schistocytosis

## Hereditary Spherocytosis

### Definition/Etiology

- most common type of hereditary hemolytic anemia
- abnormality in RBC membrane proteins (e.g. spectrin)
- autosomal dominant (variable penetrance), can also be autosomal recessive or de novo
- presents with hemolytic anemia, jaundice, splenomegaly

### Investigations

- CBC and differential blood film (shows spherocytes)
- RBC dehydration and membrane loss result in elevated MCHC
- osmotic fragility (increased)
- molecular analysis for spectrin gene
- ultrasound (splenomegaly and gallstones (pigment))

### Treatment

- genetic counselling
- in severe cases, splenectomy and vaccination against *S. pneumoniae*, *N. meningitidis*, and *H. influenzae* type b (avoid splenectomy in early childhood)

## Hereditary Elliptocytosis

### Definition/Etiology

- abnormal interactions between spectrin and other membrane proteins
- autosomal dominant
- 25-75% elliptocytes
- hemolysis is usually mild

### Treatment

- genetic counselling
- if severe hemolysis: splenectomy, folate supplementation, and immunization

## Glucose-6-Phosphate Dehydrogenase Deficiency

### Definition/Etiology

- deficiency in G6PD leads to a lack of reduced glutathione and increased RBC sensitivity to oxidative stress
- X-linked recessive, prevalent in individuals of African, Asian, and Mediterranean descent

### Clinical Features

- frequently presents as episodic hemolysis precipitated by:
  - oxidative stress
  - drugs (e.g. sulfonamide, antimalarials, and nitrofurantoin)
  - infection
  - food (fava beans)
- in neonates: can present as prolonged, pathologic neonatal jaundice

### Investigations

- neonatal screening
- G6PD assay (may not be useful if result is normal)
  - should not be done in acute crisis when reticulocyte count is high (reticulocytes have high G6PD levels)
- blood film
  - Heinz bodies
  - bite cells (consistent with oxidative hemolysis; generated by passage through spleen)

### Treatment

- genetic and prenatal counselling
- folic acid
- stop offending drugs and avoid triggers
- transfusion in severe cases

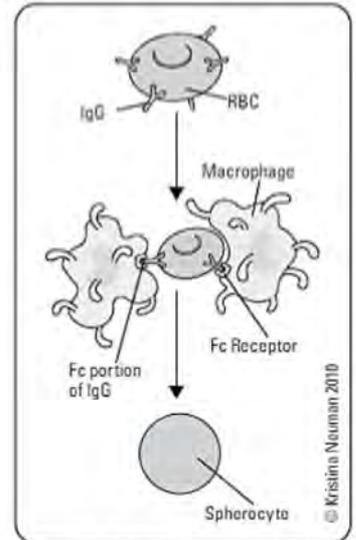

Figure 10. Spherocytosis secondary to AIHA

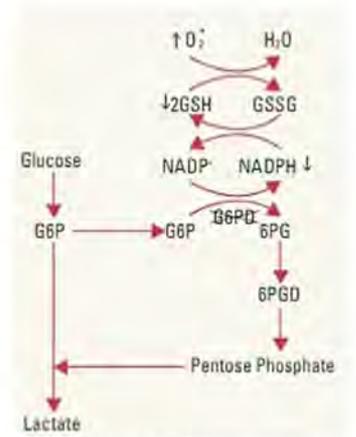

Figure 11. G6PD deficiency

## Macrocytic Anemia

- MCV >100 fL
- see Figure 2, H6

**Table 15. Comparison Between Megaloblastic and Non-Megaloblastic Macrocytic Anemia**

	Megaloblastic	Non-Megaloblastic
Morphology	Large, oval, nucleated RBC precursor Hypersegmented neutrophils	Large round RBC Normal neutrophils
Pathophysiology	Failure of DNA synthesis resulting in asynchronous maturation of RBC nucleus and cytoplasm	Reflects membrane abnormality with abnormal cholesterol metabolism

Note: MDS is a non-megaloblastic macrocytic anemia that commonly presents with oval macrocytosis

## Vitamin B12 Deficiency

- B<sub>12</sub> (cobalamin)
- binds to intrinsic factor (IF) secreted by gastric parietal cells
- absorbed in terminal ileum
- total body stores sufficient for 3-4 yr

### Etiology

**Table 16. Etiology of Vitamin B12 Deficiency**

Diet	Gastric	Intestinal Absorption	Genetic
Strict vegan More likely to present in paediatric population Vegetarian in pregnancy Malnutrition	Mucosal atrophy Gastritis, autoimmune Pernicious anemia (see below) Post-gastrectomy	Malabsorption Crohn's, celiac disease, pancreatic insufficiency, <i>H. pylori</i> Stagnant bowel Blind loop, stricture Fish tapeworm Resection of ileum Drugs Neomycin, biguanides, proton pump inhibitors, NO anesthesia, metformin	Transcobalamin II deficiency IF receptor defect

### Pathophysiology of Pernicious Anemia

- auto-Abs produced against gastric parietal cells leading to achlorhydria and lack of IF secretion
- IF is required to stabilize B<sub>12</sub> as it passes through the bowel
- decreased IF leads to decreased ileal absorption of B<sub>12</sub>
- may be associated with other autoimmune disorders (polyglandular endocrine insufficiency)
- most common in Northern European White populations, usually >30 yr (median age of 60 yr)

### Clinical Features

- neurological (severity of anemia and neurological sequelae depends on deficiency)
  - peripheral neuropathy (variable reversibility)
    - usually symmetrical, affecting lower limbs more than upper limbs
  - spinal cord (irreversible damage)
    - subacute combined degeneration
    - posterior columns: decreased vibration sense, proprioception, 2-point discrimination, and paresthesia
    - pyramidal tracts: spastic weakness, ataxia
  - cerebral (common, reversible with B<sub>12</sub> therapy)
    - confusion, delirium, and dementia
  - cranial nerves (rare)
    - optic atrophy

### Investigations

- CBC, reticulocyte count
  - anemia often severe ± neutropenia ± thrombocytopenia
  - MCV >110 fL
  - low reticulocyte count relative to the degree of anemia (<2%)
- serum B<sub>12</sub> and RBC folate
  - caution: lower serum B<sub>12</sub> leads to low RBC folate; absence of B<sub>12</sub> results in folate polyglutamate synthesis failure
  - alternatively, can measure elevated urine metabolites (methylmalonate, homocysteine)
- blood film
  - oval macrocytes, hypersegmented neutrophils

### Causes of Macrocytic Anemia

#### ABCDEF

- Alcoholism (liver disease)
- B<sub>12</sub> deficiency
- Compensatory reticulocytosis
- Drugs (cytotoxic, azidothymidine)/Dysplasia
- Endocrine (hypothyroidism)
- Folate deficiency/Fetus (pregnancy)

### Characteristics of Megaloblastic Macrocytic Anemia

- Pancytopenia
- Hypersegmented neutrophils
- Megaloblastic BM

- BM
  - hypercellularity
  - nuclear-cytoplasmic asynchrony in RBC precursors (less mature nuclei than expected from the development of the cytoplasm)
- bilirubin and LDH
  - elevated unconjugated bilirubin and LDH due to breakdown of cells in BM
- Schilling test (radiolabeled B<sub>12</sub> test, rarely done) to distinguish pernicious anemia from other causes (e.g. anti-IF antibody, anti-parietal cell antibody)

### Treatment

- treatment dose = vitamin B<sub>12</sub> 1000 µg IM weekly or 1000-1200 µg PO once daily if intestinal absorption intact; route and duration depends on cause
- maintenance dose (once replete) = vitamin B<sub>12</sub> 1000 µg IM monthly or 1000 µg PO once daily
- watch for hypokalemia and rebound thrombocytosis when treating severe megaloblastic anemia

## Folate Deficiency

- uncommon in developed countries due to extensive dietary supplementation (enriched in flour)
- folate stores are depleted in 3-6 mo
- folate commonly found in green, leafy vegetables, and fortified cereals
- maternal folate deficiency is associated with fetal neural tube defects

### Etiology

Table 17. Etiology of Folate Deficiency

Diet/Deficiency	Malabsorption	Drugs	Increased Demand
Alcohol use disorder	Celiac disease	Anti-folates (methotrexate)	Pregnancy
Substance misuse	IBD	Anticonvulsants (phenytoin)	Hemolysis
Elderly/infants	Short bowel syndrome	Alcohol	Prematurity
Poor intake		Oral contraceptive	Exfoliative dermatitis/psoriasis Hemodialysis

### Clinical Features

- anemia, mild jaundice, glossitis, diarrhea, confusion, pallor
- consider social history, alcohol use disorder/substance misuse, very poor diet (e.g. elderly, depressed)

### Investigations

- similar to B<sub>12</sub> deficiency (CBC, reticulocytes, blood film, RBC folate, and serum B<sub>12</sub>)
- if decreased RBC folate, rule out B<sub>12</sub> deficiency as cause

### Management

- folic acid 1-5 mg PO once daily x 1-4 mo; then 1 mg PO once daily maintenance if cause is not reversible

Never give folate alone to an individual with megaloblastic anemia because it will mask B<sub>12</sub> deficiency and neurological degeneration will continue

## Hemostasis

### Stages of Hemostasis

#### 1. Primary Hemostasis

- cellular defense – involves the platelet and VWF predominantly
- goal is rapid cessation of bleeding; main effect is on mucocutaneous bleeding
- vessel injury results in collagen/subendothelial matrix exposure and release of vasoconstrictors
- blood flow is impeded and platelets come into contact with damaged vessel wall (*Figure 12a, H27*)
  - adhesion: platelets adhere to subendothelium via VWF
  - activation: platelets are activated resulting in integrin activation, shape change, and granule release
  - aggregation: activated GPIIb/IIIa on platelets binds soluble ligands, which results in aggregation and the formation of a localized platelet plug

#### 2. Secondary Hemostasis

- platelet plug is reinforced by production of a fibrin clot (*Figure 12b, H27*)
- extrinsic (initiation) pathway: initiation of secondary hemostasis
- intrinsic (amplification) pathway: amplification once secondary hemostasis has started via positive feedback
- both the intrinsic and extrinsic pathways converge onto the common pathway, which results in thrombin generation and fibrin formation

#### 3. Fibrin Stabilization

- conversion from a soluble to an insoluble, cross-linked clot

#### 4. Fibrinolysis

- once healing is initiated, clot dissolution is mediated by the fibrinolytic system

**Phases of Hemostasis**

- **Primary Hemostasis**  
Vascular response and platelet plug formation via VWF
- **Secondary Hemostasis**  
Fibrin clot formation
- **Fibrin Stabilization**  
Fibrinolysis

Check out this educational module created by St. Michael's Hospital residents and hematology faculty: [www.coagtesting.com](http://www.coagtesting.com)

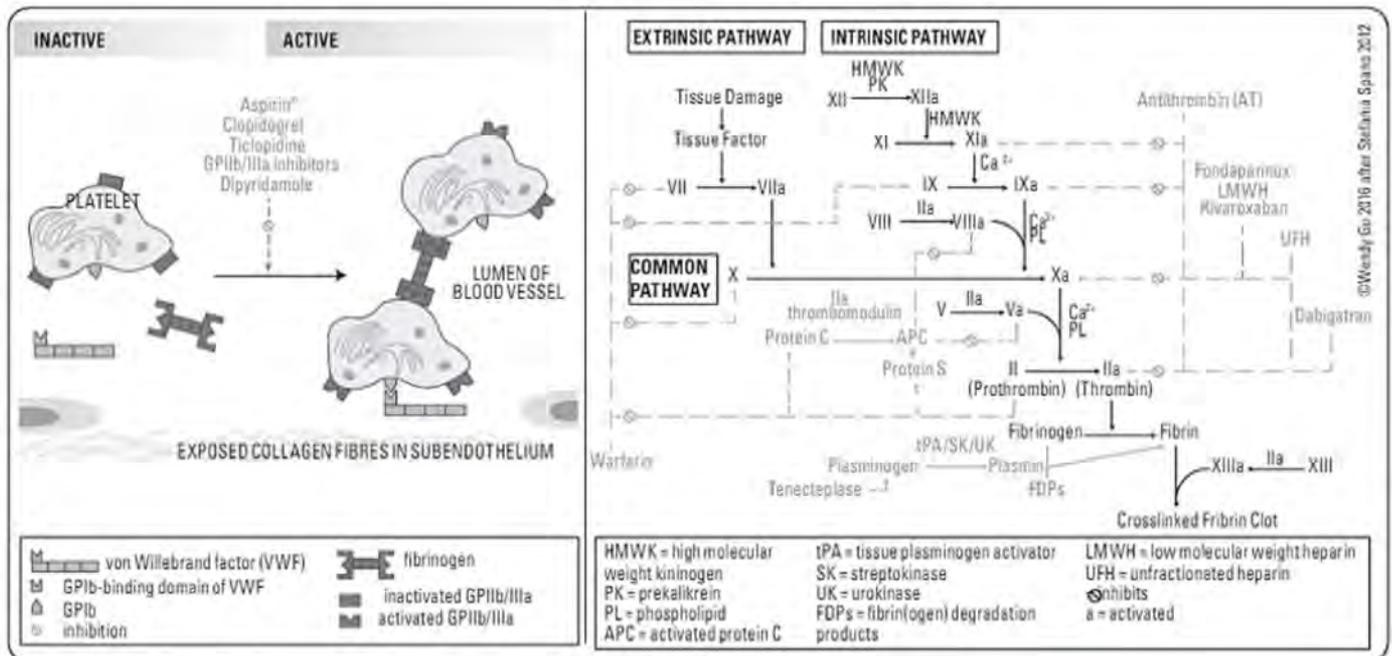

Figure 12a. Platelet activation

Figure 12b. Coagulation cascade

Table 18. Commonly Used Tests of Hemostasis

Type of Hemostasis	Test	Typical Reference Range (lab dependent)	Purpose	Examples of Associated Diagnoses
Primary	Platelet count	130-400 x 10 <sup>9</sup> /L	To quantitate platelet number	Low in ITP, HUS/TTP, DIC, HIT
Secondary	PTT	28-38 s	Measures intrinsic pathway (factors VIII, IX, XI, XII) and common pathway Used to monitor heparin and argatroban therapy	Prolonged in hemophilia A and B (if factor deficiency is below reagent threshold of detection) N.B. Prolonged if lupus anticoagulant present
	PT	10-13 s	Measures extrinsic pathway (factor VII) and common pathway	Prolonged in vitamin K deficiency, vitamin K antagonist therapy (warfarin), factor VII deficiency
	INR	0.9-1.2	Used to monitor warfarin therapy and for assessment of hepatic function	
	Mixing studies		May differentiate inhibitors of coagulation factor(s) from a deficiency in coagulation factors Mix patient's plasma with normal plasma in 1:1 ratio and repeat abnormal test	Normalization of coagulation time if deficiency of single coagulation factor (normalization may not occur if multiple coagulation factors are deficient) Lack of normalization if inhibitor present
Fibrinolysis	Euglobulin lysis time	N = 90 min	Looks for accelerated fibrinolysis	May be shortened (increased fibrinolysis) in DIC or factor XIII deficiency
Other	Fibrinogen D-dimer Specific factor assays (e.g. factor VIII) Lupus anticoagulant von Willebrand tests (VWF antigen, Ristocetin cofactor activity, factor VIII)			

Note: INR is mathematically derived from PT

Table 19. General Rules of Thumb: Signs and Symptoms of Disorders of Hemostasis

	Primary (Platelet, VWF)	Secondary (Coagulation)
Surface Cuts	Excessive, prolonged bleeding	Normal/slightly prolonged bleeding
Onset After Injury	Immediate	Delayed
Site of Bleeding	Superficial i.e. mucosal (nasal, gingival, GI tract, vaginal), skin	Deep i.e. joints, muscles (excessive, post-traumatic)
Lesions	Petechiae, ecchymoses	Hemarthroses, hematomas

Tests of Secondary Hemostasis

PT/INR: Tennis is played outside (Extrinsic pathway)  
PTT: Table Tennis is played inside (Intrinsic pathway)

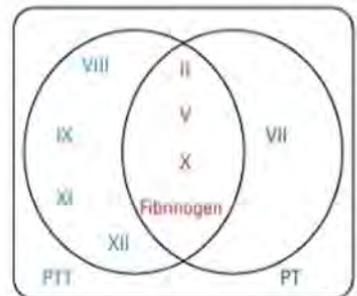

Figure 13. Coagulation factors involved in PT and PTT

Causes of a Prolonged PTT without Bleeding include:

1. Early contact factor (Factor XII, HMWK, PK) deficiency
2. Lupus anticoagulant
3. Inappropriate blood draw
4. Heparin contamination
5. Erythrocytosis (laboratory artifact)

Consider PTT

- IV heparin, argatroban monitoring
- Hemophilia A/B, factor XI deficiency, severe VWD

**Table 20. Lab Values in Disorders of Hemostasis**

	PT	PTT	Platelet Count	Hb
Hemophilia A/B	N	↑	N	N*
VWD	N	±	N/↓	N*
DIC	↑	↑	↓	N/↓
Liver Failure	↑	N/↑	N/↓	N
ITP	N	N	↓	N
TTP	N	N	↓	↓

\* = anemia may develop from progressive iron deficiency and/or active bleeding

**Consider PT/INR**

- Warfarin
- Liver disease
- Risk factor for vitamin K deficiency (e.g. malabsorption, cholestasis, malnutrition)

**Consider both PTT and PT/INR**

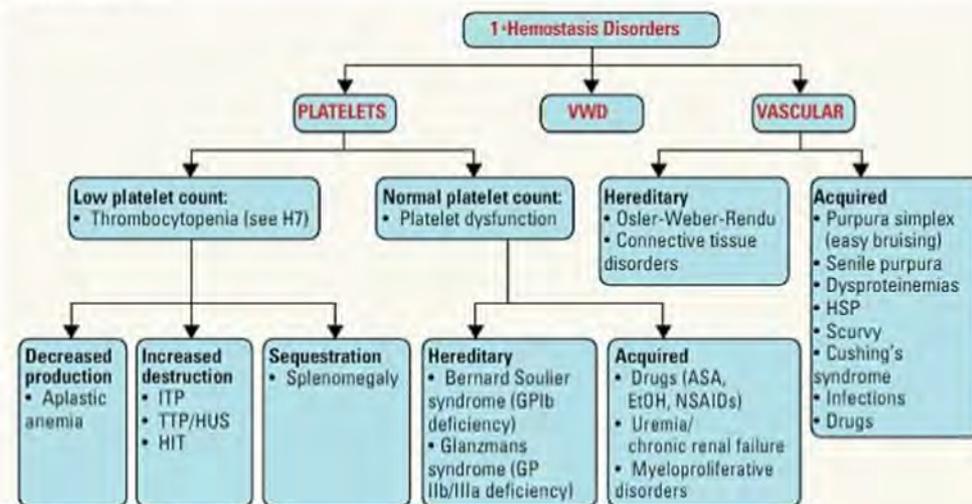

- Suspected DIC
- Trauma patient, or requiring massive transfusion protocol
- Bleeding patient
- Patient receiving thrombolytic therapy

## Disorders of Primary Hemostasis

**Definition**

- inability to form an adequate platelet plug due to:
  - disorders of blood vessels
  - disorders of platelets: abnormal function/numbers
  - disorders of VWF

**Classification**

HSP = Henoch-Schönlein purpura

Figure 14. Approach to disorders of primary hemostasis

**Drugs Commonly Associated with Thrombocytopenia**

Trimethoprim/sulfamethoxazole	Heparin	NSAIDs
Vancomycin	Digoxin	Acetaminophen
Rifampin	Amiodarone	Ethanol
Ethambutol	Quinidine	H2-antagonists
Amphotericin B	Quinine (common)	Chemotherapy

## Immune Thrombocytopenia

**Table 21. Features for Childhood vs. Adult Immune Thrombocytopenia**

Features	Childhood ITP (see Paediatrics, P53)	Adult ITP
Peak Age	2-6 yr	20-40 yr
Gender	F=M	F>M
History of Recent Infection	Common	Rare
Duration	Usually wk	Mo to yr
Spontaneous Remissions	80% or more	Uncommon

**Terminology of ITP**

- primary: isolated thrombocytopenia (platelet count <100 x 10<sup>9</sup>/L) with no other cause of thrombocytopenia
- secondary: thrombocytopenia associated with another condition (e.g. HIV, HCV, SLE, or CLL)
- drug-induced: drug-dependent anti-platelet Abs causing platelet destruction

**Classification of Primary ITP**

- acute: 3 mo from diagnosis
- persistent: 3-12 mo from diagnosis
- chronic: >12 mo from diagnosis
- refractory: post-splenectomy

### Pathophysiology

- primary or secondary ITP
- an acquired immune-mediated disorder (pathophysiology not completely understood)
  - increased platelet destruction
    - anti-platelet Abs bind to platelet surface → increased splenic clearance
    - helper T-cell and cytotoxic T-cell activation
  - impaired platelet production

### Clinical Features

- variable presentation: asymptomatic, fatigue, minimal bruising, mucocutaneous bleed (e.g. purpura, ecchymoses, petechiae, continuous epistaxis, menorrhagia), and intracranial hemorrhage
- assess for symptoms/signs suggesting a secondary cause

### Investigations

- CBC: thrombocytopenia
- PT and PTT: normal
- peripheral blood film: decreased platelets, giant platelets (rule out platelet clumping)
- HIV, HCV
- *H. pylori* testing (urea breath test, stool antigen, or endoscopy) vitamin B12, ANA, C3, C4, APLA, quantitative immunoglobulins (to rule out underlying immunodeficiency) depending on clinical symptoms
- blood group RhD typing
- BM aspirate and biopsy: increased number of megakaryocytes
  - BM aspirate and biopsy should be considered pre-splenectomy or if there is suspicion of diminished BM function (systemic symptoms, failed traditional ITP and/or abnormal blood film)

### Treatment

- rarely indicated if platelets  $>30 \times 10^9/L$  unless active bleeding, trauma, or surgery
- emergency treatment (active bleeding (CNS, GI, or GU) or in need of emergency surgery)
  - general measures: stop drugs that reduce platelet function, control blood pressure, minimize trauma
  - corticosteroids: prednisone (0.5-2 mg/kg/d) or dexamethasone (40 mg PO once daily x 4 d)
  - if corticosteroids contraindicated: IVIg 1 g/kg x 1 dose, to be repeated if necessary (raises platelet count faster than corticosteroids)
  - IVIg can be used with corticosteroids when a more rapid increase in platelet count is required
  - antifibrinolytic: tranexamic acid (1 g PO TID or 1 g IV q8 h) if mucosal bleeding
  - platelet transfusion: for refractory, major bleeding, or need for urgent surgery (expect that platelet recovery will be diminished)
  - emergency splenectomy: may be considered, vaccinations prior if possible (*S. pneumoniae*, *N. meningitidis*, and *H. influenzae* type b)
  - management of intracranial bleeding: IV steroids, IVIg, platelet transfusion
- non-urgent treatment (platelet count  $<20-30 \times 10^9/L$  and no bleeding)
  - 1st-line
    - corticosteroids (dexamethasone 40 mg PO once daily x 4 d x 1-4 cycles (not wk) or prednisone (0.5-2 mg/kg/d) x 2-3 wk then slow taper over 6 weeks)
    - IVIg 1 g/kg
    - anti-D: appropriate for Rh+ non-splenectomized patients, but can cause hemolysis (avoid if low Hb at baseline or if DAT is positive)
  - 2nd-line
    - splenectomy (need vaccinations prior to splenectomy: *S. pneumoniae*, *N. meningitidis*, and *H. influenzae* type b) – not preferred if within 12 months from diagnosis
    - thrombopoietin (TPO) receptor agonists (romiplostim, eltrombopag) – may not be accessible as second line due to funding considerations
    - rituximab
  - 3rd-line
    - immunomodulating therapy (azathioprine, cyclophosphamide, danazol, and vincristine)
    - Syk inhibitors (Fostamatinib) - blocks platelet clearance

### Definitions of Response to Treatment

- complete response: platelet count  $>100 \times 10^9/L$
- partial response: platelet count  $30-100 \times 10^9/L$
- no response: platelet count  $<30 \times 10^9/L$

### Prognosis

- ~20% will not attain a hemostatic platelet count after first and second line therapy
- fluctuating course
- life expectancy similar to general population (however, risk of mortality from bleeding/infection increases with advancing age)
- major concern is spontaneous intracranial hemorrhage, more common in the elderly

**Table 22. Heparin-Induced Thrombocytopenia (HIT)**

<b>Pathophysiology</b>	Immune mediated Ab recognizes a complex of heparin and platelet factor 4 leading to platelet activation via platelet Fc receptor and activation of coagulation system
<b>Diagnosis</b>	Suspected with intermediate or high probability HIT score Screen with immunoassays (e.g. HIT ELISA) and confirm with functional testing (Serotonin Release Assay)
<b>Onset of Decreased Platelets</b>	5-14 d (if previously exposed to heparin within 100 d, HIT can develop in hours due to an anamnestic response)
<b>Risk of Thrombosis</b>	30-50% (25% of events are arterial) if untreated
<b>Clinical Features</b>	Bleeding complications uncommon Venous thrombosis: DVT, PE, limb gangrene, cerebral venous sinus thrombosis Arterial thrombosis: MI, stroke, acute limb ischemia, organ infarct (mesentery, kidney) Heparin-induced skin necrosis (with LMWH) Non-necrotizing erythematous skin lesions Acute platelet activation syndromes: acute inflammatory reactions (e.g. fever/chills, flushing, etc.) Transient global amnesia (rare)
<b>Specific Tests</b>	Pre-test clinical scoring models can help rule-out HIT: 4Ts and the HIT Expert Probability (HEP) score 14C serotonin release assay (tests the functional ability of patient's plasma to activate platelets) ELISA for HIT-Ig (more sensitive, less specific than serotonin assay, faster turnaround time, high negative predictive value) Ultrasound of lower limb veins and upper extremity with central venous catheter for DVT
<b>Management</b>	Clinical suspicion of HIT should prompt discontinuation of UFH and LMWH including flushes (specific tests take several days) Initiate anticoagulation with a non-heparin anticoagulant: e.g. argatroban, danaparoid, fondaparinux, bivalirudin unless there is a strong contraindication (duration depends on presence or absence of thrombosis) warfarin should be started when platelet count $>150 \times 10^9/L$ DOACs can be started before platelet count recovery Allergy band and alert in patient records

**Table 23. The 4T Pre-Test Clinical Scoring Model for HIT**

Category	2 Points	1 Point	0 Points
<b>Thrombocytopenia</b>	Platelet count fall $>50\%$ AND platelet nadir $\geq 20 \times 10^9/L$	Platelet count fall 30-50% OR platelet nadir $10-19 \times 10^9/L$	Platelet count fall $<30\%$ OR platelet nadir $<10 \times 10^9/L$
<b>Timing of Platelet Count Fall</b>	Clear onset between 5-10 d of heparin exposure OR platelet count fall at $\leq 1$ d if prior heparin exposure within last 30 d	Consistent with fall in platelet count at 5-10 d but unclear (e.g. missing platelet counts) OR onset after 10 d OR fall $\leq 1$ d with prior heparin exposure within 30-100 d	Platelet count fall after $\leq 4$ d of heparin exposure, and no recent heparin
<b>Thrombosis or Other Sequelae</b>	Confirmed new thrombosis, skin necrosis, or acute systemic reaction after IV unfractionated heparin bolus, adrenal hemorrhage	Progressive or recurrent thrombosis, non-necrotizing (erythematous) skin lesions, or suspected thrombosis that has not been proven	None
<b>Other Causes for Thrombocytopenia</b>	None apparent	Possible	Definite

6-8 points = high probability of HIT; 4-5 points = intermediate probability of HIT; 0-3 points = low probability of HIT  
Cuker A, Arepally GM, Chong BH, et al. American Society of Hematology 2018 guidelines for management of venous thromboembolism: heparin-induced thrombocytopenia. *Blood Adv.* 2018;2:3360-3392

**Heparin-Induced Thrombocytopenia**  
Heparin-induced thrombocytopenia (previously known as HIT type II): immune-mediated reaction following treatment with heparin leading to platelet activation and subsequent coagulation activation  
**Heparin-associated thrombocytopenia (previously known as HIT type I):** transient thrombocytopenia following administration of heparin

**Heparin-Associated Thrombocytopenia (previously known as HIT type I)**

- Direct heparin mediated platelet aggregation (non-immune)
- Platelets  $>100 \times 10^9/L$
- Self-limited (no thrombotic risk)
- May continue with heparin therapy
- Onset 24-72 h

LMWH is also associated with HIT, but the risk is less than unfractionated heparin (2.6% in UFH vs. 0.2% in LMWH)

**American Society of Hematology Choosing Wisely Recommendation**  
Don't test or treat for HIT in patients with low pre-test probability of HIT (4T's score of 0-3) as HIT can be excluded  
Do not discontinue heparin or start a non-heparin anticoagulant in these low-risk patients because of increased risk of bleeding and increased cost of alternatives

## Thrombotic Thrombocytopenic Purpura and Hemolytic Uremic Syndrome

Table 24. TTP and HUS

	TTP	HUS (see Paediatrics, P82)
<b>Epidemiology</b>	Immune form presents predominantly in adults Congenital form presents predominantly in children	Predominantly children and elderly
<b>Etiology</b>	Deficiency of ADAMTS13: metalloproteinase that breaks down ultra-large VWF multimers Congenital (genetic absence of ADAMTS13) Acquired (drugs, malignancy, transplant, HIV-associated, and idiopathic)	Stigma toxin ( <i>E. coli</i> serotype O157:H7) in 90% Other bacteria, viruses, genetic causes, and drugs
<b>Clinical Features</b>	1. Thrombocytopenia 2. MAHA/TMA 3. Neurological symptoms: headache, confusion, focal defects, and seizures 4. Symptoms can be mild and non-specific	1. Severe thrombocytopenia 2. MAHA/TMA 3. Acute kidney injury 4. Bloody diarrhea 5. GI prodrome
<b>Investigations (both TTP, HUS)</b>	CBC and blood film: decreased platelets and increased schistocytes PT, PTT, fibrinogen: normal Markers of hemolysis: increased unconjugated bilirubin, increased LDB, and decreased haptoglobin Negative Coombs test/DAT Creatinine and urea to follow renal function (TTP has nearly no kidney injury vs. HUS/drug mediated TTP which induces severe injury that is sudden in onset) ADAMTS13 gene, activity or inhibitor testing (TTP)	
<b>Management</b>	Medical emergency: TTP mortality ~90% if untreated Plasma exchange ± steroids Platelet transfusion avoided unless life-threatening bleed (associated with microvascular thrombosis) Plasma infusion if plasmapheresis is not immediately available Caplacizumab in certain cases of acquired TTP	Supportive therapy (fluids, RBC transfusion, nutrition, etc.) Some evidence for plasma exchange Possible role of eculizumab (C5 Ab blocks complement activation) for neurologic symptoms

Note: aHUS is a complex disease with different etiology, treatment depends on genetic abnormalities

### Pathophysiology of TTP

- Normally, large VWF multimers secreted by endothelial cells are rapidly cleaved by ADAMTS13 protease
- Congenital TTP is due to a genetic deficiency in ADAMTS13
- Acquired TTP (the more common form) is due to Abs against ADAMTS13
- Without ADAMTS13, uncleaved VWF continues to promote platelet adhesion, causing excess platelet aggregation in small blood vessels

### Differential Diagnosis of TTP

- DIC
- HUS
- aHUS
- HELLP
- Catastrophic APS
- Evans syndrome (AIHA + ITP)

## von Willebrand Disease

### Pathophysiology

- most common inherited bleeding disorder (prevalence of 1%)
- usually autosomal dominant (types 2N and 3 are autosomal recessive)
- women more commonly diagnosed (heavy menstrual bleeding, peripartum bleeding)
- qualitative defect or quantitative deficiency of VWF depending on type
  - VWF mediates platelet adhesion/aggregation and acts as a chaperone for Factor VIII (extending its half-life in circulation); abnormal VWF can affect both primary and secondary hemostasis
  - VWF exists as a series of multimers ranging in size
    - largest multimers are most active in mediation of platelet adhesion/aggregation
    - both large and small multimers complex with Factor VIII
    - VWF levels vary according to blood group (lowest in group O patients) and other factors (pregnancy, hormonal medication, acute inflammation)

### Classification

- type 1: mild quantitative deficiency (decreased amount of VWF and proportional decrease in VWF activity) – 80% of cases
- type 2: qualitative defect (VWF activity disproportionately lower than quantity) – 20% of cases
  - type 2A: reduced VWF-dependent platelet adhesion due to high and intermediate molecular weight VWF multimer deficiency
  - type 2B: increased affinity for platelet GPIb
  - type 2M: reduced VWF-dependent platelet adhesion with normal VWF multimer levels
  - type 2N: decreased affinity for Factor VIII
- type 3: severe total quantitative defect (virtually no VWF produced) – 1 in 1000000

### Clinical Features

- bleeding history is the single most important predictor of an underlying bleeding disorder
- validated, standardized bleeding assessment tools (e.g. ISTH-BAT) to facilitate exploration of the bleeding history
- mucocutaneous bleeding (easy bruising, epistaxis (>10 min), heavy menstrual bleeding, peripartum bleeding, post-dental extraction bleeding, excessive postoperative bleeding, and unexplained gastrointestinal bleeding)
  - type 3 VWD patients can experience musculoskeletal bleeding due to significant deficiency in Factor VIII (lack of Factor VIII chaperoning as VWF is absent)
- family history of a bleeding disorder (a negative family history cannot be used to exclude the diagnosis)

### Investigations

- CBC, platelet, VWF:Antigen (determine how much VWF is present), VWF:Ristocetin cofactor activity (determine how well VWF binds to platelet), Factor VIII (determine how well VWF chaperones Factor VIII), and PTT
- tests to further categorize type/subtype of VWD: multimer analysis, ristocetin induced platelet agglutination, and genetic studies

Consider VWD in all women with heavy menstrual bleeding

VWD is the most common heritable bleeding disorder

**Table 25. Investigations in VWD**

Test	Expected Result	Test	Expected Result
PTT	N/↑	von Willebrand antigen	↓
Plt Count	N/↓ (can be low in type 2B)	Ristocetin activity	↓ (cofactor for VWF-Plt binding)
Blood group	Affects antigen quantification (↓ in group O)	Factor VIII	N/↓
Ferritin	Rule out secondary iron deficiency due to bleeding	VWF multimer analysis	Multimer variants

### Treatment

- DDAVP\* is effective treatment for 85-90% of patients with type 1 VWD and for some subtypes of type 2 VWD
  - causes release of VWF and Factor VIII from endothelial cells
  - variable efficacy depending on disease type; tachyphylaxis occurs after 4 consecutive doses
  - need to document responsiveness with "DDAVP\* challenge"
  - caution in children due to hyponatremia
- tranexamic acid (Cyklokapron®, antifibrinolytic) to stabilize clot formation
- VWF:Factor VIII concentrate (Humate P®, Wilate®) if DDAVP\* unresponsive/clinically ineffective or for severe bleeding episode
  - need to monitor VWF and factor VIII levels (very high factor VIII level can be prothrombotic)
- gynaecologic focused care for heavy menstrual bleeding (N.B. estrogens have the added benefit of increasing VWF levels)

### Prognosis

- patients with mild type 1 VWD usually have auto-correction of VWF deficiency in pregnancy
- most cases are mild-moderate, and only ~10% of cases require long-term prophylactic therapy

## Disorders of Secondary Hemostasis

### Definition

- inability to form an adequate fibrin clot
  - disorders of coagulation factors or cofactors
  - disorders of proteins associated with fibrinolysis
- characterized by delayed bleeding, deep muscular bleeding, and spontaneous hemarthroses

**Table 26. Classification of Secondary Hemostasis Disorders**

Hereditary	Acquired
Factor VIII deficiency: Hemophilia A, VWD	Liver disease
Factor IX deficiency: Hemophilia B (Christmas Disease)	DIC
Factor XI deficiency: Hemophilia C	Vitamin K deficiency
Other factor deficiencies are rare	Acquired inhibitors (Factor VIII most common)

## Hemophilia A (Factor VIII Deficiency)

### Pathophysiology

- X-linked recessive disorder where factor VIII is absent or deficient, 1 in 5000 males
- mild (>5% of normal factor level), moderate (1-5%), severe (<1%)

### Clinical Features

- see Table 19, H27
- patients may have also acquired HIV or HCV from contaminated blood products (no cases observed from transfusions in Canada since 1985)

### Investigations

- CBC
- prolonged PTT, normal INR (PT)
- decreased factor VIII (<40% of normal)
- VWF antigen and ristocetin activity testing to rule out VWD

### Treatment

- DDAVP\* in mild hemophilia A
- factor VIII concentrate for:
  - prophylaxis (recommended for patients with severe hemophilia A)
  - on-demand (i.e. to treat a bleed)
- antifibrinolytic agents (e.g. tranexamic acid), especially for mucosal bleeds

## Hemophilia B (Factor IX Deficiency)

- X-linked recessive, 1 in 30000 males; approximately half have severe disease (factor IX activity <1% of normal)
- clinical and laboratory features identical to hemophilia A (except decreased factor IX)
- treatment: factor IX concentrate (prophylaxis or on-demand), antifibrinolytic agents

## Factor XI Deficiency

- autosomal recessive; more common in Ashkenazi Jewish population
- usually mild, often diagnosed in adulthood
- factor XI level does not correlate proportionally with bleeding risk – risk of bleeding correlates with a previous history or family history of bleeding
- treatment: antifibrinolytic agents, FP, Factor XI concentrate, DDAVP\*

## Liver Disease

- see [Gastroenterology, G32](#)

### Pathophysiology

- thrombocytopenia secondary to: hypersplenism, nutritional deficiency, direct BM toxicity related to alcohol, diminished production from chronic viral infections (e.g. HCV), and decreased production of TPO
- deficiency in synthesis of all factors except VIII (also made in endothelium)
- aberrant or diminished synthesis of fibrinogen (factor I)
- diminished synthesis of natural anticoagulants and altered regulation of fibrinolysis

### Investigations

- CBC, peripheral blood film: thrombocytopenia, target cells
- primary hemostasis affected
  - thrombocytopenia
- secondary hemostasis affected
  - elevated INR (PT), PTT, TT
  - low fibrinogen in end-stage liver disease

### Treatment

- supportive, treat liver disease, blood products if active bleeding (FP, platelets, cryoprecipitate)

## Vitamin K Deficiency

### Etiology

- drugs
  - vitamin K antagonist (e.g. warfarin) – diminished production of functional Factors II, VII, IX, X, proteins C and S
  - antibiotics eradicating gut flora, altering vitamin K uptake
- poor diet: e.g. prolonged fasting or starvation (especially due to chronic alcohol consumption)
- biliary obstruction
- chronic liver disease (decreased stores)
- fat malabsorption (e.g. celiac disease, disorders of bile or pancreatic secretion, intestinal disease, and cystic fibrosis)
- vitamin K deficiency bleeding, see [Paediatrics, P52](#)

### Investigations

- INR (PT) is elevated out of proportion to elevation of the PTT
- decreased Factors II, VII, IX, X (vitamin K-dependent)

### Treatment

- hold anticoagulant if vitamin K antagonist on board
- vitamin K PO if no active bleeding
- if bleeding, give vitamin K 10 mg IV (reversal may take up to 12 h)
- if life-threatening bleeding and vitamin K antagonist used, give PCC or FP if PCC contraindicated
  - PCCs are relatively contraindicated in liver disease or if there is a previous history of HIT (PCC product contains heparin)

#### Investigations in Liver Disease

Factor V, VII, VIII. Expect decreased V and VII because they have the shortest half-life. Factor VIII will be normal or increased because it is produced in the endothelium

#### Vitamin K Dependent Factors

Vitamin K antagonists (e.g. warfarin) affect function of these factors: "1972 Canada vs. Soviets" X, IX, VII, II, proteins C and S

PT should improve within 24 h of adequately dosed vitamin K repletion (onset is in 6-12 h); if not, search for other causes

#### American Society of Hematology Choosing Wisely Recommendation

Do not administer plasma or prothrombin complex concentrates for non-emergent reversal of vitamin K antagonists (e.g. outside of the setting of major bleeding, intracranial hemorrhage, or anticipated emergent surgery)

## Disseminated Intravascular Coagulation

### Definition

- excessive, dysregulated release of plasmin and thrombin leading to intravascular coagulation and fibrinolysis
- depletion of platelets, coagulation factors, and fibrinogen
- risk of life-threatening hemorrhage and/or thrombosis

### Etiology

- occurs as a complication of many other severe medical, surgical, or obstetrical conditions
- widespread endothelial damage and extensive inflammatory cytokine release

Table 27. Etiology of DIC

Activation of Procoagulant Activity	Endothelial Injury	Reticuloendothelial Injury	Vascular Stasis	Other
APS Intravascular hemolysis e.g. incompatible blood, malaria	Infections/sepsis Vasculitis	Liver disease Splenectomy	Hypotension Hypovolemia PE	Acute hypoxia/acidosis (check lactate)
Tissue injury e.g. obstetric complications, trauma, burns, crush injuries	Melanotic adenocarcinoma Aortic aneurysm Giant hemangioma			
Malignancy e.g. solid tumours, hematologic malignancies (especially APL)				
Snake venom, fat embolism, heat stroke				

### Clinical Features

- presence of both hemorrhage and clotting

Table 28. Clinical Features of DIC

Signs of Microvascular Thrombosis	Signs of Hemorrhagic Diathesis
<b>Neurological:</b> multifocal infarcts, delirium, coma, seizures	<b>General:</b> Bleeding from any site in the body (secondary to decreased platelets and coagulation factors)
<b>Skin:</b> focal ischemia, superficial gangrene, purpura fulminans	<b>Neurologic:</b> intracranial bleeding
<b>Renal:</b> oliguria, azotemia, cortical necrosis	<b>Skin:</b> petechiae, ecchymosis, oozing from puncture sites
<b>Pulmonary:</b> ARDS	<b>Renal:</b> hematuria
<b>GI:</b> acute ulceration, liver dysfunction	<b>Mucosal:</b> gingival oozing, epistaxis, massive bleeding
<b>Adrenal failure:</b> adrenal hemorrhage or infarction	
<b>RBC:</b> microangiopathic hemolysis (schistocytes)	

### Investigations

- peripheral blood smear: schistocytes
- primary hemostasis: CBC, decreased platelets
- secondary hemostasis: prolonged INR (PT), PTT, TT, decreased fibrinogen and other factors
- fibrinolysis: increased FDPs or D-dimers and short euglobulin lysis time (i.e. accelerated fibrinolysis)
- extent of fibrin deposition: urine output and RBC fragmentation

### Treatment

- individualize supportive therapy according to underlying condition: recognize early and treat underlying disorder – supportive measures: hemodynamic and/or ventilator support, aggressive hydration, and RBC transfusion if severe bleed
- in bleeding phase (recommendations from ISTH Guidance Statement 2013):
  - treat the underlying condition
  - transfuse platelets in patients with active bleeding if platelet count  $<50 \times 10^9/L$  or in those with a high-risk of bleeding and a platelet count of  $<20 \times 10^9/L$
  - FP may be useful in patients with active bleeding with either prolonged PT/aPTT ( $>1.5$  times normal) or decreased fibrinogen ( $<1.5$  g/L). FP should be considered in DIC patients requiring an invasive procedure with similar laboratory abnormalities
  - fibrinogen concentrate or cryoprecipitate may be recommended in actively bleeding patients with persisting severe hypofibrinogenemia ( $<1.5$  g/L) despite FP replacement
  - PCC may be considered in actively bleeding patients if FP transfusion is not possible
- in thrombotic phase:
  - LMWH preferred over UFH in critically ill, non-bleeding patients

Table 29. Differential Diagnosis for Abnormal Coagulation Testing

Increased PT/INR Only	Increased PTT Only	Both Increased
Warfarin	Intrinsic factor deficiency: Factor VIII (Hemophilia A), Factor IX (Hemophilia B), Factor XI, Factor XII	Deficiency of common pathway factors: Prothrombin (Factor II), fibrinogen, Factor V, Factor X
Vitamin K deficiency	Heparin, DOACs	Severe liver disease
Factor VII deficiency	Antiphospholipid Ab	Factor V, Factor X, prothrombin, and fibrinogen inhibitors
Liver disease	Intrinsic factor inhibitors (e.g. Factor VIII)	Excessive anticoagulation
Factor VII inhibitors		Severe vitamin K deficiency

DIC is a spectrum which may include thrombosis, bleeding, or both

### Factor Levels in Acquired Coagulopathies

Factor	Liver Disease	Vitamin K Def	DIC
V	↓	N	↓
VII	↓	↓	↓
VIII	N	N	↓

### Important Etiologies of DIC

#### OMITS

- Obstetric complications
- Malignancy
- Infection
- Trauma
- Shock

### Clinical Prediction of DIC - International Society of Thrombosis and Hemostasis (ISTH) Calculator

Presence of an underlying, predisposing condition is a requirement

DIC diagnosis is defined as  $\geq 5$  points

Points	0	1	2	3
Platelets count $\times 10^9/L$	$>100$	50-100	$<50$	
Level of Fibrin markers (D-dimer or FDP)	No increase	Moderate increase $<5 \times ULN$	Strong increase $\geq 5 \times ULN$	
Prolonged PT (s)	$<3$	$\geq 3-6$	$\geq 6$	
Fibrinogen (g/L)	$>1.0$	$\geq 1.0$		

## Hypercoagulable Disorders

### Hypercoagulability Workup – Venous Thrombosis

- workup for hypercoagulable state is controversial and should be considered *ONLY* if it will alter treatment decisions
- includes inherited or acquired thrombophilia
  - hypercoagulability workup may be considered in patients with:
    - multiple recurrent thromboses
    - warfarin-induced skin necrosis or neonatal purpura fulminans (protein C or S deficiency)
    - thrombosis at an unusual venous site
    - abnormal blood work, constitutional symptoms, or physical exam findings suggestive of cancer
  - arterial thrombotic events due to a hypercoagulable state are typically associated with APS, HIT, JAK2+ MPNs, and PNH, not hereditary thrombophilias
- workup (if indicated)
  - initial
    - CBC, blood smear, coagulation studies, liver/renal function tests, urinalysis, and hemolysis markers (if anemic)
    - malignancy history, age appropriate cancer screening
    - serology: APLA (lupus anticoagulant will be affected by anticoagulation)
    - depending on CBC, consider JAK2
  - post-treatment (or  $\geq 6$  wk, as protein levels are depleted/consumed by clot)
    - antithrombin activity (not on heparin)
    - proteins C, S activity (not on warfarin)
- note: most of these tests do not change management, and a negative test does not rule out a hypercoagulable state
- decision to pursue hypercoagulability workup should be made in consultation with a hematologist

### SELECTED CAUSES OF HYPERCOAGULABILITY

#### Activated Protein C Resistance (Factor V Leiden)

- most common cause of hereditary thrombophilia
- 3-7% of European White population are heterozygotes
- point mutation in the Factor V gene (R506Q) results in resistance to inactivation of Factor Va by activated protein C

#### Prothrombin Gene Mutation (PT) G20210A

- 1-3% of European White population are heterozygotes
- G to A transposition at nucleotide position 20210 of the prothrombin gene promoter region results in increased levels of prothrombin, thus increased thrombin generation

#### Protein C and Protein S Deficiency

- protein C inactivates Factors Va and VIIIa using protein S as a cofactor
- protein C deficiency
  - homozygous or compound heterozygous: neonatal purpura fulminans
  - heterozygous
    - type I: decreased protein C levels
    - type II: decreased protein C activity
  - acquired: liver disease, sepsis, DIC, warfarin, and certain chemotherapeutic agents
  - 1/3 of patients with warfarin necrosis have underlying protein C deficiency
- protein S deficiency
  - type I: decreased free and total protein S levels
  - type II: decreased protein S activity
  - type III: decreased free protein S levels
  - acquired: liver disease, DIC, pregnancy, nephrotic syndrome, inflammatory conditions, and warfarin

#### Antithrombin Deficiency

- in absence of heparin: antithrombin slowly inactivates thrombin. In the presence of heparin: antithrombin rapidly inactivates thrombin
- causes/etiology: autosomal dominant inheritance, urinary losses in nephrotic syndrome, or reduced synthesis in liver disease
- diagnosis must be made outside window of acute thrombosis and anticoagulation treatment (acute thrombosis, heparin, systemic disease all decrease antithrombin levels)
- deficiency may result in resistance to UFH (LMWH may be considered, with monitoring of anti-Xa levels)
  - heparin resistance: suspect if  $>35000$  IU of UFH required during 24 h use

#### Elevated Factor VIII Levels

- an independent marker of increased incident and recurrent thrombotic risk, but levels can also be increased in numerous states as an acute phase reactant, therefore its clinical use is controversial

#### Differential Diagnosis of Elevated D-Dimer

- Arterial thromboembolic disease (e.g. MI, cerebrovascular accident, acute limb ischemia, AFib, intracardiac thrombus)
- Venous thromboembolic disease (e.g. DVT, PE)
- Abnormal fibrinolysis (e.g. use of thrombolytic agents)
- Surgery/trauma (e.g. tissue ischemia, necrosis)
- Vaso-occlusive episode of SCD
- Renal disease (nephrotic syndrome, acute/chronic renal failure)
- Pregnancy-related (e.g. normal pregnancy, preeclampsia, eclampsia)
- Cardiovascular-related (e.g. cardiovascular disease, CHF)
- Severe infection/sepsis/inflammation, systemic inflammatory response syndrome
- DIC
- Malignancy
- Severe liver disease
- Venous malformation

- Isolated prolonged INR is most commonly due to Factor VII deficiency in the extrinsic pathway since it has the shortest half-life
- Isolated elevated PTT is usually due to factor deficiency or inhibitors in the intrinsic pathway

#### American Society of Hematology Choosing Wisely Recommendations

- Do not test for thrombophilia in adult patients with venous thromboembolism occurring in the setting of major transient risk factors (i.e. surgery, trauma, or prolonged immobility)
- Do not use inferior vena cava filters routinely in patients with acute venous thromboembolism

#### Common Causes of Hypercoagulability

CALM APES  
 Protein C deficiency  
 APS  
 Factor V Leiden  
 Malignancy  
 Antithrombin deficiency  
 Prothrombin G20210A  
 Increased Factor VIII (Eight)  
 Protein S deficiency

#### Causes of Both Venous and Arterial Thrombosis include:

APS  
 MPN  
 HIT  
 Distal venous clot with patent foramen ovale  
 PNH

Protein C, protein S, and ATIII are decreased during acute thrombosis – therefore to test for deficiency, they must be tested outside of this time period

**Congenital Dysfibrinogenemia**

- may predispose to thromboembolic disease, bleeding, or both

**Disorders of Fibrinolysis**

- includes congenital plasminogen deficiency, tPA deficiency, but association with VTE risk is not clear

**Antiphospholipid Antibody Syndrome**

- definition:  $\geq 1$  clinical and  $\geq 1$  laboratory criteria
  - clinical: arterial or venous thrombosis, recurrent ( $>3$ ) early pregnancy losses  $<10$  wk, one late fetal loss  $\geq 10$  wk (morphologically normal), or premature birth before 34 wk due to (pre)eclampsia or placental insufficiency
  - laboratory (must be confirmed on two occasions, tested  $\geq 12$  wk apart): anticardiolipin IgG and IgM, anti- $\beta 2$  glycoprotein-1 Ab, or lupus anticoagulant
- mechanism: not well understood. Abs interact with platelet membrane phospholipids causing increased activation; can also interfere with thrombin regulation, fibrinolysis, and inhibit the protein C pathway
- see [Rheumatology](#), RH13

**Malignancy is a Common Cause of Acquired Hypercoagulability**

- Workup should include:**  
 Complete history and physical  
**Age appropriate screening:**  
 Mammogram, Pap, PSA, colonoscopy  
 Additional imaging/laboratory testing based on clinical suspicion  
 Close follow-up

**Screening for Occult Cancer in Unprovoked VTE (SOME)**

NEJM 2015;373:697-704  
**Purpose:** To assess the efficacy of a screening program for occult cancer that employs CT of the abdomen and pelvis in patients experiencing their first unprovoked episode of VTE.  
**Methods:** Patients ( $n=854$ ) were randomly assigned to limited occult-cancer screening or limited occult-cancer screening plus CT.  
**Results:** 3.2% of patients in the limited-screening group and 4.5% of patients in the limited-screening plus CT group received a new diagnosis of occult cancer between the randomization point and 1-year followup ( $P=0.28$ ). Four occult cancers were missed by the limited screening strategy, while five occult cancers were missed by the limited screening plus CT strategy ( $P=1.0$ ).  
**Conclusion:** Routine screening with CT in patients who had a first unprovoked VTE did not provide a clinically significant benefit.

Although lupus anticoagulant prolongs PTT, this is a misnomer, as its main clinical feature is thrombosis

**Risk of VTE in Hospitalized Patients Receiving Ineffective Antithrombotic Therapy**

Risk Factor	RR (95% CI)	P-value
Age $>75$ yr	1.79 (1.18-2.71)	0.007
Cancer	1.58 (1.01-2.51)	
Previous VTE	1.67 (1.01-2.77)	0.08
Obesity	0.94 (0.59-1.51)	0.91
Hormone therapy	0.51 (0.08-3.38)	0.70
Heart failure	1.08 (0.72-1.62)	0.82
NYHA III	0.89 (0.55-1.43)	0.72
NYHA IV	1.48 (0.84-2.6)	0.27
Acute infectious disease	1.50 (1.00-2.26)	0.06
Acute rheumatic disease	1.45 (0.84-2.50)	0.27

Source: JAMA 2004;191:963-968

**Virchow's Triad**  
 Endothelial damage  
 Blood stasis  
 Hypercoagulability

**Venous Thromboembolism**

**Definition**

- thrombus formation and subsequent inflammatory response in a superficial or deep vein
- includes superficial thrombophlebitis, DVT, and PE
- thrombi propagate in the direction of blood flow (commonly originating in calf veins)
- DVT is more common in lower extremity than upper extremity (upper extremity DVT are increasing due to more central venous access lines)
- incidence  $\sim 1\%$  if age  $>60$  yr
- most important sequelae of DVT are PE ( $\sim 50\%$  chance with proximal DVT) and chronic venous insufficiency
- acutely, PE can result in cardiorespiratory failure and death (rare in treated patients), most severe chronic sequela of PE is chronic thromboembolic pulmonary hypertension (CTEPH)

**Etiology (Virchow's Triad)**

- endothelial damage
  - exposure of procoagulant proteins on dysfunctional endothelium promotes thrombosis
  - decreases inhibition of coagulation and local fibrinolysis
  - changes to vessel wall integrity may result in turbulent blood flow
- venous stasis
  - immobilization (e.g. post-MI, CHF, stroke, and postoperative) inhibits clearance and dilution of coagulation factors
- hypercoagulability
  - inherited (see [Hypercoagulable Disorders](#), H35)
  - acquired
  - age (risk increases with age)
  - surgery (especially orthopaedic, thoracic, GI, and GU)
  - trauma (especially fractures of spine, pelvis, femur, or tibia, and spinal cord injury)
  - neoplasms (especially pancreas, stomach, lung, lymphoma, bladder, testicular, colorectal, and gynaecologic - based on the Khorana score)
  - blood dyscrasias (MPNs, especially PV, ET), PNH, hyperviscosity (multiple myeloma, polycythemia, leukemia, and SCD), hemolytic anemias
  - prolonged immobilization (e.g. CHF, stroke, MI, and leg injury)
  - hormone related (combined OCP, hormone replacement therapy, and selective estrogen receptor modulators)
  - pregnancy
  - APS
  - heart failure (risk of DVT greatest with right heart failure and peripheral edema)
    - New York Heart Association (NYHA) Class III and IV
- idiopathic (10-20% are later found to have cancer)

**Clinical Features of DVT**

- absence of physical findings does not rule out disease
- unilateral leg edema, erythema, warmth, and tenderness; purple-blue colour may indicate severe limb-threatening thrombus
- palpable cord (i.e. thrombosed vein)
- phlegmasia alba dolens (white appearance) and phlegmasia cerula dolens (acute pain and edema) with massive thrombosis
- Homan's sign (pain or resistance with foot dorsiflexion) is unreliable

**Differential Diagnosis of DVT**

- muscle strain or tear, lymphangitis or lymph obstruction, venous valvular insufficiency, ruptured popliteal cysts, cellulitis, and arterial occlusive disease

### Investigations for DVT

- D-dimer test only useful to rule out DVT if negative with low clinical suspicion of disease (Modified Wells' Pre-test Probability  $\leq 1$ ) and no other acute medical issues; positive result may be non-specific
- doppler ultrasound is most useful diagnostic test for DVT
  - sensitivity and specificity for proximal DVT ~95%
  - sensitivity for calf DVT ~70%
- venography is the gold standard, but is expensive, invasive, and higher risk
- CT pulmonary angiogram or V/Q scan if PE suspected

### Post-Thrombotic Syndrome

- development of chronic venous stasis signs and symptoms secondary to a deep venous thrombosis
- symptoms: pain, venous dilatation, edema, pigmentation, skin changes, and venous ulcers
- clinical severity can be assessed using the Villalta score
- large impact on quality of life following a DVT
- treatment: extremity elevation, exercise, compression stockings, and skin/ulcer care
- for clinical features and treatment of PE, see [Respirology, R19](#)

## Approach to Treatment of Venous Thromboembolism

### Purpose

- prevent further clot extension (minimum 3 mo duration)
- prevent acute PE (occurs in up to 50% of untreated patients)
- reduce the risk of recurrent thrombosis (duration depends on presence of other risk factors)
- treatment of massive iliofemoral thrombosis with acute lower limb ischemia and/or venous gangrene (phlegmasia cerulea dolens)
- limit development of late complications (e.g. post-thrombotic syndrome, chronic venous insufficiency, and chronic thromboembolic pulmonary HTN)

### Initial Treatment

- consider empiric treatment in patient with moderate/high suspicion of DVT and low-risk of bleeding, if diagnostic imaging will be delayed (definitive imaging should be obtained at first opportunity)
- DOACs
  - apixaban or rivaroxaban alone (with loading dose)
  - dabigatran or edoxaban require 5-10 d of parenteral anticoagulation (usually LMWH) prior to initiation
  - contraindications: during pregnancy, in breastfeeding women
  - there remains limited evidence in severe renal deficiency and some clinicians do not use DOACs in this population
- LMWH
  - administered SC, at least as effective as UFH with a lower bleeding risk
  - advantages: predictable dose response and fixed dosing schedule, lab monitoring not require, <1% HIT, safe and effective outpatient therapy (including pregnant and cancer patients)
  - disadvantages: only partially reversible by protamine, long-term use associated with osteoporosis
  - renally cleared – may require dose adjustment in patients with renal dysfunction
- UFH
  - in patients with high-risk of bleed, or requiring rapid interruption for surgical procedures; use hospital-based nomograms that use bleeding risk and patient weight to determine appropriate dose
  - advantages: rapidly reversible by protamine
  - disadvantages: must monitor aPTT or heparin levels with adjustment of dose to reach therapeutic level (~2x normal value); higher risk for development of HIT

### Long-Term Oral Treatment

- anticoagulation therapy
  - warfarin
    - should be initiated with heparin overlap: dual therapy for at least 48 h with INR >2, due to initial prothrombotic state secondary to warfarin's inhibition of natural anticoagulants protein C/S, half-life of vitamin K factors and risk of warfarin-induced skin necrosis
    - dosed to maintain INR at 2-3, monitor twice weekly for 1-2 wk
    - discontinue heparin after INR >2.0 for 2 consecutive days
  - DOACs
    - apixaban or rivaroxaban: INR not used, patients with CrCl >15 mL/min
    - dabigatran (factor IIa inhibitor) or edoxaban: LMWH or IV heparin for at least 5 d before initiating dabigatran, INR not used, patients with CrCl >30 mL/min
    - important drug interactions to consider for DOACs
    - cancer patients: LMWH more effective than warfarin at preventing recurrence of venous thrombosis in cancer patients; DOACs are as effective as LMWH (more bleeding observed for patients with GI cancer taking rivaroxaban or edoxaban)

### Wells' Score for Predicting DVT

- Paralysis, paresis, or recent orthopaedic casting of lower extremity (1)
- Recently bedridden (>3 d) or major surgery within past 4 wk (1)
- Localized tenderness in deep vein system (1)
- Swelling of entire leg (1)
- Calf swelling >3 cm compared to the other leg (measured 10 cm below the tibial tuberosity) (1)
- Pitting edema greater in the symptomatic leg (1)
- Collateral non-varicose superficial veins (1)
- Active cancer or cancer treated within 6 mo (1)
- Alternative diagnosis more likely than DVT (e.g. Baker's cyst, cellulitis, muscle damage, superficial venous thrombosis) (-2)

### Total Score Interpretation

3-8: High probability, 1-2: Moderate probability, -2-0: Low probability

### Modified Wells' Score

Same as above except with 1 additional point for a history of DVT or major surgery within past 12 wk, and the score interpretation is DVT likely for  $\geq 2$  points and DVT unlikely for  $\leq 1$  point. D-dimer is ordered for DVT unlikely patients to fully rule out DVT which can help reduce unnecessary ultrasounds.

See Landmark Hematology Trials for more information on the CLOT trial. It details the efficacy of low-molecular-weight heparin vs. oral anticoagulant agents in preventing recurrent thrombosis in patients with cancer.

### Duration of Treatment with Vitamin K Antagonists (VKA) in Symptomatic Venous Thromboembolism

Cochrane DB Syst Rev 2014;CD001367

**Purpose:** To evaluate the efficacy and safety of various durations of therapy with VKA in patients with symptomatic VTE.

**Study Selection:** RCTs comparing various durations of therapy with VKA in patients with symptomatic VTE.

**Results:** 11 studies (total 3716 participants) were included. A significant reduction in the risk of recurrent VTE was observed during prolonged VKA treatment (RR 0.20, 95% CI, 0.11 to 0.38) independent of the time elapsed since the index thrombotic event. Patients receiving prolonged treatment were at increased risk of bleeding complications (RR 2.60, 95% CI 1.51 to 4.49).

**Conclusion:** Treatment with VKA strongly reduces the risk of recurrent VTE for as long as they are used. Therapy should be discontinued when the risk of harm from major bleeding (which remains constant over time) is of greater concern than the absolute risk of recurrent VTE (which declines over time).

### Common Medications that Interact with Warfarin

Acetaminophen (interference with vitamin K metabolism)  
 Allopurinol  
 NSAIDs (GI injury)  
 Fluconazole  
 Metronidazole  
 Sulfamethoxazole  
 Tamoxifen

Activate Windows

Go to Settings to activate Windows

- LMWH
  - typically reserved as long term therapy for patients unable to tolerate oral anticoagulants (e.g. unable to absorb oral medications, high risk bleeding patients with intraluminal GI malignancy)
- duration of anticoagulant treatment
  - provoked VTE with transient risk factor: 3 mo
  - provoked VTE with ongoing risk factor: consider indefinite therapy with annual reassessment
  - first unprovoked proximal DVT or PE:  $\geq 3$  mo, consider indefinite therapy with annual reassessment
  - second unprovoked VTE: consider indefinite therapy
  - cancer-associated DVT: consider indefinite therapy for as long patient has active malignancy (in patients who have cancer in remission, anticoagulation is usually extended for 3-6 mo post last treatment)
  - inferior vena cava filters
  - temporary filter indicated only if acute DVT (<4 wk) with significant contraindications to anticoagulant therapy (i.e. active bleeding) or if anticoagulation must be interrupted (i.e. for urgent surgery)
  - must be retrieved once safe to do so as filter is pro-thrombotic in the long-term and associated with other complications (migration of filter, etc.)
- special considerations
  - pregnancy: treat with LMWH during pregnancy, then LMWH or warfarin for 6 wk post-partum (minimum total anticoagulation time of 3-6 mo, but must include 6 wk post-partum, as this is a high-risk period)
  - avoid warfarin in pregnancy due to teratogenicity outside of select patient populations (e.g. may be used by some thrombosis experts during the second and third trimesters in woman with mechanical heart valves)
  - avoid DOAC in pregnancy (due to lack of data) and if breastfeeding in postpartum period
  - surgery: avoid elective surgery in the first 3 mo after a venous thromboembolic event
    - preoperatively: IV heparin may be used up to 4-6 h preoperatively
    - perioperatively: warfarin or DOACs discontinued for at least 2-5 d preoperatively (consider mechanism of drug clearance)
    - postoperatively: IV heparin, LMWH, DOAC can be used for anticoagulation (consult with surgeon prior to re-initiation)
    - for patients at high-risk for thromboembolism (VTE <12 wk, recurrent VTE, APS, AFib with prior stroke, and mechanical heart valve), IV heparin or LMWH (bridging) may be considered before and after the procedure while the INR is below 2.0. Bridging not required for DOACs

**In Hospital Prophylaxis**

- consider for those with a moderate to high-risk of thrombosis without contraindications
- non-pharmacological measures include: early ambulation, elastic compression stockings (TEDs), and intermittent pneumatic compression (IPC)
- LMWH as per hospital protocol (e.g. enoxaparin 40 mg SC once daily, dalteparin 5000 U SC once daily), or rarely UFH 5000 IU SC BID, UFH 5000 IU SC TID
- DOACs for orthopaedic surgery thromboprophylaxis

**Table 30. Contraindications of Anticoagulant Therapy**

Absolute Contraindications to Treatment	Relative Contraindications to Treatment
Active bleeding	Mild-moderate bleeding diathesis or thrombocytopenia
Severe bleeding diathesis or platelet count <20 x 10 <sup>9</sup> /L (<20000/mm <sup>3</sup> )	Recent major trauma
	Recent stroke
	Major abdominal surgery within past 2 d
	GI/GU bleeding within 1-4 d
	Endocarditis
	Neurosurgery or ocular surgery within 10 d

**Treatment of Pulmonary Embolism**

- see [Respirology, R21](#)

**Effect of Treatment Delay on the Effectiveness and Safety of Antifibrinolytics in Acute Severe Hemorrhage: a Meta-analysis of Individual Patient-level Data from 40138 Bleeding Patients**  
Lancet 2018;391:125-132

**Purpose:** To examine if the effectiveness of antifibrinolytics in reducing death from acute severe hemorrhage is influenced by treatment delay.

**Methods:** Meta-analysis of individual patient-level data from 2 RCTs with 40138 total patients that investigated the use of tranexamic acid in acute severe bleeding. Treatment benefit was measured by absence of death from bleeding and logistic regression was used to assess the effect of treatment delay.

**Results:** Overall survival from bleeding was significantly increased by tranexamic acid (OR 1.2, 95% CI 1.00-1.33; P=0.001). Survival was improved by >10% with immediate treatment (OR 1.72, 95% CI 1.42-2.10; P<0.0001). In contrast, treatment benefit was significantly reduced by treatment delay (P<0.0001). Specifically, survival was reduced by 10% for every 15 min delay of treatment until 3 hr, at which point no benefit was demonstrated.

**Conclusion:** Patients with severe acute bleeding should be treated immediately, as even a short delay in treatment reduces the survival benefit of tranexamic acid.

**ASCO Clinical Practice Guidelines for VTE Prophylaxis and Treatment in Patients with Cancer**

J Clin Oncol 2020;38:496-520

Clinicians can offer thromboprophylaxis (apixiban, rivaroxaban, or LMWH) for:

- High-risk outpatients with cancer
- As options for VTE treatment
- For long-term anticoagulation (min. 6 mo; better efficacy profiles than vitamin K antagonists)
- Throughout hospitalization (patients with cancer and an acute medical condition)
- Major cancer surgery (prophylaxis starting prior and continuing for min. 7-10 d)

**Initiation of Warfarin Therapy Requires Bridging with Heparin Therapy for 4-5 Days**

10 mg loading dose of warfarin causes a precipitous decline in protein C levels in first 36 h resulting in a transient hypercoagulable state

Warfarin decreases Factor VII levels in first 48 h. INR is prolonged (most sensitive to Factor VII levels), however full antithrombotic effect is not achieved until Factor IX, X, and II are sufficiently reduced (occurs after ~4 d)

**Low-Risk Surgical Patients**

<40 yr, no risk factors for VTE, general anesthetic (GA) <30 min, minor elective, abdominal, or thoracic surgery

**Moderate-Risk Surgical Patients**

>40 yr, >1 risk factor for VTE, GA >30 min

**High-Risk Surgical Patients**

>40 yr, surgery for malignancy or lower extremity orthopaedic surgery lasting >30 min, inhibitor deficiency, or other risk factors

**High-Risk Medical Patients**

Heart failure, severe respiratory disease, ischemic stroke or lower limb paralysis, confined to bed, and have >1 additional risk factor (e.g. active cancer, previous VTE, sepsis, acute neurologic disease, IBD)

# Hematologic Malignancies and Related Disorders

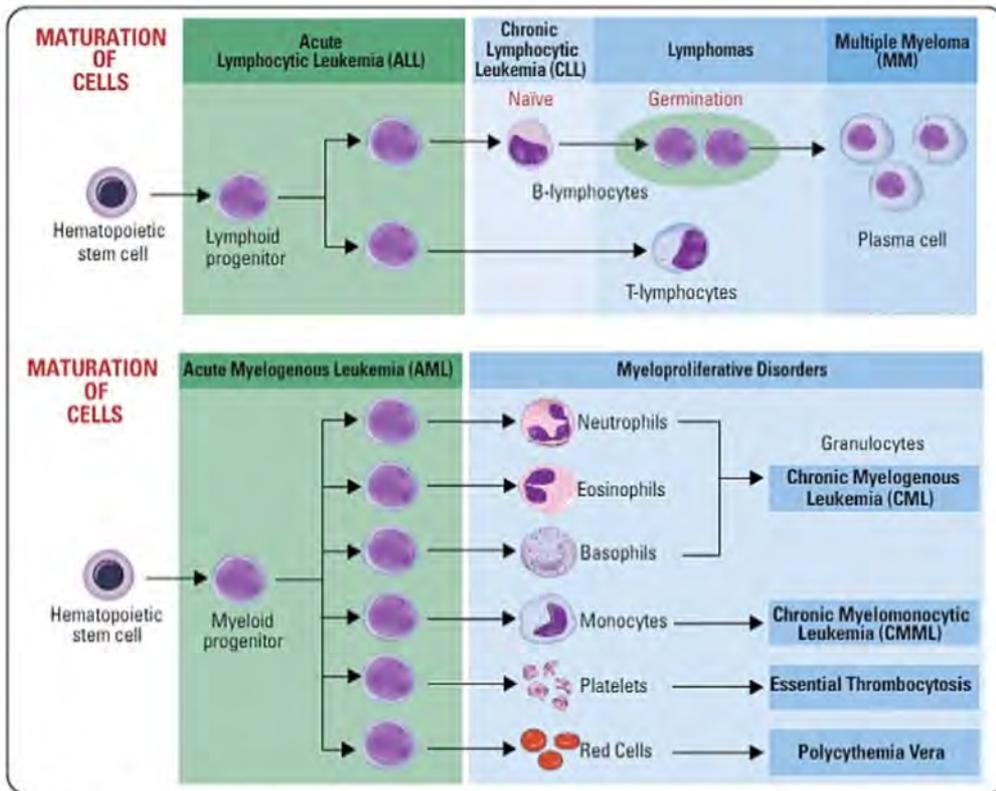

Figure 15. Hematopoietic derivation of hematologic disorders

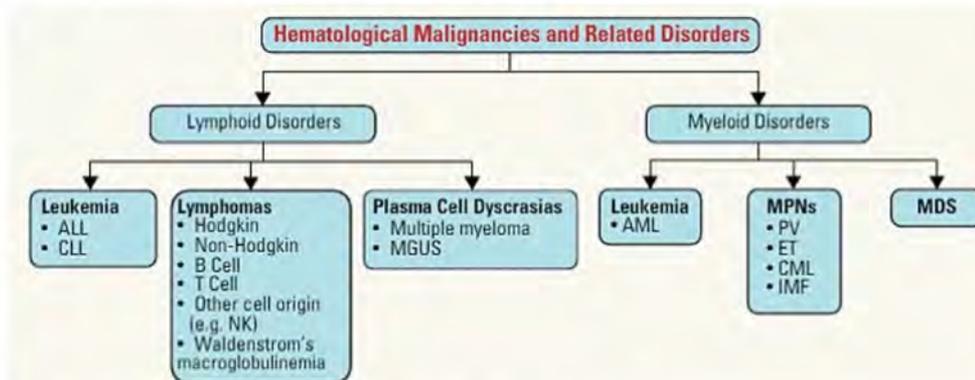

Figure 16. Overview of hematologic malignancies and related disorders

## Myeloid Malignancies

### Acute Myeloid Leukemia

**Definition**

- rapidly progressive malignancy characterized by failure of myeloid cells to differentiate beyond blast stage

**Epidemiology**

- incidence increases with age; median age of onset is 65 yr; 80% of acute adult leukemias
- accounts for 10-15% of childhood leukemias

**Risk Factors**

- male, older age, smoking, obesity, MDS, benzene, radiation, Down Syndrome, alkylating agents, and radiation therapy as treatment for previous malignancy

**Leukemia:** malignant cells arise in BM that may spread elsewhere (including blood, lymph nodes, and lymphoid tissue)

**Lymphoma:** malignant cells arise in lymph nodes and lymphoid tissues that may spread elsewhere (including blood and BM)

BUT the location where the malignant cells are found does not solely define the type of hematologic malignancy – classified based on the characteristics of the cell (histology, histochemistry, immunophenotyping, cytogenetics, molecular changes)

**Acute Leukemia**

**Definition (WHO):** presence of 20% blast cells or greater in the peripheral blood or BM at presentation

**Classification:** divided into myeloid (AML) and lymphoid (ALL) depending on whether blasts are myeloblasts or lymphoblasts, respectively

**Typical Age of Presentation of Leukemias**

- ALL: Children and older adults
- CML: 40-60 yr
- AML, CLL: >60 yr

Auer rods are pathognomonic for AML

**Basic Initial Workup for all Hematologic Malignancies:**

1. ALL WOMEN OF CHILDBEARING AGE must have a b-HCG before initiation of treatment of any cancer diagnosis
2. ALL PATIENTS MUST HAVE Hepatitis B surface antibody (HBsAb), Hepatitis B surface antigen (HBsAg), Hepatitis B core antibody (HBcAb) collected irrespective of cancer diagnosis and must be treated to avoid reactivation
3. All aggressive lymphoma patients must be screened for HIV
4. All patients must be screened for TB risk factors

**Cure:** survival that parallels age-matched population

**Complete Remission:** tumour load below threshold of detectable disease (normal peripheral blood film, normal BM with <5% blasts, normal clinical state)

### Pathophysiology

- etiology subdivided into:
  - primary: *de novo*
  - secondary: hematologic malignancies (e.g. myeloproliferative disorders and MDS) or previous chemotherapeutic agents (e.g. alkylating agents)
- uncontrolled growth of blasts in marrow leads to:
  - suppression of normal hematopoietic cells
  - appearance of blasts in peripheral blood – risk of leukostasis
  - accumulation of blasts in other sites (e.g. skin, gums)
  - metabolic consequences; TLS

### Clinical Features

- signs and symptoms develop over a period of weeks
- manifestations of BM failure
  - anemia, thrombocytopenia (associated with DIC in APL), neutropenia (and infection/fever)
- accumulation of blast cells in marrow
  - skeletal pain, bony tenderness (especially sternum)
- organ infiltration
  - gingival hypertrophy (particularly myelomonocytic leukemia) – may present to dentist first
  - CNS extramedullary involvement: confusion or altered mental status
  - hepatosplenomegaly (also present in ALL)
  - lymphadenopathy
  - skin: leukemia cutis
  - eyes: hemorrhages and/or whitish plaques, Roth spots, cotton wool spots, and vision changes (uncommon)
- leukostasis/hyperleukocytosis syndrome (medical emergency)
  - large numbers of blasts interfere with circulation and lead to hypoxia and hemorrhage – can cause diffuse pulmonary infiltrates, CNS bleeding, respiratory distress, altered mental status, and priapism
  - more commonly associated with AML than ALL
- metabolic effects (aggravated by treatment)
  - TLS
    - ♦ increased uric acid → nephropathy, gout
    - ♦ release of phosphate → decreased  $\text{Ca}^{2+}$ ; decreased  $\text{Mg}^{2+}$
    - ♦ release of procoagulants → DIC (higher risk in APL)
  - hyperkalemia pre-treatment from blastic proliferation and spontaneous TLS, further hyperkalemia after treatment (from lysed cells). Note – some forms of AML can present with hypokalemia due to secreted muramidase that causes  $\text{K}^+$  wasting from renal tubules

### Investigations

- blood work
  - CBC: anemia, thrombocytopenia, variable WBC (most often cytopenias + blasts)
  - INR, aPTT, FDP, fibrinogen (in case of DIC)
  - increased LDH, increased uric acid, increased  $\text{PO}_4^{3-}$  (released by leukemic blasts), decreased  $\text{Ca}^{2+}$ , increased/decreased  $\text{K}^+$
  - baseline renal and liver function tests
  - if considering treatment: screen for HBV, HCV, HIV, CMV serology
- peripheral blood film – circulating blasts with Auer rods (azurophilic granules) are pathognomonic for AML
- BM aspirate for definitive diagnosis
  - blast count: AML >20% (normal is <5%)
  - morphologic, cytogenetic, and/or immunophenotypic features are used to establish lineage and maturation
- CXR to rule out pneumonia; ECG, MUGA scan prior to chemotherapy (cardiotoxic)

### Treatment

- mainstay of treatment is chemotherapy (rapidly fatal without treatment)
- patients who are not eligible for intensive chemotherapy can be treated with low-dose cytarabine and hypomethylating agents in combination with venetoclax (BCL-2 inhibitor)
- all AML subtypes are treated similarly, except APL with t(15:17) translocation
  1. **induction:** chemotherapy to induce complete remission of AML
    - ♦ several possible regimens
    - ♦ patients with poor response to initial induction therapy – worse prognosis
    - ♦ supportive care - management of TLS and DIC, febrile neutropenia/infections, transfusion support (including platelet transfusions if  $<10 \times 10^9/\text{L}$ )
  2. **consolidation:** to prevent recurrence
    - ♦ intensive consolidation chemotherapy
    - ♦ stem cell transplantation – allogeneic (younger patients with better performance status and/or adverse cytogenetics)

- supportive care
  - fever: pan-cultures, CXR, and start broad-spectrum antibiotics
  - platelet and RBC transfusions
  - prevention and treatment of metabolic abnormalities
    - allopurinol, rasburicase for prevention/management of hyperuricemia
  - leukostasis
    - needs immediate cytoreductive therapy (i.e. hydroxyurea)
  - treatment strategy for APL
    - APL is an emergency as DIC is often present at diagnosis
    - ATRA added to induce differentiation (should be started ASAP if APL is in the differential); arsenic trioxide and ATRA combination therapy for APL is superior to traditional chemotherapy

### Prognosis

- achievement of first remission
  - 70-80% if  $\leq 60$  y/o, 50% if  $> 60$  y/o
  - median survival 12-24 mo
  - prognosis depends on cytogenetics, age, performance status, prior cytotoxic agents, or radiation therapy

## Myelodysplastic Syndromes

### Definition

- heterogeneous group of malignant stem cell disorders characterized by dysplastic and ineffective blood cell production resulting in peripheral cytopenias, and a variable risk of transformation to acute leukemias
- syndromes defined according to WHO classifications

### Pathophysiology

- disordered maturation: ineffective hematopoiesis despite presence of adequate numbers of progenitor cells in BM (usually hypercellular); formed elements sometimes exhibit morphological and functional defects
- intramedullary apoptosis: programmed cell death within BM
- both processes lead to reduced mature cells in periphery
- $< 30\%$  develop AML

### Risk Factors

- elderly, post-chemotherapy, exposures (benzene, tobacco, radiation), inherited genetic abnormalities
- incidence: 50 persons per million per year, rises to 200-400 per million per year for age 70 or older

### Clinical Features

- highly variable, commonly presents with symptoms of anemia (fatigue and dyspnea), thrombocytopenia (bruising, bleeding, or petechiae), and neutropenia (recurrent infections) over months-years

### Investigations

- diagnosed by:
  - anemia  $\pm$  thrombocytopenia  $\pm$  neutropenia
  - CBC and peripheral blood film
  - RBC: usually macrocytic with oval shaped red cells (macro-ovalocytes), decreased reticulocyte count
  - WBC: decreased granulocytes and abnormal morphology (e.g. bi-lobed or unsegmented nuclei = Pelger abnormality)
  - platelets: thrombocytopenia, abnormalities of size, and cytoplasm (e.g. giant hypogranular platelets)
- BM aspirate and biopsy with cytogenetic analysis required for definitive diagnosis
  - BM: dysplastic and often normocellular/hypercellular
  - cytogenetics: high-risk (partial or total loss of chromosome 7) and complex ( $> 3$  abnormalities)

### Treatment

- low-risk of transformation to acute leukemia (Revised International Prognostic Scoring System (IPSS-R) Very Low or Low)
  - EPO stimulating agents weekly is first line in reducing transfusion requirements (EPO level must be  $< 500$  IU/L)
  - if 5q deletion based on cytogenetics: lenalidomide PO
  - supportive care: RBC and platelet transfusion (consider iron chelation if frequent RBC transfusions)
- high-risk of transformation to acute leukemia (IPSS-R intermediate, high or very high)
  - supportive care (transfusion support)
  - epigenetic therapy: DNA methyltransferase inhibitors (e.g. 5-azacitidine)
  - consider stem cell transplantation according to patient factors (age, frailty, overall health)

MDS is a cause of macrocytic anemia

**Efficacy of Azacitidine Compared with that of Conventional Care Regimens in the Treatment of Higher-risk Myelodysplastic Syndromes: a Randomized, Open-label, Phase III Study**  
Lancet Oncol 2009;10:223-32

**Purpose:** To compare the efficacy of azacitidine to conventional care regimens (CCRs) in patients with high-risk MDS.

**Methods:** 358 patients were randomly assigned to receive azacitidine (75 mg/m<sup>2</sup> id for 7 days every 28 days) or CCR (intensive chemotherapy, low-dose cytarabine, or supportive care alone).

**Results:** At median follow-up of 21.1 months, azacitidine treatment was associated with significantly greater median overall survival as compared to CCRs (24.5 months vs. 15.0 months, respectively; hazard ratio 0.58; 95% CI 0.43-0.77;  $p < 0.0001$ ). 50.8% of patients receiving azacitidine were alive at 2 years as compared to 26.2% of patients receiving CCRs ( $p < 0.0001$ ). The most frequent grade 3-4 adverse event for all treatments were peripheral cytopenias.

**Conclusion:** In patients with high-risk MDS, azacitidine treatment significantly increases overall survival as compared to conventional care.

**Prognosis**

- IPSS-R uses 5 factors to estimate mean survival:
  - cytology, % BM blasts, Hb, platelets, and ANC
  - based on the calculated score, a patient's MDS prognostic risk is "Very Low", "Low", "Intermediate", "High", or "Very High" with a mean survival of 8.7, 5.3, 3.0, 1.6, and 0.8 yr, respectively

## Myeloproliferative Neoplasms

**Definition**

- clonal myeloid stem cell abnormalities leading to overproduction of one or more cell lines (erythrocytes, platelets, and other cells of myeloid lineage)

**Epidemiology**

- mainly middle-aged and older patients (peak 60-80 yr)

**Prognosis**

- may develop marrow fibrosis with time
- all disorders may progress to AML

**Table 31. Chronic Myeloproliferative Disorders**

	CML	PV	IMF	ET
Hct	+/N	++	+	N
WBC	++	+	+/+	N
Plt	+/+	+	+/+	+++
Marrow Fibrosis	±	±	+++	±
Splenomegaly	+++	+	+++	+
Hepatomegaly	+	+	++	-
Genetic Association	BCR-ABL mut.	JAK2 mut. (96%)	JAK2 mut. (~50%) CALR mut. (~30%)	JAK2 mut. (~50%) CALR mut. (~30%)

## Chronic Myeloid Leukemia

**Definition**

- myeloproliferative disorder characterized by increased proliferation of the granulocytic cell line without the loss of their capacity to differentiate

**Epidemiology**

- occurs in any age group (mostly middle age to elderly) with a median age of 65 yr

**Pathophysiology**

- Ph chromosome
  - translocation between chromosomes 9 and 22 is necessary and sufficient to result in CML
  - the *c-Abl* proto-oncogene is translocated from chromosome 9 to "breakpoint cluster region" (BCR) of chromosome 22 to produce BCR-ABL fusion gene, a constitutively active tyrosine kinase

**Clinical Features**

- 3 clinical phases
  - chronic phase: 85% diagnosed here
    - few blasts (<10%) in peripheral film
    - ± slightly elevated eosinophils and basophils
    - no significant symptoms
  - accelerated phase: impaired neutrophil differentiation
    - circulating blasts (10-20%) with increasing peripheral basophils (pruritus)
    - CBC: thrombocytopenia <100 x 10<sup>9</sup>/L or thrombocytosis
    - cytogenetic evidence of clonal evolution
    - worsening constitutional symptoms and splenomegaly (extramedullary hematopoiesis)
  - blast crisis: more aggressive course, blasts fail to differentiate
    - blasts (>20%) in peripheral blood or BM; reflective of acute leukemia (1/3 ALL, 2/3 AML)
- clinical features
  - 20-50% of patients are asymptomatic when diagnosed (incidental lab finding)
  - nonspecific symptoms
    - fatigue, weight loss, malaise, excessive sweating, fever

**Use of Epoetin and Darbepoetin in Patients with Cancer**

Blood 2008;111:25-41

Clinical practice guideline update by American Societies of Hematology and Clinical Oncology (2010).

**Initial Recommendations**

- Initiate an ESA when Hb is 100 g/L (10 g/dL) in patients with palliative chemotherapy-associated anemia to decrease the need for transfusions
- Discontinue ESAs when patient not responding to treatment beyond 6-8 wk
- Monitor iron stores and supplement iron intake for ESA-treated patients when necessary
- Use ESAs cautiously with chemotherapy or in patients with an elevated risk for thromboembolic complications
- It is not recommended that ESA be used for therapy in patients with cancer who are not receiving chemotherapy, as it increases thromboembolic risks and lowers survival rate. Patients with low-risk myelodysplasia are an exception

MDS ineffective maturation  
MPN overproduction of mature cells

Basophilia is uncommon in other medical conditions

**Chronic Myeloproliferative Neoplasias: 11-Year Follow-Up of Patients Receiving Imatinib for the First-Line Treatment of CML**

NEJM 2017;376:917-927

**Study:** Long-term outcomes of imatinib treatment for chronic myeloid leukemia.

**Methods:** 1106 patients with P19+ CML in the chronic phase were randomized 1:1 to imatinib or interferon alpha plus cytarabine. Crossover to imatinib was allowed if no response by 6 mo or major cytogenetic response by 12 mo.

**Results:** Assessing the imatinib arm after a median of 11 years of follow-up, the complete cytogenetic response rate was 83%. Among patients who attained a major molecular response after 18 mo of imatinib therapy, the overall survival at 10 years was 93% and freedom from CML-related deaths was 100%.

**Conclusion:** This 11-year update of IRIS demonstrates the efficacy and safety of imatinib as first-line therapy for CML patients.

- secondary to splenic involvement
  - early satiety, LUQ pain/fullness, shoulder tip pain (referred)
  - splenomegaly (most common physical finding)
- anemia
- bleeding: secondary to platelet dysfunction
- pruritus, PUD: secondary to increased blood histamine
- leukostasis, priapism, encephalopathy (rare): secondary to very elevated WBC (rare)

### Investigations

- CBC with differential
  - elevated WBCs, decreased/normal RBCs, increased/decreased platelets, increased basophils
  - WBC differential shows a bimodal distribution, with predominance of myelocytes and neutrophils
- peripheral blood film
  - leukoerythroblastic picture (immature red cells and granulocytes present, e.g. myelocytes and normoblasts)
  - presence of different mid-stage progenitor cells differentiates it from AML
- BM biopsy
  - myeloid hyperplasia with left shift, increased megakaryocytes, mild fibrosis
- molecular and cytogenetic studies of BM or peripheral blood for Ph chromosome (or BCR-ABL transcripts)
- abdominal imaging for spleen size

### Treatment

- **prophylactic:** allopurinol
- **chronic phase**
  - imatinib mesylate inhibits proliferation and induces apoptosis by inhibiting tyrosine kinase activity in cells positive for BCR-ABL. 2nd/3rd generation can be used as first line therapy
    - if loss of response or intolerance (~40%), trial of 2nd or 3rd generation TKIs: dasatinib, nilotinib, or bosutinib. Note: ponatinib only provided for the T315I mutation
  - interferon- $\alpha$ : may improve response to TKIs; typically now only used for pregnant patients
  - hydroxyurea in palliative setting to reduce WBCs
- **accelerated phase or blast phase**
  - for imatinib-naïve patients, use imatinib
  - refer for clinical trial or 2nd/3rd generation TKI and prepare for allogeneic stem cell transplant patients, in blast phase typically get standard induction for acute leukemia
- stem cell transplantation may be curative: to be considered in young patients who do not meet therapeutic milestones
- treatment success is monitored based on therapeutic milestones
  - hematologic: improved WBC and platelet counts, reduced basophils
  - cytogenetic: undetectable Ph chromosome in the BM
  - molecular: reduction/absence of BCR-ABL transcripts in periphery and marrow

### Prognosis

- survival dependent on response
  - those achieving complete cytogenetic response (CCR) on imatinib by 18 mo of therapy: 6 yr overall survival >90%
  - those who do NOT achieve CCR on imatinib: 6 yr overall survival of 66%
- acute phase (blast crisis - usually within 3-5 yr of presentation if untreated CML)
  - 2/3 acute phase CML have cellular features similar to AML
    - unresponsive to remission induction
  - 1/3 acute phase CML have cellular features similar to ALL
    - remission induction (return to chronic phase) achievable

## Polycythemia Vera

### Definition

- stem cell disorder characterized by elevated RBC mass (erythrocytosis)  $\pm$  increased white cell and platelet production
- diagnosis (WHO 2016) requires meeting either all 3 major criteria, or the first 2 major criteria and the minor criterion
  - Major Criteria
    1. Hb >165 g/L in men, >160 g/L in women, OR Hct >49% in men or >48% in women, OR increased red cell mass (>25% above mean normal predicted value)
    2. BM biopsy showing hypercellularity for age with trilineage growth (panmyelosis) with prominent erythroid, granulocytic, and megakaryocytic proliferation
    3. presence of JAK2 V617F or JAK2 exon 12 mutation
  - Minor Criterion
    1. serum EPO level below reference range for normal (must have the first two major criteria if using EPO level)

Erythromelalgia is a pathognomonic microvascular thrombotic complication in PV and ET

Cardiovascular Events and Intensity of Treatment in Polycythemia Vera  
NEJM 2013;368:22-33

**Study:** Prospective, RCT, mean follow-up of 28.9 mo. Blinding not described.

**Population:** 365 patients with JAK2-positive polycythemia vera being treated with phlebotomy, hydroxyurea, or both.

**Intervention:** Patients were randomized to a target hematocrit <45% (low-hematocrit group) or 45-50% (high-hematocrit group).

**Outcome:** Composite of time until death from cardiovascular causes of major thrombotic events.  
**Results:** The hazard ratio (HR) for the primary outcome was 3.91 (95% CI 1.45-10.53, P=0.007), while the HR for the primary outcome plus superficial venous thrombosis was 2.69 (95% CI 1.19-6.12, P=0.02) for the high-hematocrit vs. low-hematocrit group.

**Conclusions:** The hematocrit target of <45% was associated with a lower incidence of CV death, major thrombotic events, and superficial venous thrombosis in patients with polycythemia vera.

### Clinical Features

- symptoms are secondary to high red cell mass and hyperviscosity (see *Erythrocytosis, H7*)
- thrombotic complications: DVT, PE, Budd-Chiari (hepatic vein thrombosis), portal vein thrombosis, thrombophlebitis, increased incidence of stroke/TIA, and MI
  - due to increased blood viscosity, increased platelet number, and/or activity
  - bleeding complications: epistaxis, gingival bleeding, ecchymoses, and GI bleeding
  - if high platelet counts: associated with acquired VWD (although seen more with ET)
- erythromelalgia (burning pain in hands and feet and erythema of the skin)
  - associated with platelets  $>400 \times 10^9/L$
  - pathognomonic microvascular thrombotic complication in PV and ET
- pruritus, especially after warm bath or shower (40%) due to cutaneous mast cell degranulation and histamine release
- epigastric distress, PUD
  - due to increased histamine from tissue basophils, alterations in gastric mucosal blood flow due to increased blood viscosity
- gout (hyperuricemia), due to increased cell turnover
- characteristic physical findings
  - plethora (ruddy complexion) of face (70%), palms
  - splenomegaly (70%), hepatomegaly (40%)

### Investigations (see *Erythrocytosis, H7*)

- must rule out secondary polycythemia if high EPO level

### Treatment

- phlebotomy to keep hematocrit  $<45\%$
- hydroxyurea (prior thrombosis or symptoms, severe coronary artery disease, refractory to phlebotomy)
- ruxolitinib for those with insufficient response or intolerance to hydroxyurea
- low-dose ASA (for antithrombotic prophylaxis, will also treat erythromelalgia)
- allopurinol: as needed
- antihistamines: as needed

### Prognosis

- 10-20 yr survival with treatment
- complicated by thrombosis, hemorrhage, leukemic transformation (AML)

## Idiopathic Myelofibrosis

### Definition

- excessive BM fibrosis leading to marrow failure
- characterized by anemia, extramedullary hematopoiesis, leukoerythroblastosis, teardrop red cells in peripheral blood, and hepatosplenomegaly

### Epidemiology

- rare, median age at presentation is 65 yr

### Pathophysiology

- abnormal myeloid precursor postulated to produce dysplastic megakaryocytes that secrete fibroblast growth factors
  - stimulates fibroblasts and stroma to deposit collagen in marrow
- increasing fibrosis causes early release of hematopoietic precursors leading to:
  - leukoerythroblastic blood film (see below)
  - migration of precursors to other sites: extramedullary hematopoiesis (leading to hepatosplenomegaly)

### Clinical Features

- anemia (severe fatigue is most common presenting complaint, pallor on exam in  $>60\%$ )
- weight loss, fever, night sweats  $\rightarrow$  secondary to hypermetabolic state
- splenomegaly (90%)  $\rightarrow$  secondary to extramedullary hematopoiesis; may cause early satiety and severe left upper quadrant pain.
- hepatomegaly (70%)  $\rightarrow$  may develop portal hypertension
- bone and joint pain  $\rightarrow$  secondary to osteosclerosis, gout
- signs of extramedullary hematopoiesis (depends on organ involved)

### Investigations

- CBC: anemia, variable platelets, variable WBC
- biochemistry: increased ALP (liver involvement, bone disease), increased LDH ( $2^\circ$  to ineffective hematopoiesis), increased uric acid (increased cell turnover), increased B $_{12}$  ( $2^\circ$  to increased neutrophil mass)
- blood film: leukoerythroblastosis with teardrop RBCs, nucleated RBCs, variable polychromasia, large platelets, and megakaryocyte fragments
- molecular test: JAK2 (70%) and CALR (25%) mutations
- BM aspirate: "dry tap" in as many as 50% of patients (no marrow spicules aspirated)
- BM biopsy (essential for diagnosis): fibrosis, atypical megakaryocytic hyperplasia, thickening and distortion of the bony trabeculae (osteosclerosis)

### Efficacy and Safety of Low-dose Aspirin<sup>®</sup> in Polycythemia Vera

NEJM 2004;350:114-124

**Study:** Double-blind, placebo-controlled, RCT. Participants: 518 patients with polycythemia vera (PV) with no clear indication for, or contraindication to, ASA therapy.

**Intervention:** Patients received either low-dose ASA 100 mg daily (n=253) or placebo (n=265) and were followed for up to 5 yr.

**Primary Outcome:** Cumulative rate of (I) nonfatal MI, nonfatal stroke, or death from cardiovascular causes and the cumulative rate of (II) the previous 3 plus PE and major venous thrombosis.

**Results:** Primary outcomes (I) and (II) were reduced with treatment compared to placebo (RR 0.41; P=0.09 and RR 0.4; P=0.03, respectively). There were no differences in overall or cardiovascular mortality and major bleeding episodes.

**Conclusion:** Low-dose ASA can safely prevent thrombotic complications in patients with PV.

### Ruxolitinib Versus Standard Therapy for the Treatment of Polycythemia Vera

NEJM 2015;372:426-35

**Purpose:** To evaluate the efficacy and safety of ruxolitinib vs. standard therapy in patients with PV who had insufficient responses or intolerable side effects with hydroxyurea.

**Methods:** 222 phlebotomy-dependent patients with splenomegaly were randomly assigned to receive ruxolitinib or standard therapy.

**Primary Outcome:** Hematocrit control through week 32 and spleen volume reduced  $>35\%$  at week 32.

**Results:** 21% of patients on ruxolitinib vs. 1% of those on standard therapy achieved the primary outcome (P<0.001). 60% of patients on ruxolitinib and 20% on standard therapy achieved hematocrit control,  $\geq 35\%$  reduction in spleen volume was seen in 38% and 1% of patients in the two groups, respectively. Compared to standard therapy, ruxolitinib was associated with a significantly greater rate of complete hematologic remission (24% vs. 9%; P=0.003).

**Conclusion:** Ruxolitinib was superior to standard therapy in controlling hematocrit, reducing the spleen volume, and improving symptoms associated with PV in patients who had insufficient responses or intolerable side effects with hydroxyurea.

Myelofibrosis can be either primary (idiopathic) or occur as a transformation of an antecedent PV or ET

A "leukoerythroblastic" blood film (RBC and granulocyte precursors) implies BM infiltration with malignancy (e.g. leukemias, solid tumour metastases) or fibrosis (e.g. IMF)

IMF typically has a dry BM aspirate and teardrop RBCs (aspiration gives no blood cells)

### Treatment

- allogeneic stem cell transplant is potentially curative
- JAK2 inhibitors (ruxolitinib, fedratinib, or hydroxyurea)
- symptomatic treatment
  - transfusion for anemia
  - EPO: 30-50% of patients respond
  - androgens for anemia (e.g. danazol has shown transient response with response rates of <30%)
  - hydroxyurea for splenomegaly, thrombocytosis, leukocytosis, and systemic symptoms
    - interferon- $\alpha$  (as second line therapy)
    - splenectomy (as third line therapy; associated with high mortality and morbidity)
  - radiation therapy for symptomatic extramedullary hematopoiesis, and symptomatic splenomegaly

### Prognosis

- Dynamic International Prognostic Scoring System (DIPSS) Plus for IMF uses 5 risk factors along with karyotype, platelet count, and transfusion status to predict survival
  - presence of constitutional symptoms; age >65; Hb <100 g/L; leukocyte count >25000/mm<sup>3</sup>; circulating blast cells  $\geq$ 1%
  - based on the calculated score, a patient's IMF is categorized as "low", "intermediate 1", "intermediate 2", or "high" with a mean survival of 185, 78, 35, and 16 mo, respectively
  - eligible patients with intermediate 2 or high risk DIPSS are considered for allogeneic stem cell transplant
- risk of transformation to AML (8-10%)

## Essential Thrombocythemia

### Definition

- overproduction of platelets in the absence of recognizable stimulus
- must rule out secondary thrombocythemia

### Epidemiology

- increases with age; F:M=2:1, but F=M at older age

**Diagnosis** (2008 WHO Criteria Revised in 2016) requires meeting all four criteria

1. sustained platelet count >450 x 10<sup>9</sup>/L
2. BM biopsy specimen showing proliferation mainly of the megakaryocytic lineage with increased number of enlarged, mature megakaryocytes; no significant increase or left shift of neutrophil granulopoiesis or erythropoiesis
3. not meeting WHO criteria for PV, primary myelofibrosis, BCR-ABL CML, or MDS or other myeloid neoplasms
4. most patients have a mutation in JAK2 V617F, CALR, or MPL. A minority (~10%) have a mutation in some other gene, which causes proliferation (hence "clonal marker")

### Clinical Features

- often asymptomatic
- vasomotor symptoms (40%)
  - headache (common), dizziness, syncope
  - erythromelalgia (burning pain of hands and feet, dusky colour, usually worse with heat, caused by platelet activation  $\rightarrow$  microvascular thrombosis)
- thrombosis (arterial and venous)
- bleeding (often GI; associated with platelets >1000 x 10<sup>9</sup>/L)
- constitutional symptoms, splenomegaly
- pregnancy complications; increased risk of spontaneous abortion
- risk of transformation to AML (0.6-5%), myelofibrosis

### Investigations

- CBC: increased platelets; may have abnormal platelet aggregation studies or VWD studies
- JAK2 (and other) mutational assays
- BM hypercellularity, megakaryocytic hyperplasia, giant megakaryocytes
- increased K<sup>+</sup>, increased PO<sub>4</sub><sup>3-</sup> (2 $\circ$  to release of platelet cytoplasmic contents)
- diagnosis: exclude other myeloproliferative disorders and reactive thrombocytosis

### Treatment

- low dose ASA
- cytoreductive therapy if thrombosis or thrombotic symptoms: hydroxyurea (HU) (1st-line therapy), anagrelide, interferon- $\alpha$ , or 32P (age >80 or lifespan <10 yr)

#### A Double-Blind, Placebo-Controlled Trial of Ruxolitinib for Myelofibrosis

NEJM 2012;366:799-807

**Study:** Double-blinded RCT of 309 patients with myelofibrosis randomized to ruxolitinib or placebo.

**Outcome:** Primary outcome was reduction in spleen volume of >35% at 24 wk. Secondary outcomes were durability of response, symptom burden, and overall survival.

**Results:** A greater proportion of patients on ruxolitinib had reduction in spleen volume >35% (41.9% vs. 0.7%) and this was sustained in 67% at 48 wk. Ruxolitinib also led to greater symptom improvement (45% vs. 5.3%) and less mortality (13 vs. 24). There was no difference in rate of discontinuation due to adverse events (11.0% vs. 10.6%) but anemia and thrombocytopenia were more common with ruxolitinib.

**Conclusions:** Ruxolitinib reduced spleen size, and improved symptoms and survival, compared with placebo.

#### Etiology of Secondary Thrombocythemia

Infection  
Inflammation (IBD arthritis)  
Malignancy  
Hemorrhage  
Iron deficiency  
Hemolytic anemia  
Post-splenectomy  
Post-chemotherapy  
Drugs (vinca alkaloids)

There is an asymptomatic "benign" form of essential thrombocythemia with a stable or slowly rising platelet count; treatment includes observation, ASA, sulfipyrazone, or dipyridamole

# Lymphoid Malignancies

## Acute Lymphoblastic Leukemia

75% of ALL occurs in children <6 yr;  
second peak at age 40

### Definition

- malignant disease of the BM in which early lymphoid precursors proliferate and replace normal hematopoietic cells
- WHO subdivides ALL into two types depending on cell of origin
  - 1. B-cell: precursor B lymphoblastic leukemia
  - 2. T-cell: precursor T lymphoblastic leukemia
- the French-American-British (FAB) classification (L1, L2, L3) is no longer encouraged, as morphology is not prognostic

### Clinical Features

- see *Acute Myeloid Leukemia, H39* for full list of symptoms
- distinguish ALL from AML based on Table 32
- clinical symptoms usually secondary to:
  - BM failure: anemia, neutropenia (50% present with fever; also infections of oropharynx, lungs, perianal region), and thrombocytopenia
  - organ infiltration: tender bones, lymphadenopathy, hepatosplenomegaly, meningeal signs (headache, N/V, visual symptoms; especially in ALL relapse)

### Investigations

- >20% BM or peripheral blood lymphoblasts, with samples collected for flow cytometry, cytogenetics, and molecular studies
- Ph chromosome in ~25% of adult ALL cases
- CBC: increased leukocytes  $>100 \times 10^9/L$  (occurs in 50% of patients); neutropenia, anemia, or thrombocytopenia
- screen for TLS: increased uric acid,  $K^+$ ,  $PO_4^{3-}$ , low  $Ca^{2+}$ , high LDH
- screen for DIC: PT, aPTT, fibrinogen
- CXR: patients with ALL may have a mediastinal mass
- CT C/A/P and testicular ultrasound to screen for extranodal disease
- mandatory lumbar puncture to assess for CNS involvement (ensure adequate platelet count and PT/PTT and delay until blasts have cleared from peripheral blood) at the time treatment is initiated
- HIV, HBV, HCV serologies, CMV Ab testing

### Treatment

- eliminate abnormal clonal cells
  1. induction chemotherapy: to induce complete remission, <5% blasts (restore normal hematopoiesis)
  2. consolidation and/or intensification of chemotherapy
    - consolidation: continuing same chemotherapy to eliminate subclinical leukemic cells
    - intensification: high doses of different (non-cross-reactive) chemotherapy drugs to eliminate cells with resistance to primary treatment
  3. maintenance chemotherapy: low dose intermittent chemotherapy over prolonged period (1 yr) to prevent relapse
  4. prophylaxis: CNS radiation therapy or methotrexate (intrathecal or systemic)
- hematopoietic stem cell transplantation (for certain indications): potentially curative (due to pre-transplant myeloablative chemoradiation and post-transplant graft-versus-leukemia effect) but relapse rates and non-relapse mortality high
  - if BCR-ABL positive, tyrosine kinase inhibitors started up front and given continuously
  - in relapse setting, CAR T-cell therapy, inotuzumab, or blinatumomab

### Prognosis

- depends on response to initial induction, minimal residual disease testing or if remission is achieved following relapse
- good prognostic factors: young, WBC  $<30 \times 10^9/L$ , T-cell phenotype, absence of Ph chromosome, early attainment of complete remission
- achievement of first remission: 60-90%
- childhood ALL: 75% long-term remission (>5 yr)
  - higher cure rates in children because of better chemotherapy tolerance, lower prevalence of BCR-ABL fusion gene (associated with chemotherapeutic resistance)
- adult ALL: 30-40% 5 yr survival

**Treatment of ALL vs. AML**  
No proven benefit of maintenance chemotherapy in AML  
No routine CNS prophylaxis in AML

**Table 32. Differentiating AML From ALL**

AML	ALL
Big people (adults)	Small people (kids)
Big blasts	Small blasts
Big mortality rate	Small mortality rate (kids)
Lots of cytoplasm	Less cytoplasm
Lots of nucleoli (3-5)	Few nucleoli (1-3)
Lots of granules and Auer rods	No granules and no Auer rods
Myeloperoxidase, Sudan black stain	PAS (periodic acid-Schiff)
Maturation defect beyond myeloblast or promyelocyte	Maturation defect beyond lymphoblast

To Differentiate AML from ALL:  
Remember Big and SmALL

# Lymphomas

## Definition

- collection of lymphoid malignancies in which malignant lymphocytes accumulate in lymph nodes and lymphoid tissues
  - leading to lymphadenopathy, extranodal disease, and constitutional symptoms

**Table 33. Ann Arbor System for Staging Lymphomas**

Stage	Description
I	Involvement of a single lymph node region or extralymphatic organ/site (Stage IE)
II	Involvement of $\geq 2$ lymph node regions or an extralymphatic site and $\geq 1$ lymph node regions on same side of diaphragm
III	Involvement of lymph node regions on both sides of the diaphragm; may or may not be accompanied by single extra lymphatic site or splenic involvement
IV	Diffuse involvement of one or more extralymphatic organs including BM

- subtypes
  - A = absence of B-symptoms (see *Approach to Lymphadenopathy, H12*)
  - B = presence of B-symptoms

**Table 34. Chromosome Translocations**

Translocation	Gene Activation	Associated Neoplasm
t(2;5)	ALK1 mutation	Anaplastic large cell lymphoma
t(8;14)	c-Myc activation	Burkitt's lymphoma
t(14;18)	Bcl-2 activation	Follicular lymphoma
t(11;14)	Overexpression of cyclin D1 protein	Mantle cell lymphoma
t(11;18)	MALT1 activation	Mucosa-associated lymphoid tissue (MALT)

## Hodgkin Lymphoma

### Definition

- malignant proliferation of lymphoid cells with Reed-Sternberg cells

### Epidemiology

- bimodal distribution with peaks at 20 yr and  $>50$  yr
- association with Epstein-Barr virus in up to 50% of cases and causal role not determined

### Clinical Features

- asymptomatic lymphadenopathy (70%)
  - non-tender, rubbery consistency
  - cervical/supraclavicular (60-80%), axillary (10-20%), inguinal (6-12%)
- splenomegaly (50%)  $\pm$  hepatomegaly
- mediastinal mass
  - found on routine CXR, may be symptomatic (cough)
  - rarely may present with superior vena cava syndrome and pleural effusion
- systemic symptoms
  - B-symptoms ( $\geq 1$  of: unintentional weight loss  $\geq 10\%$  of body weight within previous 6 mo, temperature  $>38^\circ\text{C}$ , or night sweats for  $\geq 2$  wk without evidence of infection), extreme fatigue especially in widespread disease, and pruritus
- non-specific/paraneoplastic
- starts at a single site in lymphatic system (node) and spreads first to adjacent nodes
  - disease progresses in contiguity with lymphatic system

### Investigations

- CBC
  - anemia (chronic disease, rarely hemolytic), eosinophilia, lymphopenia, platelets normal or increased early disease, and decreased in advanced disease
- biochemistry
  - HIV, HBV, HCV serologies
  - liver enzymes and/or LFTs (liver involvement)
  - renal function tests (prior to initiating chemotherapy)
  - ALP, Ca<sup>2+</sup> (bone involvement)
  - ESR (prognosis), LDH (staging, monitor disease progression)

**American Society of Hematology**  
**Choosing Wisely Recommendation**  
 Limit surveillance CT scans in asymptomatic patients after curative-intent treatment for aggressive lymphoma

- Ann Arbor staging can be used for both Hodgkin and non-Hodgkin lymphoma, but grade/histology is more important for non-Hodgkin lymphoma because the outcome differs significantly depending on type of lymphoma
- Prognostic scores are different for indolent vs. aggressive lymphomas
- Highly aggressive lymphomas act like acute leukemias

Hodgkin is distinguished from non-Hodgkin lymphoma by the presence of Reed-Sternberg cells

Hodgkin lymphoma classically presents as a painless, non-tender, firm, rubbery enlargement of superficial lymph nodes, most often in the cervical region

- imaging
  - CT chest (lymph nodes, mediastinal mass), CT abdomen/pelvis (liver or spleen involvement), and PET scan
  - cardiac function assessment (MUGA scan or echocardiography): for patients at high-risk of pre-treatment cardiac disease (age >60, history of HTN, CHF, PUD, CAD, MI, CVA), treatment can be cardiotoxic
  - PFTs: if history of lung disease (COPD, smoking, and previous radiation to lung)
- excisional lymph node or core biopsy confirms diagnosis
- BM biopsy to assess marrow infiltration (only necessary if B-symptoms, PET positive marrow on imaging, or cytopenia)

### Treatment

- stage I-II: chemotherapy (ABVD (adriamycin, bleomycin, vinblastine, dacarbazine)) followed by involved field or involved site radiotherapy (XRT)
- stage III-IV: chemotherapy (ABVD or BEACOPP (bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine, and prednisone)) ± XRT for bulky disease
- relapse, resistant to therapy: high dose chemotherapy and autologous stem cell transplant, anti-CD30 Ab therapy
  - PET scan results essential in assessing disease response

### Complications of Treatment

- cardiac disease: secondary to XRT, adriamycin cardiomyopathy (1% of patients)
- pulmonary disease: secondary to bleomycin (interstitial pneumonitis)
- infertility: <3% with ABVD (important to discuss sperm banking/egg retrieval prior to initiation of chemotherapy)
- secondary malignancy in irradiated field
  - <2% risk of MDS, AML (secondary to treatment, usually within 8 yr)
  - solid tumours of lung or breast (>8 yr after treatment)
  - non-Hodgkin lymphoma
- hypothyroidism: post XRT

### Prognosis

- Hasenclever adverse prognostic factors:
  1. serum albumin <40 g/L
  2. Hb <105 g/L
  3. male
  4. stage IV disease
  5. age ≥45 yr
  6. leukocytosis (WBC >15 x 10<sup>9</sup>/L)
  7. lymphocytopenia (lymphocytes <0.06 x 10<sup>9</sup>/L or <8% of WBC count or both)
- each additional adverse prognostic factor decreases freedom from progression at 5 yr (FFP)

Treatment of HL depends on stage; treatment of NHL depends on histologic subtype

### International Prognostic Factors Project 1998

Prognostic Factors	FFP
0	84%
1	77%
2	67%
3	60%
4	51%
5-7	42%

FFP = freedom from progression at 5 yr

## Non-Hodgkin Lymphoma

### Definition

- malignant proliferation of lymphoid cells of progenitor or mature B- or T-cells

### Classification

- can originate from both B- (85%) and T- or NK- (15%) cells
  - B-cell NHL: e.g. diffuse large B-cell lymphoma, follicular lymphoma, Burkitt's lymphoma, and mantle cell lymphoma
  - WHO/REAL classification system: 3 categories of NHLs based on natural history
    1. indolent (35-40% of NHL): e.g. follicular lymphoma, small lymphocytic lymphoma/CLL, and mantle cell lymphoma
    2. aggressive (~50% of NHL): e.g. diffuse large B-cell lymphoma
    3. highly aggressive (~5% of NHL): e.g. Burkitt's lymphoma
  - T-cell NHL: e.g. mycosis fungoides (indolent TCL of the skin), peripheral T-cell lymphoma-not otherwise specified (PTCL-NOS), and anaplastic large cell lymphoma

### Clinical Features

- painless superficial lymphadenopathy, usually >1 lymph node region, rapid growth in aggressive lymphomas
- can have localized or widespread adenopathy (more common in indolent NHL)
- constitutional symptoms are less common in Hodgkin lymphoma
- cytopenia: anemia ± neutropenia ± thrombocytopenia can occur when BM is involved
- abdominal signs ± hepatosplenomegaly, retroperitoneal, and mesenteric involvement
- oropharyngeal involvement in 5-10% with sore throat and obstructive apnea
- extranodal involvement: most commonly GI tract, testes, bone, and kidney
- CNS involvement in 1% (often with HIV, testicular DLBCL or >2 extranodal sites)

## Investigations

- CBC
  - normocytic normochromic anemia
  - autoimmune hemolytic anemia rare (more common in CLL)
  - advanced disease: thrombocytopenia, neutropenia, and leukoerythroblastic blood film
- peripheral blood film may show lymphoma cells
- flow cytometry of peripheral blood only if lymphocytosis is present
- biochemistries, HIV, HBV, HCV serologies
  - increase in uric acid
  - abnormal LFTs in liver metastases
  - increased LDH (rapidly progressing disease and poor prognostic factor)
- SPEP and immunoglobulin quantitation (screen for high IgM monoclonal protein and hyperviscosity in indolent lymphomas, specifically lymphoplasmacytic lymphoma)
- staging: CT neck, chest, abdomen, pelvis, and BM biopsy
- PET imaging pre- and post-therapy to ensure post treatment remission
- diagnosed by:
  - lymph node biopsy: excisional biopsy is preferred, core biopsy (FNA is unreliable)
  - BM biopsy: sub-optimal mode of diagnosis as BM is involved in only 30% of high-grade lymphomas

## Treatment

- indolent NHL, localized disease (e.g. stage I or II)
  - radiotherapy to primary site and adjacent nodal areas
  - splenectomy: splenic marginal zone lymphoma
- goal of treatment in stage III or IV indolent NHL is symptom management
  - watchful waiting
  - radiation therapy for localized symptomatic disease
  - bendamustine plus rituximab, an anti-CD20 Ab, is superior to CHOP and rituximab (CHOP-R) for advanced stage disease
  - obinutuzumab (novel anti-CD20 Ab) is superior to rituximab for advanced stage follicular lymphoma (GALLIUM Trial)
- aggressive lymphoma: goal of treatment is curative
  - combination chemotherapy: CHOP is mainstay, plus rituximab if B-cell lymphoma
  - radiation for localized/bulky disease
  - CNS prophylaxis with high-dose methotrexate if certain sites involved (e.g. testes)
  - relapse, resistant to therapy: high dose chemotherapy, autologous SCT, CAR T-cell therapy in second relapse
- highly aggressive lymphoma
  - Burkitt lymphoma: short bursts of intensive chemotherapy; "CODOX-M" chemotherapy regimen also often used  $\pm$  IVAC with rituximab
  - CNS prophylaxis and (TLS) prophylaxis

## Complications

- hypersplenism
- infection
- autoimmune hemolytic anemia and thrombocytopenia
- vascular obstruction (from enlarged nodes)
- bowel perforation
- (TLS particularly in very aggressive lymphoma); see *Tumour Lysis Syndrome, H54*

## Prognosis

- follicular lymphoma: Follicular Lymphoma International Prognostic Index is used: age >60; >4 nodal areas; >6 cm nodal areas; elevated LDH; Lugano stage III-IV; Hb <120 g/L; high  $\beta$ -2 microglobulin; BM involvement
  - based on calculated risk, mean 5 yr survival ranges from 53-91%
  - rarely curative, typically relapsing and remitting course with risk of transformation to aggressive lymphoma such as diffuse large B-cell lymphoma
- diffuse large B-cell lymphoma: The International Prognostic Factor Index is used (5 adverse prognostic factors): age >60; Ann Arbor stage (III-IV); performance status (ECOG/Zubrod 2-4); elevated LDH; >1 extranodal site
  - based on calculated risk, mean 5 yr survival ranges from 26-73%
  - ~40% rate of cure

**NHL: Associated Conditions**  
Immunodeficiency (e.g. HIV)  
Autoimmune diseases (e.g. SLE)  
Infections (e.g. EBV)

**Common Chemotherapeutic Regimens**  
**R-CHOP:** cyclophosphamide, hydroxydoxorubicin (Adriamycin<sup>®</sup>), vincristine (Oncovin<sup>®</sup>), prednisone  
**ABVD:** adriamycin, bleomycin, vinblastine, dacarbazine  
**BEACOPP:** bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine, and prednisone

**Table 35. Characteristics of Select Non-Hodgkin Lymphomas**

	Follicular Lymphoma	DLBCL	Burkitt Lymphoma	Mantle Cell Lymphoma
Percentage of NHLs	22-30%	33%	<1% adult NHLs 30% childhood NHLs	6%
Genetic Mutation	Bcl-2 activation	Bcl-2, Bcl-6, Myc rearrangements	c-Myc activation	Overexpression of cyclin D1 (Bcl-1 activation)
Classification	Indolent	Aggressive (high-grade)	Very aggressive	Indolent
Risk Factors	Middle-age – elderly	Previous CLL (Richter's transformation: 5% CLL patients progress to DLBCL)	1. Endemic: African origin, EBV-associated 2. Sporadic: no EBV 3. HIV-related: AIDS-defining illness	Male (M:F=4:1)
Clinical Features	Widespread painless LAD* ± BM involvement Frequent transformation to aggressive lymphoma Very responsive to chemoradiation treatment	Rapidly progressive LAD and extranodal infiltration 50% present at stage I/II, 50% widely disseminated	Endemic form: massive jaw LAD "Starry-sky" histology High-risk of tumour lysis syndrome upon treatment	Often presents as stage IV with palpable LAD Involvement of GI tract (lymphomatosis polyposis), Waldeyer's Ring 5 yr survival 25% 8 symptoms present in 1/3 of patients

## Malignant Clonal Proliferations of Mature B-Cells

**Table 36. Characteristics of B-Cell Malignant Proliferation**

	CLL	Lymphoplasmacytic Lymphoma	Myeloma
Cell Type	Lymphocyte	Plasmacytoid	Plasma cell
Protein	IgM if present	IgM	IgG, A, light chain (rarely M, D, or E)
Lymph Nodes	Very common	Common	Rare
Hepatosplenomegaly	Common	Common	Rare
Bone Lesions	Rare	Rare	Common
Hypercalcemia	Rare	Rare	Common
Renal Failure	Rare	Rare	Common
Immunoglobulin Complications	Common	Rare	Rare

Rouleaux formation on peripheral blood smear, if not artifact, denotes hyperglobulinemia (but not necessarily monoclonality)

## Chronic Lymphocytic Leukemia

### Definition

- indolent disease characterized by clonal malignancy of mature B-cells

### Epidemiology

- most common leukemia in Western world
- mainly older patients; median age 70 yr
- M>F

### Pathophysiology

- accumulation of neoplastic lymphocytes in blood, BM, lymph nodes, and spleen

### Clinical Features

- 25% asymptomatic (incidental finding)
- 5-10% present with B-symptoms ( $\geq 1$  of: unintentional weight loss  $\geq 10\%$  of body weight within previous 6 mo, temperature  $>38^\circ\text{C}$ , or night sweats for  $\geq 2$  wk without evidence of infection), extreme fatigue
- lymphadenopathy (50-90%), splenomegaly (25-55%), hepatomegaly (15-25%)
- immune dysregulation: autoimmune hemolytic anemia (DAT positive), ITP, hypogammaglobulinemia  $\pm$  neutropenia
- BM failure: late, secondary to marrow involvement by CLL cells

### Investigations

- CBC: clonal population of B lymphocytes  $>5 \times 10^9/\text{L}$
- peripheral blood film
  - lymphocytes are small and mature
  - smudge cells
- flow cytometry characteristics of peripheral blood
  - CD5, CD20dim, CD23, light chain restriction
- cytogenetics: FISH (dictates response to therapy and prognosis) imaging must be done post-therapy to ensure post treatment remission

- BM aspirate
  - infiltration of marrow by lymphocytes in 4 patterns: nodular (10%), interstitial (30%), diffuse (35%, worse prognosis), or mixed (25%)

### Natural History and Treatment

- natural history: indolent and incurable; most cases show slow progression
- small minority present with aggressive disease; usually associated with chromosomal abnormalities (e.g. p53 deletion)
- first line therapy is dictated by cytogenetic status and patient co-morbidities
  - observation if early, stable, asymptomatic
    - treatment options vary by region; commonly fludarabine + cyclophosphamide + rituximab (FCR) in fit patients age <65, with normal creatinine clearance and lack of 17p deletion/p53 disease
    - chlorambucil (or venetoclax + obinutuzumab in the elderly)
    - ibrutinib or acalabrutinib in patients with unmutated IgVH and/or 17p deletion/p53 positivity
  - autoimmune phenomena: corticosteroids, rituximab
  - radiotherapy for isolated bulky nodes
- molecular therapies
  - idelalisib – PI3K inhibitor
  - ibrutinib, acalabrutinib – BTK (Bruton's tyrosine kinase) inhibitor
  - venetoclax – Bcl-2 inhibitor

### Prognosis

- 9 yr median survival, but varies greatly
- prognosis: Rai staging, Binet staging or Revised CLL International Prognostic Index (includes age >65, Rai/Binet stage, B2M, IGHV mutation status, 17p del or TP53 mutation positivity)

### Complications

- BM failure
- immune complications: AIHA, ITP, immune deficiency (hypogammaglobulinemia, and impaired T-cell function)
- polyclonal or monoclonal gammopathy (often IgM)
- hyperuricemia with treatment
- 5% undergo Richter's transformation: aggressive transformation to diffuse large B-cell lymphoma (see Table 35, H50)

## Multiple Myeloma

### Definition

- neoplastic clonal proliferation of plasma cells producing a monoclonal immunoglobulin resulting in end organ dysfunction
- usually a single clone of plasma cells, although biclonal myeloma also occurs; rarely non-secretory
- preceded by smoldering myeloma or MGUS

### Epidemiology

- incidence 3 in 100000, most common plasma cell malignancy
- increased frequency with age; median age of diagnosis is 68 yr; M>F

### Pathophysiology

- malignant plasma cells secrete monoclonal Ab
  - 95% produce M protein (monoclonal Ig = identical heavy chain + identical light chain, or light chains only)
    - IgG 50%, IgA 20%, IgD 2%, IgM 0.5%
    - 15-20% produce free light chains or light chains alone found in either:
      - serum has an increase in the quantity of either kappa or lambda light chain (with an abnormal kappa:lambda ratio)
      - urine has Bence-Jones protein
  - <5% are non-secretors

### Clinical Features and Complications

- bone disease: pain (usually back), bony tenderness, pathologic fractures
  - lytic lesions are classical (skull, spine, proximal long bones, ribs)
  - increased bone resorption secondary to osteoclast activating factors such as PTHrP
- anemia: weakness, fatigue, pallor
  - secondary to BM suppression
- weight loss
- infections
  - usually *S. pneumoniae* and Gram-negatives
  - secondary to suppression of normal plasma cell function
- hypercalcemia: N/V, confusion, constipation, polyuria, and polydipsia
  - secondary to increased bone turnover

Smudge cells are artifacts of damaged lymphocytes from slide preparation

Multiple Myeloma

### SUM CRAB

Sixty percent plasma cells in BM specimen  
 Light chain ratio >100  
 MRI lytic lesion >0.5 cm  
 Calcium >2.80 mmol/L  
 Renal failure (Cr >176 mmol/L)  
 Anemia  
 Bony lesions (lytic lesions or osteoporosis felt to be caused by myeloma)

### Amyloid

- The general term for a variety of proteinaceous materials that have a similar structural organization and are abnormally deposited in tissues
- Found in a variety of clinical disorders and can cause systemic (e.g. MM (light chains)) or localized amyloidosis (e.g. Alzheimer disease (Aβ amyloid))

- renal disease/renal failure
  - most frequently causes cast nephropathy (see [Nephrology, NP35](#))
- bleeding
  - secondary to thrombocytopenia, may see petechiae, purpura
  - can also be caused by acquired VWD
- extramedullary plasmacytoma
  - soft tissue mass composed of monoclonal plasma cells, purplish colour
- hyperviscosity: may manifest as headaches, stroke, angina, and MI
  - rare in MM as secondary to increased viscosity caused by IgM protein (more common in WM/LPL)
- amyloidosis
  - accumulation of insoluble fibrillar protein (Ig light chain) in tissues; can cause infiltration of any organ system: cardiac infiltration – diastolic dysfunction, cardiac arrhythmias, syncope, sudden death; GI involvement – malabsorption, beefy large or laterally scalloped tongue; neurologic involvement – orthostatic hypotension, carpal tunnel syndrome
  - may cause Factor X deficiency if fibrils bind Factor X → bleeding (raccoon eyes)
- neurologic disease: muscle weakness, pain, and paresthesias
  - radiculopathy caused by vertebral fracture and extramedullary plasmacytoma
  - spinal cord compression (10-20% of patients) is a medical emergency

### Investigations

- CBC
  - normocytic anemia, thrombocytopenia, and leukopenia
  - rouleaux formation on peripheral film
- biochemistry
  - increased  $\text{Ca}^{2+}$ , increased ESR, decreased anion gap, increased Cr, albumin,  $\beta_2$ -microglobulin, and LDH (as part of staging), and proteinuria (24 h urine collection)
- monoclonal proteins
  - SPEP: demonstrates monoclonal protein spike in serum in 80% (i.e. M protein)
  - UPEP: demonstrates light chains in urine = Bence-Jones protein (15% secrete only light chains)
  - immunofixation: demonstrates M protein and identifies Ig type; also identifies light chains
  - serum free light chain quantification: kappa and lambda light chains, calculated ratio
- BM aspirate and biopsy
  - often focal abnormality, greater than 10% plasma cells, abnormal morphology, clonal plasma cells; send for fluorescence in situ hybridization (FISH) or cytogenetics (prognostic implications)
- skeletal series (x-rays), MRI if symptoms of cord compression, PET imaging to pick up lytic lesions in asymptomatic MM
  - presence of lytic lesions and areas at risk of pathologic fracture
  - bone scans are not useful since they detect osteoblast activity
- elevated  $\beta_2$ -microglobulin and LDH, and low albumin, are poor prognosticators
  - HBV surface and core Abs, and HBV surface antigen

### Diagnosis

- International Myeloma Working Group Criteria ("SLiM CRAB"):
  - $\geq 60\%$  clonal plasma cells on BM examination
  - light chain ratio (free, involved/uninvolved) of  $\geq 100$  in the blood (involved must be at least 100 mg/L)
  - MRI with more than one bone lesion ( $\geq 5$  mm)
  - CRAB – presence of end-organ damage related to plasma cell dyscrasia, such as:
    - increased serum  $\text{Ca}^{2+}$
    - renal failure
    - anemia
    - lytic bone lesions

### Treatment

- non-curative
- treatment goals
  - improvement in quality of life (improve anemia, reverse renal failure, prevent fractures)
  - prevention of progression and complications
  - increase overall survival
- autologous transplant if  $\leq 70$  yr
  - usually preceded by 4-6 mo of cytoreductive therapy: steroid based with novel agents (i.e. IMiDs or PIs)
- transplant ineligible if  $>70$  yr or comorbidities
  - pending on patient comorbidities can include a combination of: melphalan, prednisone, cyclophosphamide, PI (i.e. bortezomib), IMiDs (revlimid), anti-CD38 agents (e.g. daratumumab)
- supportive management
  - bisphosphonates for those with osteopenia or lytic bone lesions (requires renal dosing)
  - local XRT for bone pain, spinal cord compression
  - kyphoplasty for vertebral fractures to improve pain relief and regain height
  - treat complications: hydration for hypercalcemia and renal failure, bisphosphonates for severe hypercalcemia, prophylactic antibiotics, EPO for anemia, and DVT prophylaxis
- all patients will relapse; choice of retreatment regimen depends on duration of remission, organ involvement, patient's comorbidities, and preferences

Routine urinalysis will not detect light chains as dipstick detects albumin. Need sulfosalicylic acid or 24 h urine protein for immunofixation or electrophoresis

#### Light Chain Disease

- 15% of MM produce only light chains
- Renal failure is a major problem
- Kappa > lambda light chain has better prognosis

#### Serum Free Light Chain Ratio is an Independent Risk Factor for Progression in MGUS

Blood 2005;106:812-817

**Purpose:** To determine whether the presence of monoclonal free kappa or lambda immunoglobulin light chains in MGUS increases the risk of progression to malignancy.

**Methods:** Retrospective study with median follow-up of 15 yr. Baseline serum samples obtained from 1383 MGUS patients seen at the Mayo Clinic between 1960-1994. 1148 baseline samples were obtained within 30 d of diagnosis.

**Results:** Malignant progression had occurred in 87 (7.6%) patients. In 379 (33%) patients, an abnormal serum free light chain (FLC) ratio was detected. There was a significantly higher risk of progression in patients with an abnormal FLC ratio relative to patients with a normal ratio (hazard ratio, 3.5; 95% CI 2.3-5.5;  $P < 0.001$ ). This finding was independent of the size and type of the serum monoclonal (M) protein. In high-risk MGUS patients (abnormal serum FLC ratio, non-IgG MGUS, high serum M protein level [ $>1.5$  gm/dL]), the risk of progression at 20 yr was 58% compared to 37% in high-intermediate-risk MGUS (two risk factors), 21% low-intermediate risk (with one risk factor) and 5% low-risk (no risk factors).

**Conclusions:** The presence of an abnormal FLC ratio is a clinically and statistically significant predictor of progression in MGUS. The low-risk subset of patients with MGUS accounts for 40% of all MGUS patients and have a small lifetime risk of progression, thus less follow-up can be justified.

**Prognosis**

- International Staging System (ISS) ( $\beta$ 2-microglobulin and albumin) used to stage and estimate prognosis
- revised ISS for risk stratification: combination of original ISS, cytogenetic profile (i.e. p53 mutation associated with poor survival and resistance to chemotherapy), and LDH
- median survival based on stage, usually 5-10 yr

**Monoclonal Gammopathy of Unknown Significance****Definition**

- presence of M protein in serum in absence of any clinical or laboratory evidence of a plasma cell dyscrasia or lymphoproliferative disorders
  - incidence: 0.15% in general population, 5% of people >70 yr
  - asymptomatic

**Diagnosis**

- presence of a serum monoclonal protein (M protein) at a concentration <30 g/L
- <10% plasma cells in BM
- absence of SLiM CRAB
- 0.3-1% of patients develop a hematologic malignancy each yr
  - patients with M protein peak  $\geq$ 15 g/L, abnormal free light chain ratio, or patients with IgA or IgM MGUS are at higher risk of malignant transformation
  - patients with abnormal serum free light chains ratio are at increased risk of malignant transformation
- monitor with history q6-12 mo, physical, CBC, Cr, calcium, albumin, LDH, and SPEP (considered pre-malignant)

**Lymphoplasmacytic Lymphoma****Definition**

- LPL/Waldenström's macroglobulinemia
- proliferation of lymphoplasmacytoid cells
  - presence of monoclonal IgM paraprotein

**Clinical Features**

- chronic disorder of elderly patients; median age 64 yr
- symptoms: weakness, fatigue, bleeding (oronasal), weight loss, recurrent infections, dyspnea, CHF (triad of anemia, hyperviscosity, plasma volume expansion), neurological symptoms, peripheral neuropathy, and cerebral dysfunction
- signs: pallor, splenomegaly, hepatomegaly, lymphadenopathy, and retinal lesions
- key complication to avoid: hyperviscosity syndrome
  - because IgM (unlike IgG) are large and confined mainly to intravascular space

**Investigations and Diagnosis**

- BM shows plasmacytoid lymphocytes
- bone lesions usually not present
- blood work rarely shows hypercalcemia
- cold hemagglutinin disease possible: Raynaud's phenomenon, hemolytic anemia precipitated by cold weather
- normocytic anemia, rouleaux, and high ESR if hyperviscosity not present
- HBV, HCV serologies (note: can be associated with HCV; HCV eradication can put LPL into remission)

**Treatment**

- chemotherapy + rituximab (most commonly bendamustine + rituximab)
- if HCV positive – treat HCV prior to a trial of chemotherapy
- corticosteroids
- plasmapheresis for hyperviscosity: acute reduction in serum IgM

Waldenström's macroglobulinemia accounts for 85% of all cases of hyperviscosity syndrome

**Complications of Hematologic Malignancies****Hyperviscosity Syndrome****Definition**

- refers to clinical sequelae of increased blood viscosity (when relative serum viscosity >5-6 units), resulting from increased circulating serum Igs or from increased cellular blood components in hyperproliferative disorders (e.g. multiple myeloma, leukemia, PV)
- Waldenström's macroglobulinemia accounts for 85% of cases

**Clinical Features**

- hypervolemia causing: CHF, headache, lethargy, dilutional anemia
- CNS symptoms due to decreased cerebral blood flow: headache, vertigo, ataxia, and stroke
- retina shows venous engorgement and hemorrhages
- bleeding diathesis
  - due to impaired platelet function, absorption of soluble coagulation factors (e.g. nasal bleeding, oozing gums)
- ESR usually very low

**Treatment**

- plasmapheresis, chemotherapy

**Tumour Lysis Syndrome****Definition**

- group of metabolic complications that result from spontaneous or treatment-related breakdown of cancer cells
- more common in diseases with large tumour burden and high proliferative rate (high grade lymphoma, acute leukemia)

**Clinical Features**

- metabolic abnormalities
  - cells lyse, releasing  $K^+$ , uric acid,  $PO_4^{3-}$  (increased levels)
  - $PO_4^{3-}$  binds  $Ca^{2+}$  (decreased  $Ca^{2+}$ )
- complications
  - lethal cardiac arrhythmia (increased  $K^+$ )
  - acute kidney injury (formerly known as renal failure) see [Nephrology, NP20](#)

**Treatment**

- prevention
  - aggressive IV hydration
  - alkalinization not recommended due to risk of calcium phosphate or xanthine precipitation in renal tubules
  - allopurinol (prevents uric acid accumulation) or rasburicase (lowers existing uric acid)
  - correction of pre-existing metabolic abnormalities
- dialysis

**Blood Products and Transfusions****Blood Products**

- RBCs, platelets, and coagulation factors (FP, cryoprecipitate, factor concentrates) are available for transfusion
- donated blood (1 U = 450-500 mL) is fractionated into these various components
  - centrifugation separates whole blood into RBCs and plasma
  - plasma is further fractionated
    - need to pool multiple units of platelets and WBCs to obtain therapeutic amounts
    - FP (previously known as FFP) is plasma frozen within 24 h of collection
    - cryoprecipitate is the high MW precipitate generated when FP is thawed at low temperatures
  - single donor platelets and plasma can also be obtained by apheresis donations

**Specialized Products**

- irradiated blood products
  - prevent proliferation of donor T-cells in recipients at risk of GVHD
  - used for patients with severe T-cell immunodeficiency, on purine analogue chemotherapy, with Hodgkin lymphoma, candidates for BM transplant, or receiving directed transfusions from first-degree relatives, HLA-matched products, or intrauterine transfusions
- CMV-negative blood products
  - seronegative pregnant women
  - intrauterine transfusions

**Red Blood Cells****Packed Red Blood Cells**

- stored at 4°C
- shelf life is 42 d after collection
- infuse each unit over 2 h (max of 4 h)

**Blood Groups**

Group	Antigen (on RBC)	Antibody (in serum)
O	H	Anti-A, anti-B
A	A	Anti-B
B	B	Anti-A
AB	A and B	Nil

In Canada, blood products are leukodepleted via filtration immediately after donation; therefore it is considered:

- Low in lymphokines, resulting in a lower incidence of febrile nonhemolytic transfusion reactions
- CMV safe (because CMV is found in leukocytes)

1 unit of pRBC will increase Hb by approximately 10 g/L

**Indications for Packed RBC Transfusion**

- Hb <70 g/L; this may change as per patient's tolerance or symptoms
  - maintain Hb between 70 and 90 g/L during active bleeds
- consider maintaining a higher Hb for patients with:
  - CAD/unstable coronary syndromes
  - uncontrolled, unpredictable bleeding

**Selection of Red Cells for Transfusion**

- when anticipating an RBC transfusion, the following should be ordered:
  - group and screen: determines the blood group and Rh status of the recipient as well as the presence of auto- or alloantibodies against major/minor blood group antigens in the patient's plasma
  - cross-match: involves mixing the recipient's blood with potential donor blood and looking for agglutination (takes 30-45 min)
- when blood is required, several options are available
  - 1st-line: fully crossmatched blood, electronic crossmatch is becoming more widely used (not always available in emergency situations)
  - 2nd-line: donor blood of the same group and Rh status as the recipient
  - 3rd-line: O- blood for females of reproductive age; O + blood for all others

**American Society of Hematology  
Choosing Wisely Recommendation**  
Do not transfuse more than the minimum number of RBC units necessary to relieve symptoms of anemia or to return the patient to a safe Hb range (70-80 g/L) in stable non-cardiac patients

**Platelets**

**Table 37. Platelet Products**

Product	Indication
Random Donor (Pooled)	Thrombocytopenia with bleeding
Single Donor Platelets	Potential BMT recipients. Refractory to pooled platelets
HLA Matched Platelets	Refractory to pooled or single donor platelets, presence of HLA Abs

- stored at 20-24°C
- random donor platelets come in a pool of 4 units; while a unit of apheresis platelets comes from a single donor
- 1 platelet pool should increase the platelet count by  $\geq 15 \times 10^9/L$
- if an increase in the platelet count is not seen post-transfusion: autoantibodies (i.e. ITP), alloantibodies (Anti-HLA or Anti-HPA), consumption (bleeding, sepsis, DIC), or hypersplenism may be present

**Table 38. Indications for Platelet Transfusion**

Plt ( $\times 10^9/L$ )	Indications
<10	Non-immune thrombocytopenia
<20	Procedures not associated with significant blood loss
<50	Procedures associated with blood loss or major surgery (>500 mL estimated blood loss)
<100	Pre-neurosurgery or head trauma
Any	Platelet dysfunction (or antiplatelet agents) and marked bleeding

**Relative Contraindications of Platelet Transfusion**

- TTP, HIT, post-transfusion purpura, and HELLP

**Coagulation Factors**

**Table 39. Coagulation Factor Products**

Product	Indication
FP	Depletion of multiple coagulation factors (e.g. sepsis, DIC, dilution, TTP/HUS, liver disease), emergency reversal of life-threatening bleeding secondary to warfarin overdose when factor concentrates are not available
Cryoprecipitate (enriched fibrinogen, VWF, VIII, XIII)	Hemophilia A (Factor VIII deficiency) and von Willebrand disease – use in emergencies when specific factor concentrates are not available Hypofibrinogenemia
Fibrinogen Concentrate (FC)	Hypofibrinogenemia
Humate P or Wilate	von Willebrand disease and Hemophilia A
Factor VIII concentrate	Factor VIII deficiency (Hemophilia A)
Factor IX concentrate	Factor IX deficiency (Hemophilia B)
Recombinant factor VIIa	Factor VII deficiency with bleeding/surgery, Hemophilia A or B with inhibitors, Glanzmann's thrombasthenia
Prothrombin complex concentrate; PCC (Octaplex®, Beriplex®)	Reversal of warfarin therapy or vitamin K deficiency in bleeding patient or in patient requiring urgent (<6 h) surgical procedure, urgent non-specific "reversal" of direct Xa inhibitors
Activated prothrombin complex concentrate; aPCC (FEIBA)	Hemophilia A or B with inhibitors

See Landmark Hematology Trials for more information on the FOCUS trial. It details the efficacy of liberal or restrictive transfusion in high-risk patients after hip surgery

**Group & Screen vs. Cross-Matching:**  
G&S: ABO group + Rh factor  
Cross-Matching: match recipient's serum with donor's packed RBC or Abs

## Acute Blood Transfusion Reactions

### IMMUNE

#### Acute Hemolytic Transfusion Reactions

- ABO incompatibility resulting in intravascular hemolysis secondary to complement activation, occurs immediately after transfusion
- most commonly due to incorrect patient identification
- risk per unit of blood is  $<1/40000$
- presentation: fever, chills, hypotension, back or flank pain, dyspnea, hemoglobinuria
- acute renal failure ( $<24$  h) and DIC
- treatment
  - stop transfusion
  - notify blood bank and check for clerical error
  - send new specimen to blood bank for repeat testing and draw hemolysis labs: CBC, bilirubin, LDH, reticulocytes, DAT
  - maintain BP with vigorous IV fluids  $\pm$  inotropes
  - maintain urine output with diuretics, crystalloids, dopamine

#### Febrile Nonhemolytic Transfusion Reactions

- due to alloantibodies to WBC, platelets or other donor plasma antigens, and release of cytokines from blood product cells
- occurs within 6 h of transfusion
- risk per unit of blood is  $1/100$  (minor),  $1/10000$  to  $40000$  (severe)
- presents with fever  $\pm$  rigors, facial flushing, headache, myalgia
- look for serious symptoms of shaking, chills/rigors, hypotension, tachycardia, anxiety, dyspnea, back/chest pain, N/V
- treatment
  - rule out hemolytic reaction or infection
  - if temperature  $<39^{\circ}\text{C}$  and no serious symptoms, continue with transfusion but decrease rate and give antipyretics
  - if temperature  $\geq 39^{\circ}\text{C}$  or presence of serious symptoms, stop transfusion, investigate the reaction, and start supportive measures

#### Allergic Nonhemolytic Transfusion Reactions

- alloantibodies (IgE) to proteins in donor plasma result in mast cell activation and release of histamine
- occurs mainly in those with history of multiple transfusions or multiparous women
- risk per unit of blood is  $1/100$
- presents mainly as urticaria and occasionally with fever
- can present as anaphylactoid reaction with bronchospasm, laryngeal edema, and hypotension ( $1/40000$ )
- can occur in some IgA deficient patients with anti-IgA
- treatment
  - mild: slow transfusion rate and give diphenhydramine
  - moderate to severe: stop transfusion, give IV diphenhydramine, steroids, epinephrine, IV fluids, and bronchodilators

#### Transfusion-Related Acute Lung Injury

- new-onset acute lung injury that occurs during transfusion or within 6 h of transfusion completion
  - profound hypoxemia ( $\text{PaO}_2/\text{FiO}_2 < 300$  mmHg)
  - bilateral pulmonary edema on imaging
  - no clinical evidence of left atrial hypertension or if present, judged not to be the main contributor
- pathogenesis uncertain; perhaps due to binding of donor Abs to WBC of recipient and release of mediators that increase capillary permeability in the lungs
- typically occurs 2-4 h post-transfusion and resolves in 24-72 h
- risk per unit of blood is  $1/10000$ 
  - is currently the leading cause of transfusion-related morbidity and mortality
- treatment: supportive therapy (oxygen)
- inform blood bank; patient and donor testing will be arranged

### NONIMMUNE

#### Transfusion-Associated Circulatory Overload

- due to impaired cardiac function and/or excessively rapid transfusion
- presentation: dyspnea, orthopnea, hypertension, tachycardia, crackles at base of lungs, and increased venous pressure
- incidence:  $1/100$
- risk factors: age  $>70$  yr, heart failure, history of MI, renal failure, positive fluid balance
- treatment: stop transfusion, give diuretics, and oxygen. Transfuse at lower rate  $\pm$  diuretics to prevent

#### DDx of Post-Transfusion Fever

- Acute hemolytic transfusion reaction
- Febrile non-hemolytic transfusion reaction (FNHTR)
- Bacterial contamination
- Allergy

#### DDx of Post-Transfusion Dyspnea

- Transfusion-associated circulatory overload (TACO)
- Transfusion-related acute lung injury (TRALI)
- Allergy (bronchospasm/anaphylaxis)

**Bacterial Infection**

- Gram-positive: *S. aureus*, *S. epidermidis*, *Bacillus cereus*
- Gram-negative: *Klebsiella*, *Serratia*, *Pseudomonas*, *Yersinia*
- overall risk is 1/100000 for RBC and 1/10000 for platelets
- never store blood >4 h after bag has left blood bank
- treatment: stop transfusion, blood cultures, IV antibiotics, fluids

**Hyperkalemia**

- due to  $K^+$  release from stored RBC
- risk increases with storage time and if blood is irradiated; decreases with fresh blood
- occurs in 5% of massively transfused patients
- treatment: see [Nephrology](#), NP14

**Citrate Toxicity**

- occurs with massive transfusion and in patients with liver disease – patients are unable to clear citrate from blood
- citrate binds to  $Ca^{2+}$  and causes signs and symptoms of hypocalcemia and exacerbates coagulopathy
- treatment: IV calcium gluconate 1 g

**Dilutional Coagulopathy**

- occurs with massive transfusion (>10 units)
- pRBC contains no coagulation factors, fibrinogen, cryoprecipitate, or platelets
- treatment: FP, cryoprecipitate, and platelets

**Delayed Blood Transfusion Reactions****IMMUNE****Delayed Hemolytic**

- due to alloantibodies to minor antigens such as Rh, Kell, Duffy, and Kidd
- level of Ab at time of transfusion is too low to be detected and to cause hemolysis; Ab levels increase later due to secondary stimulus and causes extravascular hemolysis
- occurs 3-14 d after transfusion
- presentation: anemia and mild jaundice
- treatment: no specific treatment required; important to note for future transfusion
- N.B. serologic transfusion reactions are the development of alloantibodies in the absence of frank hemolysis

**Transfusion-Associated Graft Versus Host Disease**

- transfused T-lymphocytes recognize and react against "host" (recipient)
- occurs 4-30 d following transfusion
- most patients already have severely impaired immune systems (e.g. Hodgkin lymphoma or leukemia)
- presentation: fever, diarrhea, liver function abnormalities, and pancytopenia
- can be prevented by giving irradiated blood products

**NONIMMUNE****Iron Overload**

- due to repeated transfusions over long period of time (e.g.  $\beta$ -thalassemia major)
- can cause secondary hemochromatosis
- treatment: iron chelators or phlebotomy if no longer requiring blood transfusion and not anemic

**Viral Infection Risk**

- HBV 1/7000000
- HCV 1/12000000
- HIV 1/20000000
- Human T-lymphotropic virus (HTLV) 1/600000000
- other infections include EBV, CMV, WNV (West Nile virus)

**Allogeneic SCT GVHD**

To reduce risk of GVHD development after allogeneic SCT, administer inhibitors of T-cell activation, including cyclosporin A or tacrolimus

# Common Medications

## Antiplatelet Therapy

• see Figure 12a, H27

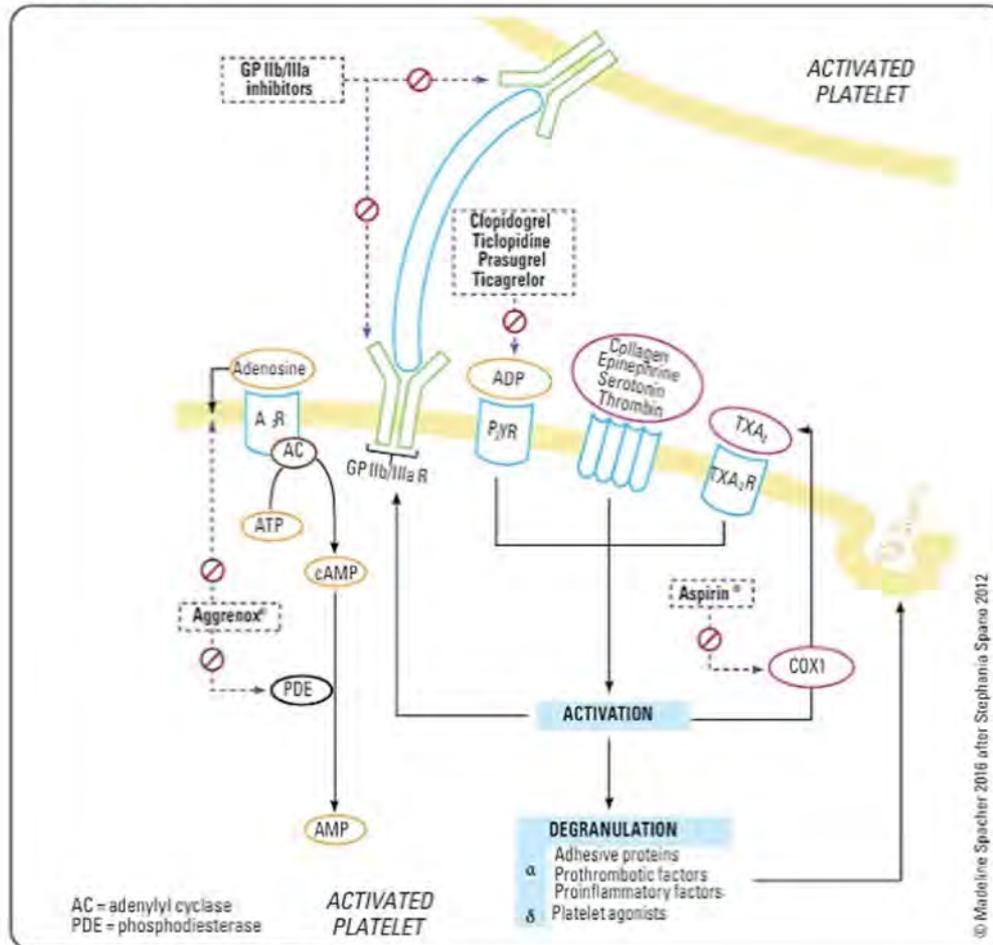

Figure 17. Mechanisms of action of antiplatelet therapy

Table 40. Antiplatelet Therapy

	Mechanism of Action	Typical Dose/ Route of Administration	Onset/Peak/ Duration	Specific Side Effects	Remarks
<b>Aspirin® (ASA)</b>	Irreversibly acetylates COX, inhibiting thromboxane A2 (TXA2) synthesis, thus inhibiting platelet aggregation	Single loading 200-300 mg PO, followed by dose of 75-100 mg PO daily	Onset: 5-30 min Peak: 0.25-3 h Duration: 3-6 h (platelet inhibition lasts 7-10 d)	GI ulcer/bleeding Tinnitus Bronchospasm Angioedema Reye's syndrome in pediatric patients	Indicated for stroke/MI prophylaxis Reduce incidence of recurrent MI Decrease mortality in post-MI patients Contraindicated in patients with GI ulcers
<b>Aggrenox® (ASA + Dipyridamole)</b>	Dipyridamole increases intracellular cAMP levels, which inhibits TXA2 synthesis, leading to decreased platelet aggregation	1 capsule PO BID	Peak: 75 min	H/A Dyspepsia N/V Abdominal pain Cardiac failure Hemorrhoids	More effective than ASA in secondary prevention of stroke Dipyridamole potentiates antiplatelet action of ASA
<b>Clopidogrel (Plavix®)</b>	Irreversibly inhibits ADP binding to platelets, thus decreased platelet aggregation	Loading dose 300 mg PO, then 75 mg daily	Onset: 2 h (loading dose) Peak: 6 h (loading dose) Duration: 5 d	URI Chest pain H/A Flu-like syndrome Depression UTI GI hemorrhage Pancytopenia May cause TTP	Prevention of cardiovascular events in high-risk patients Clopidogrel is a prodrug requiring two-step activation to active metabolite CYP2C19 poor metabolizers have diminished response to clopidogrel Caution with hepatic/renal impairment
<b>Prasugrel (Effient®)</b>	Same as clopidogrel	Loading dose 60 mg, then 5-10 mg PO daily	Onset: 30 min (loading dose) Peak: 4 h (loading dose) Duration: 5-10 d	Dizziness H/A Nervousness Blurry vision	Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients Higher potency compared to clopidogrel No significant drug-drug interactions, although more data is required

Table 40. Antiplatelet Therapy

	Mechanism of Action	Typical Dose/ Route of Administration	Onset/Peak/ Duration	Specific Side Effects	Remarks
<b>Ticagrelor (Brilinta<sup>®</sup>)</b>	Reversibly inhibits ADP binding to platelets	Loading dose 180 mg, then 90 mg PO BID	Onset: 30 min (loading dose) Peak: 1.5 h for prodrug, 2.5 h for active metabolite	Difficulty or laboured breathing Shortness of breath Tightness in chest Dizziness	Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients Higher potency compared to clopidogrel Ticagrelor does not need metabolic activation to serve its antiplatelet function Drug-drug interactions with CYP3A4 inhibitors and inducers Prasugrel is a prodrug requiring metabolic activation mainly by CYP3A5 and CYP2B6
<b>Glycoprotein IIb/IIIa Inhibitors Reopro<sup>®</sup> (abciximab), Integrilin<sup>®</sup> (eptifibatid)</b>	Blocking GPbII/IIIa receptor inhibits fibrinogen and VWF binding, leading to decreased platelet aggregation	Variable IV	Variable	Hypotension Back pain N/V Chest pain Abdominal pain Thrombocytopenia	Used most commonly in cardiac catheterization Contraindicated in PUD Monitoring aPTT/activated clotting time

## Anticoagulant Therapy

Table 41. Anticoagulant Therapy

	Mechanism of Action	Dose/Route of Administration	Onset/Peak/ Duration	Reversing Agent	Monitoring	Specific Side Effects	Remarks
<b>Heparin</b>	Inhibition of Factor Xa and Factor IIa, mediated via antithrombin	Variable, depends on indication; can be used IV or SC	Onset: Immediate (IV); 20-30 min (SC)	Protamine sulfate	aPTT (intrinsic pathway), UFH (anti-Xa) levels	Hemorrhage HIT Increased liver enzymes	Pregnancy: safe (does not cross placenta)
<b>Warfarin</b>	Vitamin K antagonist; inhibits production of Factors II, VII, IX, X, proteins C and S	Individualized dosing by monitoring PT/INR; PO	Onset: 24-72 h Peak: 5-7 d Duration: 2-5 d	Vitamin K PCC FP	INR; maintain 2-3 (2.5-3.5 for certain mechanical valves)	Hemorrhage Cholesterol embolism syndrome Intraocular hemorrhage	Pregnancy: not used, can cross placenta (teratogenic)
<b>LMWH (enoxaparin, dalteparin, tinzaparin)</b>	Mainly Factor Xa inhibition, some FIIa inhibition, both mediated via antithrombin	Variable, weight-based dose, depends on indication; SC/IV	Onset: 1-2 h Peak: 3-5 h Duration: 12-24 h	Partial reversibility with protamine sulfate	Anti-Xa levels in pediatrics, extremes of weight, or renal insufficiency	Hemorrhage Fever Increased liver enzymes <1% HIT	Higher bioavailability than heparin Can accumulate in patients with low CrCl (<30 mL/min) Standard treatment of VTE in pregnancy and patients with malignancy
<b>Fondaparinux</b>	Selective Factor Xa inhibition, mediated via antithrombin	Variable SC daily	Onset: 2 h Peak: 2-3 h	Not reversible	None	Anemia Fever Nausea Rash	Long half-life (17-21 h) Contraindicated in renal failure
<b>Rivaroxaban</b>	Direct Factor Xa inhibitor	Variable, depends on indication; PO	Onset: 1-3 h Peak: 1-3 h	Andexanet α	Anti-Xa levels validated for rivaroxaban may be used to detect presence of drug only	Syncope GI hemorrhage Menorrhagia Gastroenteritis Cough	Indicated for treatment of acute VTE, secondary VTE prevention, thromboprophylaxis in orthopaedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl >30 mL/min; must be taken with food; contraindicated in mechanical heart valves
<b>Apixaban</b>	Direct Factor Xa inhibitor	PO BID	Onset: 1-3 h Peak: 1-3 h	Andexanet α	Anti-Xa levels validated for apixaban may be used to detect presence of drug only	Hemorrhage Nausea Anemia	Indicated for treatment of acute VTE, secondary VTE prevention, thromboprophylaxis in orthopaedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl >25 mL/min; contraindicated in mechanical heart valves
<b>Edoxaban</b>	Direct Factor Xa inhibitor	PO daily	Onset: 1-2 h Peak: 1-2 h	Andexanet α	Not typically available	Hemorrhage Rash	Indicated for treatment of acute VTE, secondary VTE prevention, stroke prophylaxis in non-valvular AFib; contraindicated in mechanical heart valves; dose reduction in renal insufficiency, avoid in CrCl <15 mL/min
<b>Argatroban</b>	Direct thrombin inhibitor	Variable IV	Onset: 5-10 min Duration: 20-40 min	Not reversible	aPTT	Dyspnea Hypotension Fever	Indicated for treatment of heparin-induced thrombocytopenia, PCI; contraindicated in mechanical heart valves
<b>Dabigatran</b>	Direct thrombin inhibitor	150 mg PO BID	Onset: 1-3 h Peak: 1-3 h	Idarucizumab	Dilute thrombin time may be used to detect presence of drug only; TT also sensitive for drug presence	GI upset Dyspepsia	Indicated for treatment of acute VTE (after 5-10 d parenteral therapy), secondary VTE prevention, thromboprophylaxis in orthopaedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl >30 mL/min; should be stored in original packaging; contraindicated in mechanical heart valves

### Adverse Reactions to Heparin

- hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- HIT a hematologic emergency associated with venous or arterial thrombosis (see Table 22, H30)
- osteoporosis: with long-term use

### Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)

- increased bioavailability compared to unfractionated heparin
- increased duration of action
- SC route of administration

- do not need to monitor aPTT
- adverse reactions less common than UFH
- patients with renal failure (CrCl <30 mL/min) can accumulate LMWH, therefore may need to adjust dose
- only partially reversible with protamine sulfate
- HIT is less common

**Table 42. Recommended Management of a Supratherapeutic INR**

INR	Bleeding Present	Recommended Action
>Therapeutic to 4.5	No	Lower warfarin dose or omit a dose and resume warfarin at a lower dose when INR is in therapeutic range or no dose reduction needed if INR is minimally prolonged
>4.5 to 10.0	No	Omit the next 1-2 doses of warfarin, monitor INR more frequently and resume treatment at a lower dose when INR is in therapeutic range OR omit a dose and administer oral vitamin K 1-2.5 mg in patients with increased risk of bleeding
>10.0	No	Hold warfarin and administer oral vitamin K 2.5 to 5 mg; monitor INR more frequently and administer more vitamin K as needed; resume warfarin at a lower dose when INR is in therapeutic range
Any	Serious or life threatening	Hold warfarin and administer vitamin K 10 mg by slow IV infusion; supplement with four-factor prothrombin complex concentrate; monitor and repeat as needed

## Chemotherapeutic and Biologic Agents Used in Oncology

**Table 43. Selected Chemotherapeutic and Biologic Agents**

Class	Example	Mechanism of Action or Target
<b>Alkylating Agent</b>	chlorambucil, cyclophosphamide, melphalan (nitrogen mustards) carboplatin, cisplatin dacarbazine, procarbazine busulfan bendamustine	Damage DNA via alkylation of base pairs Leads to cross-linking of bases, abnormal base-pairing, DNA breakage
<b>Antimetabolites</b>	methotrexate (folic acid antagonist) 6-mercaptopurine, fludarabine (purine antagonist) 5-fluorouracil (5-FU) (pyrimidine antagonist) hydroxyurea cytarabine	Inhibit DNA synthesis
<b>Antibiotics</b>	adriamycin (anthracycline) bleomycin mitomycin C daunorubicin	Interfere with DNA and RNA synthesis
<b>Taxanes</b>	paclitaxel docetaxel	Stabilize microtubules against breakdown once cell division complete
<b>Vinca-alkaloids</b>	vinblastine vincristine vinorelbine	Inhibit microtubule assembly (mitotic spindles), blocking cell division
<b>Topoisomerase Inhibitors</b>	irinotecan, topotecan (topo I) etoposide (topo II)	Interfere with DNA unwinding necessary for normal replication and transcription
<b>Steroids</b>	prednisone dexamethasone	Immunosuppression
<b>Purine Analogues</b>	fludarabine cladribine	Interferes with DNA synthesis
<b>Monoclonal Antibodies</b>	trastuzumab (Herceptin <sup>®</sup> ) bevacizumab (Avastin <sup>®</sup> ) rituximab (Rituxan <sup>®</sup> ), ofatumumab (Arzerra <sup>®</sup> ), obinutuzumab (Gazyva <sup>®</sup> ) cetuximab (Erbix <sup>®</sup> ) daratumumab	HER2 antagonist VEGF antagonist CD20 antagonist EGFR antagonist CD38 antagonist
<b>Small Molecule Inhibitors</b>	imatinib mesylate (Gleevec <sup>®</sup> ) dasatinib nilotinib bosutinib erlotinib (Tarceva <sup>®</sup> ) gefitinib (Iressa <sup>®</sup> ) bortezomib (Velcade <sup>®</sup> ) sunitinib (Sutent <sup>®</sup> ) ibrutinib (Imbruvica <sup>®</sup> ) idecitasib (Zydelig <sup>®</sup> ) ruxolitinib (Jakavi <sup>®</sup> ) venetoclax lenalidomide, pomalidomide	BCR-ABL inhibitor BCR-ABL inhibitor BCR-ABL inhibitor BCR-ABL inhibitor EGFR antagonist EGFR antagonist 26S proteasome inhibitor VEGFR, PDGFR antagonist BTK inhibitor PI3K inhibitor JAK2 inhibitor BCR-ABL inhibitor Bcl-2 inhibitor immunomodulators
<b>CAR T cell therapy</b>	tisagenlecleucel (Kymriah <sup>®</sup> ) axicabtagene ciloleucel (Yescarta <sup>®</sup> )	Target CD19

## Landmark Hematology Trials

Trial Name	Reference	Clinical Trial Details
<b>Hematologic Malignancies and Related Disorders</b>		
Long-term outcomes of imatinib treatment for chronic myeloid leukemia	NEJM 2017;376:917-927	<p><b>Title:</b> Long-Term Outcomes of Imatinib Treatment for Chronic Myeloid Leukemia</p> <p><b>Purpose:</b> To compare the efficacy of imatinib with that of IFN-<math>\alpha</math> plus low-dose cytarabine in newly diagnosed chronic-phase CML.</p> <p><b>Methods:</b> 1106 patients with Ph-positive CML in the chronic phase were randomized 1:1 to imatinib or interferon <math>\alpha</math> plus cytarabine. Crossover to imatinib were allowed if no response by 6 mo or major cytogenetic response by 12 mo.</p> <p><b>Results:</b> Assessing the imatinib arm after a median of 11 years of follow-up specifically at the sixth year point, the complete cytogenetic response rate was 83%. Among patients who attained a major molecular response after 18 mo of imatinib therapy, the overall survival at 10-years was 93% and freedom from CML-related death 100%.</p> <p><b>Conclusions:</b> This 116-year update of IRIS demonstrates the efficacy and safety of imatinib as first-line therapy for CML patients.</p>
Ibrutinib Versus Ofatumumab in Previously Treated Chronic Lymphoid Leukemia. Byrd et al. 2014	NEJM 2014;371:213-23	<p><b>Title:</b> Ibrutinib Versus Ofatumumab in Previously Treated Chronic Lymphoid Leukemia</p> <p><b>Purpose:</b> To evaluate the efficacy of ibrutinib in patients with CLL and small lymphocytic lymphoma (SLL) at risk for poor outcomes.</p> <p><b>Methods:</b> 391 patients with relapsed or refractory CLL or SLL were randomly assigned to daily ibrutinib or ofatumumab.</p> <p><b>Results:</b> Ibrutinib significantly improved progression-free survival (hazard ratio, 0.22; <math>P &lt; 0.001</math>), overall survival (0.43; <math>P = 0.005</math>) with a higher overall response rate (42.6% vs. 4.1%, <math>P = 0.001</math>) as compared with patients on ofatumumab. Overall survival was 90% in the ibrutinib group and 81% in the ofatumumab group at 12 mo.</p> <p><b>Conclusion:</b> Ibrutinib significantly improved progression-free survival, overall survival, and response rate among patients with previously treated CLL or SLL.</p>
POLLUX	NEJM 2016;375:1319-31	<p><b>Title:</b> Daratumumab, Lenalidomide, and Dexamethasone for Multiple Myeloma</p> <p><b>Purpose:</b> To assess if daratumumab lengthens PFS when added to lenalidomide and dexamethasone therapy in patients with relapsed or refractory myeloma.</p> <p><b>Methods:</b> 569 patients with MM who had been previously treated were randomly assigned to either lenalidomide and dexamethasone (control group) or daratumumab plus lenalidomide and dexamethasone (daratumumab group). The primary endpoint was PFS.</p> <p><b>Results:</b> PFS at 12 mo was 83.2% in the daratumumab group and 60.1% in the control group. Daratumumab had a significantly higher overall response as compared to the control group (<math>P &lt; 0.001</math>). Neutropenia was more frequent in the daratumumab group (51.9% vs. 37.0%).</p> <p><b>Conclusion:</b> PFS was significantly lengthened by addition of daratumumab to lenalidomide and dexamethasone for patients with relapsed or refractory MM but was associated with higher rates of neutropenia.</p>
GALLIUM	NEJM 2017;377:1331-44	<p><b>Title:</b> Obinutuzumab for the First-Line Treatment of Follicular Lymphoma</p> <p><b>Purpose:</b> To compare rituximab-based chemotherapy with obinutuzumab-based chemotherapy in patients with untreated advanced-stage follicular lymphoma.</p> <p><b>Methods:</b> 1202 patients were randomly assigned to receive induction treatment with obinutuzumab-based chemotherapy (obinutuzumab) or rituximab-based chemotherapy (rituximab).</p> <p><b>Results:</b> Risk of progression, relapse, or death was significantly lower on obinutuzumab vs. rituximab (estimated 3-yr PFS, 80.0% vs. 73.3%; hazard ratio for progression, relapse, or death, 0.66; 95% CI, 0.51-0.85; <math>P = 0.001</math>). There were more adverse events in the obinutuzumab group (grade 3-5: 74.6% vs. 67.8%; serious events: 46.1% vs. 39.9%).</p> <p><b>Conclusion:</b> Obinutuzumab-based chemotherapy resulted in longer PFS than rituximab-based therapy but more frequent high-grade adverse events.</p>
Long-Term Follow-up of CD19 CAR Therapy in Acute Lymphoblastic Leukemia. Park et al. 2018	NEJM 2018;378:449-59	<p><b>Title:</b> Long-Term Follow-up of CD19 CAR Therapy in Acute Lymphoblastic Leukemia</p> <p><b>Purpose:</b> To investigate the use of CAR-T in relapsed B-cell ALL.</p> <p><b>Methods:</b> Phase 1 trial including 53 adults with relapsed B-cell ALL received an infusion of autologous T cells expressing the 19-28z CAR.</p> <p><b>Results:</b> Severe cytokine release syndrome occurred in 26% of patients following infusion (95% CI, 15-40); 1 patient died. 83% of patients experienced complete remission. At median 29 mo follow-up, median overall survival was 12.9 mo (8.7-23.4) and median event-free survival was 6.1 mo (5.0-11.5).</p> <p><b>Conclusion:</b> Median overall survival was 12.9 mo in the entire cohort. More adverse events occurred in patients with high disease burden.</p>
<b>Thrombosis</b>		
CLOT	NEJM 2003;349:146-53	<p><b>Title:</b> Low-Molecular-Weight Heparin Versus a Coumarin for the Prevention of Recurrent Venous Thromboembolism in Patients with Cancer</p> <p><b>Purpose:</b> To compare the efficacy of LMWH with an oral anticoagulant for preventing recurrent thrombosis in cancer patients.</p> <p><b>Methods:</b> Cancer patients with acute, symptomatic proximal DVT, PE, or both were randomly assigned to dalteparin (LMWH) for 5-7 d plus a coumarin derivative for 6 mo or dalteparin alone for 6 mo.</p> <p><b>Results:</b> At 6 mo, the rate of recurrent thromboembolism was 17% in the oral-anticoagulant group and 9% in the dalteparin group. Rates of major bleeding were not significantly different between groups (6% vs. 4%, respectively); any bleeding (14% vs. 19%).</p> <p><b>Conclusions:</b> Dalteparin was superior to an oral anticoagulant in cancer patients for reducing recurrent thromboembolism rates without increasing bleeding risk.</p>
Influence of Preceding Length of Anticoagulant Treatment and Initial Presentation of Venous Thromboembolism on Risk of Recurrence After Stopping Treatment: Analysis of Individual Participants' Data From Seven Trials. Bouillon et al. 2011	BMJ 2011;342:d3036	<p><b>Title:</b> Influence of Preceding Length of Anticoagulant Treatment and Initial Presentation of Venous Thromboembolism on Risk of Recurrence After Stopping Treatment: Analysis of Individual Participants' Data From Seven Trials</p> <p><b>Purpose:</b> To determine how length of anticoagulation of VTE influences recurrence risk after treatment is stopped.</p> <p><b>Methods:</b> Individual participants' data was pooled from 7 RCTs including 2925 men or women with a first VTE who did not have cancer and had varying durations of anticoagulant treatment.</p> <p><b>Results:</b> Recurrence was higher if anticoagulation was stopped at 1-1.5 mo vs. <math>\geq 3</math> mo (hazard ratio 1.52, 1.14-2.02) and similar if treatment was stopped at 3 mo vs. <math>\geq 6</math> mo (1.19, 0.86-1.65).</p> <p><b>Conclusion:</b> Risk of recurrent VTE was similar when anticoagulation was stopped after 3 mo vs. stopping after a longer course of treatment.</p>
EINSTEIN-PE	NEJM 2012;366:1287-97	<p><b>Title:</b> Oral Rivaroxaban for the Treatment of Symptomatic Pulmonary Embolism</p> <p><b>Purpose:</b> To investigate the efficacy and safety of a fixed-dose rivaroxaban regimen for the treatment of PE.</p> <p><b>Methods:</b> 4832 patients who had acute symptomatic PE <math>\pm</math> DVT were randomly assigned to rivaroxaban or standard therapy with enoxaparin followed by a vitamin K antagonist.</p> <p><b>Results:</b> Rivaroxaban was noninferior to standard therapy for the primary efficacy outcome (symptomatic recurrent VTE), 2.1% in rivaroxaban vs. 1.8% in standard-therapy (hazard ratio, 1.12; 95% CI, 0.75-1.68). Clinically relevant bleeding occurred in 10.3% of patients on rivaroxaban and 11.4% of those on standard-therapy (0.90; 0.76-1.07; <math>P = 0.23</math>).</p> <p><b>Conclusion:</b> For initial and long-term treatment of PE, fixed-dose rivaroxaban alone was noninferior to standard therapy with a potentially better benefit-risk profile.</p>

Trial Name	Reference	Clinical Trial Details
AMPLIFY	NEJM 2013;369:799-808	<p><b>Title:</b> Oral Apixaban for the Treatment of Acute Venous Thromboembolism</p> <p><b>Purpose:</b> To investigate the efficacy and safety of fixed-dose apixaban for the treatment of VTE.</p> <p><b>Methods:</b> 5395 patients with acute VTE were randomly assigned to receive apixaban or conventional therapy (SC enoxaparin, followed by warfarin).</p> <p><b>Results:</b> Apixaban was noninferior to conventional therapy for the primary efficacy outcome (symptomatic recurrent VTE or death from VTE) (<math>P &lt; 0.001</math>). Major bleeding or clinically relevant nonmajor bleeding occurred in 4.3% of patients on apixaban vs. 9.7% of those on conventional-therapy (RR, 0.44; 95% CI, 0.36-0.55; <math>P &lt; 0.001</math>).</p> <p><b>Conclusion:</b> For the treatment of acute VTE, fixed-dose apixaban alone was noninferior to conventional therapy with significantly less bleeding.</p>
RE-VERSE AD	NEJM 2015;373:511-20	<p><b>Title:</b> Idarucizumab for Dabigatran Reversal</p> <p><b>Purpose:</b> To investigate the efficacy and safety of idarucizumab for reversing the anticoagulant effects of dabigatran.</p> <p><b>Methods:</b> 90 patients with either a serious bleed or one requiring an urgent procedure secondary to dabigatran received idarucizumab.</p> <p><b>Results:</b> Idarucizumab normalized test results in 88-98% of patients, which was evident within minutes. Unbound dabigatran concentrations remained <math>&lt; 20</math> ng/mL at 24 h in 79% of patients.</p> <p><b>Conclusion:</b> The anticoagulant effect of dabigatran was completely reversed by idarucizumab within minutes.</p>
CACTUS	Lancet Haematol 2016;3:e556-e562	<p><b>Title:</b> Anticoagulant Therapy for Symptomatic Calf Deep Vein Thrombosis (CACTUS): A Randomised, Double-Blind, Placebo-Controlled Trial</p> <p><b>Purpose:</b> To investigate the efficacy and safety of anticoagulant treatment in patients with acute symptomatic DVT of the calf.</p> <p><b>Methods:</b> 259 low-risk outpatients without active cancer or previous VTE with a first acute symptomatic calf DVT were randomly assigned to receive either nadroparin (LMWH) or placebo for 6 wk.</p> <p><b>Results:</b> No significant difference between groups was seen in the composite primary outcome (extension of calf DVT to proximal veins, contralateral proximal DVT, and symptomatic pulmonary embolism at day 42). Bleeding occurred in 4% of patients on nadroparin and no patients on placebo (risk difference 4.1, 95% CI 0.4-9.2; <math>p = 0.0255</math>).</p> <p><b>Conclusion:</b> In low-risk outpatients with symptomatic calf DVT, nadroparin was non-superior to placebo in reducing the risk of proximal extension or VTE, but it did increase bleeding risk.</p>
<b>Blood Products and Transfusion</b>		
FOCUS	NEJM 2011;365:2453-2462	<p><b>Title:</b> Liberal or Restrictive Transfusion in High-Risk Patients after Hip Surgery (FOCUS)</p> <p><b>Purpose:</b> To determine whether a higher threshold for blood transfusion would improve recovery in patients who had undergone surgery for hip fracture.</p> <p><b>Methods:</b> 2016 patients <math>&gt; 50</math> yr with a history of or risk factors for cardiovascular disease and Hb level below 10 g/dL after hip-fracture surgery were randomly assigned to a liberal transfusion strategy (a Hb threshold of 10 g/dL) or a restrictive transfusion strategy (anemia symptoms or at physician discretion for a Hb level less than 8 g/dL).</p> <p><b>Results:</b> The primary outcome was death or inability to walk across a room without human assistance on a 60 d follow-up. Primary outcome rates were 35.2% in the liberal transfusion strategy group and 34.7% in the restrictive transfusion strategy group. Rates of complications were similar in the two groups.</p> <p><b>Conclusion:</b> A liberal transfusion strategy did not reduce mortality rates or the inability to walk independently on 60 d follow-up compared to a restrictive transfusion strategy in elderly patients with high cardiovascular risk factors after hip surgery.</p>
TRICC BP	NEJM 1999;340:409-17	<p><b>Title:</b> A Multicenter, Randomized, Controlled Clinical Trial of Transfusion Requirements in Critical Care. Transfusion Requirements in Critical Care Investigators, Canadian Critical Care Trials Group</p> <p><b>Purpose:</b> To determine if equivalent results can be achieved by a restrictive strategy of red-cell transfusion and a liberal strategy in critically ill patients.</p> <p><b>Methods:</b> 838 critically ill patients with euvoolemia (after initial treatment and Hb <math>&lt; 9</math> g/dL within 72 h of ICU admission) received either (1) a restrictive strategy (transfusion if Hb <math>&lt; 7.0</math> g/dL, maintained at 7-9 g/dL) or (2) a liberal strategy (transfusions if Hb <math>&lt; 10.0</math> g/dL, maintained at 10-12 g/dL).</p> <p><b>Results:</b> Mortality rates at 30 d were similar between groups. However, among less acutely ill patients and those <math>&lt; 55</math> yr of age, mortality rates were significantly lower in RS than LS: 8.7% vs. 16.1%, <math>P = 0.03</math> and 5.7% vs. 13%, <math>P = 0.02</math>, respectively.</p> <p><b>Conclusion:</b> In critically ill patients, a RS of red cell transfusion is as effective as a LS transfusion.</p>
Therapeutic Platelet Transfusion Versus Routine Prophylactic Transfusion in Patients With Haematological Malignancies: An Open-Label, Multicentre, Randomised Study. Wandt et al. 2012	Lancet 2012;380:1309-16	<p><b>Title:</b> Therapeutic Platelet Transfusion Versus Routine Prophylactic Transfusion in Patients With Haematological Malignancies: An Open-Label, Multicentre, Randomised Study</p> <p><b>Purpose:</b> To investigate the influence of a novel therapeutic platelet transfusion strategy on the number of transfusions and safety in patients with hypoproliferative thrombocytopenia.</p> <p><b>Methods:</b> Patients (16-80 yr) undergoing chemotherapy for AML or autologous haemopoietic stem-cell transplantation were randomly assigned to receive either platelet transfusion when bleeding occurred (therapeutic strategy) or when morning platelet counts were <math>&lt; 10 \times 10^9/L</math> (prophylactic strategy; current standard of care).</p> <p><b>Results:</b> In all patients, the therapeutic strategy reduced the mean number of platelet transfusions by 33.5% (95% CI 22.2-43.1; <math>p &lt; 0.0001</math>). Major haemorrhage was not increased in patients who had undergone autologous transplantation. Risk of non-fatal grade 4 bleeding was increased in patients with AML.</p> <p><b>Conclusion:</b> The therapeutic strategy should be considered for patients following autologous stem-cell transplantation but not for patients with AML.</p>
Transfusion Strategies for Acute Upper Gastrointestinal Bleeding. Villanueva et al. 2013	NEJM 2013;368:11-21	<p><b>Title:</b> Transfusion Strategies for Acute Upper Gastrointestinal Bleeding</p> <p><b>Purpose:</b> To compare the efficacy and safety of a restrictive transfusion strategy with a liberal transfusion strategy in patients with acute upper GI bleeds.</p> <p><b>Methods:</b> 921 patients with severe acute upper GI bleeding were assigned to either a restrictive strategy (transfusion when Hb <math>&lt; 7</math> g/dL; target Hb = 7-9 g/dL) or a liberal strategy (transfusion when Hb <math>&lt; 9</math> g/dL; target Hb = 9-11 g/dL).</p> <p><b>Results:</b> Survival at 6 wk was higher in the restrictive-strategy group than in the liberal-strategy group (95% vs. 91%; hazard ratio, 0.55; 95% CI, 0.33-0.92; <math>P = 0.02</math>). Further bleeding was more common in patients on restrictive-strategy than liberal-strategy (10% vs. 16%; <math>P = 0.01</math>); adverse events were also more common (40% vs. 48%; <math>P = 0.02</math>).</p> <p><b>Conclusion:</b> A restrictive transfusion strategy led to better outcomes than a liberal strategy in patients with acute upper GI bleeding.</p>

Trial Name	Reference	Clinical Trial Details
<b>Anemia</b>		
CHOIR	NEJM 2006;355:2085-98	<p><b>Title:</b> Correction of Anemia with Epoetin <math>\alpha</math> in Chronic Kidney Disease</p> <p><b>Purpose:</b> To determine the optimal level of hemoglobin correction by recombinant human erythropoietin (epoetin <math>\alpha</math>) in anemic CKD patients.</p> <p><b>Methods:</b> 1432 patients with CKD were randomly assigned to receive a dose of epoetin alfa targeted to achieve a hemoglobin level of 13.5 g/dL or a dose targeted to achieve a level of 11.3 g/dL.</p> <p><b>Results:</b> 125 composite events (death, MI, hospitalization for CHF, or stroke) were seen in the high-hemoglobin group, as compared with 97 events in the low-hemoglobin group (hazard ratio, 1.34; 95% CI, 1.03-1.74; <math>P=0.03</math>).</p> <p><b>Discussion:</b> In patients with anemia and CKD, targeting a lower Hb reduced incidence of death, MI, CHF-related hospitalization, and stroke.</p>
<b>Other</b>		
CRASH-2	Health Technol Assess 2013;17(10):1-79	<p><b>Title:</b> The CRASH-2 Trial: A Randomised Controlled Trial and Economic Evaluation of the Effects of Tranexamic Acid on Death, Vascular Occlusive Events and Transfusion Requirement in Bleeding Trauma Patients</p> <p><b>Purpose:</b> To assess how early administration of a short course of tranexamic acid (TXA) influences rates of death, vascular occlusive events and blood transfusions in trauma patients.</p> <p><b>Methods:</b> 20211 adult trauma patients within 8 h of injury that had, or were at risk for, significant bleeding were randomized to receive TXA or matching placebo.</p> <p><b>Results:</b> TXA significantly reduced all-cause mortality at 28 d (14.5% in TXA vs. 16.0% in placebo; <math>p=0.0035</math>). Death rates caused by bleeding were significantly reduced (4.9% vs. 5.7%; <math>p=0.0077</math>). The risk of death due to bleeding was increased by treatment given after 3 h (4.4% vs. 3.1%; <math>p=0.004</math>).</p> <p><b>Conclusion:</b> The risk of death was safely reduced by early TXA in bleeding trauma patients. Beyond 3 h of injury, treatment is likely ineffective.</p>

DEET	N,N-Diethyl-meta-toluamide	HHV	human herpes virus	O&P	ova and parasites
DVT	deep vein thrombosis	Hib	<i>Haemophilus influenzae</i> b	PCP	<i>Pneumocystis pneumonia</i>
EBV	Epstein-Barr virus	HPF	high power field	PI	protease inhibitor
EHEC	enterohemorrhagic <i>E. coli</i>	HPV	human papillomavirus	PJP	<i>Pneumocystis jirovecii</i>
EIA	enzyme immunoassay	HRtg	human rabies immunoglobulin		pneumonia
EIEC	enteroinvasive <i>E. coli</i>	HSV	herpes simplex virus	PMN	polymorphonuclear leukocytes
ETEC	enterotoxigenic <i>E. coli</i>	HTLV-1	Human T-lymphotropic virus 1	PNS	peripheral nervous system
FDP	fibrinogen degradation products	HUS	hemolytic uremic syndrome	PPD	purified protein derivative
FTA-ABS	fluorescent <i>Treponema</i> antibody-absorption	IE	infective endocarditis	RPR	rapid plasma reagin
FUO	fever of unknown origin	IFN	interferon	RSV	respiratory syncytial virus
		Ig	immunoglobulin	RTI	respiratory tract infection
		INH	isoniazid		
		INSTI	integrase strand transfer		

## Principles of Microbiology

### Bacteriology

#### Bacteria Basics

- bacteria are prokaryotic cells that divide asexually by binary fission
- Gram stain divides most bacteria into two groups based on their cell wall
  - GP: thick, rigid layer of peptidoglycan
  - GN: thin peptidoglycan layer + outer membrane composed of lipoproteins and lipopolysaccharides
  - clinical significance: Gram stain results are used to guide tailored empiric treatment prior to availability of culture and susceptibility testing results
- acid-fast bacilli: high mycolic acid content in cell wall, "acid fast" as washout phase with acid-alcohol is ineffective in acid-fast bacteria (e.g. *Mycobacteria*)
- partially acid-fast bacilli: some bacteria have moderate amounts of mycolic acid content that will decolorize with the acid-alcohol used in AFB stains but are considered partially acid-fast positive using a modified acid-fast stain with a weaker acid during the washout phase (e.g. *Nocardia*); note that *Nocardia* will be acid-fast stain negative but modified acid-fast stain positive while mycobacteria will be acid-fast stain positive and modified acid-fast positive
- "atypical" bacteria: not seen on Gram stain and difficult to culture
  - obligate intracellular bacteria: e.g. *Chlamydia*
  - bacteria lacking a cell wall: e.g. *Mycoplasma*
  - spirochetes: e.g. *Treponema pallidum*
- O<sub>2</sub> can be either vital or detrimental to growth
  - obligate aerobes: require O<sub>2</sub>
  - obligate anaerobes: require environment without O<sub>2</sub>
  - facultative anaerobes: can survive in environments with or without O<sub>2</sub>

#### Mechanisms of Bacterial Disease

1. adherence to and colonization of skin or mucous membranes
  - fimbriae (pili): microfilaments extending through the cell wall attach to epithelial cells (e.g. *E. coli* in the urinary tract)
2. invasion or crossing epithelial barriers
3. evasion of host defense system through:
  - inhibition of phagocytic uptake via polysaccharide capsule (e.g. *S. pneumoniae*, *N. meningitidis*, *H. influenzae*)
  - presence of surface proteins (e.g. *Staphylococcus*, *Streptococcus*)
4. toxin production
  - exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria are not present (e.g. *Clostridium*)
  - endotoxins are structural components of GN bacterial cell walls and may be shed by live cells or released during cell lysis
5. intracellular growth
  - obligate intracellular: *Rickettsia*, *Chlamydia*
  - facultative intracellular: *Salmonella*, *Neisseria*, *Brucella*, *Mycobacteria*, *Listeria*, *Legionella*
6. biofilm
  - an extracellular polysaccharide network forming mesh around the bacteria (e.g. *S. epidermidis*) which can coat prosthetic devices such as IV catheters

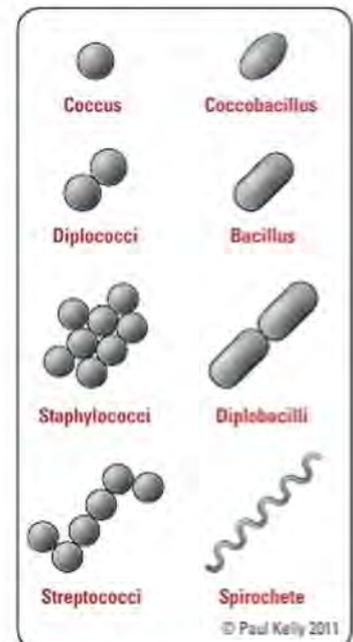

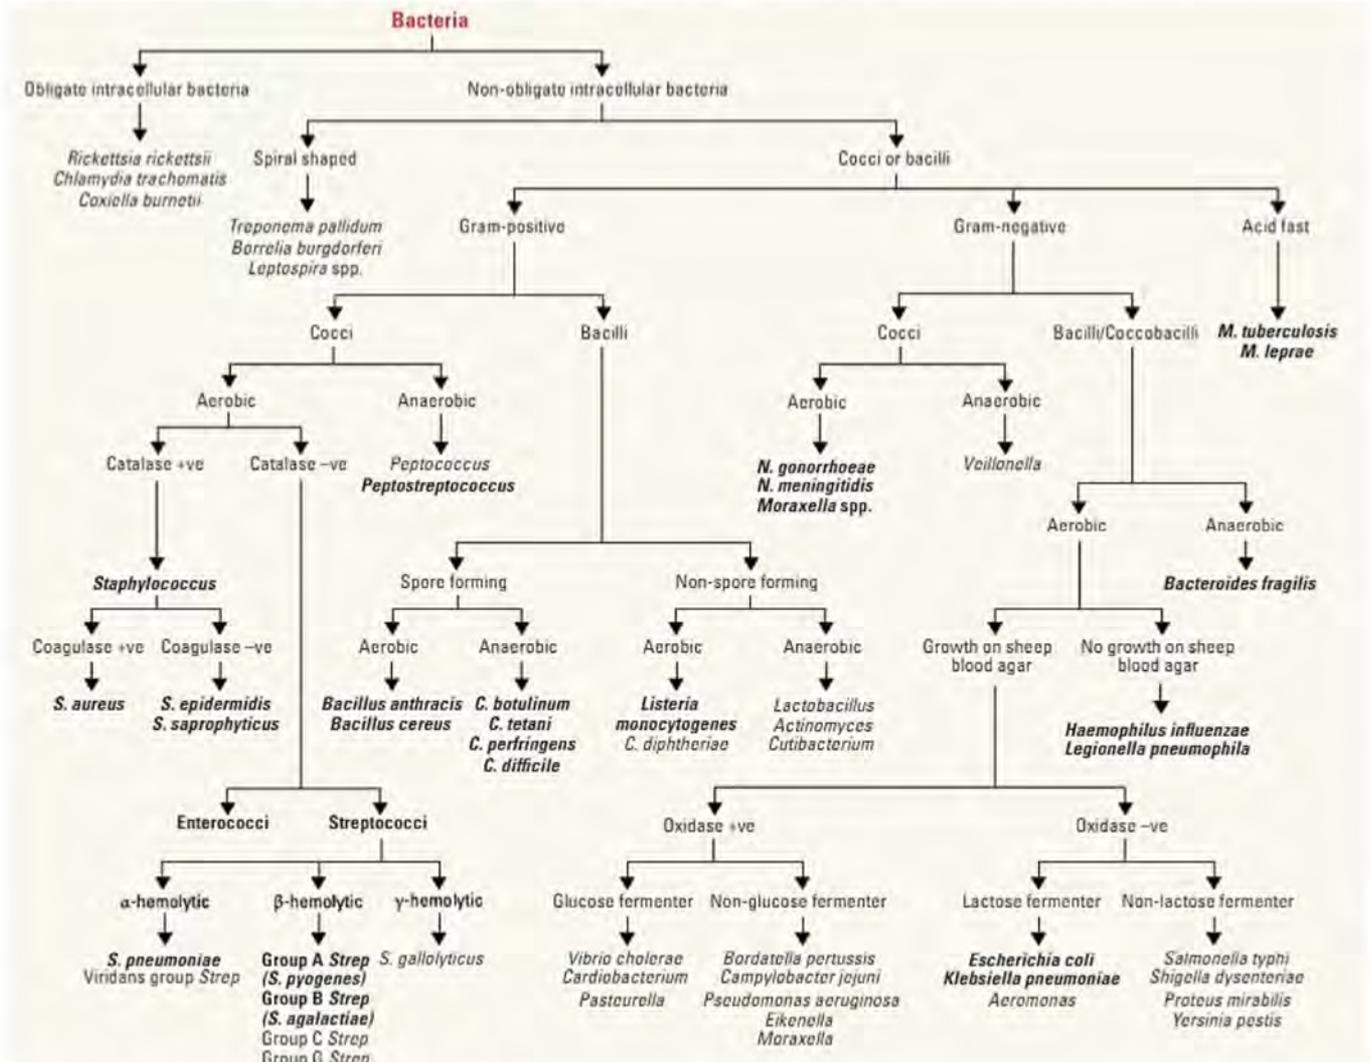

Figure 1. Bacteria morphology

**Table 1. Common Bacteria**

	GP Bacteria		GN Bacteria		Not Seen on Gram Stain	
	Cocci (round)	Bacilli (rod-like)	Diplococci	Bacilli (rod-like)	Acid-Fast	Others
<b>Aerobes</b>	<i>Staphylococcus</i> <i>S. aureus</i> <i>S. saprophyticus</i> <i>S. epidermidis</i> <i>S. lugdunensis</i> <i>Streptococcus</i> <i>S. pneumoniae</i> <i>S. pyogenes</i> (GAS) <i>S. agalactiae</i> (GBS) <i>S. anginosus</i> group <i>Enterococcus</i> <i>E. faecalis</i>	<i>Bacillus</i> <i>B. anthracis</i> <i>Listeria</i> <i>Nocardia</i> (modified acid-fast positive)  <i>Clostridioides difficile</i> <i>Clostridium</i> <i>C. tetani</i> <i>C. botulinum</i> <i>C. perfringens</i> <i>Cutibacterium</i> <i>(Propionibacterium) acnes</i>	<i>Neisseria</i> <i>N. meningitidis</i> <i>N. gonorrhoeae</i> <i>Moraxella</i> <i>M. catarrhalis</i>	<i>Enterobacterales</i> <i>E. coli</i> <i>Klebsiella</i> <i>Salmonella</i> <i>Shigella</i> <i>Yersinia</i> <i>Campylobacter</i> <i>Legionella</i> <i>Pseudomonas</i> <i>Haemophilus</i> <i>H. influenzae</i>	<i>Mycobacteria</i> <i>M. tuberculosis</i> <i>M. leprae</i> <i>M. avium</i> complex	Obligate intracellular <i>Rickettsiae</i> <i>Chlamydia</i> <i>C. trachomatis</i> <i>C. pneumoniae</i>  No cell wall <i>Mycoplasma</i>  Spirochete (spiral) <i>Treponema pallidum</i>
<b>Anaerobes</b>	<i>Peptostreptococcus</i>			<i>Bacteroides</i> <i>B. fragilis</i>		

**Table 2. Commensal Flora**

Site	Organisms
<b>Skin</b>	Coagulase-negative staphylococci, <i>Corynebacterium</i> , <i>C. acnes</i> , <i>Bacillus</i> , <i>S. aureus</i>
<b>Oropharynx</b>	Viridans group streptococci, <i>Haemophilus</i> , <i>Neisseria</i> , anaerobes ( <i>Peptostreptococcus</i> , <i>Bacteroides</i> , <i>Veillonella</i> , <i>Fusobacterium</i> , <i>Actinomyces</i> , <i>Prevotella</i> )
<b>Small Bowel</b>	<i>E. coli</i> , anaerobes (low numbers)
<b>Colon</b>	<i>E. coli</i> , <i>Klebsiella</i> , <i>Enterobacter</i> , <i>Enterococcus</i> , anaerobes ( <i>Bacteroides</i> , <i>Peptostreptococcus</i> , <i>Clostridium</i> )
<b>Vagina</b>	<i>Lactobacillus acidophilus</i> , viridans group streptococci, coagulase-negative staphylococci, facultative anaerobes

**Figure 2. Laboratory identification of bacterial species**

# Virology

## Viral Basics

- viruses are infectious particles consisting of RNA or DNA covered by a protein coat
  - infect cells and use host metabolic machinery to replicate
  - nucleic acid can be double stranded (ds) or single stranded (ss)
  - can be enveloped or naked
- virions are mature virus particles that can be released into the extracellular environment
- host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

## Viral Disease Patterns

- acute infections (e.g. adenovirus)
  - host cells are lysed in the process of virion release
  - some produce acute infections with late sequelae (e.g. measles virus-induced subacute sclerosing panencephalitis)
- chronic infections (>6 mo) (e.g. HBV, HIV)
  - host cell machinery is used to produce and chronically release virions
- latent infections
  - viral genome remains latent in host cell nucleus
  - can reactivate (e.g. HSV, VZV)

Table 3. Common Viruses

Nucleic Acid	Enveloped	Virus Family	Major Viruses	Medical Importance	
dsDNA	No	Adenoviridae	Adenovirus	URTI Conjunctivitis Gastroenteritis	
	No	Papillomaviridae	HPV1,4 HPV6,11 HPV16,18, etc.	Plantar warts Genital warts Cervical/anal dysplasia and cancer	
	Yes	Herpesviridae	HHV1-HSV1 HHV2-HSV2 HHV3-VZV HHV4-EBV HHV5-CMV HHV6* HHV8-KSHV	Oral, ocular, and genital herpes; encephalitis Genital, oral, and ocular herpes; encephalitis Chicken pox, shingles Mononucleosis, viral hepatitis Retinitis, pneumonitis, hepatitis, encephalitis Roseola Kaposi's sarcoma, multicentric Castleman's disease, body cavity lymphoma	
	No	Polyomaviridae	JC virus	Progressive multifocal leukoencephalopathy	
	Yes	Hepadnaviridae	Hepatitis B	Hepatitis	
	Yes	Poxviridae	Monkeypox Smallpox	Monkeypox Smallpox	
	ssDNA	No	Parvoviridae	Parvovirus B19	Erythema infectiosum (Fifth disease)
(+/-) ssRNA	No	Caliciviridae	Noroviruses Hepatitis E	Gastroenteritis Acute hepatitis	
	No	Picornaviridae	Poliovirus Echovirus Rhinovirus Coxsackie virus Hepatitis A	Poliomyelitis URTIs, viral meningitis URTIs Hand-foot-and-mouth, viral meningitis, myocarditis Acute hepatitis	
	Yes	Coronaviridae	Coronavirus	URTIs, SARS, MERS, COVID-19	
	Yes	Flaviviridae	Yellow fever Dengue fever Hepatitis C West Nile Zika	Yellow fever Dengue fever Hepatitis Encephalitis, flaccid paralysis Zika virus disease	
	Yes	Togaviridae	Rubella Chikungunya	Rubella (German measles) Chikungunya	
	(+) ssRNA-RT	Yes	Retroviridae	HIV HTLV-1	AIDS T-cell leukemia and lymphoma
	(-) ssRNA	Yes	Arenaviridae	Lassa	Lassa fever
		Yes	Filoviridae	Ebola, Marburg	Hemorrhagic fever
		Yes	Orthomyxoviridae	Influenza A, B, C	Influenza
		Yes	Paramyxoviridae	Measles Mumps Parainfluenza RSV	Measles Mumps URTIs, croup, bronchiolitis Bronchiolitis, pneumonia
Yes		Rhabdoviridae	Rabies	Rabies	
dsRNA	No	Reoviridae	Rotavirus	Gastroenteritis	

Note: \_\_\_viridae = family, \_\_\_virus = genus, # = species (e.g. Retroviridae HIV-2)  
\*Roseolovirus, Herpes lymphotropic virus

## Mycology

### Fungal Basics

- fungi are eukaryotic organisms, they can have the following morphologies
  - yeast (unicellular)
  - moulds, i.e. filamentous fungi (multicellular with hyphae)
  - dimorphic fungi (found as mould at room temperature but grow as yeast-like forms at body temperature)

Table 4. Membrane and Cell Wall Compositions

	Membrane Sterol	Cell Wall
Bacteria	–	Peptidoglycan
Human Cell	Cholesterol	–
Fungi	Ergosterol	Chitin (complex glycopolysaccharide)

### Mechanisms of Fungal Disease

- primary fungal infection by:
  - overgrowth of normal flora (e.g. *Candida* spp.)
  - inhalation of fungal spores
  - traumatic inoculation into skin
- toxins produced by fungi (e.g. ingestion of aflatoxins)
- allergic reactions to fungi (e.g. bronchopulmonary aspergillosis)

## Parasitology

### Parasite Basics

- parasite: an organism that lives in or on another organism (host) and damages the host in the process
- parasites with complex life cycles require more than one host to reproduce
  - reservoir host: maintains a parasite and may be the source for human infection
  - intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed through the larval stages
  - definitive host: allows the parasite to develop to the adult stage where reproduction occurs
- 2 major groups of parasites: protozoa and helminths
- see Table 25, ID33 and Table 26, ID39 for examples of clinically important parasites

Table 5. Differences Between Protozoa and Helminths

Protozoa	Helminths
Unicellular	Multicellular
Motile trophozoite, inactive cyst	Adult → egg → larva
Multiplication	No multiplication in human host
Eosinophilia unusual	Eosinophilia (proportional to extent of tissue invasion)*
Indefinite life span	Definite life span

\*Adult *Ascaris* (roundworm) does not cause eosinophilia; migratory larval phases of *Ascaris*, however, cause high-grade eosinophilia

### Characteristics of Parasitic Disease

- symptoms are usually proportional to parasite burden
- tissue damage is due to the parasite and host immune response
- chronic infections may occur with or without overt disease
- immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
- eosinophilia may suggest a parasitic worm infection

### Mechanisms of Parasitic Disease

- mechanical obstruction (e.g. ascariasis, clonorchiasis)
- competition with host for resources (e.g. anemia in hookworm disease, vitamin B<sub>12</sub> deficiency in diphyllobothriasis)
- cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
- inflammatory
  - acute hypersensitivity (e.g. pneumonitis in Loeffler's syndrome)
  - delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
  - cytokine-mediated (e.g. systemic illness of malaria, disseminated strongyloidiasis)
- immune-mediated injury
  - autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
  - immune complex (e.g. nephritis of malaria, schistosomiasis)

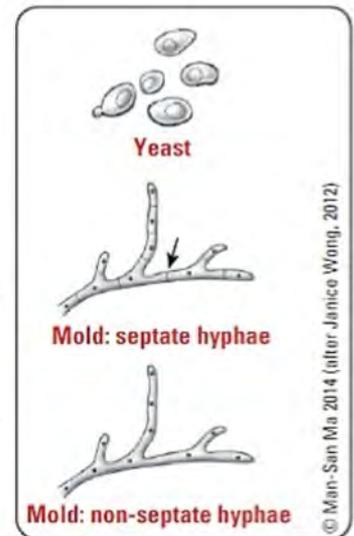

Figure 4. Common fungus morphology

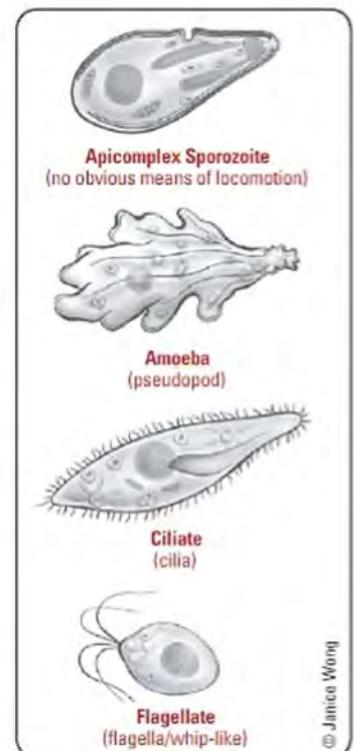

Figure 5. Classification of protozoa based on movement

Parasite sampling may need to be repeated on several occasions before infection can be ruled out

## Transmission of Infectious Diseases

**Table 6. Mechanism of Transmission**

Mechanism	Mode of Transmission	Examples	Preventative Measure
Contact	Direct physical contact, or indirect contact with a fomite	Skin-to-skin (MRSA) Sexual ( <i>N. gonorrhoeae</i> , <i>C. trachomatis</i> , HSV, HIV) Blood-borne (HIV, HBV, HCV)	For patients in healthcare facilities: Contact precautions Barrier precautions Safe needlestick/sharp practices
Droplet/Contact	Respiratory droplets (>5 µm) can be projected short distances (<2 m) and deposit on mucosal surfaces of the recipient (e.g. by coughing, sneezing, or talking); transmission can also occur by direct physical contact of respiratory fluids or indirect contact with a fomite contaminated with respiratory fluids	Influenza, mumps, <i>N. meningitidis</i> , <i>Bordetella pertussis</i>	For patients in healthcare facilities: Contact/droplet precautions
Airborne	Airborne droplet nuclei (<5 µm) remain infectious over time and distance	<i>M. tuberculosis</i> , disseminated VZV, measles	For patients in healthcare facilities: Airborne precautions
Food/ Waterborne	Ingestion of contaminated food or water	<i>V. cholerae</i> , <i>Salmonella</i> , HAV, HEV	Prophylactic vaccinations where available Ensure clean food/water supply For patients in healthcare facilities: Contact precautions used for admitted patients with fecal incontinence when stool is unable to be contained in diapers
Zoonotic/Vector-borne	Disease transmission from animals to humans either directly or via an insect vector, or disease transmission from human to human via an insect vector	Direct animal transmission (rabies, Q fever) Arthropod mediated transmission (malaria, Lyme disease, West Nile virus)	Prophylactic medications, vaccinations Protective clothing, insect repellent, mosquito nets, tick inspection
Vertical	Spread of disease from parent to offspring	Congenital syndromes (TORCH infections) Perinatal (HIV, HBV, GBS)	Prenatal screening Prophylactic treatment

## Nosocomial Infections

- definition:** infections acquired >48 h after admission to a healthcare facility OR within 30 d from discharge
- risk factors:** prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, immunodeficiency
  - patients with nosocomial infections have higher mortality, longer hospital stays, and higher healthcare costs
- hand hygiene is an essential precaution

**Table 7. Common Nosocomial Infectious Agents**

Bacteria	Characteristics	Manifestation	Investigations	Management
MRSA	GP cocci	Skin and soft tissue infection Bacteremia Pneumonia Endocarditis Osteomyelitis	Admission screening culture from nares and peri-anal region identifies colonization Culture of infection site CXR	Contact precautions For infection: vancomycin or daptomycin or linezolid To decolonize: chlorhexidine 2% wash once daily (+ rifampin + doxycycline or TMP/SMX) + mupirocin cream BID to nares) x 7 d
VRE	Majority are <i>E. faecium</i> Resistant if minimum inhibitory concentration of vancomycin is $\geq 32$ µg/mL	Rarely causes disease in healthy people UTI Bacteremia Endocarditis Meningitis	Rectal or perirectal swab OR stool culture for colonization Culture of infected site	Contact precautions* Ampicillin if susceptible Otherwise, linezolid, tigecycline, or daptomycin depending on site of infection No effective decolonization methods identified
<i>Clostridioides difficile</i> ( <i>C. difficile</i> )	Releases exotoxins A and B Hypervirulent strain (NAP1/B1/O27) has been responsible for increase in incidence and severity	Fever, nausea, abdominal pain Watery diarrhea Pseudomembranous colitis Severe: toxic megacolon Risk of bowel perforation Associated with antibiotic use Leukocytosis	Stool PCR for toxin A and B genes Stool immunoassay for toxins A and B (less sensitive than PCR) Abdominal x-ray (may see colonic dilatation) Sigmoidoscopy for pseudomembranes; avoid if known colonic dilatation	Contact precautions Stop culprit antibiotic therapy (primarily fluoroquinolones and clindamycin) Supportive therapy (IV fluids) Empiric treatment with either vancomycin or fidaxomicin If access to empiric treatment is limited, then metronidazole may be used For fulminant <i>C. difficile</i> infection (previously called severe), oral vancomycin is used. IV metronidazole added to regimen if ileus present
Extended Spectrum $\beta$ -lactam Producers (e.g. ESBL producing <i>E. coli</i> , <i>K. pneumoniae</i> )	Resistant to most $\beta$ -lactam antibiotics except carbapenems e.g. penicillins, aztreonam**, and cephalosporins	UTI Pulmonary infection Bacteremia Liver abscess in susceptible patients Meningitis	Blood, sputum, urine, or aspirated body fluid culture Imaging at infection site (CXR, CT, U/S)	Contact precautions* Carbapenems or non- $\beta$ -lactam antibiotics can be used for empiric therapy
Carbapenemase-producing Enterobacteriales (CPE)	Resistant to $\beta$ -lactam antibiotics including carbapenems	UTI Pulmonary infection Bacteremia Liver abscess in susceptible patients Meningitis	Blood, sputum, urine, or aspirated body fluid culture Imaging at infection site (CXR, CT, U/S)	Contact precautions Colistin, tigecycline can be used varying on susceptibility Cefiderocol, ceftazidime-avibactam, plazomin are other options available through the Special Access Program

\*The use of contact precautions for VRE and ESBL varies depending on institutional policies. \*\*Not available in Canada

## Respiratory Infections

### Pneumonia

- see [Paediatrics](#), P93

### Definition

- infection of the lung parenchyma

### Etiology and Risk Factors

- impaired lung defenses
  - poor cough/gag reflex (e.g. illness, drug-induced)
  - impaired mucociliary transport (e.g. smoking, cystic fibrosis)
  - immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
- increased risk of aspiration
  - impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia)
- mechanical obstruction
- no organism identified in 75% of hospitalized cases, and >90% of ambulatory cases

**Table 8. Common Organisms in Pneumonia**

Community-Acquired	Nosocomial	Aspiration	Immunocompromised Patients	Alcohol Use Disorder
<i>Typical Bacteria</i>	Enteric GNB (e.g. <i>E. coli</i> )	Oral anaerobes (e.g. <i>Bacteroides</i> )	<i>Pneumocystis jirovecii</i>	<i>Klebsiella</i>
<i>Streptococcus pneumoniae</i>			Fungi (e.g. <i>Cryptococcus</i> )	Enteric GNB
<i>Moraxella catarrhalis</i>	<i>Pseudomonas</i>	Enteric GNB	<i>Nocardia</i>	<i>S. aureus</i>
<i>Haemophilus influenzae</i>	<i>aeruginosa</i>	<i>S. aureus</i>	CMV	Oral anaerobes (aspiration)
<i>Staphylococcus aureus</i>	<i>S. aureus</i>	Gastric contents	HSV	TB
GAS	(including MRSA)	(chemical pneumonitis)	TB	
<i>Atypical Bacteria</i>				
<i>Mycoplasma pneumoniae</i>				
<i>Chlamydia pneumoniae</i>				
<i>Legionella pneumophila</i>				
<i>Viral</i>				
<i>Influenza virus</i>				
<i>Adenovirus</i>				
<i>SARS-CoV-2</i>				

\*See [Paediatrics](#), P93, Table 45. *Common Causes and Treatment of Community-Acquired Pneumonia*

### Clinical Features

- cough ( $\pm$  sputum), fever, pleuritic chest pain, dyspnea, tachypnea, tachycardia
- elderly often present atypically; altered LOC is sometimes the only sign
- evidence of consolidation (dullness to percussion, bronchial breath sounds, crackles)
- features of parapneumonic effusion (decreased air entry, dullness to percussion)
- complications: ARDS, lung abscess, parapneumonic effusion/empyema, pleuritis  $\pm$  hemorrhage

### Investigations

- pulse oximetry to assess severity of respiratory distress
- CBC and differential, electrolytes, urea, Cr, arterial blood gas (ABG) (if respiratory distress)
- sputum Gram stain/C&S, blood C&S,  $\pm$  viral detection (influenza testing)  $\pm$  serology,  $\pm$  pleural fluid C&S (if effusion >5 cm or respiratory distress)
- CXR  $\pm$  CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate  $\pm$  cavitation
- bronchoscopy  $\pm$  washings for:
- (1) severely ill patients refractory to treatment and (2) immunocompromised patients

### Treatment

- airway/breathing/circulation, O<sub>2</sub>, IV fluids, consider salbutamol (nebulized or metered-dose inhaler)
- determine prognosis and need for hospitalization and antibiotics

### Criteria for Hospitalization

- along with clinical judgment, validated clinical prediction rules for prognosis can be used to determine the need for hospitalizations in adults diagnosed with community-acquired pneumonia (e.g. the CURB-65 Score or Pneumonia Severity Index (PSI))

**Table 9. CURB-65 Score – Pneumonia Clinical Prediction Tool**

Component*	Measurement(s)	Points	Total Score	Mortality	Disposition
Confusion	Altered mental status	1	0-1	<5%	Can treat as outpatient
Urea/BUN	Urea >7 mmol/L or BUN >20 mg/dL	1	2-3	5-15%	Consider hospitalization
Respiratory Rate	>30 breaths/min	1	4-5	15-30%	Consider ICU
Blood Pressure	sBP <90 mmHg or dBP <60 mmHg	1			
Age	65 or older	1			

\*A CRB-65 score may also be applied in community acquired pneumonia. Its criteria depends on clinical assessment alone

When *Klebsiella* causes pneumonia:  
see red currant jelly sputum

### 3 As of *Klebsiella*

Aspiration pneumonia  
Alcohol use disorder and patients with diabetes  
Abscess in lungs

Aspiration pneumonias more commonly manifest as infiltrates in the right middle or lower lobes due to the larger calibre and more vertical orientation of the right bronchus

### Healthcare-Associated Infections and Antimicrobial Resistance in Canadian Acute Care Hospitals

Can Commun Dis Rep 2020;46:99-112

**Purpose:** To describe the trends of healthcare-associated infections (HAIs) and antimicrobial resistance (AMR) from 2014 to 2018 using surveillance data from the Canadian Nosocomial Infection Surveillance Program.

**Methods:** Data were collected from 70 Canadian sentinel hospitals regarding *Clostridioides difficile* infection (CDI), MRSA bloodstream infections, VRE bloodstream infections, and carbapenemase-producing Enterobacteriaceae.

**Results:** Rates per 10,000 patient-days increased for MRSA (59%; 0.66-1.05, P=0.023) and VRE bloodstream infections (143%; 0.14-0.34, P=0.023). However, CDI rates decreased by 12.5% (from 6.16-5.39, P=0.042). Carbapenemase-producing Enterobacteriaceae colonization increased by 375% (0.04-0.19; P=0.014) but infection rates remained low and stable.

**Conclusion:** Standardized surveillance data from acute care hospitals in addition to antimicrobial stewardship will be crucial for the ongoing prevention of HAIs and AMR in Canada.

For a report on nosocomial infections in the US, please refer to: NEJM 2014;370:1198-208. Consult your local hospital statistics for the most applicable information for your workplace.

### Diagnosis of Ventilator-Associated Pneumonia in Critically Ill Adult Patients: A Systematic Review and Meta-Analysis

Intensive Care Med 2020;46:1170-79

**Purpose:** To identify and compare the accuracy of the following measures for diagnosing VAP: physical examination, chest radiography, endotracheal aspirate (ETA), bronchoscopic sampling cultures (protected specimen brush (PSB) and bronchoalveolar lavage (BAL)), and CPIS-6.

**Study Selection:** Eligible observational studies and RCTs included >90% patients over 16 y/o with measures conducted in the ICU, including patients with minimum 48 h of invasive mechanical ventilation.

**Results:** The collective sensitivity and specificity of VAP physical examination findings were poor: fever (66.4% and 53.9%, respectively) and purulent secretions (77.0%, 39.0%); any infiltrate on chest radiography (88.9%, 26.1%); ETA (75.7%, 67.9%). Among bronchoscopic sampling methods, PSB (61.4%, 76.5%); BAL (71.1%, 79.6%); CPIS-6 (73.8%, 66.4%).

**Conclusion:** VAP misdiagnosis and potentially unnecessary antimicrobial use may result from reliance on classical clinical measures used in isolation.

**Table 10. Pneumonia Severity Index – Clinical Prediction Rule for Prognosis**

Risk Factor	Points	Total Score	Risk Class	Mortality	Recommendation
<b>Demographics</b>		<51	I	0.1%	Consider outpatient
Men	Age (yr)				
Women	Age (yr) – 10				
Nursing home resident	+10				
<b>Coexisting Illness</b>		51-70	II	0.6%	Consider outpatient
Neoplastic disease	+30				
Liver disease	+20				
Congestive heart failure	+10				
Cerebrovascular disease	+10				
Renal disease	+10				
<b>Physical Exam</b>		71-90	III	0.9-2.8%	Consider outpatient
Altered mental status	+20				
Respiratory rate ≥30 breaths/min	+20				
≤BP <90 mmHg	+20				
T <35°C or ≥40°C	+15				
HR ≥125 bpm	+10				
<b>Investigations</b>		91-130	IV	8.2-9.3%	Hospitalize
Arterial pH <7.35	+30				
BUN ≥30 mg/dL	+20				
Sodium <130 mmol/L	+20				
Glucose ≥250 mg/dL	+10	>130	V	27.0-29.2%	Hospitalize
Hematocrit <30%	+10				
Partial pressure of arterial O <sub>2</sub> <60 mmHg	+10				
Pleural effusion	+10

**Table 11. IDSA/ATS Community-Acquired Pneumonia Treatment Guidelines 2019**

Setting	Circumstances	Treatment
Outpatient	No comorbidities or risk factors for MRSA or <i>P. aeruginosa</i> <sup>1</sup>	Amoxicillin OR Doxycycline OR Macrolide (local pneumococcal resistance <25%) <sup>2</sup>
	Comorbidities <sup>3</sup>	Amoxicillin/clavulanate or cephalosporin <sup>4</sup> AND Macrolide <sup>2</sup> or doxycycline OR Respiratory fluoroquinolone <sup>5</sup>
Inpatient	Nonsevere inpatient pneumonia <sup>6</sup> and no risk factors for MRSA or <i>P. aeruginosa</i> <sup>1</sup>	β-lactam <sup>7</sup> ± macrolide <sup>2</sup> OR respiratory fluoroquinolone <sup>5</sup>
	Severe inpatient pneumonia <sup>6</sup> and no risk factors for MRSA or <i>P. aeruginosa</i> <sup>1</sup>	β-lactam <sup>7</sup> + macrolide <sup>2</sup> OR β-lactam <sup>7</sup> + fluoroquinolone <sup>5</sup>

Given different regional resistance patterns, therapy should be based on local epidemiology and site-specific recommendations. Refers to empiric treatment to be started. Appropriate antibiotic therapy should be tailored if pathogen is identified

1. Previous respiratory isolation of MRSA or *P. aeruginosa* or recent hospitalization AND parenteral antibiotic use in last 3 mo a locally validated risk factors

2. **Macrolide:** use azithromycin or clarithromycin

3. **Comorbidities:** chronic heart, lung, liver, or renal disease, DM, alcohol use disorder, malignancy, asplenia

4. **Cephalosporin:** cefpodoxime or cefuroxime

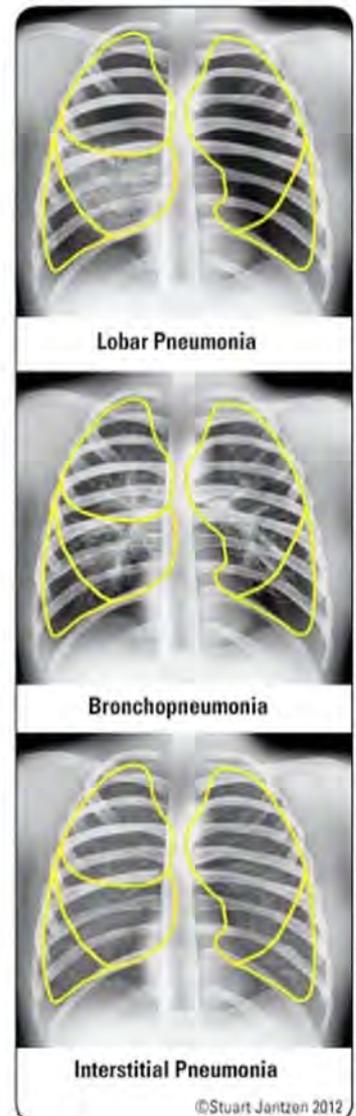

5. **Respiratory fluoroquinolone:** moxifloxacin, levofloxacin

6. Severe = 1 major criterion or ≥3 minor criteria. Minor criteria: respiratory rate ≥30 breaths/min, PaO<sub>2</sub>/FIO<sub>2</sub> ratio ≤250, multilobar infiltrates, confusion/disorientation, BUN ≥20 mg/dL, WBC <4000/μL due to infection, Plt <100000/μL, T <36°C, hypotension with aggressive fluid resuscitation. Major criteria: septic shock with vasopressors, respiratory failure with mechanical ventilation

7. **β-lactam:** ampicillin sulbactam\*, cefotaxime, ceftriaxone, ceftaroline\*

**IDSA:** Infectious Diseases Society of America  
**ATS:** American Thoracic Society

\*Available in Canada through the Special Access Program

**Figure 6. Lobar, broncho-, and interstitial pneumonia**

**Diagnosis and Treatment of Adults with Community-Acquired Pneumonia: An Official Clinical Practice Guideline of the American Thoracic Society and Infectious Diseases Society of America**

*Am J Respir Crit Care Med* 2019;200:e45-e67

- The Pneumonia Severity Index is preferred over the CURB-65 tool for determining inpatient vs. outpatient treatment.
- Test for influenza with a rapid influenza molecular assay when it is circulating in the community.
- Obtaining blood C&S or sputum Gram stain/C&S routinely in adults with CAP managed in the outpatient setting is not recommended.
- Obtaining pre-treatment blood C&S and sputum Gram stain/C&S is recommended in adults with CAP managed in the hospital setting who (1) are classified as severe CAP or (2) are being empirically treated for MRSA or *P. aeruginosa* or (3) were previously infected with MRSA or *P. aeruginosa* or (4) were hospitalized and received parenteral antibiotics in the last 90 d.

**Table 12. IDSA/ATS Hospital-Acquired (HAP) and Ventilator-Associated (VAP) Pneumonia Clinical Practice Guidelines 2016**

Setting	Treatment
Clinically suspected HAP (non-VAP) with no increase in likelihood of MRSA and not at high-risk of mortality	<b>One of:</b> piperacillin-tazobactam OR cefepime OR levofloxacin OR imipenem OR meropenem
Clinically suspected HAP (non-VAP) with increasing likelihood of MRSA and not at high-risk of mortality	<b>One of:</b> piperacillin-tazobactam OR cefepime or ceftazidime OR levofloxacin or ciprofloxacin OR imipenem or meropenem OR aztreonam* <b>PLUS one of:</b> vancomycin or linezolid for MRSA coverage
Clinically suspected HAP (non-VAP) with high-risk of mortality or recipient of IV antibiotics in last 90 d	<b>Two of the following (avoid 2 <math>\beta</math>-lactams):</b> piperacillin-tazobactam OR cefepime or ceftazidime OR levofloxacin or ciprofloxacin OR imipenem or meropenem OR aztreonam* OR amikacin or gentamicin or tobramycin <b>PLUS either MRSA or MSSA coverage:</b> MRSA: vancomycin or linezolid OR MSSA: piperacillin-tazobactam, cefepime, levofloxacin, imipenem, meropenem
Clinically suspected VAP in units where empiric MRSA coverage and double antipseudomonal/GN coverage are appropriate	<b>One of:</b> $\beta$ -lactam/ $\beta$ -lactamase inhibitor (piperacillin/tazobactam) OR antipseudomonal cephalosporin (cefepime or ceftazidime) OR antipseudomonal carbapenem (imipenem or meropenem) OR monobactam (aztreonam*) <b>PLUS one of:</b> antipseudomonal fluoroquinolone (ciprofloxacin or levofloxacin) OR aminoglycoside (amikacin, gentamicin, or tobramycin) OR polymyxins (colistin or polymyxin B) <b>PLUS one of:</b> vancomycin or linezolid for MRSA coverage

Refers to empiric treatment to be started. Appropriate antibiotic therapy should be tailored if pathogen is identified

\*Available in Canada through the Special Access Program

Risk factors for mortality include need for ventilatory support due to pneumonia and septic shock

Risk factors for MDR VAP: prior IV antibiotic use within 90 d, septic shock at time of VAP, ARDS preceding VAP, 5+ d of hospitalization prior to VAP onset, acute renal replacement therapy prior to VAP onset

Risk factors for MDR HAP, MRSA VAP/HAP, or MDR *Pseudomonas* VAP/HAP: Prior IV antibiotic use within 90 d

Note: Indications for MRSA coverage includes IV antibiotic treatment during the prior 90 d and treatment in a unit where prevalence of MRSA of *S. aureus* isolates is not known or is >20%

Note: These guidelines may be less applicable in Canada given lower rates of antibiotic resistance among common nosocomial pathogens

## Prevention

- Public Health Agency of Canada recommends the following
  - vaccine for influenza A and B annually for all ages  $\geq 6$  mo
  - pneumococcal polysaccharide vaccine (Pneumovax\*) for all adults  $\geq 65$  yr and in younger patients  $\geq 24$  mo at high-risk for invasive pneumococcal disease (e.g. functional or anatomic asplenia, congenital or acquired immunodeficiency)
  - pneumococcal conjugate vaccine (Pneumnar-13\*) for children and adolescents ages 5-17 yr at high risk for invasive pneumococcal disease and who have not previously received Pneumnar-13\* (CDC recommends giving Pneumnar-13\* to all adults at high-risk for invasive pneumococcal disease)
  - Pfizer-BioNTech (Comirnaty\*) COVID-19 vaccine for children ages 5-11 yr, Moderna (Spikevax\*) COVID-19 vaccine (half-dose, 50  $\mu$ g) for children ages 6-11 yr, and mRNA COVID-19 vaccine for all ages  $\geq 12$  yr who do not have contraindications

## Influenza

### Definitions and Etiology

- influenza viruses A and B
- influenza A further divided into subtypes based on envelope glycoproteins
  - hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
  - main circulating influenza viruses: influenza A (H1N1), influenza A (H3N2), and influenza B
  - associated with antigenic drift (gradual, minor changes due to random point mutations)
  - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
  - outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
  - associated with antigenic shift: abrupt, major changes due to mixing of two different viral strains from different hosts
  - may create a new viral strain resulting in a pandemic outbreak (worldwide)
  - antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

### Does this Patient have Community-Acquired Pneumonia?

#### Diagnosing Pneumonia by History and Physical Examination

JAMA 1997;278:1440-1445

**Study:** Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult community-acquired pneumonia.

**Results:** The presence of fever or immunosuppression had a positive likelihood ratio (+LR) of 2, while a history of dementia had a +LR of 3; however, these traits are not confirmatory. The presence of an abnormality in any vital sign, including tachycardia, tachypnea, or fever had a +LR ranging from 2-4, which was not significantly affected by different cut-points. The absence of vital sign abnormality had a -LR ranging from 0.5-0.8. The combination of respiratory rate  $>30$  breaths/min, heart rate  $>100$  bpm, and temperature  $>37.8$  C had a -LR of 0.18. Findings on chest exam raised the likelihood of diagnosis but were uncommonly seen in studies (e.g. presence of asymmetric respirations essentially confirmed the diagnosis but was only present in 4% of patients). In patients with a clinical diagnosis but normal radiograph, only ~10% will develop radiographic findings in 72 h.

**Conclusions:** Evidence suggests no single item on clinical history or physical exam is sufficient to rule in or out pneumonia without CXR. Vital sign abnormalities were correlated with a diagnosis of pneumonia. Findings on chest exam significantly raised the likelihood of pneumonia but were uncommonly seen in studies.

### Beware! Do Not Confuse *H. influenzae* with Influenza Virus

*H. influenzae*: a bacterium (Types A, B, C, D, E, and F refer to capsule)

Influenza: a virus (Types A and B refer to strain)

### Vaccines for Preventing Influenza in Healthy Adults

Cochrane DB Syst Rev 2018;CD001269

**Study:** 52 RCTs and quasi-RCTs evaluating influenza vaccines compared to placebo or no intervention in healthy individuals 16-65 y/o. Observational comparative studies were not included.

**Results:** Inactivated influenza vaccines reduce influenza in healthy adults from 2.3% to 0.9% and reduce influenza-like illness (ILI) from 21.5% to 18.1%. The preventative effect of vaccination is small, with 71 healthy adults needing to be vaccinated to prevent one from experiencing influenza, and 29 needing to be vaccinated to prevent one from experiencing ILI. Vaccination leads to a small reduction in the risk of hospitalization from 14.7% to 14.1%, and a small reduction in days off work. Effectiveness of the influenza vaccine is less in mothers and newborns compared to the general population.

**Conclusions:** Influenza vaccines have a very modest effect in reducing influenza, associated symptoms, hospitalization, and days off work in healthy adults.

Table 13. Difference Between Influenza Strains

	Influenza A	Influenza B
Host(s)	Humans, birds, mammals	Humans only
Antigenic Drift	Yes, new strains	Yes, new strains
Antigenic Shift	Yes, new subtypes	No
Epidemics	Yes	Yes
Pandemics	Yes	No

### Clinical Features

- incubation period 1-4 d and symptoms typically resolve in 7-10 d
- acute onset of systemic (fever, chills, myalgias, arthralgias, headache, fatigue) and respiratory symptoms (cough, dyspnea, pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, Guillain-Barré syndrome)
- severe disease more likely in the elderly, children, pregnant women, immunocompromised patients, asthma, COPD, cardiovascular disease (CVD), DM, and obesity

### Investigations

- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for RT-PCR (gold standard), or rapid antigen detection (DFA, direct fluorescent antibody) which has lower sensitivity
- lower respiratory specimens for RT-PCR
- serology: rarely used for clinical management

### Treatment and Prevention

- primarily supportive unless severe infection or high-risk for complications
- neuraminidase inhibitors: oseltamivir (Tamiflu<sup>®</sup>) or zanamivir (Relenza<sup>®</sup>) for treatment and prophylaxis against types A and B or peramivir (Rapivab<sup>™</sup>) for the treatment against types A and B
  - decreases duration (by ~1 d) and severity of symptoms if given within 48 h of onset
  - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- vaccine for influenza A and B viruses is recommended annually for all ages ≥6 mo
- vaccine is reformulated each year to reflect circulating influenza A and B strains

### High-risk for Complications

- anyone who is hospitalized, patients with severe illness/chronic medical conditions, immunocompromised patients, children <2 yr, elders ≥65 yr, pregnant women or women ≤2 wk postpartum

### Acute Myocardial Infarction after Laboratory-Confirmed Influenza Infection

N. EJM 2018; 378:345-353

**Purpose:** To investigate the association between laboratory-confirmed influenza infection and acute MI.

**Methods:** Self-controlled case-series. Risk interval defined as first 7 d after respiratory specimen collection and control interval as 1 yr before and 1 yr after the risk interval.

**Results:** Increased incidence ratio of an admission for acute MI during risk interval vs. control interval (6.05, 95% CI 3.86-9.50). No increased incidence after 7 d. Increased incidence ratios for acute MI within 7 d after detection of influenza B (10.11, 95% CI 4.37-23.38), influenza A (5.17, 95% CI 3.02-8.84), and respiratory syncytial virus (3.51, 95% CI 1.11-11.12).

**Conclusions:** Significant association between respiratory infections, especially influenza, and acute MI.

## COVID-19

### Definitions and Etiology

- an acute infectious respiratory disease caused by the SARS-CoV-2 virus
- SARS-CoV-2 is an enveloped, positive-sense, ssRNA virus
- transmission: droplet and airborne transmission
- incubation period 2-14 d, usually ~5 d

### Pathophysiology

- invasion of host cells via the viral spike protein which binds to angiotensin-converting enzyme 2 (ACE2) expressed on the surface epithelium of the lungs
- virus induced cytotoxic damage particularly to the alveolar epithelium
- dysregulated immune response can lead to a cytokine storm causing organ failure or death

### Clinical Features

- can be asymptomatic (estimated to be 1 in 3 of those infected)
  - children are more likely to be asymptomatic or to have mild disease
- most common: fever, fatigue, dry cough
- common: dyspnea, loss of smell and/or taste (may vary depending on the variant circulating), loss of appetite, myalgia
- less common: nausea, vomiting, abdominal pain, sore throat, headache, thromboembolic events
- course: can range from mild disease (lasts 1-2 wk) to severe or critical disease (lasts 3+ wk); may be complicated by post-COVID condition which is associated with a wide range of diverse symptoms across multiple organ systems that may fluctuate in intensity, often exacerbated by mental and physical over-exertion

### Diagnosis

- nasopharyngeal swabs for RT-PCR (gold standard) or nasal/oral-nasal swabs for rapid antigen detection point of care tests which have lower sensitivity
- lower respiratory specimens for RT-PCR

### Treatment (accurate as of April 1, 2022)

- please see updated guidance through the Ontario Science Table (<https://covid19-sciencetable.ca/science-briefs/#infectious-diseases-clinical-care>)

- for critically ill adults >18 yr requiring ventilatory and/or circulatory support:
  - dexamethasone PO or IV for 10 d (or until discharge)
  - tocilizumab if on recommended steroid dose + admitted to hospital or diagnosed with COVID-19 in hospital within 14 d
  - prophylactic low molecular-weight or unfractionated heparin
- for adults >18 yr requiring low-flow supplemental O<sub>2</sub>:
  - dexamethasone PO or IV for 10 d (or until discharge)
  - remdesivir IV for 5 d
  - tocilizumab if serum CRP  $\geq 75$  mg/L + disease progression despite 24-48 h of recommended steroid dose + admitted to hospital or diagnosed with COVID-19 in hospital within 14 d
  - prophylactic low molecular-weight or unfractionated heparin
- for mildly ill adults >18 yr who do not require supplemental O<sub>2</sub> in any setting:
  - stratify by risk of severe disease (i.e.  $\geq 5\%$  risk of hospitalization)
  - for patients with  $\geq 5\%$  risk of hospitalization:
    - nirmatrelvir/ritonavir (Paxlovid) if presenting within 5 d of symptom onset
    - remdesivir if presenting within 7 d of symptom onset
- for patients with <5% risk of hospitalization: reassurance and self-monitoring of symptoms

**Table 14. Risk of Hospitalization in Mildly Ill Adults >18 yr with COVID-19 (accurate as of April 1, 2022)**

- Higher risk individuals are those who have a  $\geq 5\%$  risk of hospitalization if they develop COVID-19. Standard risk individuals are those who have a <5% of hospitalization.
- Indigenous people, Black people, and members of other racialized communities may be at increased risk of disease progression due to disparate rates of comorbidity, increased barriers to vaccination, and social determinants of health. They should be considered priority populations for access to COVID-19 drugs and therapeutics.

Age (Years)	Number of Vaccine Doses			Risk Factors
	0 Doses	1 or 2 Doses	3 Doses	
<20 <sup>1</sup>	Higher risk if $\geq 3$ risk factors <sup>1</sup>	Standard risk <sup>1</sup>	Standard risk <sup>1</sup>	Obesity (BMI $\geq 30$ kg/m <sup>2</sup> ) Diabetes Heart disease, hypertension, congestive heart failure
20 to 39	Higher risk if $\geq 3$ risk factors	Higher risk if $\geq 3$ risk factors	Standard risk	Chronic respiratory disease, including cystic fibrosis
40 to 69	Higher risk if $\geq 1$ risk factors	Higher risk if $\geq 3$ risk factors	Standard risk	Cerebral palsy
$\geq 70$	Higher risk	Higher risk if $\geq 1$ risk factors	Higher risk if $\geq 3$ risk factors	Intellectual disability Sickle cell disease
Immunocompromised <sup>2</sup> individuals of any age	Higher risk: Therapeutics should always be recommended for immunocompromised individuals not expected to mount an adequate immune response to COVID-19 vaccination or SARS-CoV-2 infection due to their underlying immune status, regardless of age or vaccine status <sup>1,2</sup>			Moderate or severe kidney disease (eGFR <60 mL/min)
Pregnancy	Higher risk <sup>3</sup>	Standard risk	Standard risk	Moderate or severe liver disease (e.g. Child Pugh Class B or C cirrhosis)

- Evidence for the safety and efficacy of sotrovimab and nirmatrelvir/ritonavir (Paxlovid) in children  $\leq 10$  years of age is limited. While early evidence on risk factors for moderate and severe COVID-19 in children is emerging, the ability to reliably predict disease progression in children remains very limited, and the frequency of progression is rare. While not routinely recommended in children  $\leq 18$  years of age, the use of these agents may be considered in exceptional circumstances (e.g. severe immunocompromise and/or multiple risk factors, clinical progression) on a case-by-case basis. Multidisciplinary consultation with Infectious Diseases (or Pediatric Infectious Diseases) and the team primarily responsible for the child's care is recommended to review the individual consideration of these medications.
- Examples of immunocompromised or immunosuppressed individuals include receipt of treatment for solid tumours and hematologic malignancies (including individuals with lymphoid malignancies who are being monitored without active treatment), receipt of solid-organ transplant and taking immunosuppressive therapy, receipt of chimeric antigen receptor (CAR)-T-cell or hematopoietic stem cell transplant (within 2 years of transplantation or taking immunosuppression therapy), moderate or severe primary immunodeficiency (e.g. DiGeorge syndrome, Wiskott-Aldrich syndrome, common variable immunodeficiency, Good's syndrome, hyper IgE syndrome), advanced or untreated HIV infection, active treatment with high-dose corticosteroids (i.e.  $\geq 20$  mg prednisone or equivalent per day when administered for  $\geq 2$  weeks), alkylating agents, antimetabolites, transplant-related immunosuppressive drugs, cancer chemotherapeutic agents classified as severely immunosuppressive, tumour-necrosis factor (TNF) blockers, and other biologic agents that are immunosuppressive or immunomodulatory. These individuals should have a reasonable expectation for 1-year survival prior to SARS-CoV-2 infection.
- Therapeutics should always be recommended for pregnant individuals who have received zero vaccine doses.

### Prevention (accurate as of June 7, 2022)

- complete series of mRNA COVID-19 vaccine for all ages  $\geq 12$  yr who do not have contraindications
- Pfizer-BioNTech (Comirnaty<sup>®</sup>) COVID-19 vaccine for children ages 5-11 yr, Moderna (Spikevax<sup>®</sup>) COVID-19 vaccine (half-dose, 50  $\mu$ g) for children ages 6-11 yr, and mRNA COVID-19 vaccine for all ages  $\geq 12$  yr who do not have contraindications

## Skin and Soft Tissue Infections

### Cellulitis

#### Definition

- acute infection of the skin principally involving the dermis and subcutaneous tissue

#### Etiology

- common causative agents:  $\beta$ -hemolytic streptococci (most common cause of non-purulent cellulitis), *S. aureus*, and occasionally *S. lugdunensis*
- immunocompromised patients or water exposure: may also include GN rods and fungi
  - bite wounds: consider skin flora of "bitee" and mouth flora of "biter"
  - risk factors
    - trauma with direct inoculation, recent surgery
    - peripheral vascular disease, lymphedema, DM, cracked skin in feet/toes (tinea pedis)

#### Clinical Features

- pain, edema, erythema with indistinct borders  $\pm$  regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
- can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

**Investigations**

- CBC and differential, blood C&S if patient has malignancy, severe systemic features, or unusual predisposing factors, such as immersion injury, animal bites, neutropenia, and severe cell-mediated immunodeficiency
- skin swab ONLY if open wound with pus

**Treatment**

- consult local guidelines for appropriate antibiotic therapy
- antibiotics: cephalexin (broader coverage if risk factors for GN rods)
- if extensive erythema or systemic symptoms, consider cefazolin IV
- if MRSA is suspected, empiric coverage for MRSA may be considered (see *A Simplified Look at Antibiotics, ID46*)
- limb rest and elevation may help reduce swelling

**Necrotizing Fasciitis****Definition**

- life- and limb-threatening infection of the deep fascia characterized by rapid spread

**Etiology**

- two main forms
  - Type I: polymicrobial infection – aerobes and anaerobes (e.g. *S. aureus*, *Bacteroides*, *Enterobacteriales*)
  - Type II: monomicrobial infection with GAS, or less commonly *S. aureus*

**Clinical Features**

- pain out of proportion to clinical findings and beyond border of erythema
- edema ± crepitus (subcutaneous gas from anaerobes)
- infection spreads rapidly
- rapid onset of systemic symptoms (e.g. tachycardia, hypotension, lightheadedness, disorientation, lethargy, and fever)
- late findings
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of hemorrhagic bullae
  - loss of sensation in the affected area (paresthesias)

**Investigations**

- clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
- blood and tissue C&S
- serum Creatine Kinase (CK) – elevated CK usually means myonecrosis (a late sign)
- plain film x-ray or CT (soft tissue gas may be visualized)
- surgical exploration for debridement of infected tissue

**Treatment**

- resuscitation with IV fluids
- emergency surgical debridement to confirm diagnosis and remove necrotic tissue (may require amputation)
- IV antibiotics
  - unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV ± vancomycin if MRSA is considered
  - Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
  - Type II (monomicrobial): with confirmed GAS infection, penicillin G + clindamycin IV; with confirmed *S. aureus* infection, cefazolin (or cloxacillin) + clindamycin IV
  - with Type II, evaluate for streptococcal toxic shock syndrome and the need for IVIg

**Acquired Oral Lesions****Etiology**

- infection (e.g. candidiasis, gonococcal infection), HSV
- malignancy (e.g. adenocarcinoma, leukoplakia)
- poor oral hygiene (e.g. caries, periodontal disease)
- trauma (e.g. abuse)
- toxic ingestion
- xerostomia (e.g. age, medications)
- systemic diseases (e.g. lichen planus, Behçet disease)

**Table 15. Comparison between Oral Infection vs. Oral Carcinoma**

	Oral Candidiasis	Oral Squamous Cell Carcinoma
<b>Risk Factors</b>	Antibiotics, chemotherapy, radiation therapy Immunocompromised, inhaled corticosteroids Age – infants, older adults with dentures	Tobacco use (smoked and smokeless) Betel use Alcohol HPV, especially HPV-16
<b>Morphology</b>	Pseudomembranous: confluent, white patches or plaques, can be wiped off with a gauze, exposing an erythematous base Atrophic candidiasis: red patches localized mainly to the palate and dorsum of the tongue	A lesion of three or more weeks duration: Red or red and white lesion Ulcer Lump Especially when in combination or if indurated (firm on palpation)
<b>Diagnosis</b>	Cytology, biopsy, or culture	Biopsy and histopathologic examination
<b>Treatment</b>	Topical antifungal	Referral to ENT

## Gastrointestinal Infections

- see [Gastroenterology, G14](#) and [Paediatrics, P40](#)

## Traveller's Diarrhea

- see [Gastroenterology, G18](#)

## Chronic Diarrhea

- see [Gastroenterology, G19](#)

## Peptic Ulcer Disease (*Helicobacter pylori*)

- see [Gastroenterology, G13](#)

## Bone and Joint Infections

### Septic Arthritis

#### Definition

- infection of one or more joints by pathogenic microbes

#### Routes of Infection

- hematogenous (most common)  
from distant infection (e.g. abscesses, wound infection, bacteremia)
- direct inoculation via skin/trauma
  - iatrogenic (e.g. surgery, arthroscopy, arthrocentesis, joint injection)
  - trauma (e.g. open wounds around the joint, penetrating trauma)
- contiguous spread (e.g. septic bursitis, osteomyelitis)

#### Etiology

- gonococcal
  - *N. gonorrhoeae*: previously accounted for 75% of septic arthritis in young sexually active adults
- non-gonococcal
  - *S. aureus*: affects all ages, rapidly destructive, accounts for most non-gonococcal cases of septic arthritis in adults (especially in those with rheumatoid arthritis)
  - *Streptococcus* spp. (Group A and B)
  - GNs: affect neonates, elderly, injection drug users, immunocompromised
  - *S. pneumoniae*: affects children
  - *Kingella kingae*: affects children <4 yr
  - *Haemophilus influenzae* type B (Hib) now rare due to Hib vaccine: consider in unvaccinated children
  - *Salmonella* spp.: characteristic of sickle cell disease
  - coagulase-negative Staphylococcus spp.: prosthetic joints
- if culture-negative: partially treated infection (prior to oral antibiotics), reactive arthritis, rheumatic fever, less common bacterial causes such as *Borrelia* spp. (Lyme disease) or *Tropheryma whippelii* (Whipple's disease), and non-infectious causes

#### Medical Emergency

Septic arthritis is a medical emergency!  
If untreated, rapid joint destruction will occur

#### Disseminated Gonococcal Infection Triad

- Migratory arthralgias
- Tenosynovitis next to inflamed joint
- Pustular skin lesions

**Risk Factors**

- gonococcal
- age <40 yr, multiple partners, unprotected intercourse, MSM
- non-gonococcal
  - most affected children are previously healthy with no risk factors: occasionally preceding history of minor trauma
  - bacteremia (extra-articular infection with hematogenous seeding, endocarditis)
  - prosthetic joints/recent joint surgery
  - underlying joint disease (e.g. rheumatoid arthritis, osteoarthritis)
  - immunocompromised (e.g. DM, chronic kidney disease, alcohol use disorder, cirrhosis)
  - loss of skin integrity (e.g. cutaneous ulcer, skin infection)
  - age >80 yr

**Clinical Features of Gonococcal Arthritis**

- two forms (although often overlap):
  - septic arthritis form: local symptoms in involved joint (swelling, warmth, pain, inability to weight bear, decreased range of motion)
  - bacteremic form: systemic symptoms of fever, malaise, chills

**Clinical Features of Non-Gonococcal Arthritis**

- acute onset of pain, swelling, warmth, decreased range of motion ± fever and chills; in children, refusal to weight bear
- most often in large weight-bearing joints (knee, hip, ankle) and wrists
- usually monoarticular (polyarticular risk factors: rheumatoid arthritis, endocarditis, GBS)

**Investigations**

- consider rheumatologic causes for monoarthritis (see [Rheumatology, Table 4, RH3](#))
- gonococcal: blood C&S, as well as endocervical, urethral, rectal, and oropharyngeal testing
- non-gonococcal: blood C&S
- arthrocentesis (synovial fluid analysis) is mandatory, CBC and differential, Gram stain, C&S, examine for crystals
  - infectious = opaque, increased WBCs (>15000/mm<sup>3</sup> → likelihood of infection increases with increasing WBCs), PMNs >90%, culture positive
  - growth of *N. gonorrhoeae* from synovial fluid is successful in <50% of cases
- ± plain x-ray: assess for osteomyelitis, provides baseline to monitor treatment

**Treatment**

- medical
  - empiric IV antibiotics: specific choice depends on clinical scenario and local guidelines; for most adults, cefazolin ± vancomycin is reasonable; for fully vaccinated children, cefazolin or cloxacillin IV unless MRSA is a consideration – delay may result in joint destruction
  - Gram stain and cultures guide subsequent treatment
  - gonococcal: ceftriaxone (+ azithromycin for concurrent treatment of *C. trachomatis*), 7 d of therapy usually sufficient
  - non-gonococcal: antibiotics against *Streptococcus* spp. (2-3 wk IV followed by PO), *S. aureus* (4 wk IV minimum), or GNB (4 wk, newer evidence suggests early switch to PO is safe and effective)
- surgical intervention if (see [Orthopaedic Surgery, OR11](#))
  - would consider surgical intervention on all cases of septic arthritis if possible
  - persistent positive joint cultures on repeat arthrocentesis
  - hip joint involvement, especially in paediatric population
  - prosthetic joint
- daily joint aspirations until culture sterile
- physiotherapy

**Prognosis**

- gonococcal: responds well after 24-48 h of initiating antibiotics (usually complete recovery)
- non-gonococcal: in children, generally good outcome if treated promptly; in adults, up to 50% morbidity (decreased joint function/mobility)

## Diabetic Foot Infections

**Etiology**

- neuropathy, peripheral vascular disease, and hyperglycemia contribute to foot ulcers that heal poorly, and are predisposed to infection
- organisms in mild infection: *Streptococcus* spp., *S. aureus*
- organisms in moderate/severe infection: polymicrobial with aerobes (*S. aureus*, *Streptococcus*, *Enterococcus*, GNB) and anaerobes (*Peptostreptococcus*, *Bacteroides*, *Clostridium*)

**Clinical Features**

- not all ulcers are infected
- consider infection if: probe to bone (see below), ulcer present >30 d, recurrent ulcers, trauma, PVD, prior amputation, loss of protective sensation, renal disease, or history of walking barefoot

Intra-articular steroids are contraindicated until septic arthritis has been excluded

**IWGDF Guidance on the Diagnosis and Management of Foot Infections in Persons with Diabetes - Recommendations for Diagnosing Osteomyelitis**

Diabetes Metab Res Rev 2016;32:45-74

Perform a probe-to-bone test for an infected open wound; a negative test likely rules out osteomyelitis in low-risk patients, while a positive test is likely diagnostic in high-risk patients.

In suspected cases, dramatically elevated serum inflammatory markers (especially ESR) are suggestive of osteomyelitis.

When in doubt, positive results on microbiological or histological exam of an aseptically obtained bone sample are usually required for a definitive diagnosis of bone infection.

Bone infection is probable if there are positive results on a combination of diagnostic tests (probe-to-bone, serum inflammatory markers, plain x-ray, MRI, or radionuclide scanning).

For all cases of non-superficial diabetic foot infection, plain x-rays of the foot should be obtained.

When advanced imaging is required for diagnosis, MRI is preferred.

See Landmark Infectious Disease Trials table for more information on the OVIVA trial. It details whether oral antibiotic therapy is noninferior to IV antibiotic therapy for the management of complex orthopaedic infections.

- diagnosis of infected ulcer:  $\geq 2$  of the cardinal signs of inflammation (redness, warmth, swelling, pain) OR the presence of pus
- $\pm$  crepitus, osteomyelitis, systemic toxicity
- visible bone or probe to bone: osteomyelitis
- infection severity
  - mild = superficial (no bone/joint involvement)
  - moderate = deep (beneath superficial fascia, involving bone/joint) or erythema  $>2$  cm
  - severe = infection in a patient with systemic toxicity (fever, tachypnea, leukocytosis, tachycardia, hypotension)

### Investigations

- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infections)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages) or MRI/bone scan if high clinical suspicion
- if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity

### Treatment

- mild to moderate: cefazolin or cephalexin
- severe: options include: 1. ceftriaxone + metronidazole; 2. piperacillin/tazobactam  $\pm$  vancomycin; 3. meropenem  $\pm$  vancomycin
- optimize glycemic control, pressure offloading, wound care, consider revascularization
  - this is empiric treatment, and specific treatment needs to be adjusted based on culture and response to therapy

## Osteomyelitis

- see [Orthopaedic Surgery](#), OR11

# Cardiac Infections

## Infective Endocarditis

### Definition

- infection of cardiac endothelium, most commonly the valves
- classifications: acute vs. subacute, native valve vs. prosthetic valve, right sided vs. left sided
- leaflet vegetations are made of platelet-fibrin thrombi, WBCs, and bacteria

### Risk Factors and Etiology

- predisposing conditions
  - high-risk: prosthetic cardiac valve, previous infective endocarditis (IE), congenital heart disease (unrepaired, repaired within 6 mo, or repaired with defects), cardiac transplant with valve disease (surgically constructed systemic-to-pulmonary shunts or conduits)
  - moderate risk: other congenital cardiac defects, acquired valvular dysfunction, hypertrophic cardiomyopathy
  - low/no risk: secundum atrial septal defect (ASD) or surgically repaired ASD < ventricular septal defect (VSD), patent ductus arteriosus (PDA), mitral valve (MV) prolapse, ischemic heart disease, previous coronary artery bypass graft (CABG)
  - opportunistic bacteremia: IVDU, indwelling venous catheter, hemodialysis, poor dentition, DM, HIV
- frequency of valve involvement MV  $\gg$  aortic valve (AV)  $>$  tricuspid valve (TV)  $>$  pulmonary valve (PV)
  - in 50% of IVDU-related IE the tricuspid valve is involved

**Table 16. Microbial Etiology of Infective Endocarditis Based on Risk Factors**

Native Valve	IVDU	Prosthetic Valve (recent surgery <2 mo)	Prosthetic Valve (remote surgery >2 mo)
<b><i>Streptococcus</i></b> <sup>1</sup> (36%)	<b><i>S. aureus</i></b> (68%)	<b><i>S. aureus</i></b> (36%)	<b><i>Streptococcus</i></b> (20%)
<b><i>S. aureus</i></b> (28%)	<b><i>Streptococcus</i></b> (13%)	<b><i>S. epidermidis</i></b> (17%)	<b><i>S. aureus</i></b> (20%)
<b><i>Enterococcus</i></b> (11%)	<i>Enterococcus</i>	<i>Enterococcus</i>	<b><i>S. epidermidis</i></b> (20%)
<i>S. epidermidis</i>	GNB	GNB	<b><i>Enterococcus</i></b> (13%)
GNB	<i>Candida</i>	Other <sup>2</sup>	Other <sup>2</sup>
Other <sup>2</sup>	Other <sup>1</sup>		

Organisms in bold are the most common isolates

1. *Streptococcus* includes mainly viridans group streptococci

2. Other includes less common organisms such as:

- *Streptococcus gallolyticus* (previously known as *S. bovis*; usually associated with underlying GI malignancy and cirrhosis)
- Culture-negative organisms including *Abiotrophia*, *Granulicatella*, *Bartonella*, *Coxiella*, *Chlamydia*, *Legionella*, *Brucella*
- *Haemophilus*, *Aggregatibacter*, *Cardiobacterium*, *Eikenella*, and *Kingella* (HACEK)
- *Candida*

3. IVDU endocarditis pathogens depend on substance used to dilute the drugs (i.e. tap water = *Pseudomonas*, saliva = oral flora, toilet water = GI flora)

### Clinical Features

- systemic
  - fever (80-90%), chills, weakness, rigors, night sweats, weight loss, anorexia

- cardiac
  - dyspnea, chest pain, clubbing (subacute)
  - regurgitant murmur (new onset or increased intensity)
  - signs of CHF (secondary to acute mitral regurgitation (MR), atrial regurgitation (AR))
- embolic/vascular
  - petechiae over legs, splinter hemorrhages (linear, reddish-brown lesion within nail bed)
  - Janeway lesions (painless, 5 mm, erythematous, hemorrhagic pustular lesions on soles/palms)
  - focal neurological signs (CNS emboli), headache (mycotic aneurysm)
  - splenomegaly (subacute)
  - microscopic hematuria, flank pain (renal emboli) ± active sediment
- immune complex
  - Osler's nodes (painful, raised, red/brown, 3-15 mm on digits)
  - glomerulonephritis
  - arthritis
  - Roth's spots (retinal hemorrhage with pale centre)

### Diagnosis

- Modified Duke Criteria
  - definitive diagnosis if: 2 major, OR 1 major + 3 minor, OR 5 minor
  - possible diagnosis if: 1 major + 1 minor, OR 3 minor

**Table 17. Modified Duke Criteria**

Major Criteria (2)	
1. Positive blood cultures for IE	• Typical microorganisms for IE from 2 separate blood cultures ( <i>Streptococcus viridans</i> , HACEK group, <i>Streptococcus gallolyticus</i> , <i>Staphylococcus aureus</i> , community-acquired enterococci) OR
	• Persistently positive blood culture, defined as recovery of a microorganism consistent with IE from blood drawn >12 h apart OR
	• All of 3 or a majority of 4 or more separate blood cultures, with first and last drawn >1 h apart OR
	• Single positive blood culture for <i>Coxiella burnetii</i> or antiphase 1 IgG antibody titer >1:800
2. Evidence of endocardial involvement	• Positive echocardiogram for IE (oscillating intracardiac mass on valve or supporting structures, or in the path of regurgitant jets, or on implanted material in the absence of an alternative anatomic explanation OR abscess OR new partial dehiscence of prosthetic valve); and new valvular regurgitation (insufficient if increase or change in pre-existing murmur)
Minor Criteria (5)	
1. Predisposing condition (abnormal heart valve, IVDU)	
2. Fever (38.0°C/100.4°F)	
3. Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysms, intracerebral hemorrhage (ICH), conjunctival hemorrhages, Janeway lesions	
4. Immunologic phenomena: glomerulonephritis, rheumatoid factor, Osler's nodes, Roth's spots	
5. Positive blood culture but not meeting major criteria OR serologic evidence of active infection with organism consistent with IE	

### Investigations

- serial blood cultures: 3 sets (each containing one aerobic and one anaerobic sample) collected from different sites >1 h apart
  - persistent bacteremia is the hallmark of an endovascular infection (e.g. IE)
- repeat blood cultures (at least 2 sets) after 48-72 h of appropriate antibiotics to confirm clearance
- blood work: CBC and differential (normochromic, normocytic anemia), ESR (increased), rheumatoid factor (RF) (+), urea/Cr
- urinalysis (proteinuria, hematuria, red cell casts) and urine C&S
- ECG: prolonged PR interval may indicate perivalvular abscess
- echo findings: vegetations, regurgitation, abscess
  - TTE (poor sensitivity) indicated for all suspected IE, inadequate in 20% (obesity, COPD, chest wall deformities)
  - TEE indicated if TTE is non-diagnostic in patients with at least possible endocarditis or if suspect prosthetic valve endocarditis or complicated endocarditis (e.g. paravalvular abscess/perforation) (~90% sensitivity)

### Treatment

- medical
  - usually non-urgent and can wait for confirmation of etiology before initiating treatment unless patient is septic
  - empiric antibiotic therapy if patient is unstable; administer ONLY after blood cultures have been taken. Generally, *S. aureus*, coagulase-negative *Staphylococcus* (CNS), and GN coverage is important
    - ♦ first line empiric treatment for native valve: vancomycin + ceftriaxone OR gentamicin
    - ♦ first line empiric treatment for prosthetic valve: vancomycin + gentamicin + rifampin
  - targeted antibiotic therapy: antibiotic and duration (usually 4-6 wk) adjusted based on valve, organism, and susceptibilities
  - monitor for complications of IE (e.g. heart failure (HF), conduction block, new emboli) and complications of antibiotics (e.g. renal disease)
  - post-treatment prophylaxis only recommended for high-risk individuals listed above with dental procedures that may lead to bleeding OR invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy OR procedures on infected skin, skin structure, or musculoskeletal tissue

#### Clinical Features of Infective Endocarditis

##### FROM JANE

Fever  
Roth's spots  
Osler's nodes  
Murmur  
Janeway lesions  
Anemia  
Nail-bed hemorrhages (i.e. splinter hemorrhages)  
Emboli

#### TEE TTE

Transesophageal echo  
Transthoracic echo

- dental/respiratory procedures: amoxicillin single dose 30-60 min prior; clindamycin if truly penicillin-allergic
- infected skin/soft tissue procedures: cephalexin single dose 30-60 min prior; clindamycin if truly penicillin-allergic (modify based on etiology of skin/soft tissue infection)
- surgical
  - most common indication is refractory CHF
  - other indications include: valve ring abscess, valve perforation, unstable prosthesis, large vegetation >1cm, recurrent emboli despite adequate antimicrobial treatment, antimicrobial failure (persistently positive blood cultures), fungal etiology, *S. aureus* on a prosthetic valve

**Prognosis**

- adverse prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess, embolization, persistent bacteremia, altered mental status
- mortality: prosthetic valve IE (25-50%), non-IVDU *S. aureus* IE (30-45%), IVDU *S. aureus* or streptococcal IE (10-15%)

# CNS Infections

## Meningitis

- see Paediatrics, P65

**Definition**

- inflammation of the meninges

**Etiology**

**Table 18. Common Organisms in Meningitis**

Bacterial			Viral	Fungal	Other
Age 0-4 wk	Age 1-3 mo	Age >3 mo			
GBS	GBS	<i>S. pneumoniae</i>	HSV-1, 2	Cryptococcus	Lyme disease
<i>E. coli</i>	<i>E. coli</i>	<i>N. meningitidis</i>	VZV	Coccidioides	Neurosyphilis
<i>L. monocytogenes</i>	<i>S. pneumoniae</i>	<i>L. monocytogenes</i>	Enteroviruses		TB
<i>Klebsiella</i>	<i>N. meningitidis</i>	(likely if age >50 and comorbidities)	Parechoviruses		
	<i>H. influenzae</i>		West Nile		

**Risk Factors**

- lack of immunization against *H. influenzae* type B, *S. pneumoniae*, and *N. meningitidis* in children
- most cases of bacterial meningitis are due to hematogenous spread from a mucosal surface (nasopharynx)
- direct extension from a parameningeal focus (otitis media, sinusitis) less common
- penetrating head trauma or iatrogenic
- anatomical meningeal defects – CSF leaks
- immunodeficiency (corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency, etc.)
- contact with colonized or infected persons

**Clinical Features**

- neonates and children: fever, lethargy, irritability, vomiting, poor feeding
- older children and adults: fever, headache, neck stiffness, confusion, lethargy, altered LOC, seizures, focal neurological signs, nausea/vomiting, photophobia, papilledema
- petechial rash in meningococcal meningitis (purpura fulminans), seen more frequently on trunk or lower extremities

**Investigations**

- blood work: CBC and differential, electrolytes (for SIADH), blood C&S
  - CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
  - AFB, fungal C&S, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure
  - PCR for HSV, VZV, enteroviruses; in infants <6 mo, parechoviruses
  - West Nile virus serology in blood and CSF during summer and early fall if viral cause suspected
- imaging/neurologic studies: CT, MRI, EEG if focal neurological signs present

**Table 19. Typical CSF Profiles for Meningitis**

CSF Analysis	Bacterial	Viral
Glucose (mmol/L)	Decreased	Normal
Protein (g/L)	Markedly increased	Increased
WBC	500-10000/µL	10-500/µL
Predominant WBC	Neutrophils	Lymphocytes

See Landmark Infectious Diseases Trials for more information on the POET trial, which investigated the efficacy and safety of shifting from IV to oral antibiotics in patients with IE.

**Corticosteroids for Acute Bacterial Meningitis**  
Cochrane DB Syst Rev 2015;CD004405

**Purpose:** To examine the effect of adjunct corticosteroid therapy vs. placebo on mortality, hearing loss, and neurological sequelae with acute bacterial meningitis.

**Methods:** RCTs of corticosteroids for acute bacterial meningitis.

**Results:** 25 studies, 4121 participants. Corticosteroids were associated with non-significant mortality reductions (RR 0.90, 95% CI 0.80-1.01). Corticosteroids were associated with lower rates of hearing loss (RR 0.74, 95% CI 0.63-0.87) and neurological sequelae (RR 0.83, 95% CI 0.69-1.00). Corticosteroids were associated with increase in recurrent fever (RR 1.27, 95% CI 1.09-1.47).

**Conclusions:** Corticosteroids significantly reduced hearing loss and neurological sequelae but did not reduce mortality. Data supports use in high-income countries but no benefit in low-income countries.

**Brudzinski's Sign**  
Passive neck flexion causes involuntary flexion of hips and knees

**Kernig's Sign**  
Resistance to knee extension when hip is flexed to 90°

**Jolt Accentuation of Headache**  
Headache worsens when head turned horizontally at 2-3 rotations; more sensitive than Brudzinski's and Kernig's

- CSF Gram Stain Findings**
- *S. pneumoniae* – GP diplococci
  - *N. meningitidis* – GN diplococci
  - *H. influenzae* – Pleomorphic GN coccobacilli
  - *L. monocytogenes* – GP rods

**Does this Adult Patient have Acute Meningitis?**  
JAMA 1999;281:175-181

**Study:** Systematic review of literature analyzing the accuracy and precision of the clinical examination in the diagnosis of adult meningitis.

**Results:** Clinical history items have a low accuracy for the diagnosis of meningitis in adults. The sensitivity for headaches is 50% and the sensitivity for nausea/vomiting is 30%. On physical examination, absence of fever, neck stiffness, and altered mental status eliminates meningitis with a sensitivity of 99%.

**Conclusions:** The clinical examination aids in excluding a diagnosis of meningitis in adults with a low-risk clinical presentation. In high-risk patients, clinicians need to proceed directly to lumbar puncture given the serious implications of the infection.

**Treatment**

- bacterial meningitis is a medical emergency: do not delay antibiotics for CT or LP
- empiric antibiotic therapy
  - age  $\leq 28$  d: ampicillin + cefotaxime
  - age 29 d-3 mo: ceftriaxone/cefotaxime + vancomycin  $\pm$  ampicillin
  - age  $>3$  mo: ceftriaxone + vancomycin
    - add ampicillin IV if risk factors for infection with *L. monocytogenes* present: age  $>50$ , alcohol use disorder, immunocompromised
- steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics
  - continue in those patients with proven pneumococcal meningitis
  - not recommended for patients with suspected bacterial meningitis in some resource-limited countries
  - not recommended for neonatal meningitis

**Prevention**

- see Paediatrics, P65
- immunization
  - children: immunization against *H. influenzae* type B (Pentacel<sup>®</sup>), *S. pneumoniae* (Synflorix<sup>®</sup>, Prevnar-13<sup>®</sup>), *N. meningitidis* (Menjugate<sup>®</sup>, Menactra<sup>®</sup>, Nimenrix<sup>®</sup>, Menveo<sup>®</sup>, Bexsero<sup>®</sup>)
  - adults: immunization against *N. meningitidis* in selected circumstances (immunocompromised, outbreaks, travel, epidemics) and *S. pneumoniae* (Pneumovax<sup>®</sup>) for high-risk groups
- prophylaxis: close contacts of patients infected with *H. influenzae* type B should be treated with rifampin if they live with an inadequately immunized ( $<4$  yr) or immunocompromised child ( $<18$  yr); ciprofloxacin, rifampin, or ceftriaxone if close or household contact of a patient with *N. meningitidis*; meningococcal vaccines are also recommended for post-exposure prophylaxis for close contacts and in outbreak control

**Prognosis**

- complications
  - death, headache, seizures, cerebral edema, hydrocephalus, SIADH, residual neurological deficit (especially CN VIII), deafness
- mortality
  - *S. pneumoniae* 25%; *N. meningitidis* 5-10%; *H. influenzae* 5%
  - worse prognosis if: extremes of age, delays in diagnosis and treatment, stupor or coma, seizures, focal neurological signs, septic shock at presentation

## Encephalitis

**Definition**

- inflammation of the brain parenchyma

**Etiology**

- identified in only 40-70% of cases
  - when cause is identified, the most common etiology is viral: HSV, VZV, EBV, CMV, enteroviruses, parechoviruses, West Nile and other arboviruses, influenza and other respiratory viruses, HIV, mumps, measles, rabies, polio
  - bacteria: *L. monocytogenes*, mycobacteria, spirochetes (Lyme, syphilis), *Mycoplasma pneumoniae*
  - parasites: protozoa (e.g. *Toxoplasma*) and helminths (rare)
  - fungi: e.g. *Cryptococcus*
  - post-infectious (e.g. acute disseminated encephalomyelitis (ADEM))

**Pathophysiology**

- acute inflammatory disease of the brain due to direct invasion or pathogen-initiated immune response
- viruses may reach the CNS via peripheral nerves (e.g. rabies, HSV)
- herpes simplex encephalitis
  - acute, necrotizing, asymmetrical hemorrhagic process with lymphocytic and plasma cell reaction which usually involves the medial, temporal, and inferior frontal lobes
  - associated with HSV-1, less likely caused by HSV-2
- influenza and other respiratory viruses are associated with acute necrotizing encephalopathy (ANE); likely mediated by pathogen-initiated immune response

**Clinical Features**

- constitutional: fever, chills, malaise, nausea/vomiting
- meningeal involvement (meningoencephalitis): headache, nuchal rigidity
- parenchymal involvement: seizures, altered mental status, focal neurological signs
- herpes simplex encephalitis
  - acute onset ( $<1$  wk) of focal neurological signs: hemiparesis, ataxia, aphasia, focal or generalized seizures
  - temporal lobe involvement: behavioural disturbance
  - usually rapidly progressive over several days and may result in coma or death
  - common sequelae: memory and behavioural disturbances
  - rare complication: development of encephalopathy and Klüver-Bucy syndrome characteristics 1 mo after completion of treatment for HSV encephalopathy

**Public Health Agency of Canada  
Indications for Adult Immunization**
**Pneumococcal Polysaccharide Vaccine (i.e. Pneumovax<sup>®</sup>)**

$\geq 65$  yr (option to also give pneumococcal conjugate vaccine; if so, to give polysaccharide vaccine 8 wk after conjugate vaccine)

**Pneumococcal Polysaccharide Vaccine (i.e. Pneumovax<sup>®</sup>) and Pneumococcal Conjugate Vaccine**

Chronic cardiovascular/respiratory/hepatic/renal disorders, asplenia, sickle cell, or immunosuppression (polysaccharide vaccine to be given 8 wk after pneumococcal conjugate vaccine)

**Meningococcal Quadrivalent Vaccine (Menactra<sup>®</sup> or Menomune<sup>®</sup>)**

Healthy young adults  
Asplenia

Travellers to high-risk areas  
Military recruits or laboratory personnel  
Complement, factor D, or properdin deficiency or acquired terminal complement deficiency through receipt of eculizumab

**Multicomponent Meningococcal Serogroup B Vaccine (Bexsero<sup>®</sup>)**

Asplenia  
Military recruits or laboratory personnel  
Complement, factor D, or properdin deficiency, or acquired terminal complement deficiency through receipt of eculizumab

Meningitis and encephalitis patients can be distinguished based on their cerebral function. Cerebral function is abnormal in encephalitis patients (e.g. altered mental status, motor or sensory deficits, altered behaviour, speech or movement disorders), but may be normal in patients with meningitis. Note however, that there is considerable overlap between the two syndromes ("meningoencephalitis")

**Investigations**

- CSF: opening pressure; cell count and differential; glucose; protein; Gram stain; bacterial C&S; PCR for HSV, VZV, EBV, enteroviruses/parechoviruses, *M. pneumoniae*, and selectively for other less common etiologies
- serology: may aid diagnosis of certain causes of encephalitis (e.g. EBV, West Nile virus, rabies, *Bartonella henselae*)
- imaging/neurologic studies: CT, MRI, EEG to define anatomical sites affected
- invasive testing: brain tissue biopsy may be required for culture, histological examination, and immunocytochemistry (if diagnosis not clear via non-invasive means)
- findings in herpes simplex encephalitis (must rule out due to high mortality)
  - CT/MRI: medial temporal lobe necrosis
  - EEG: early focal slowing, periodic discharges

**Treatment**

- general supportive care
- monitor vital signs carefully
- IV acyclovir empirically until HSV encephalitis ruled out

**Generalized Tetanus****Etiology and Pathophysiology**

- caused by *Clostridium tetani*: motile, spore forming, anaerobic GP bacillus
  - found in soil, splinters, rusty nails, GI tract (humans and animals)
- traumatic implantation of spores into tissues with low oxygenation (e.g. puncture wounds, burns, non-sterile surgeries or deliveries)
- upon inoculation, spores develop into *C. tetani* bacilli that produce tetanus toxins
- toxin travels via retrograde axonal transport to the CNS where it irreversibly binds presynaptic neurons to prevent the release of inhibitory neurotransmitters (e.g. GABA)
  - net effect is the disinhibition of spinal motor reflexes which results in tetany and autonomic hyperactivity

**Clinical Features**

- generalized tetanus
  - initially present with painful spasms of masseters (trismus or "lockjaw")
  - sustained contraction of skeletal muscle with periodic painful muscle spasms (triggered by sensory stimuli, e.g. loud noises)
  - paralysis descends to involve large muscle groups (neck, abdomen)
  - apnea, respiratory failure, and death secondary to tonic contraction of pharyngeal and respiratory muscles
- autonomic hyperactivity
  - diaphoresis, tachycardia, HTN, fever as illness progresses

**Investigations**

- primarily a clinical diagnosis, often although not always with a history of a traumatic wound and lack of immunization
- culture wounds, CK may be elevated

**Treatment**

- stop toxin production
    - wound debridement to clear necrotic tissue and spores
    - antimicrobial therapy: IV metronidazole; IV penicillin G is an effective alternative
  - neutralize unbound toxin with tetanus immune globulin (TIG)
  - supportive therapy: intubation, spasmolytic medications (benzodiazepines), quiet environment, cooling blanket
- control autonomic dysfunction:  $\alpha$ - and  $\beta$ -blockade (e.g. labetalol), magnesium sulfate

**Prevention**

- infection with *C. tetani* does not produce immunity – vaccinate patients on diagnosis
- tetanus toxoid vaccination (see [Paediatrics, P5](#) and [Emergency Medicine, ER17](#))

**Rabies****Definition**

- acute progressive encephalitis caused by RNA virus (genus *Lyssavirus* of the *Rhabdoviridae* family)

**Etiology and Pathophysiology**

- any mammal can transmit the rabies virus
  - most commonly transmitted by raccoon, skunk, bat, fox, cat, and dog; monkeys also a risk in the tropics and sub-tropics
- transmission: breaching of skin by teeth or direct contact of infectious tissue (saliva, neural tissue) with skin or mucous membranes
  - almost all cases due to bites
  - animals can be carriers for several days before manifest signs of disease

Antimicrobial therapy (e.g. metronidazole) may fail to treat *C. tetani* unless adequate wound debridement is performed

- virus travels via retrograde axonal transport from PNS to CNS
- virus multiplies rapidly in brain, then spreads to other organs, including salivary glands
- development of clinical signs occurs simultaneously with excretion of rabies virus in saliva
  - infected animal can transmit rabies virus as soon as it shows signs of disease

### Clinical Features

- five stages of disease
  1. incubation period
    - 1-3 mo on average (can range from days to years, depending on distance from bite site to CNS)
  2. prodrome (<1 wk)
    - low-grade fever, malaise, anorexia, nausea/vomiting, headache, sore throat
    - pain, pruritus, and paresthesia may occur at wound site
    - once prodromal symptoms develop, there is rapid, irreversible progression to death
      - progression from prodrome to coma and death may occur without an intervening acute neurologic syndrome
  3. acute neurologic syndrome: 2 types (<1 wk)
    - a. encephalitic (most common): hyperactivity, fluctuating LOC, hydrophobia, aerophobia, hypersalivation, fever, seizures
      - painful pharyngeal spasms on encountering gust of air or swallowing water cause aerophobia and hydrophobia, respectively
    - b. paralytic: quadriplegia, loss of anal sphincter tone, fever
  4. coma
    - complete flaccid paralysis, respiratory, and cardiovascular failure
  5. death (within days to weeks of initial symptoms)

### Investigations

- purpose of diagnosis by investigations is to limit patient contact with others and to identify others exposed to the infectious source
- antemortem: direct immunofluorescence or PCR on multiple specimens: saliva, skin biopsy, serum, CSF
- post-mortem: direct immunofluorescence in nerve tissue, presence of Negri bodies (inclusion bodies in neurons)

### Treatment

- post-exposure prophylaxis depends on regional prevalence and circumstances surrounding injury
- mandatory to report animal bite/contact that may result in rabies to Public Health Authority
- if not previously immunized:
  - wound care: clean wound promptly and thoroughly with soap and running water for 15 min
  - passive immunization: rabies immunoglobulin (RIG) infiltrated into wound site, with any remaining volume administered IM in anatomical site distant from vaccine administration. Due to variable response rates, vaccine should not be administered into gluteal muscle
  - active immunization: inactivated human diploid cell rabies virus vaccine (HDCV) – series of 4 shots post-exposure on d 0, 3, 7 and 14. Vaccine administered into deltoid
- if previously immunized:
  - wound care: clean wound promptly and thoroughly with soap and running water for 15 min
  - two doses of HDCV into deltoid on d 0 and 3
  - no RIG administered
  - treatment is supportive once victim manifests signs and symptoms of disease

### Prevention

- pre-exposure vaccination
  - recommended for high-risk persons: laboratory staff working with rabies, veterinarians, animal and wildlife control workers, long-term travellers to endemic areas

## Systemic Infections

### Sepsis and Septic Shock

- see [Respirology](#), R32

#### Definitions

- bacteremia: bacteria in blood from primary bloodstream infection or secondary to infection of another body system
- sepsis: severe organ dysfunction resulting from dysregulated host response to infection
  - organ dysfunction identified via acute change in SOFA score  $\geq 2$  points
  - qSOFA score used initially to screen patients for suspected sepsis using three criteria:
    1. respiratory rate  $\geq 22$ /min
    2. sBP  $\leq 100$  mmHg
    3. altered mentation (GCS  $< 15$ )
- septic shock: subset of sepsis with circulatory and cellular/metabolic dysfunction; clinically defined in cases where despite adequate volume resuscitation there is both
  1. persistent hypotension requiring vasopressors to maintain MAP  $\geq 65$  mmHg AND
  2. serum lactate  $> 2$  mmol/L

SOFA score  $> 2$  = 10% mortality risk in patient with suspected infection  
Hospital mortality with septic shock  $> 40\%$

qSOFA score  
1. Respiratory rate  $\geq 22$ /min  
2. sBP  $\leq 100$  mmHg  
3. Altered mentation (GCS  $< 15$ )

The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3) in 2016 re-defined sepsis using the Sequential Organ Failure Assessment (SOFA) score for diagnosis and Quick-SOFA (qSOFA) for screening of end-organ failure. The terms severe sepsis and systemic response inflammatory response syndrome (SIRS) are no longer part of the sepsis definition.

### Pathophysiology

- causative agents are identified in only 50-70% of cases
- when organisms are identified, GP and GN organisms are the cause in 90% of cases
- bacteremia → local immune response → pro-inflammatory cytokine release → spread of immune response beyond local environment → unregulated, exaggerated systemic immune response → vasodilation and hypotension → distributive shock and reduced O<sub>2</sub> delivery to tissues → anaerobic metabolism and lactic acid production → metabolic acidosis → multiple organ failure

### Clinical Features

history: symptoms and signs specific to an infectious source (e.g. cough, headache, dysuria, purulent exudate, rash)

- general symptoms of infection: fever, chills, pain, dyspnea, cool extremities, fatigue, malaise, anxiety, confusion

physical: abnormal vitals (e.g. fever, tachypnea, tachycardia, hypotension), flushed skin, altered mental status, local signs of infection (e.g. pharyngitis, septic arthritis, neck stiffness, skin wounds/ulcers, or murmurs)

### Investigations

- CBC and differential, electrolytes, urea, creatinine, liver enzymes, ABG, lactate, INR, PTT, troponin, blood C&S x2, urinalysis, urine C&S, and cultures of any wounds or lines
- CXR (other imaging depends on suspicion of focus of infection)
- nasopharyngeal swab/stool/sputum cultures, throat swabs, genital swab, LP as indicated

### Treatment (see [Respirology, R33](#))

- respiratory support: O<sub>2</sub> ± intubation
- cardiovascular support: IV fluids ± blood transfusion + vasopressors + ICU
- IV antibiotics (empirical, guided by suspected source)
  - consider broad spectrum antibiotics (e.g. piperacillin/tazobactam or meropenem) ± additional agents depending on patient risk factors, suspected etiology or focus of infection, and local microbial susceptibilities (± aminoglycoside for drug-resistant Gram-negatives or vancomycin for MRSA)
  - breadth of empiric coverage should take into account i) estimated adequacy of spectrum of activity and ii) degree of instability or severity of infection
  - narrow once organism and susceptibilities are known
- source control: procedure to control focus of infection (catheter removal, abscess drainage)
- hydrocortisone IV may be added in patients with septic shock unresponsive to fluid resuscitation and vasopressors

## Leprosy (Hansen's Disease)

### Etiology

- Mycobacterium leprae*: obligate intracellular bacteria, slow-growing (doubling time 12.5 d), survives in macrophages
- bacteria transmitted from nasal secretions, potentially via skin lesions
- invades skin and peripheral nerves leading to chronic granulomatous disease

### Clinical Features

- lesions involve cooler body tissues (e.g. skin, superficial nerves, nose, eyes, larynx)
- spectrum of disease determined by host immune response to infection
  - paucibacillary "tuberculoid" leprosy (intact cell-mediated immune response)
    - ≤5 hypoesthetic lesions, usually hypopigmented, well-defined, dry
    - early nerve involvement, enlarged peripheral nerves, neuropathic pain
    - may be self-limited, stable, or progress over time to multibacillary "lepromatous" form
  - multibacillary "lepromatous" leprosy (weak cell-mediated immune response)
    - ≥6 lesions, symmetrical distribution
    - leonine facies (nodular facial lesions, loss of eyebrows, thickened ear lobes)
    - extensive cutaneous involvement, late and insidious nerve involvement causing sensory loss at the face and extremities
  - borderline leprosy
    - lesions and progression lie between tuberculoid and lepromatous forms

### Investigations

- skin biopsy down to fat or slit skin smears for AFB staining, PCR
- histologic appearance: intracellular bacilli in spherical masses (lepra cells), granulomas involving cutaneous nerves

### Treatment

- regimens based on WHO recommendations
- paucibacillary: dapsones daily + rifampin monthly + clofazimine monthly AND low dose clofazimine once daily x 6 mo
- multibacillary: dapsones daily + rifampin monthly + clofazimine monthly x 12 mo AND low dose clofazimine once daily for 12 mo

- treatment of leprosy (along with other precipitants of immune responsiveness such as viral illness, immunization, hormonal fluctuations of pregnancy and parturition) can cause an immune reaction to killed or dying bacteria (e.g. erythema nodosum leprosum [a type of antigen-antibody complex deposition panniculitis] and reversal reaction [upgrading cell-mediated immune response]): symptomatic management with NSAIDs if mild, prednisone with 12-24 wk taper if severe; thalidomide for erythema nodosum leprosum

### Prognosis

- curable with WHO approved treatment regimens
- complications: muscle atrophy, contractures, blindness, trauma/superinfection of lesions, crippling/loss of digits and limbs, erythema nodosum leprosum, social stigmatization due to clofazimine hyperpigmentation
- long post-treatment follow-up warranted to monitor for relapse and immune reactions

## Lyme Disease

### Etiology/Epidemiology

- spirochete bacteria: *Borrelia burgdorferi* (North America), *B. garinii*, *B. afzelii* (Europe and Asia)
- transmitted by *Ixodes* tick
- reported in 49 of the 50 U.S. states, but most cases occur in the Northeast, the Midwest, and Northern California
- as a result of climate change, Lyme disease has spread into higher latitudes. In Canada, reported in southern and southeastern Quebec, southern and eastern Ontario, southeastern Manitoba, New Brunswick, and Nova Scotia, as well as southern British Columbia
- small rodents (mice) serve as primary reservoir, while larger animals (white-tailed deer) serve as hosts for ticks
- human contact usually May-August in fields with low brush near wooded areas, but may start earlier in the spring or later in the fall as a result of warmer winters due to climate change
- infection usually requires >36 h tick attachment
- as a result of climate change, other tick-borne diseases are expected to increase in prevalence: Anaplasmosis, Babesiosis, Powassan virus, and *B. miyamotoi* disease

**BAKE a Key Lyme Pie**  
 Bell's palsy  
 Arthritis  
 Cardiac block  
 Lyme  
 Erythema chronicum migrans

### Clinical Features

- stage 1 (early localized stage: 7-14 d post-bite)
  - malaise, fatigue, headache, myalgias
  - erythema migrans: expanding, non-pruritic bulls-eye (target) lesions (red with clear centre) at site of tick bite
- stage 2 (early disseminated stage: weeks post-infection)
  - CNS: aseptic meningitis, CN palsies (CN VII palsy), peripheral neuritis
  - cardiac: heart block or myocarditis
- stage 3 (late persistent stage: months to years post-infection)
  - may not have preceding history of early-stage infection
  - MSK: chronic monoarticular or oligoarticular arthritis
  - acrodermatitis chronicum atrophicans (due to *B. afzelii*)
  - neurologic: encephalopathy, meningitis, neuropathy

### Investigations

- order Public-Health-Lab-approved Lyme disease testing and interpret results on basis of symptoms
- a negative test for Lyme Disease does not preclude a tick-borne disease; further testing may be indicated if symptoms are present

### Prevention

- early identification, investigation of symptoms, and reporting of tick-borne illnesses
- use of protective clothing (tuck pants into socks), insect repellent, inspection for ticks, and prompt removal of tick
- doxycycline single dose prophylaxis within 72 h of removal of an engorged *Ixodes scapularis* tick in hyperendemic area (local rate of infection of ticks  $\geq 20\%$ ) for patients >8 yr who are not pregnant or lactating

### Treatment

- stage 1: doxycycline/amoxicillin/cefuroxime
- stage 2-3: ceftriaxone or doxycycline

## Toxic Shock Syndrome

### Etiology

- superantigens produced by some strains of *S. aureus* or GAS cause widespread T-cell activation and pro-inflammatory cytokine release (IL-1, IL-6, TNF)
- course of disease is precipitous and leads to acute fever, shock, multiorgan failure
- staphylococcal Toxic Shock Syndrome (TSS) involves the production of superantigen toxic shock syndrome toxin 1 (TSST-1)
- streptococcal TSS involves the production of superantigens SPEA, SPEB, SPEC

**Risk Factors**

- staphylococcal: tampon use, nasal packing, wound infections (e.g. postpartum vaginal or cesarean or surgical infections)
- streptococcal: minor trauma, surgical procedures, preceding viral illness (e.g. chickenpox), use of NSAIDs

**Clinical Features and Investigations**

- acute onset
- staphylococcal TSS
  - $T > 38.9^{\circ}\text{C}$
  - sBP  $\leq 90$  mmHg
  - diffuse erythroderma with subsequent desquamation, especially on palms and soles
  - involvement of 3 or more organ systems: GI (vomiting, diarrhea), muscular (myalgia, increased CK), mucous membranes (hyperemia), renal, hepatic, hematologic (thrombocytopenia), CNS (disorientation)
  - isolation of *S. aureus* is not required for diagnosis (*S. aureus* is rarely recovered from blood in TSS)
- streptococcal TSS
  - sBP  $\leq 90$  mmHg
  - isolation of GAS from a normally sterile site (e.g. blood, pleural, tissue biopsy, or surgical wound)
  - $\geq 2$  of coagulopathy, liver involvement, ARDS, soft tissue necrosis (necrotizing fasciitis, myositis, gangrene), renal impairment, erythematous macular rash that may desquamate

**Treatment**

- supportive care, fluid resuscitation, surgical debridement of infected tissue
- streptococcal: IV penicillin and clindamycin and  $\pm$  IVIG
- staphylococcal: for methicillin-susceptible *S. aureus*: clindamycin + cloxacillin (IV); for MRSA: clindamycin + vancomycin x 10-14 d

**Cat Scratch Disease****Etiology**

- *Bartonella henselae*: intracellular bacteria
- cat-to-human transmission via cat scratch/bite

**Clinical Features**

- skin lesion appears 30 d post-inoculation
- may be followed by fever, malaise, tender regional lymphadenopathy
- in some patients, organism may disseminate causing FUO, hepatosplenomegaly, retinitis, encephalopathy, infective endocarditis, uveitis
- in patients with advanced HIV, can present with violaceous nodular skin lesions + underlying bone involvement, known as "bacillary angiomatosis"
- usually self-limited

**Investigations**

- serology, PCR, lymph node biopsy

**Treatment**

- the disease may be self-limited but treatment is recommended by the Infectious Disease Society of America with a 5 d course of azithromycin for immunocompetent patients with mild to moderate illness
- needle aspiration of painful suppurative lymph nodes may hasten the relief of symptoms
- combination therapy consisting of doxycycline or azithromycin plus rifampin often used for disseminated disease (neuroretinitis, hepatosplenic involvement)

**Rocky Mountain Spotted Fever****Etiology**

- *Rickettsia rickettsii*: obligate intracellular GN organism
- reservoir hosts: rodents, dogs
- vectors: *Dermacentor* ticks in North America; *Rhipicephalus* ticks in Mexico and Central America
- organisms cause inflammation of endothelial lining of small blood vessels, leading to small hemorrhages and thrombi
- can cause widespread vasculitis leading to headache, and CNS changes; can progress to death if treatment is delayed

**Clinical Features**

- usually occurs in summer following tick bite
- influenza-like prodrome: acute onset fever, headache, myalgia, nausea/vomiting, anorexia
- macular rash appearing on d 2-4 of fever
  - begins on wrists and ankles, then spreads centrally to arms/legs/trunk/palms/soles
  - occasionally "spotless" (10% of patients)

**Investigations**

- skin biopsy and serology (indirect fluorescent antibody test)

**Treatment**

- empiric doxycycline, usually 5-7 d (treat for 3 d after defervescence)

## West Nile Virus

**Epidemiology**

- virus has been detected throughout the United States and much of southern Canada (Ontario and Manitoba)
- case-fatality rates in severe cases are ~10%

**Transmission**

- primarily from mosquitoes that have fed on infected birds (crows, blue jays)
- transplacental, blood products (rare), organ transplantation
- rising temperatures linked to increased mosquito survival and geographical range, increased biting rates, increased replication of virus within mosquitoes, shorter reproduction rates, and longer transmission seasons. Climate change also affects bird migration patterns and timing, causing changes in virus spread

**Clinical Features**

- 80% are asymptomatic
- most symptomatic cases are mild (West Nile fever): acute onset of headache, back pain, myalgia, anorexia, maculopapular non-pruritic rash involving chest, back, arms
- severe complications: encephalitis, meningoencephalitis, and acute flaccid paralysis (especially in those >60 yr)

**Investigations**

- IgM antibody in serum or CSF is the best test (cross reactivity with yellow fever and Japanese encephalitis vaccines, and with dengue fever and St. Louis virus infection); may not reflect current illness as IgM antibody can last for >6 mo
- viral isolation by PCR from CSF, tissue, blood, and fluids (all have low sensitivity due to transient viremia)
- CSF: elevated lymphocytes and protein if CNS involvement

**Treatment and Prevention**

- treatment: supportive
- prevention: mosquito repellent (DEET, picaridin), drain stagnant water, community mosquito control programs

## Syphilis

**Etiology**

- *Treponema pallidum*: thick motile spirochetes historically detectable by dark-field microscopy
- transmitted sexually, vertically, or parenterally (rare)

**Clinical Features**

- see [Dermatology, D38](#) and [Gynaecology, GY30](#)
- multi-stage disease
  1. primary syphilis (3-90 d post-infection)
    - painless chancre at inoculation site (any mucosal surface)
    - regional lymphadenopathy
    - acute disease lasts 3-6 wk, 25% progress to secondary syphilis without treatment
  2. secondary syphilis = systemic infection (2-8 wk following chancre)
    - maculopapular non-pruritic rash including palms and soles
    - generalized lymphadenopathy, fever, malaise, headache, aseptic meningitis, ocular/otic syphilis
    - condylomata lata: painless, wart-like lesion on palate, vulva, or scrotum (highly infectious)
  3. latent syphilis
    - asymptomatic infection that follows untreated primary/secondary syphilis
    - early latent (<1 yr post-infection) or late latent/unknown duration (>1 yr post-infection)
    - increased transmission risk with early latent; longer treatment duration required for late latent
  4. tertiary syphilis (1-30 yr post-infection)
    - gummatous syphilis: nodular granulomas of skin, bone, liver, testes, brain
    - aortic aneurysm and aortic insufficiency
  5. congenital syphilis
    - causes spontaneous abortions, stillbirths, congenital malformations, developmental delay, deafness
    - most infected newborns are asymptomatic
    - clinical manifestations in early infancy include rhinitis (snuffles), lymphadenopathy, hepatosplenomegaly, pseudoparalysis (bone pain associated with osteitis), and rash (usually maculopapular and involving palms and soles)

**Argyll Robertson Pupil**

Accommodates but does not react to light

**Those with Untreated 1° or 2° Syphilis**

1/3 Cure  
1/3 Latent indefinitely  
1/3 3° syphilis

**Causes of False Positive VDRL and RPR Tests**

Vi viruses (mononucleosis, hepatitis)  
Drugs and substance misuse  
Rheumatic fever  
Lupus and leprosy

- late onset manifestations (>2 yr of age) include saddle nose, saber shins, Clutton joints, Hutchinson's teeth, mulberry molars, rhagades, CN VIII deafness, interstitial keratitis, juvenile paresis
6. neurosyphilis
- headache, dementia, difficulty in coordination, paralysis, sensory deficits, personality changes, Argyll-Robertson pupils, tabes dorsalis
  - can occur from secondary stage onward

### Investigations

- syphilis tests are conducted by Public Health labs. Thus, order set for syphilis is simplified and does not require specification of which test to complete. Below are details on what tests are conducted at the Public Health lab
- initial screening tests: traditionally non-treponemal tests (RPR, VDRL), or treponemal tests in some jurisdictions (EIA, CMIA, CLIA)
- confirmatory tests: treponemal tests (TPPA, FTA-ABS, MHA-TP, TPI)
- LP for neurosyphilis if: seropositive and symptoms of neurosyphilis or treatment failure/other tertiary symptoms, or with HIV and late latent/unknown duration syphilis; consider in others
- for congenital syphilis, LP is essential; long bone x-rays may also be helpful

### Treatment

- for 1<sup>o</sup>, 2<sup>o</sup>, early latent: benzathine penicillin G 2.4 million units IM x 1
- for 3<sup>o</sup>, late latent: benzathine penicillin G 2.4 million units IM weekly x 3
- if truly allergic to penicillin: doxycycline 100 mg PO BID x 14 d is a second line therapy (x 28 d in late disease)
- for pregnant patients allergic to penicillin, oral desensitization techniques are considered safe
- neurosyphilis: aqueous penicillin G 16-24 million units/d IV x 14 d ± single dose of benzathine penicillin
- for congenital syphilis, penicillin G IV x 10 d
- see [Family Medicine, FM46](#) for generalized ST1 workup

Patients with 2<sup>o</sup> or 3<sup>o</sup> syphilis treated with penicillin may experience a Jarisch-Herxheimer reaction. Lysis of organisms releases pyrogens thought to cause fever, chills, myalgia, and flu-like symptoms that may last up to 24 h

<b>VDRL</b>	Venereal Disease Research Laboratory
<b>RPR</b>	Rapid Plasma Reagin
<b>EIA</b>	Enzyme Immunoassay
<b>CLIA</b>	Chemiluminescent ImmunoAssay
<b>CMIA</b>	Chemiluminescent Microparticle ImmunoAssay
<b>FTA-ABS</b>	Fluorescent Treponema Antibody-Absorption
<b>MHA-TP</b>	Microhemagglutination Assay <i>T. pallidum</i>
<b>TPPA</b>	<i>T. pallidum</i> Particle Agglutination Assay
<b>TPI</b>	<i>T. pallidum</i> immobilization test

## Tuberculosis

### Etiology, Epidemiology, and Natural History

- 1/3 of the world's population is infected with TB
- contracted by aerosolized inhalation of *Mycobacterium tuberculosis*, a slow growing aerobe (doubling time = 18 h) that can evade innate host defenses, survive, and replicate in macrophages
- inhalation and deposition in the lung can lead to one of the following outcomes
  1. immediate clearance of the pathogen
  2. latent TB: asymptomatic infection contained by host immune defenses (represents 90% of infected people)
  3. primary TB: symptomatic, active disease (represents 5% of infected people)
  4. secondary TB: symptomatic reactivation of previously dormant TB (represents 5-10% of those with latent TB, most often within the first 1-2 yr of initial infection) at a pulmonary or extra-pulmonary site

### Risk Factors

- social and environmental factors
  - travel or birth in a country with high TB prevalence (e.g. Asia, Latin America, Sub-Saharan Africa, Eastern Europe)
  - the incidence of TB is 25 times higher in Canadian-born Indigenous peoples (highest in Inuit) compared to Canadian-born non-Indigenous peoples
  - personal/occupational contact, crowded living conditions, low socioeconomic status (SES), people experiencing homelessness, IVDU
- host factors
  - immunocompromised (especially HIV), including extremes of age
  - immunosuppressed (TNF- $\alpha$  inhibitors, glucocorticoids)
  - silicosis
  - chronic kidney disease requiring dialysis
  - diabetes
  - malignancy and chemotherapy
  - substance use (e.g. drug use, alcohol use disorder, smoking)

### Clinical Features

- primary infection usually asymptomatic, although progressive primary disease may occur, especially in children and immunosuppressed patients
- secondary infection/reactivation usually produces constitutional symptoms (fatigue, anorexia, night sweats, weight loss) and site-dependent symptoms
  1. pulmonary TB
    - chronic productive cough + hemoptysis, fever, night sweats, weight loss, chest pain, anorexia
    - CXR consolidation or cavitation, lymphadenopathy, predominantly upper lung findings but variable
    - non-resolving pneumonia despite standard antimicrobial therapy
  2. miliary TB
    - widely disseminated spread especially to lungs, abdominal organs, marrow, CNS
    - CXR: multiple small 1-5 mm millet seed-like lesions throughout lung

**Tuberculous Polyserositis**  
Pleural + pericardial + peritoneal effusions (usually from granuloma breakdown that spills TB into pleural cavity – very rare)

### 3. extra-pulmonary TB

- can occur in any organ - lymphadenitis, pleurisy, pericarditis, hepatitis, peritonitis, meningitis, osteomyelitis (vertebral = Pott disease), adrenal (causing Addison disease), renal, ovarian

### Investigations

- screening for latent TB may be done via TST or IFN- $\gamma$  release assay (IGRA)
  - both can be used to diagnose prior TB exposure. IGRA has fewer false positives as it does not detect antigens in BCG vaccine or most types of non-tuberculosis mycobacteria
    - neither should be used for active TB diagnosis or monitoring anti-TB treatment response
    - TST preferred when repeat testing planned to assess risk of new infection (e.g. serial testing in healthcare)
- IGRA preferred when BCG vaccine after 1 y/o, vaccination more than once, or unable to return for reading
- diagnostic tests/investigations for active pulmonary TB
  - sputum specimens (either spontaneous or induced) should be collected for AFB smear and culture; the three specimens can be collected on the same day, a minimum of 1 h apart
  - BAL if other lung pathology (e.g. lung cancer) also suspected, or TB suspected despite negative sputum samples
  - CXR
    - classic triad: apical-posterior infiltrates, lung volume loss, cavitation
    - atypical features: hilar/mediastinal lymphadenopathy, non-cavitary infiltrates
    - signs of complications: endobronchial spread, pleural effusion, pneumothorax
    - Ghon complex: a parenchymal granuloma, indicating a previous tuberculosis infection, and an involved hilar lymph node on the same side

### Prevention

- primary prevention
  - airborne isolation for active pulmonary disease
  - BCG vaccine
    - ~80% effective against paediatric miliary and meningeal TB
    - effectiveness in adults debated (anywhere from 0-80%)
    - recommended in high-incidence communities in Canada for infants in whom there is no evidence of HIV infection or immunodeficiency; widely used in other countries
- prevention of reactivation of latent infection
  - rifampin (RIF) (10 mg/kg (600 mg maximum)) daily for 4 mo (active disease must be ruled out)
  - isoniazid (INH) (15 mg/kg (900 mg maximum)) + pyridoxine (B6) and rifapentine (RPT) (dose by weight) weekly for 3 mo
  - INH (5 mg/kg (300 mg maximum)) + pyridoxine (B6) daily for 9 mo (previous standard regimen, recommended when rifamycin regimens cannot be used)
  - INH (5 mg/kg (300 mg maximum)) + pyridoxine (B6) daily for 6 mo
  - INH (5 mg/kg (300 mg maximum)) + pyridoxine (B6) and RIF (10 mg/kg (600 mg maximum)) daily for 3 mo

### Treatment of Active Infection

- given the nuances of TB treatment, active TB infection should be managed by an experienced TB clinician
- pulmonary TB: INH + rifampin + pyrazinamide + ethambutol x 2 mo (initiation phase), then INH + rifampin x 4 mo in fully susceptible TB (continuation phase), total 6 mo. Extend continuation phase to 7 mo if >65 y/o, pregnant, or risk of hepatotoxicity
- extrapulmonary TB: same regimen as pulmonary TB but increase to 12 mo in bone/joint, CNS, and miliary/disseminated TB + corticosteroids for meningitis, pericarditis
- for patients taking INH, pyridoxine should be added in cases of diabetes, renal failure, malnutrition, substance use disorders, seizure disorders, pregnancy/breastfeeding, risk of neuropathy
- empiric treatment of suspected MDR or extensively drug-resistant (XDR) TB requires referral to a specialist
  - MDR = resistance to INH and rifampin  $\pm$  others
  - XDR = resistance to INH + rifampin + fluoroquinolone + >1 of injectable, second-line agents
    - very difficult to treat, global public health threat, 5 documented cases in Canada from 1997-2008
  - suspect MDR TB if previous treatment failed, exposure to known MDR index case, or immigration from a high-risk area
- note: TB is a reportable disease to Public Health (please see Public Health Agency of Canada website for more information)

#### Positive TST Test

If induration at 48-72 h  
 >5 mm if immunocompromised, close contact with active TB  
 >10 mm all others; positive PPD; CXR;  
 decision to treat depends on individual risk factors  
**False(-)**: poor technique, anergy, immunosuppression, infection <10 wk or remotely  
**False(+)**: BCG after 12 mo of age in a low-risk individual, nontuberculous mycobacterial (NTM)  
**Booster effect**: initially false(-) result boost to a true(+) result by the testing procedure itself (usually if patient was infected long ago so had diminished delayed type hypersensitivity reaction or if history of BCG)

#### TB Treatment

**RIPE**  
 Ri fampin  
 INH  
 Pyrazinamide  
 Ethambutol

# HIV and AIDS

## Epidemiology

### Canadian Situation (Public Health Agency of Canada, 2016)

- estimated 65040 Canadians living with HIV infection at the end of 2016, 20% unaware of HIV-positive status
- 2090 new infections were reported in 2013; MSM account for 53% of cases, PWID 19%

### Global Situation (WHO and UNAIDS Core Epidemiology Slides, July 2018)

- estimated 36.7 million people living with HIV/AIDS at the end of 2016
- estimated 1.8 million newly infected in 2016
- estimated 1 million AIDS-related deaths in 2016

## Etiology

- HIV is a retrovirus that causes progressive immune system dysfunction, predisposing patients to various opportunistic infections and malignancies
- HIV virion includes an envelope (gp41 and gp120 glycoproteins), matrix (p17), and capsid (p24), enclosing 2 single-stranded copies of RNA plus enzymes in its core
- virion glycoproteins bind CD4 and CCR5/CXCR4 on CD4+ T lymphocytes (T-helper cells) to fuse and enter the cells
- RNA converted to dsDNA by viral reverse transcriptase; dsDNA is integrated into host genome by viral integrase
- virus DNA transcribed and translated using host cell machinery, post-translational modifications include proteolytic activity of virally encoded protease enzymes
- newly produced virions bud out of host cell, incorporating host cell membrane; additional maturation steps are required before virion is considered infectious
- exact mechanisms of CD4 depletion incompletely characterized but likely include direct viral cytopathic effects, apoptosis, and increased cell turnover

## Modes of Transmission

Table 20. Modes of Transmission in Adolescents and Adults by Site and Medium

HIV Invasion Site	Sub-Location	Transmission Medium	Transmission Probability per Exposure Event
Female genital tract	Vagina, ectocervix, endocervix	Semen	1 in 200 to 1 in 2000
Male genital tract	Inner foreskin, penile urethra	Cervicovaginal and rectal secretions and desquamations	1 in 700 to 1 in 3000
Intestinal tract	Rectum	Semen	1 in 20 to 1 in 300
		Semen	1 in 2500
	Upper GI tract	Maternal blood/genital secretions (intrapartum)	1 in 5 to 1 in 10
		Breastmilk	1 in 5 to 1 in 10
Placenta	Chorionic villi	Maternal blood (intrauterine)	1 in 10 to 1 in 20
Blood stream		Contaminated blood products	95 in 100 to 1 in 150
		Sharp/needlestick injuries	

Adapted with permission from Macmillan Publishers Ltd., Hladik F, McElrath MJ. Setting the stage: host invasion by HIV. Nat Rev Immunol 2008;8:447-457.

NOTE: these estimates are for "all comers" i.e. they estimate transmission risk for anyone with HIV infection and do not take into account treatment status of the HIV+ person (in contrast to results of PARTNER study)

p24 = capsid protein  
gp41 = fusion and entry  
gp120 = attachment to host Tcell

Homozygosity for A32 mutation in CCR5 gene confers relative resistance to HIV infection  
Heterozygosity for A32 mutation in CCR5 gene associated with slower disease course

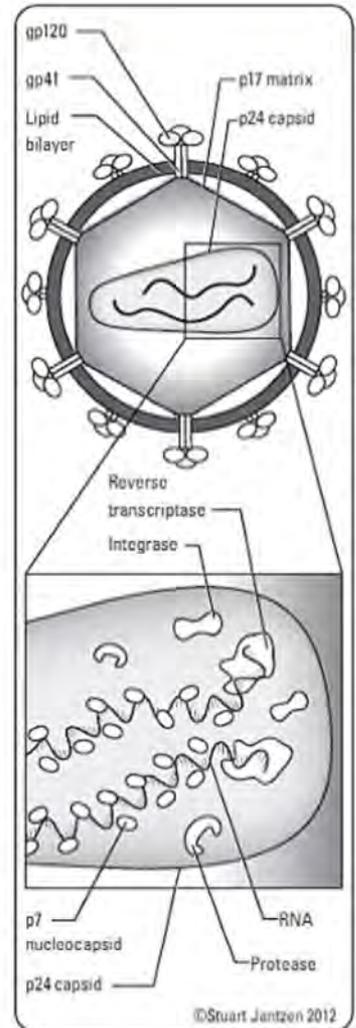

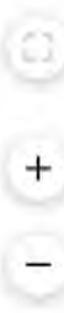

Figure 7. HIV viral particle

## Natural History

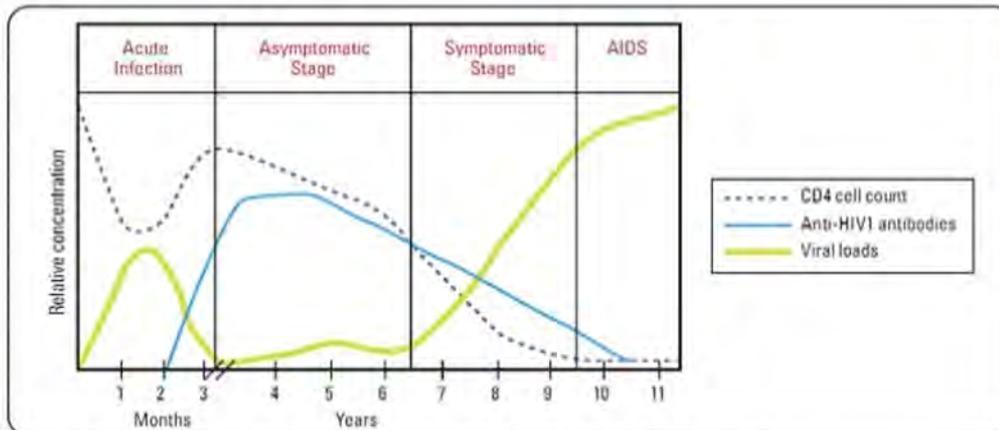

Figure 8. Relationships between CD4 T-cell count, viral load, and anti-HIV1 antibodies

### Acute (Infection) Retroviral Syndrome

- 40-90% experience an acute non-specific illness (may include fever, pharyngitis, lymphadenopathy, rash, arthralgias, myalgias, headache, GI symptoms, oral ulcers, weight loss) 2-6 wk post-exposure lasting 10-15 d
- hematologic disturbances (lymphopenia, thrombocytopenia)
- 10-20% present with aseptic meningitis, CN palsies, or other neurological presentations; HIV RNA and/or p24 may be detected in CSF
- associated with a high level of plasma viremia and therefore high-risk of transmission

### Asymptomatic (Latent) Stage

- during latent phase, HIV infects and replicates in CD4+ T lymphocytes (lymph nodes)
- normal CD4 count in adults: 500-1100 cells/mm<sup>3</sup>
- CD4 count drops 60-100 cells/mm<sup>3</sup> per yr but is variable
- by 10 yr post-infection, 50% have advanced HIV (i.e. AIDS), 30% demonstrate milder symptoms, and <20% are asymptomatic if untreated

### Definition of AIDS

- HIV-positive AND one or more of the clinical illnesses that characterize AIDS, including: opportunistic infections (e.g. *Pneumocystis jirovecii* pneumonia (PJP, previously PCP), esophageal candidiasis, CMV, *Mycobacterium avium* complex (MAC), TB, toxoplasmosis), malignancy (Kaposi's sarcoma, invasive cervical cancer), wasting syndrome OR CD4 <200 (or <15%); this is largely historical because ART can reverse CD4 count decline

Table 21. Symptomatic Stage (CD4 count thresholds for classic clinical manifestations)

CD4 Counts	Possible Manifestations
<500 cells/mm <sup>3</sup>	Often asymptomatic Constitutional symptoms: fever, night sweats, fatigue, weight loss Mucocutaneous lesions: seborrheic dermatitis, HSV, VZV (shingles), oral hairy leukoplakia (EBV), candidiasis (oral, esophageal, vaginal), KS Recurrent bacterial infections, especially pneumonia Pulmonary and extrapulmonary tuberculosis Lymphoma
<200 cells/mm <sup>3</sup>	<i>Pneumocystis jirovecii</i> pneumonia (formerly PCP) KS Oral thrush Local and/or disseminated fungal infections: <i>Cryptococcus neoformans</i> , <i>Coccidioides immitis</i> , <i>Histoplasma capsulatum</i>
<100 cells/mm <sup>3</sup>	Progressive multifocal leukoencephalopathy (PML) – JC virus CNS toxoplasmosis
<50 cells/mm <sup>3</sup>	CMV infection: retinitis, colitis, cholangiopathy, CNS disease MAC Bacillary angiomatosis (disseminated <i>Bartonella</i> ) Primary CNS lymphoma (PCNSL)

### Laboratory Diagnosis

- anti-HIV antibodies detectable after a median of 3 wk, virtually all by 3 mo (therefore 3 mo window period)
- initial screening test (3rd generation antibody test): ELISA detects serum antibody to HIV; sensitivity >99.5%
- increasingly, combination p24 antigen/HIV antibody tests (4th generation) used for screening; improved sensitivity in early or acute infection and sensitivity/specificity approach 100% for chronic infection
- confirmatory test: if positive screen, Western blot confirmation by detection of antibodies to at least two different HIV protein bands (p24, gp41, gp120/160); specificity >99.99%

### Sexual Activity without Condoms and Risk of HIV Transmission in Serodifferent Couples when the HIV-Positive Partner is using Suppressive Antiretroviral Therapy

JAMA 2016;316(2):171-181

**Purpose:** To evaluate the rate of within-couple HIV transmission (heterosexual and MSM) during periods of sex without condoms and when the HIV+ partner had HIV-1 RNA <200 copies/mL.

**Methods:** Prospective, observational PARTNER study, enrolled 1166 HIV serodifferent couples (in which the HIV+ partner was taking ART) who reported having condomless sex. Primary outcome was risk of within-couple HIV transmission to HIV- partner.

**Results:** Enrolled couples provided 1238 eligible couple-years of follow-up. Couples reported condomless sex for a median of 2 yr and condomless sex with other partners was reported by 108 HIV- MSM and 21 heterosexuals. While 11 HIV- partners became HIV+ (10 MSM; 1 heterosexual), no phylogenetically linked transmissions occurred over eligible couple-years of follow-up (within-couple HIV transmission = 0, 95% CI 0.30-0.71 per 100 couple-years).

**Conclusions:** Among serodifferent heterosexual and MSM couples in which HIV+ partner was using ART and who reported condomless sex, during median 1.3 yr couple follow-up, there were no documented cases of within-couple transmission.

**Seroconversion:** Development of detectable anti-HIV antibodies

**Window Period:** Time between infection and development of anti-HIV antibodies; when serologic tests (ELISA, Western blot) are negative

All infants born to HIV-infected mothers have positive enzyme linked immunosorbent assay (ELISA) tests because of circulating maternal anti-HIV antibodies, which disappear by 18 mo; early diagnosis is made by detection of HIV RNA in plasma

### HLA-B\*5701 Testing

Abacavir hypersensitivity reactions usually only occur in individuals carrying this HLA allele (~5-7% of White individuals, lower prevalence in other ethnic groups)  
Routine screening for HLA-B\*5701 at baseline and definitely prior to abacavir use

### HIV Status

- CD4 count: progress and stage of disease
- Viral load: rate of progression

### HIV Non-disclosure Laws in Ontario

In 2017, Ontario changed HIV non-disclosure laws for people living with HIV, where non-disclosure of HIV status to a sexual partner is no longer considered a criminal offense if one of the following criteria is met:

- On antiretroviral therapy with a viral load <200 copies/mL for at least 6 mo
- Viral load between 200-1500 copies/mL and a condom is used properly and does not break

- rapid (point-of-care) antibody tests: higher false positives, therefore need to confirm positive results with traditional serology
- p24 antigen: detection by ELISA may be positive during "window period"

### Management of the HIV-Positive Patient

- verify positive HIV test
- complete baseline history and physical exam, then follow-up every 3-6 mo
- laboratory evaluation
  - if non-stable and non-suppressed viral load, order routine CD4 count to measure status of the immune system
  - routine HIV-RNA levels (viral load) also important indicator of effect of ART
  - baseline HIV resistance testing to guide ARV therapy
  - HLA-B\*5701 genetic test to screen for abacavir hypersensitivity if considering abacavir in treatment regimen
  - CCR5 tropism testing if considering CCR5 antagonist in treatment regimen
  - baseline tuberculin skin test (PPD): induration greater than 5 mm is positive
  - baseline serologies (hepatitis A, B, and C, syphilis, toxoplasmosis, CMV, VZV)
  - routine biochemistry and hematology, CXR, urinalysis
  - annual fasting lipid profile and fasting glucose (due to ART side effects)
- education
  - regular follow-up on viral loads (q3-6 mo) as well as strict adherence to ART improves prognosis; routine monitoring of CD4 counts until consistently over 500 cells/ $\mu$ L with suppressed viral load
  - prevention of further transmission through safer sex and clean needles for IDU
  - HIV superinfection (transmission of different HIV strains from another HIV+ person) can rarely occur so barrier protection during sex is still recommended
  - discuss importance of disclosing HIV status to partners including risk of criminal prosecution of non-disclosure in jurisdictions where applicable
  - connect to relevant community groups and resources
- health care maintenance
  - assessment of psychosocial concerns and referral to psychiatry or social work if appropriate
  - vaccines: influenza annually, 23-valent pneumococcal every 5 yr, HBV (if not immune), HAV (if seronegative), HPV
  - annual screening (PAP smear), regular STI screening
  - management of comorbid conditions and provision of general primary care

1<sup>st</sup> and 2<sup>nd</sup> prophylaxis may be discontinued if CD4 count is above threshold for  $\geq 6$  mo while on ART

### Anti-Retroviral Pre-Exposure Prophylaxis for Preventing HIV in High-Risk Individuals

Cochrane DB Syst Rev 2012;7:CD007188

**Purpose:** To evaluate the efficacy of oral anti-retroviral prophylactic therapy in preventing HIV infection.

**Study:** Systematic review of 12 randomized controlled trials with 6 trials forming the core analysis.

**Population:** 9849 HIV-uninfected patients at high risk of contracting HIV including MSM, serodiscordant couples, and others.

**Outcome:** New infection with HIV.

**Results:** Daily oral tenofovir disoproxil fumarate (TDF) plus emtricitabine (FTC) reduced the risk of HIV acquisition compared to placebo (RR 0.49; 95% CI 0.28-0.85). TDF alone also showed significant risk reduction in trials with fewer patients (RR 0.33; 95% CI 0.20-0.55). There was no significant increase in adverse events in any of the treatment groups. Sexual practices and adherence did not differ between treatment and placebo arms.

**Conclusions:** Pre-exposure prophylaxis with TDF with or without FTC effectively reduces the risk of HIV acquisition in high-risk, HIV-uninfected patients without causing significant adverse effects.

### Reasons for Deterioration of a Patient with HIV/AIDS

- Opportunistic infections
- Neoplasms
- Medication-related toxicities
- Co-infections (e.g. HBV, HCV, STIs)
- Non-AIDS-related comorbidities (e.g. cardiovascular, renal, hepatic, neurocognitive, bone disease)

### Treatment Failure

- Assess adherence
- Assess drug interactions
- Resistance testing
- Rule out opportunistic infections
- Rule out marrow suppression
- Construct new combination drug regimen

**Table 22. Prophylaxis Against Opportunistic Infections in HIV-infected Patients**

Pathogen	Indication for Prophylaxis	Preferred Prophylactic Regimen
<i>Pneumocystis jirovecii</i>	CD4 count <200 cells/mm <sup>3</sup>	TMP/SMX 1SS or DS once daily
<i>Toxoplasma gondii</i>	IgG antibody to <i>Toxoplasma</i> and CD4 count <100 cells/mm <sup>3</sup>	TMP/SMX 1DS once daily
<i>Mycobacterium tuberculosis</i>	PPD reaction $\geq 5$ mm or contact with case of active TB	INH + pyridoxine daily x 9 mo
<i>Mycobacterium avium</i> complex	CD4 count <50 cells/mm <sup>3</sup>	No prophylaxis if patients are started on ARTs

SS = single strength; DS = double strength

See USPHS/IDSA guidelines for preventing opportunistic infections among HIV-infected persons (Relevant Sections updated 2013, 2015). Available from: <http://aidsinfo.nih.gov/>

## Anti-Retroviral Treatment

### Overall Treatment Principles

- recommended that all HIV-positive patients initiate combination ART to restore and preserve immune function, reduce morbidity, prolong survival, and prevent transmission
- patients starting ART should be committed to treatment and understand the importance of adherence; poor compliance can lead to viral resistance; may defer treatment on the basis of clinical and psychosocial factors on case-by-case basis
- consider results of baseline resistance testing and complete ART history before initiating or re-initiating ART
- goal: keep viral load below limit of detection i.e. <40 copies/mL (undetectable); viral load should decrease 10-fold within 4-8 wk, be undetectable by 6 mo, and restore immunological function
- strong evidence against intermittent ART or "drug holidays"
- patient with undetectable viral load adhering to ART does not transmit HIV to sexual partners

### ART Recommendations for Treatment of Naïve Patients

- 2 NRTIs + 1 INSTI or "boosted" PI (combined with ritonavir or cobicistat for improved pharmacokinetics)
- note: guidelines are subject to frequent change. Combination therapy is suggested, preferably with single pill regimens

### Treatment Failure

- defined primarily by viral load (persistently >200 copies/mL)
- ensure that viral load >40 is not just a transient viremia or 'blip'; confirm medication adherence, assess drug interactions, perform resistance testing

**Table 23. Anti-Retroviral Drugs**

Class	Drugs	Mechanism	Adverse Effects
<b>Nucleoside reverse transcriptase inhibitors (NRTIs)</b>	abacavir (ABC) emtricitabine (FTC) lamivudine (3TC) Tenofovir disoproxil fumarate (TDF) tenofovir alafenamide (TAF) zidovudine (AZT) didanosine (ddI) stavudine (d4T) <b>Combination Tablets:</b> AZT/3TC (Combivir®) AZT/3TC/ABC (Trizivir®) ABC/3TC (Kivexa®) TDF/FTC (Truvada®) TAF/FTC (Descovy®)	Incorporated into the growing viral DNA chain, thereby competitively inhibiting reverse transcriptase and terminating viral DNA growth	Lactic acidosis (often secondary to mitochondrial toxicity) Lipodystrophy Rash Nausea/vomiting/diarrhea Bone marrow suppression (AZT) Peripheral neuropathy (ddI, d4T) Drug-induced hypersensitivity (ABC) Pancreatitis (ddI/d4T) Myopathy (AZT)
<b>Non-nucleoside reverse transcriptase inhibitors (NNRTIs)</b>	delavirdine (DLV) doravirine (DOR) efavirenz (EFZ) etravirine (ETR) nevirapine (NVP) rilovirine (RPV)	Non-competitively inhibit function of reverse transcriptase, thereby preventing viral RNA replication	Rash, Stevens-Johnson syndrome CNS: dizziness, insomnia, somnolence, abnormal dreams (efavirenz) Hepatotoxicity (nevirapine – avoid in females with CD4 >250, men with CD4 >400) CYP3A4 interactions
<b>Protease inhibitors (PIs)*</b>	atazanavir (ATV) amprenavir (APV) darunavir (DRV) darunavir/cobicistat (DRV/c) lopinavir/ritonavir (LPV/r) nelfinavir (NFV) rilonavir (RTV) tipranavir (TPV) indinavir	Prevent maturation of infectious virions by inhibiting the cleavage of polyproteins	Lipodystrophy, metabolic syndrome Nausea/vomiting/diarrhea Nephrolithiasis (indinavir) Rash (APV) Hyperbilirubinemia (atazanavir, indinavir) CYP3A4 interactions Hyperlipidemia
<b>Integrase strand transfer inhibitors (INSTIs)</b>	bictegravir cabotegravir dolutegravir (DTG) elvitegravir (EVG) raltegravir (RAL)	Inhibits integration of HIV DNA into the human genome thus preventing HIV replication	
<b>Fusion inhibitor (only used if resistance)</b>	enfuvirtide (T-20)	Inhibit viral fusion with T-cells by inhibiting gp41, preventing cell infection	Injection site reactions, rash, infection, diarrhea, nausea, fatigue
<b>CCR5 antagonist</b>	maraviroc (MVC)	Inhibit viral entry by blocking host CCR5 co-receptor	Fever, cough, dizziness

\*Standard of care is to pharmacologically boost most PIs with ritonavir to increase concentrations

**Single Tablet ART Regimens**

- reduces pill burden and increases adherence
- generally better tolerated

**Table 24. Single Tablet ART Regimens**

Name	Contents	Common Side Effects
Biktarvy®	bictegravir/emtricitabine/tenofovir alafenamide	good side effect profile
Genvoja®	tenofovir/emtricitabine/elvitegravir/cobicistat	good side effect profile
Complera®	rilpivirine/emtricitabine/tenofovir	good side effect profile
Odefsey®	rilpivirine/emtricitabine/tenofovir alafenamide	good side effect profile
Stribild®	elvitegravir/cobicistat/emtricitabine/tenofovir	good side effect profile
Truneq®	dolutegravir/bacavir/lamivudine	good side effect profile; use only in HLAB*5701 negative patients
Atripla®	efavirenz/tenofovir/emtricitabine	psychiatric events, vivid dreams

**Recommended ARV Regimens for Treatment-Naïve HIV-infected Adults**

- initial regimens for treatment (most include an integrase inhibitor and a pair of NRTIs):
  1. bictegravir/TAF/FTC
  2. Dolutegravir/ABC/3TC (in patients confirmed to be HLB\*5701 negative)
  3. dolutegravir + (TAF or TDF)/(FTC or 3TC)
  4. raltegravir + TAF (or TDF)/FTC
  5. DTG/3TC
- note: not all regimens are available in all regions

**Recommended ARV Regimens for Individuals of Childbearing Potential**

- there is an increased risk of neural tube defects in infants born to women on dolutegravir at time of conception
- it is not known if other INSTIs also increase risk of neural tube defects
- therefore, before beginning an INSTI-containing treatment regimen in individuals of childbearing potential, the following should be considered:
  - completing a pregnancy test
  - a discussion on risks and benefits of dolutegravir, and lack of information on other INSTIs
  - for individuals attempting to conceive: RAL + TDF/FTC, TDF/3TC, or ABC/3TC are preferred regimens; DTG regimens to be used as an alternative only
  - for individuals not attempting to conceive but are sexually active and not using contraception, consider effectiveness/tolerability, patient preferences in decision
  - for individuals using effective contraception, treatment approach is similar to that of individuals in the general population with HIV

**Lactic Acidosis**

- Occurs secondary to mitochondrial toxicity
- Symptoms include abdominal pain, fatigue, nausea/vomiting, muscle weakness

**Lipodystrophy**

Body fat redistribution (mainly with old ARVs)

- Lipohypertrophy (e. g. dorsal fat pad, breast enlargement, increased abdominal girth) thought to be caused primarily by protease inhibitors
- Lipodystrophy (e. g. facial thinning, decreased adipose tissue in the extremities) is thought to be caused by thymidine analogue NRTIs such as d4T and AZT
- Metabolic abnormalities: lipids (increased LDL, increased TGs), glucose (insulin resistance, T2DM), increased risk of CVD

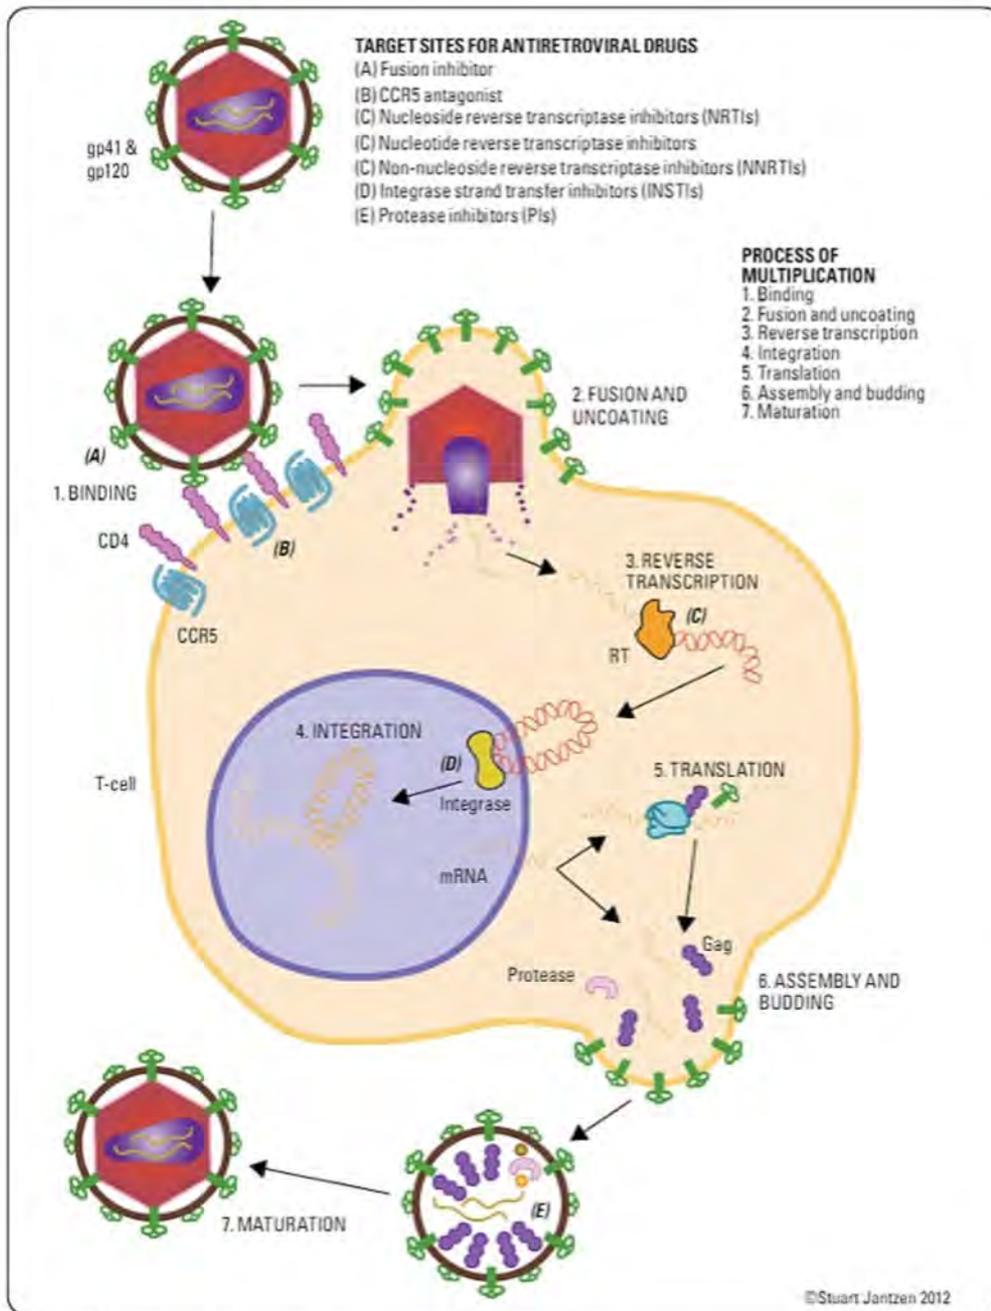

Figure 9. Mechanism of HIV replication

## Prevention of HIV Infection

- education, including harm reduction
  - safer sexual practices: condoms for vaginal and anal sex, barriers for oral sex
  - harm reduction for IVDU: avoid sharing needles
- prevention of vertical HIV infection: treatment with ART should be initiated prior to pregnancy or as early as possible during pregnancy. The risk of vertical HIV transmission can be reduced to <1% if maternal ART is started in a timely manner and the maternal viral load is undetectable prior to delivery
- universal blood and body precautions for healthcare workers
  - post-exposure prophylaxis (PEP) after occupational (e.g. needle-stick injury) and non-occupational (e.g. consensual sex, sexual assault) exposure to HIV: 2- or 3-drug regimen initiated immediately (<72 h) after exposure and continuing for 4 wk
- recent data has demonstrated efficacy of pre-exposure prophylaxis (oral PrEP or topical microbicides) in preventing HIV
- ART associated with 96% reduction in risk of transmitting HIV to sexual partners
- screening of blood and organ donation

Early identification of HIV is essential for patients to receive the maximal benefit from ART

**Efficacy, Safety, and Effect on Sexual Behaviour of On-Demand Pre-Exposure Prophylaxis for HIV in Men who have Sex with Men: An Observational Cohort Study**

Lancet HIV 2017;4:402-410

**Purpose:** Assess the efficacy, safety, and effect of on-demand pre-exposure prophylaxis (PrEP) on sexual behaviour.

**Methods:** Men and transgender women who have sex with men, previously enrolled in the placebo-controlled ANRS IPERGAM trial. On demand tenofovir disoproxil fumarate (300 mg) and emtricitabine (200 mg) to be taken before and after sexual intercourse and participants assessed for incidence of HIV, PrEP adherence, safety, and sexual behaviour.

**Results:** HIV incidence was 0.19/100 person-years (95% CI 0.01-1.08) vs. 6.60/100 person-years (95% CI 3.60-11.05) in the placebo group, relative risk reduction of 97%. Drug-related GI events were reported in 14% of participants but were self-limiting. Participants reporting condomless sex at their last receptive anal intercourse increased from 77 to 86% at 18 mo follow-up.

**Conclusions:** On-demand oral PrEP is highly effective at preventing HIV infection among high-risk MSM. This represents an alternative to daily PrEP.

**Use of a Vaginal Ring Containing Dapivirine for HIV-1 Prevention in Women**

NEJM 2016;375:2121-2132

**Purpose:** To evaluate whether longer-acting methods of anti-retroviral therapy (i.e. vaginal rings) may simplify use of medications and provide HIV-1 protection.

**Methods:** Phase 3, randomized, double-blind, placebo-controlled trial of monthly vaginal ring containing dapivirine in women (aged 18-45) in Malawi, South Africa, Uganda, and Zimbabwe.

**Results:** Among 2629 women enrolled, the incidence of HIV-1 infection was 3.3/100 person-years in dapivirine group and 4.5/100 person-years in placebo group. Post hoc analysis identified higher rates of HIV-1 protection in women >21 yr (56%, 95% CI 31-71) but not among those <21 yr (-27%, 95% CI -133-31), which correlated with reduced adherence.

**Conclusions:** Monthly vaginal ring containing dapivirine reduced risk of HIV-1 infection among African women.

## Types of Testing

### 1. Nominal/Name-Based HIV Testing

- person ordering the test knows the identity of the person being tested for HIV
- HIV test is ordered using the name of the person being tested
- person ordering the test is legally obligated to notify Public Health officials if test results are positive for HIV
- test result is recorded in the healthcare record of the person being tested

### 2. Non-Nominal/Non-Identifying HIV Testing

- similar to nominal/name-based testing on all points except:
- HIV test is ordered using a code or the initials of the person being tested

### 3. Anonymous Testing

- available at specialized clinics
- person ordering the HIV test does not know the identity of the person being tested
- HIV test is carried out using a unique non-identifying code that only the person being tested for HIV knows
- test results are not recorded on the healthcare record of the person being tested
- patient identification and notification of Public Health required to gain access to ART

## HIV Pre- and Post-Test Counselling

- a diagnosis of HIV can be overwhelming and is often associated with stigma and discrimination
- consider pre- and post-test counselling, regardless of the results
- goals include: assessing risk, making informed decision to be tested, education to protect themselves and others from virus exposure, where to go for more information and support
- HIV-positive individuals should be connected with local support services

# FUNGAL INFECTIONS

## Skin and Subcutaneous Infections

### Superficial Fungal Infections

- see [Dermatology](#), D32, D33, D37, D45 D46, and D49

### Dermatophytes

- see [Dermatology](#), D31

### Subcutaneous Fungal Infections

#### Etiology

- subcutaneous inoculation by fungi that naturally reside in the soil, including *Sporothrix schenckii*, which usually occurs in gardeners injured by a rose thorn or splinter

#### Clinical Features

- causes subcutaneous nodules at the point of entry, may develop into an ulcer
- fungi may migrate up lymphatic vessels creating nodules along the way – “nodular lymphangitis”

#### Treatment

- oral azole
- IV amphotericin B for severe or disseminated infection

## Endemic Mycoses

### Etiology

- fungal infection that occurs through the inhalation of spores (from soil, bird droppings, vegetation) or inoculation injury
- thermally dimorphic organisms: mould in cold temperature (e.g. soil), and yeast at higher temperature (e.g. tissue)
- in North America, the three major endemic mycoses are: histoplasmosis, blastomycosis, and coccidioidomycosis

### Clinical Features

- may be asymptomatic
- all can cause pneumonia and may disseminate hematogenously
- may reactivate or disseminate during immunocompromised states

Histoplasmosis is commonly associated with exposure to chicken coops, bird roosts, and bat caves

Table 25. Endemic Mycoses

Disease	Endemic Region	Clinical Features	Investigations
<i>Histoplasma capsulatum</i>	Ohio and Mississippi River valleys in central USA, Ontario, Quebec; widespread	Asymptomatic (in most people) Primary pulmonary Fever, cough, chest pain, headache, myalgia, anorexia CXR (acute): pulmonary infiltrates ± hilar lymphadenopathy CXR (chronic): pulmonary infiltrates, cavitary disease Disseminated (rare) Occurs primarily in immunocompromised patients Spread to bone marrow (pancytopenia), GI tract (ulcers), lymph nodes (lymphadenitis), skin, liver, adrenals, CNS	Fungal culture, fungal stain Antigen detection (urine and serum) Serology
<i>Blastomyces dermatitidis</i>	States east of Mississippi River, Northern Ontario, and along the Great Lakes	May be asymptomatic Primary: acute or chronic pneumonia Fever, cough, chest pain, chills, night sweats, weight loss CXR (acute): lobar or segmental pneumonia CXR (chronic): lobar infiltrates, fibronodular interstitial disease Disseminated Spread to skin (verrucous lesions that mimic skin cancer, ulcers, subcutaneous nodules), bones (osteomyelitis, osteolytic lesions), genitourinary tract (prostatitis, epididymitis)	Sputum smear and culture Direct examination of clinical specimens for characteristic broad-based budding yeast (sputum, tissue, purulent material)
<i>Coccidioides immitis</i>	Deserts in southwest USA, northwest Mexico	Primary "Valley fever": subacute fever, chills, cough, chest pain, sore throat, fatigue that lasts for wk to mo Can develop hypersensitivity with arthralgias, erythema nodosum Disseminated Rare spread to skin (ulcers), joints (synovitis), bones (lytic lesions), meninges (meningitis) Common opportunistic infection in patients with HIV	Sputum culture Direct examination of clinical specimens for characteristic yeast (sputum, tissue, purulent material)

## Opportunistic Fungi

### *Pneumocystis jirovecii* (formerly *P. carinii*) Pneumonia: PJP or PCP

### Etiology

- respiratory exposure to unicellular fungi (previously classified as a protozoa)
- can be transmitted from person to person
- without prophylaxis, HIV-positive patients with a CD4 count  $<200$  cells/mm<sup>3</sup> have an 80% lifetime risk of PJP
- most cases of PJP occur in patients who are unaware of their HIV infection, do not seek medical care for HIV, or who do not use prophylaxis
- in HIV-negative patients, PJP occurs almost exclusively in immunocompromised patients (e.g. organ transplant patients, inflammatory conditions, hematological malignancies)

### Clinical Features

- symptoms of pneumonia: fever, non-productive cough, progressive dyspnea (and hypoxia)
- classic CXR findings of interstitial pneumonia
- most clinical disease is due to reactivation of latent infection or reinfection by a different genotype in immunocompromised patients (steroid use, HIV)

### Investigations

- CXR: bilateral symmetrical interstitial infiltrates
- ABG: reduced pO<sub>2</sub> and elevated alveolar-arterial (A-a) gradient
- serum LDH: elevated ( $>220$  IU/L)
- induced sputum or lower airway sampling: positive for *Pneumocystis*, traditional test was immunofluorescence however many labs using quantitative PCR

#### CXR in *P. jirovecii*

- Bilateral, diffuse opacities
- CXR may be normal (20-30% cases)
- CT shows cysts (hence the name *Pneumocystis*) but almost never pleural effusions

### Treatment and Prevention

- oxygen to keep SaO<sub>2</sub> >90%
- antimicrobial options
  - TMP/SMX (PO or IV) is preferred therapy
  - dapsone and TMP
  - clindamycin and primaquine
  - pentamidine (IV) is second line in severe disease
  - atovaquone
- corticosteroids used as adjuvant therapy in those with severe hypoxia (pO<sub>2</sub> <70 mmHg or A-a gradient O<sub>2</sub> >35 mmHg)
- prophylactic TMP/SMX for those at high-risk of infection (HIV patients when CD4 <200 cells/mm<sup>3</sup> or non-HIV immunocompromised patients under specific conditions)

## Cryptococcus spp.

### Etiology

- inhalation of airborne encapsulated yeast from soil contaminated with pigeon droppings (*C. neoformans*) or certain tree species such as Eucalyptus or Douglas fir (*C. gattii*)
- C. neoformans* tends to affect immunocompromised hosts vs. *C. gattii* which tends to affect immunocompetent hosts

### Clinical Features

- asymptomatic
- pulmonary
  - usually asymptomatic or self-limited pneumonitis
  - only 2% of HIV+ patients present with pulmonary symptoms including productive cough, chest tightness, and fever
- disseminated
  - frequently disseminates in HIV+ population
  - CNS: meningitis (leading cause of meningitis in patients with HIV)
  - skin: umbilicated papules that resemble large lesions of Molluscum contagiosum
  - other: bone, lymph nodes, bone marrow, soft tissues, eyes, prostate

### Investigations

- serum cryptococcal antigen
- CSF for meningitis: India-ink stain or cryptococcal antigen test, culture to confirm
- lateral flow cryptococcal antigen assay from serum and CSF
- LP with measurement of opening pressure

### Treatment

- in patients with HIV who have cryptococcal meningitis or severe pulmonary disease:
  - amphotericin B (+ flucytosine) is used in the first 2 wk for induction therapy; limited duration due to side effects
  - switch to fluconazole for at least 8 wk as consolidation therapy, then continue at lower dose for prolonged maintenance
  - serial lumbar puncture or other method of managing increased ICP an important adjunct to therapy

*C. gattii* has a limited geographical distribution including Vancouver Island, Northern Australia, and Papua New Guinea

India-ink sensitivity for Cryptococcus is only 50% (higher in HIV patients); now replaced by cryptococcal antigen test in most laboratories

## Candida albicans

### Etiology

- overgrowth of *C. albicans* (normally found as part of the microbiome of the skin, mouth, vagina, and GI tract)
- risk factors for overgrowth:
  - immunocompromised state (DM, corticosteroids)
  - critically ill patients (broad-spectrum antibiotic use, central venous catheters, total parenteral nutrition)
  - obesity: maceration and moisture in intertriginous areas, pannus, under breasts

### Clinical Features

- mucocutaneous
  - oral thrush, esophagitis (chest pain, odynophagia), vulvovaginitis (see [Gynaecology](#), GY26), balanitis, cutaneous (diaper rash, skin folds, folliculitis), chronic mucocutaneous
  - small satellite lesions beyond the margin of the rash
- invasive
  - candidemia, endophthalmitis, endocarditis, UTI (upper tract), hepatosplenic disease

**Treatment**

- thrush: clotrimazole troches, miconazole mucoadhesive buccal tablets, or nystatin suspension or pastilles for mild disease, fluconazole for severe or refractory disease
- vulvovaginal candidiasis: topical agents (imidazole or nystatin), oral fluconazole for recurrent disease
- cutaneous infection: topical imidazole
- opportunistic infections in HIV, other systemic infections: fluconazole or echinocandin
- chronic mucocutaneous: azoles

***Aspergillus* spp.****Etiology**

- infection with *Aspergillus* fungi (*A. fumigatus*, *A. flavus*) which is found ubiquitously in the air and the environment
- *Aspergillus* produces a toxin called aflatoxin that contaminates nuts, grains, and rice

**Clinical Features**

- allergic bronchopulmonary aspergillosis (ABPA)
  - IgE-mediated asthma-type reaction with dyspnea, high fever, and transient pulmonary infiltrates
  - occurs more frequently in patients with asthma and allergies
- aspergilloma (fungus ball)
  - ball of hyphae in a pre-existing lung cavity
  - symptoms range from asymptomatic to massive hemoptysis
  - CXR: round opacity surrounded by a thin lucent rim of air, often in upper lobes ("air crescent" sign)
- invasive aspergillosis
  - associated with prolonged and persistent neutropenia or transplantation
  - pneumonia – most common
  - may disseminate to other organs: brain, skin
  - severe symptoms with fever, cough, dyspnea, cavitation; fatal if not treated early and aggressively
  - CXR: local or diffuse infiltrates ± pulmonary infarction, pulmonary nodules with surrounding ground glass ("halo" sign)
- mycotoxicosis
  - aflatoxin produced by *A. flavus* (nuts, grains, rice)
  - results in liver hemorrhage, necrosis, and hepatocellular carcinoma formation

**Treatment Options**

- voriconazole or amphotericin B for invasive aspergillosis
- surgical resection for aspergilloma
- corticosteroids ± itraconazole for ABPA

See Landmark Infectious Disease Trials table for more information on the voriconazole vs. amphotericin B for invasive aspergillosis trial. It compared voriconazole with amphotericin B for primary therapy of invasive aspergillosis.

**PARASITIC INFECTIONS****Protozoa – Intestinal/Genitourinary Infections*****Entamoeba histolytica* (Amoebiasis)****Etiology**

- infection with *E. histolytica* occurs when the cysts are transmitted via the oral-fecal route in areas of poor sanitation that have been contaminated by other infected humans, or via sexual activity
- seen in migrants, travellers, institutionalized individuals, Indigenous peoples, MSM

**Clinical Features**

1. asymptomatic carriers
2. amoebic dysentery
  - abdominal pain, cramping, colitis, dysentery, low grade fever with bloody diarrhea secondary to local tissue destruction, and ulceration of large intestine
3. amoebic abscesses (liver abscesses, see [General and Thoracic Surgery](#), GS52)
  - most common in liver (hematologic spread); presents with right upper quadrant pain, weight loss, fever, hepatomegaly
  - can also occur in lungs and brain

**Investigations**

- serology, fecal/serum antigen testing, stool microscopic exam (for cysts and trophozoites), colon biopsy, single stool for multiplex enteric parasite PCR
- *E. histolytica* indistinguishable microscopically from the non-pathogen *E. dispar* (distinguish by specific stool antigen detection or multiplex stool PCR assay)

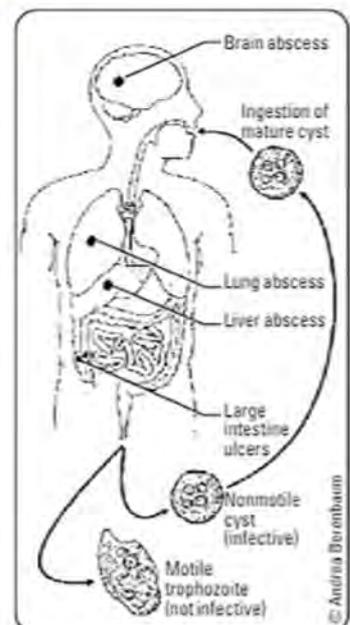

Figure 10. *Entamoeba* life cycle

**Treatment and Prevention**

- metronidazole
- for invasive disease or cyst elimination: follow with iodoquinol or paromomycin
- aspiration of hepatic abscess if risk of abscess rupture, poor response to medical therapy, or diagnostic uncertainty
- asymptomatic cyst shedding: iodoquinol or paromomycin alone
- good personal hygiene, purification of water supply by boiling, filtration (not chlorination)

***Giardia lamblia*****Etiology**

- infection with *G. lamblia* occurs via the fecal-oral route with the ingestion of cysts from water/food contaminated by infected humans and other mammals (especially in the Rockies)
- risk factors: travel, camping, institutions, daycare centres, MSM

**Clinical Features**

- giardiasis ("beaver fever")
  - symptoms vary from asymptomatic to self-limited mild watery diarrhea to malabsorption syndrome (chronic giardiasis where the parasite coats the small intestine and thus prevents fat absorption)
  - nausea, malaise, abdominal cramps, bloating, flatulence, fatigue, weight loss, steatorrhea
  - no hematochezia (no invasion into intestinal wall), no mucous in stool

**Investigations**

- multiple stool samples (daily x 3 d) for microscopy; single stool for multiplex enteric parasite PCR; stool antigen used occasionally
- occasionally small bowel aspirate or biopsy

**Treatment and Prevention**

- metronidazole; nitazoxanide if symptomatic
- good personal hygiene and sanitation, water purification (iodine better than chlorination), outbreak investigation

***Trichomonas vaginalis*****Etiology**

infection with *T. vaginalis* occurs via sexual contact

**Clinical Features**

- often asymptomatic (10-50%), especially males (occasionally urethritis, prostatitis)
- *Trichomonas* vaginitis (see [Gynaecology, GY26](#))
- vaginal discharge (profuse, malodorous, yellow-green or grey, frothy), pruritus, dysuria, dyspareunia

**Investigations**

- wet mount (motile parasites), antigen detection, culture
- urine PCR to detect in males

**Treatment**

- metronidazole for patient and partner(s)

***Cryptosporidium* spp.****Etiology**

- infection with *Cryptosporidium* spp. via the fecal-oral route occurs with the ingestion of cysts from water contaminated by infected humans and other animals (including cows)
- risk factors: summer and fall, young children (daycare), MSM, contact with farm animals, immunodeficiency

**Clinical Features**

- range from self-limited watery diarrhea (immunocompetent) to chronic, severe, non-bloody diarrhea with nausea/vomiting, abdominal pain, and anorexia resulting in weight loss and death (immunocompromised)

**Investigations**

- modified acid-fast stain of stool specimen, microscopic identification of oocysts in stool or tissue, stool antigen detection by direct fluorescent antibody, single stool for multiplex enteric parasite PCR

**Treatment and Prevention**

- supportive care
- in HIV+ patients, (re)initiate ART and try to increase their CD4 count to >100; if fails, try nitazoxanide or macrolides
- good personal hygiene, water filtration

*Trichomonas* causes 25% of vaginitis

## Blood and Tissue Infections

### *Plasmodium* spp. (Malaria)

#### Etiology

- transmission of *Plasmodium* spp. (*P. falciparum*, *P. vivax*, *P. ovale*, *P. malariae*, *P. knowlesi*) primarily occurs during the blood meal of an infected female Anopheles mosquito
- sporozoites injected during the blood meal then infect human liver cells, where they multiply and are released as merozoites; merozoites infect RBCs and cause disease
- infection with malaria parasites can also occur via vertical transmission (rare) or blood transfusion
- occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

#### Clinical Features

- flu-like prodrome (may include fever, chills, fatigue, diaphoresis, cough, rash, arthralgias, myalgias, headache, GI symptoms)
- paroxysms of high spiking fever and shaking chills (due to synchronous systemic lysis of RBCs) that can last several hours
  - P. vivax* and *P. ovale*: chills and fever x 48 h but can be variable
  - P. malariae*: chills and fever x 72 h but can be variable
  - P. falciparum*: less predictable fever interval, can be highly variable
- abdominal pain, diarrhea, myalgia, headache, and cough
- hepatosplenomegaly and thrombocytopenia without leukocytosis
- >90% of patients infected with *P. falciparum* are ill within 30 d
- relapsing malarial attacks may occur after many months due to the reactivation (entering the erythrocytic cycle) of dormant liver hypnozoites of either *P. ovale* or *P. vivax*
- complications:
  - P. falciparum* (most common and most lethal): CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute kidney injury, ARDS, primarily responsible for fatal disease
  - P. knowlesi*, and rarely *P. vivax*, can be fatal

#### Investigations

- CBC screen (assess for triad of: thrombocytopenia, elevated LDH, and anemia)
- microscopy: blood smear q12-24 h (x3) to rule out infection
  - thick smear (Giemsa stain) for presence of organisms
  - thin smear (Giemsa stain) for species identification and quantification of parasites
- rapid antigen detection tests
- PCR

#### Treatment and Prevention

- all spp. of malaria can lead to severe infection (*P. falciparum* most likely to cause severe disease and death)
  - markers of severity: clinical features + parasitemia
  - in any patient with clinical evidence of severe disease: parenteral treatment (artemisinin combination therapy)
- P. falciparum*: most areas of the world show chloroquine resistance – check local resistance patterns
  - artemisinin combination therapy (e.g. artesunate + doxycycline or artemether-lumefantrine)
  - atovaquone/proguanil combination (Malarone®)
  - quinine + doxycycline or clindamycin
  - mefloquine and artemisinin resistance increasing in southeast Asia (check local resistance)
- P. vivax*, *P. ovale*: chloroquine (and primaquine to eradicate liver forms)
- P. vivax*, chloroquine resistant: atovaquone/proguanil + primaquine or quinine and doxycycline + primaquine
- P. malariae*, *P. knowlesi*: chloroquine
- prevention with antimalarial prophylaxis (although quality may vary regionally), covering exposed skin, insecticide-treated bed nets, insect repellent
- prevention of relapse for *P. vivax*: primaquine or the newly FDA-licensed tafenoquine (in patients ≥16 y/o who are receiving appropriate antimalarial therapy for acute *P. vivax* infection)

#### Mefloquine for Preventing Malaria during Travel to Endemic Areas

Cochrane DB Syst Rev 2017;CD006491

**Purpose:** To summarize efficacy and safety of mefloquine used as prophylaxis for malaria in travellers.

**Methods:** Randomized control trials (for efficacy and safety) and non-randomized cohort studies (for safety) to compare prophylactic mefloquine with placebo, no treatment, or alternative antimalarial agent.

**Results:** Participants were more likely to discontinue mefloquine (6%) vs. atovaquone-proguanil (3%) due to adverse effects (including nausea, vomiting, abnormal dreams, insomnia, anxiety, and depressed mood during travel). No difference in serious adverse effects or discontinuation due to adverse effects was found between mefloquine and doxycycline or mefloquine and chloroquine.

**Conclusions:** Absolute risk of malaria during short-term travel appears low with mefloquine, doxycycline, and atovaquone-proguanil therapy. Choice of agent depends on how individual travellers assess importance of specific adverse effects, pill burden, and cost.

Malaria is the most common fatal infectious disease worldwide

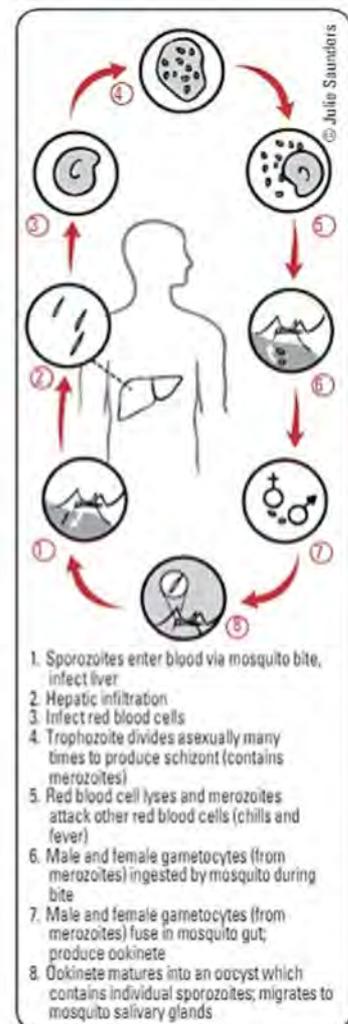

Figure 11. Life cycle of *Plasmodium* spp.

## Trypanosoma cruzi

### Etiology

- found in Mexico, South America, and Central America
- transmission by reduviid insect vector ("Kissing Bug"), which defecates on skin and trypomastigotes in the stool are rubbed into bite site or intact mucous membranes by host
- trypomastigotes can penetrate intact buccal mucosa when orally inoculated (e.g. via sugar cane-sweetened unpasteurized juices)
  - also transmitted via placental transfer, organ transplantation, blood transfusion, and ingestion of food or drink contaminated by an infected triatomine
  - congenital acquisition increasingly recognized as a risk factor for Chagas disease being detected in non-endemic areas

### Clinical Features

- American trypanosomiasis (Chagas disease)
  - acute: usually asymptomatic, local swelling at site of inoculation (Chagoma) with variable fever, lymphadenopathy, cardiomegaly, and hepatosplenomegaly
  - if inoculation via conjunctiva: "Romana's sign," usually unilateral
  - acute myocarditis, pericardial effusion, meningoencephalitis in severe cases
  - chronic indeterminate phase: asymptomatic but increasing levels of antibody in blood; most infected persons (60-70%) remain in this phase, and do not go on to manifest a determinate form of Chagas disease
  - chronic determinate: leads to chronic dilated cardiomyopathy, esophagomegaly, and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

### Investigations

- wet prep and Giemsa stain of thick and thin blood smear, serology, PCR

### Treatment and Prevention

- acute: benznidazole or nifurtimox
- indeterminate: increasing trend to treat as acute infection for children and adults under age 50
- chronic determinate: symptomatic therapy, surgery as necessary including heart transplant, esophagectomy, and colectomy; there is unlikely a clinical benefit to antiparasitic treatment at the determinate stage of disease
- insect control, bed nets

## Toxoplasma gondii

### Etiology

- infection with *T. gondii* occurs through exposure to cat feces (oocysts), ingestion of undercooked meat (tissue cysts), transplacental transmission, organ transplantation, gardening without gloves (cat oocyst exposure), whole blood transfusions, contaminated water sources

### Clinical Features

- congenital
  - result of acute primary infection of mother during pregnancy (TORCH infection)
  - stillbirth (rare), chorioretinitis, blindness, seizures, severe developmental delay, microcephaly
  - initially asymptomatic infant may develop reactivation of chorioretinitis as adolescent or adult-blurred vision, scotoma, ocular pain, photophobia, epiphora, hearing loss, developmental delay
- acquired
  - usually asymptomatic or mononucleosis-like syndrome in immunocompetent patient
  - infection remains latent for life unless reactivation due to immunosuppression
- immunocompromised (most commonly AIDS with CD4 < 200)
  - encephalitis with focal CNS lesions seen as single or multiple ring-enhancing masses on CT (headache and focal neurological signs)
  - lymph node, liver, spleen enlargement, and pneumonitis
  - chorioretinitis

### Investigations

- serology, CSF Wright-Giemsa stain, antigen or DNA detection (PCR); pathology provides definitive diagnosis
- immunocompromised patients: consider CT scan (ring-enhancing lesion in cortex or deep nuclei) and ophthalmologic examination

### Treatment and Prevention

- no treatment if: immunocompetent, not pregnant, no severe organ damage
- immunocompromised: pyrimethamine + sulfadiazine + folinic acid
- pregnancy: spiramycin if fetal status unknown, pyrimethamine + sulfadiazine + folinic acid if confirmed or highly suspected fetal infection, avoid undercooked meat and refrain from emptying cat litter boxes
- HIV: TMP/SMX
- proper hand hygiene, cook meat thoroughly to proper temperature

See Landmark Infectious Disease Trials table for more information on the BENEFIT trial. It details the role of trypanocidal therapy in patients with established Chagas cardiomyopathy.

**Classic Triad of Congenital Toxoplasmosis**

- Chorioretinitis
- Hydrocephalus
- Intracranial calcifications

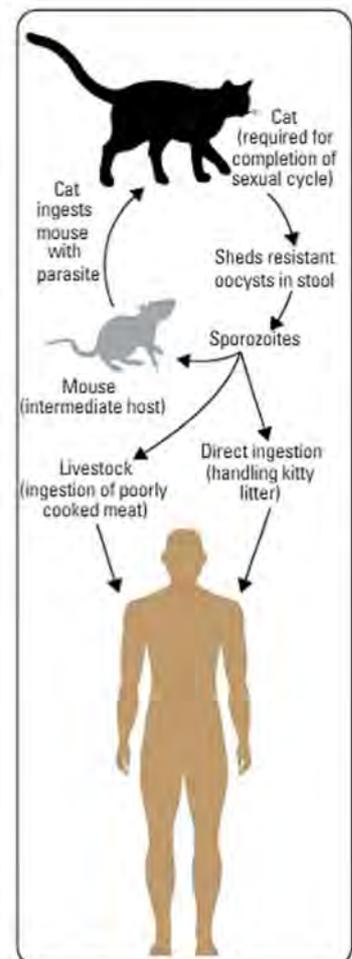

Figure 12. Life cycle of *Toxoplasma gondii*

1/3 of Ontario's population is infected with *Toxoplasma gondii*

# Helminths

## Roundworms – Nematodes

Table 26. Nematodes (Roundworms)

Nematode	Epidemiology	Transmission	Clinical Presentation	Treatment
<i>Ascaris lumbricoides</i>	Worldwide (most common in tropical and subtropical areas)	Human feces, ingestion of contaminated food or water containing eggs	Often asymptomatic, abdominal discomfort Heavy infections may cause intestinal blockage, growth impairment Cough, dyspnea, pulmonary infiltrates from larval migration through lungs (Löfller's syndrome)	Mebendazole OR albendazole OR pyrantel pamoate OR ivermectin
<i>Trichuris trichiura</i> (whipworm)	Worldwide (most common in tropical areas)	Ingestion of eggs in soil	Diarrhea ( $\pm$ mucous, blood), abdominal pain, rectal prolapse, stunted growth	Mebendazole OR albendazole
<i>Onchocerca volvulus</i>	Sub-Saharan Africa, Latin America	Blackfly bite	River blindness (onchocerciasis), dermatitis	Ivermectin + doxycycline
<i>Wuchereria bancrofti</i>	Tropics	Mosquito bite	Damage to lymphatics causes lymphadenopathy, lymphedema, lymphatic filariasis (elephantiasis), hydrocele Tropical pulmonary eosinophilia	Diethylcarbamazine + doxycycline
<i>Loa loa</i>	West and Central African rainforest (e.g. Cameroon, Central African Republic)	Deerfly bite	Loiasis is mostly asymptomatic. Symptoms can include episodic angioedema (Calabar swellings) and subconjunctival migration resulting in eye pain and itching	Surgical removal of adult worms, diethylcarbamazine, albendazole
<i>Enterobius vermicularis</i> (pinworm)	Worldwide	Human host: fecal-oral self-inoculation and fomite person-to-person transfer Adult worms live in cecum and deposit eggs in peri-anal skin	Asymptomatic carriers or severe nocturnal peri-anal itching (pruritus ani) Occasional vaginitis, ectopic migration to appendix or other pelvic organs Abdominal pain, nausea/vomiting with high worm burden	Slicky tape test: eggs adhere to tape applied to perianal skin (need 5-7 tests to rule out) Examination of perianal skin at night may reveal adult worms Usually no eosinophilia as no tissue invasion Mebendazole, albendazole; pyrantel in pregnancy Change underwear, bathe in morning, pajamas to bed, wash hands, trim fingernails Treat all family members simultaneously Reinfection common
<i>Strongyloides stercoralis</i> (threadworm)	Subtropical, tropical, and temperate (including southern US)	Fecal contamination of soil; transmission via unbroken skin, walking barefoot Autoinfection: penetration of larvae through GI mucosa or perianal skin Adult worms live in mucosa of small intestine	One of few worms able to multiply in human host Mostly asymptomatic infection or can have pruritic dermatitis at site of larval penetration Transient pulmonary symptoms during pulmonary migration of larvae (eosinophilic pneumonitis = Löfller's syndrome) Abdominal pain, diarrhea, pruritus ani, larva currens (itchy rash) Hyperinfection: occasional fatal cases caused by massive auto-infection in immunocompromised host; immunoablative therapy, including high-dose corticosteroids, is the most common risk factor for disseminated infection	Ivermectin and/or albendazole

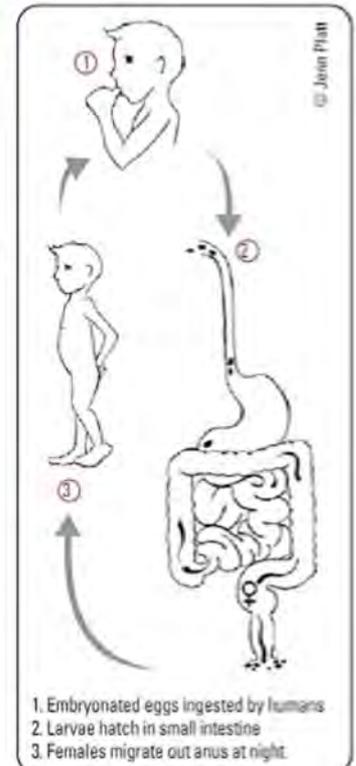

Figure 13. Life cycle of Enterobius

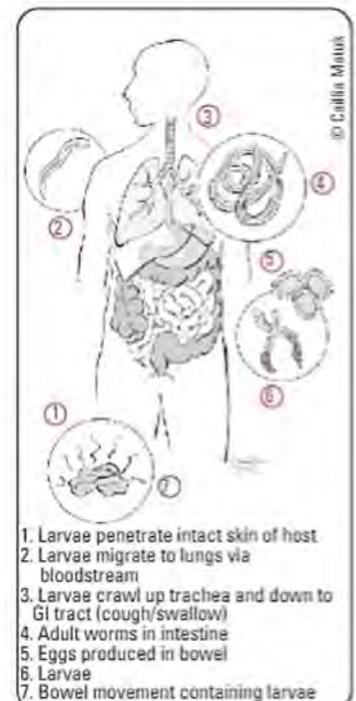

Figure 14. Life cycle of Strongyloides

## Flatworms – Cestodes/Trematode

Table 27. Cestodes/Trematodes (Flatworms)

	Epidemiology	Transmission	Clinical Presentation	Treatment
<b>CESTODES</b>				
<i>Taenia solium</i> (pork tapeworm)	Worldwide, but more common in places with poor sanitation	Undercooked pork (larvae), human feces (eggs)	Taeniasis: mild GI symptoms Cysticercosis: mass lesions in CNS, eyes, skin, seizures	Corticosteroids + albendazole + praziquantel for most cysticercosis Antiepileptics if seizures Praziquantel for adult tapeworm in gut (taeniasis)
<i>Taenia saginata</i> (beef tapeworm)	Worldwide, but more common wherever contaminated raw beef is eaten	Undercooked beef (larvae)	Taeniasis: mild GI symptoms	Praziquantel
<i>Diphyllobothrium latum</i>	Europe, North America, Asia	Raw fish	Vitamin B12 deficiency leading to macrocytic anemia and posterior column deficits	Praziquantel
<i>Echinococcus granulosus</i>	Rural areas, sheep-raising countries	Dog feces (eggs)	Liver/lung cysts (enlarge between 1-20 yr; may cause mass effect or rupture) Risk of anaphylaxis if cystic fluid released during surgical evacuation	Albendazole + praziquantel alone Surgery + perioperative albendazole Percutaneous aspiration + perioperative albendazole
<b>TREMATODES</b>				
<i>Clonorchis sinensis</i>	Japan, Taiwan, China, Southeast Asia	Raw fish	Exists in bile ducts, causes inflammation and sometimes cholangiocarcinoma	Praziquantel
<i>Schistosoma spp.</i>	Africa, Southeast Asia, focal in Western Hemisphere	Fresh water exposure	Chronic sequelae secondary to long-term infection (e.g. chronic liver disease, squamous cell carcinoma (SCC) of the bladder)	Praziquantel

## Schistosoma spp.

### Etiology

infection with *Schistosoma* spp. (*S. mansoni*, *S. hematobium*, *S. japonicum*) occurs following penetration of unbroken skin by their larvae (cercariae) which are found in infested fresh water

- adult worms live in terminal venules of bladder/bowel passing eggs into urine/stool
- schistosomes cannot multiply in or pass between humans
- more common in individuals from sub-Saharan Africa, South America, Asia, Caribbean, Eastern Mediterranean/North Africa

### Clinical Features

- most asymptomatic; symptoms seen in travellers (nonimmune)
- swimmer's itch: pruritic skin rash at site of penetration (cercarial dermatitis)
- acute schistosomiasis (Katayama fever): hypersensitivity to migrating parasites (4-8 wk after infection)
  - fever, hives, headache, weight loss, cough, abdominal pain, chronic diarrhea, high-grade eosinophilia
- chronic schistosomiasis (can persist for years):
  - *S. mansoni*, *S. japonicum*
  - worms in mesenteric vein, eggs in portal tracts of liver and bowel
  - heavy infections: intestinal polyps, portal and pulmonary HTN, splenomegaly (2° to portal HTN), hepatomegaly
  - *S. hematobium*
    - worms in vesical plexus, eggs in distal ureter and bladder induce granulomas and fibrosis
    - hematuria and obstructive uropathy; associated with squamous cell bladder cancer
  - neurologic complications: spinal cord neuroschistosomiasis (transverse myelitis), cerebral or cerebellar neuroschistosomiasis (increased ICP, focal CNS signs, seizures)
  - pulmonary complications: granulomatous pulmonary endarteritis, pulmonary HTN, cor pulmonale; especially in patients with hepatosplenic involvement

### Investigations

- serology (high sensitivity and specificity), CBC (eosinophilia, anemia, thrombocytopenia), loop-mediated isothermal amplification, circulating serum antigen test
- *S. mansoni*, *S. japonicum*: eggs in stool, liver U/S shows peri-portal fibrosis, rectal biopsy
- *S. hematobium*: bladder biopsy, eggs in urine and occasionally stool, kidney and bladder U/S

### Treatment and Prevention

- praziquantel
- add prednisone if acute schistosomiasis or neurologic complications develop
- proper disposal of human waste, molluscicide (pesticide against molluscs), avoidance of infested fresh water while travelling

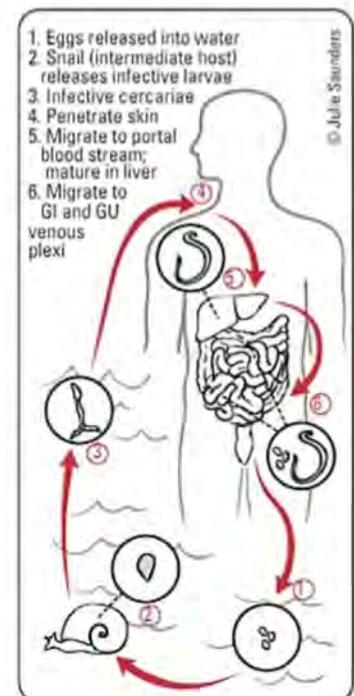

Figure 15. Life cycle of *Schistosoma*

## Ectoparasites

- scabies, lice
- see [Dermatology, D33](#)

**Table 28. Important Exposures**

Insect Bites	
Mosquito	<i>Plasmodium</i> spp. (Malaria) Dengue Chikungunya Lymphatic filariasis ( <i>Elephantiasis</i> ) West Nile encephalitis Yellow Fever Japanese encephalitis Zika
Tick	<i>Borrelia burgdorferi</i> (Lyme Disease) <i>Rickettsia rickettsii</i> (Rocky Mountain Spotted Fever)
Fly	<i>Trypanosoma brucei</i> spp. (African sleeping sickness) <i>Leishmania</i> spp. (Leishmaniasis) <i>Bartonella bacilliformis</i> (Bartolomellosis)
Flea	<i>Yersinia</i> (Plague) <i>Tunga penetrans</i> (Tungiasis)
Mammal Bites	
Dog/Cat	Rabies, <i>Pasteurella</i> , anaerobes, <i>Streptococcus</i> , <i>S. aureus</i> , <i>Bartonella henselae</i> , Tetanus
Human	<i>Streptococcus</i> , <i>S. aureus</i> , oral anaerobes, <i>Eikenella</i>
Oral Exposures	
Unpasteurized Milk	<i>Brucella</i> spp., non-tuberculous Mycobacteria, <i>Salmonella</i> , <i>E. coli</i> , <i>Listeria</i>
Undercooked Meat/Fish	Enteric bacteria, helminths, protozoa (e.g. <i>Toxoplasma</i> )
Water	Hepatitis A/E, Norovirus, cholera, <i>Salmonella</i> , <i>Shigella</i> , <i>Giardia</i> , poliovirus, <i>Cryptosporidium</i> , <i>Cyclospora</i>
Environmental Exposures	
Fresh Water	<i>Leptospira</i> spp., schistosomes, <i>Acanthamoeba</i> , <i>Naegleria fowleri</i>
Soil	Hookworms, <i>Toxocara</i> spp. (visceral larva migrans), <i>Leptospira interrogans</i> (leptospirosis)

Adapted with permission from *Lancet* 2003;361:1459-1469

## Travel Medicine

### General Travel Precautions

- vector-borne: long sleeves, long pants, hats, insecticides (containing permethrin) applied to clothes, belongings, and bed nets; and skin repellents (e.g. DEET, icaridin) applied to exposed skin
- food/water: avoid eating raw meats/seafood, uncooked vegetables, and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions (e.g. Lake Malawi), fresh-water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rainfalls
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveller's diarrhea (bismuth salicylate, rifaximin)
- standard vaccines up to date (hepatitis B, MMR, tetanus/diphtheria, varicella, pertussis, polio, influenza)
- travel vaccines: hepatitis A/B, Japanese encephalitis, typhoid fever, yellow fever, rabies, ETEC, cholera
- sexually transmitted and blood-borne infections: safe sex practices, avoidance of percutaneous injury through razors, tattoos, piercings

### Infectious Diseases to Consider

- vector-borne: malaria, dengue fever, chikungunya, yellow fever, spotted fever rickettsioses, West Nile virus, trypanosomiasis, Japanese encephalitis, tick-borne encephalitis, leishmaniasis, Zika virus, filariasis
- sexually transmitted: HIV, HBV, acute HSV, syphilis, usual STIs, e.g. gonorrhea and chlamydia
- zoonotic: rabies, hantavirus, tularemia, Q fever, anthrax, brucellosis, Ebola
- airborne: TB, measles, varicella
- food/water: HAV, HEV, brucellosis, typhoid, paratyphoid, amoebiasis, dysentery, traveller's diarrhea, cholera, *Campylobacter* spp.
- soil/water: schistosomiasis, strongyloidiasis, leptospirosis, cutaneous larva migrans, histoplasmosis, paracoccidioidomycosis

## Fever in the Returned Traveller

### Etiology

- commonly identified causes of fever in the returned traveller
  - parasitic: malaria (20-30%)
  - viral: non-specific mononucleosis-like syndrome (4-25%), dengue (5%), viral hepatitis (3%)
  - bacterial: typhoid from *Salmonella* (2-7%), rickettsioses (3%)
  - diverse group of causative pathogens: traveller's diarrhea (10-20%), respiratory tract infection (10-15%), UTI/STI (2-3%)
  - Fever in a returned traveller from a malaria endemic area is considered malaria until proven otherwise
- can be caused by routine infections that are common in non-travellers (e.g. URTI, UTI)
- less commonly, fever can be due to non-infectious causes (e.g. DVT/PE, drug fever, inflammatory disorder unmasked by travel-acquired infection)

### History

- pre-travel preparation
- travel itinerary: when, where, why, what, who, how?
  - dates of travel (determine incubation period)
  - season of travel: wet or dry
  - destination: country, region (urban or rural), environment (jungle, desert, etc.)
  - purpose of trip
- persons visiting friends and family are more likely to be exposed to local population and pathogens
  - style of travel: lodgings, camping, adventure travelling
  - local population: sick contacts
  - transportation: use of animals
- exposure history
  - street foods, untreated water: increased risk of traveller's diarrhea, enteric fever
  - uncooked meat/unpasteurized dairy: increased risk of parasitic infection
  - body fluids (sexual contacts, tattoos, piercings, IVDU, other injections)
  - increased risk of HBV, HCV, HIV, GC, C. trachomatis, syphilis
  - animal/insect bites: increased risk of malaria, dengue, rickettsioses, rabies
- fever pattern
- incubation period: use the earliest and latest possible dates of exposure to narrow the differential diagnosis and exclude serious infections
  - <21 d: consider malaria, typhoid fever, dengue fever, chikungunya, Zika, rickettsioses, traveller's diarrhea, respiratory tract infections (e.g. ILL, COVID-19); exclude HBV, TB
  - >21 d: consider malaria, TB, typhoid fever; exclude dengue fever, chikungunya, traveller's diarrhea, rickettsioses
- body systems affected: GI, respiratory, CNS, skin

### Investigations

- all travellers with fever should undergo the following tests
  - blood work: CBC and differential, liver enzymes, electrolytes, creatinine, thick and thin blood smears x3 (for malaria), blood C&S
  - urine: urinalysis, urine C&S if dysuria or other localizing signs
- special tests based on symptoms, exposure history, and geography
  - stool: C&S, O&P
  - CXR
  - viral serology (hepatitis, HIV)
  - dengue serology for IgM, dengue PCR

### Treatment

- empiric treatment if ongoing fever for 48-72 h and negative malaria smears and all cultures pending
- travelled to India, Southeast Asia: azithromycin ± doxycycline
- travelled elsewhere: ciprofloxacin ± doxycycline

Table 29. Fever in the Returned Traveller

Illness	Geography/ Timing	Pathogen	Incubation Period	Clinical Manifestations	Diagnosis	Treatment
Malaria	Africa, India, Central and South America, Southeast Asia Usually rare, night-biting mosquitoes	<i>Plasmodium falciparum</i> <i>Plasmodium vivax</i> <i>P. malariae</i> <i>P. ovale</i> <i>P. knowlesi</i>	7-30 d to mo or yr	Fever and flu-like illness (shaking chills, headache, muscle aches, and fatigue) Nausea/vomiting and diarrhea Anemia and jaundice <i>Plasmodium falciparum</i> : (severe) kidney failure, seizures, mental confusion, prostration, coma, death, respiratory failure	Blood smear (thick and thin) x3 Rapid diagnostic test (with smear or PCR confirmation) Antigen detection PCR	Artesunate (for severe disease) + Malarone®, doxycycline, or clindamycin Quinine sulfate + doxycycline or clindamycin Chloroquine + primaquine
Dengue	Southeast Asia, Caribbean Usually urban, day-biting mosquitoes	Dengue viruses 1-4	3 d to 2 wk	Sudden onset of fever, headache, retro-orbital pain, myalgias, and arthralgias Leukopenia Thrombocytopenia hemorrhagic manifestations (rare in travellers)	Anti-dengue IgM positivity PCR	Symptom relief: Acetaminophen (avoid using NSAIDs and ASA because of antiplatelet properties)
Typhoid (enteric fever)	Global but mostly Indian subcontinent	<i>Salmonella enterica</i> serotype Typhi or serotype Paratyphi	3 to 60 d	Sustained fever 39°-40°C (103°-104°F) Abdominal pain, headache, loss of appetite, cough, constipation	Stool, urine, or blood culture positive for <i>S. Typhi</i> or <i>S. Paratyphi</i>	Quinolone antibiotic (e.g. ciprofloxacin), ceftriaxone, or macrolide
Tick Typhus	Mediterranean, South Africa, India	<i>Rickettsia</i>	1 to 2 wk	Fever, headache, myalgia, spotted rash Eschar at site of tick bite Thrombocytopenia Elevated liver enzymes	Serology Presence of classic tick eschar	Doxycycline
TB	Global	<i>M. tuberculosis</i>	Variable	Fever, cough, hemoptysis	CXR Sputum culture and acid-fast stain Nucleic Acid Amplification Test (NAAT)	Isoniazid (INH), rifampin (RIF), pyrazinamide (PZA), ethambutol (EMB) + Vitamin B6
Mononucleosis	Caribbean, Central and South America	EBV or CMV	30 to 50 d	Malaise, fatigue, pharyngitis, lymphadenopathy, splenomegaly	Atypical lymphocytes on blood smear and positive heterophilic antibody (monospot) test	Acetaminophen or NSAIDs, fluids
Zika Virus Disease	Africa, Southeast Asia, South America; spreading	Zika virus	Unknown, likely 3 to 12 d	Headache, malaise, myalgia, arthralgia, mild fever, rash, conjunctivitis	RT-PCR Serology	Rest, fluids, analgesics/ antipyretics (avoid NSAIDs until Dengue ruled out). condom use, avoid pregnancy

## Fever of Unknown Origin

Table 30. Classification of Fever of Unknown Origin (FUO) – Temp &gt;38.3°C/101°F on several occasions

Classical FUO	Nosocomial FUO	Neutropenic FUO	HIV-associated FUO
Duration >3 wk	Hospitalized patient Infection not present/incubating on admission	Neutrophil count <500/mL or is expected to fall to that level in 1-2 d	HIV infections Duration >4 wk for outpatients, >3 d for hospitalized patients
Diagnosis uncertain after 3 outpatient visits or 3 d in hospital or 1 wk of intensive ambulatory investigation	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures

Causes of Nosocomial FUO  
B, C, D, E

Bacterial and fungal infections of respiratory tract and surgical sites  
Catheters (intravascular and urinary)  
Drugs  
Emboli

### Etiology of Classic FUO

- infectious causes (~30%)
  - TB; extrapulmonary (most common), miliary, pulmonary (if pre-existing disease)
  - abscess: subphrenic, liver, splenic, pancreatic, perinephric, diverticular, pelvic, psoas
  - osteomyelitis
  - bacterial endocarditis (culture negative)
  - other: viral (CMV, EBV, HIV), bacterial (brucellosis, bartonellosis), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amoebiasis, malaria)
- neoplastic causes (~20%)
  - most commonly lymphomas (especially non-Hodgkin) and leukemias, multiple myeloma, myelodysplastic syndrome
  - solid tumours: renal cell carcinoma (most common), breast, liver (hepatocellular carcinoma), colon, pancreas, or liver metastases
- collagen vascular diseases (~30%)
  - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, polyarteritis nodosa), juvenile RA, Still disease
- miscellaneous (~20%)
  - drugs (e.g. anti-microbials, anti-arrhythmics), factitious fever
  - sarcoidosis, granulomatous hepatitis, IBD
  - hereditary periodic fever syndromes (such as familial Mediterranean fever)
  - venous thromboembolic disease: PE, DVT
  - endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
  - unknown in 30-50% despite detailed workup

**Approach to Classic FUO**

- careful and repeated history: travel, environmental/occupational exposures, infectious contacts, medication history, immunizations, TB history, sexual history, past medical history, comprehensive review of systems (including symptoms that resolved before interview)
- thorough physical exam: fever pattern, rashes (skin, mucous membranes), murmurs, arthritis, lymphadenopathy, organomegaly
- initial investigations as appropriate
  - blood work: CBC and differential, electrolytes, urea, Cr, calcium profile, liver enzymes, ESR, CRP, ferritin, muscle enzymes, RF, ANA, serum protein electrophoresis (SPEP), blood film
  - cultures: blood (x3 sets), urine, sputum, stool C&S and O&P, other fluids as appropriate
  - serology: HIV, Monospot, CMV IgM, syphilis
  - imaging: CXR, abdominal imaging
- if there are diagnostic clues from any of the above steps, proceed with directed exam, biopsies or invasive testing as required, followed by directed treatment once a diagnosis is established
- if no diagnosis with the above, consider empiric therapy vs. watchful waiting
  - without intervention: patients that remain undiagnosed despite extensive workup have good prognosis
- immunocompromised hosts have increased susceptibility to infections from pathogens that are typically low virulence, commensal, or latent

## Infections in the Immunocompromised Host

**Factors that Compromise the Immune System**

- general: age (very young or elderly), malnutrition
- immune disease: HIV, malignancies, asplenia (functional or anatomic), hypogammaglobulinemia, neutropenia
- DM
- iatrogenic: corticosteroids, chemotherapy, radiation treatment, anti-TNF therapy, other immunosuppressive drugs (e.g. in transplant patients)

**Table 31. Types of Immunodeficiency**

Type	Conditions	Vulnerable To
Cell-Mediated Immunity	HIV, Hodgkin, hairy cell leukemia, cytotoxic drugs, SCID, DiGeorge syndrome	Latent viruses Fungi Parasites Non-tuberculosis mycobacterium (NTM)
Humoral Immunity	CLL, lymphosarcoma, multiple myeloma, nephrotic syndrome, protein-losing enteropathy, burns, sickle cell anemia, asplenia, splenectomy, selective Ig deficiencies, Wiskott-Aldrich syndrome	Encapsulated organisms ( <i>S. pneumoniae</i> , <i>H. influenzae</i> , <i>N. meningitidis</i> , <i>Salmonella enterica</i> serotype <i>Typhi</i> , GBS)
Neutrophil Function	Chemotherapy, myelodysplasia, paroxysmal nocturnal hemoglobinuria, radiation, cytotoxic drug therapy, C3 or C5 deficiencies, chronic granulomatous disease	Catalase-producing organisms ( <i>Staphylococcus</i> , <i>Serratia</i> , <i>Nocardia</i> , <i>Aspergillus</i> )

## Febrile Neutropenia

**Definition**

- fever ( $\geq 38.3^{\circ}\text{C}/101^{\circ}\text{F}$  or  $\geq 38.0^{\circ}\text{C}/100.4^{\circ}\text{F}$  for  $\geq 1$  h)
- neutropenia: ANC  $< 1.0$
- ANC (absolute neutrophil count) =  $\text{WBC} \times (\% \text{neutrophils} + \% \text{bands})$
- severe neutropenia: ANC  $< 0.5$

**Pathophysiology**

- decreased neutrophil production
  - marrow: infection, aplastic/myelophthitic anemia, leukemia, lymphoma, myelodysplastic syndromes
  - iatrogenic: cancer chemotherapy, radiation, drugs
  - deficiencies: vitamin B<sub>12</sub>, folate
- increased peripheral neutrophil destruction
  - autoimmune: Felty's syndrome, SLE, antineutrophil antibodies
  - splenic sequestration

**Epidemiology/Etiology**

- most common life-threatening complication of cancer therapy
- 8 cases per 1000 cancer patients per yr in the U.S.
- causative organism identified only 1/3 of the time
- GN (especially *Pseudomonas*) historically most common
- GP more common now
- fungal superinfection if neutropenia prolonged or if concurrent antibiotic use (especially *Candida*, *Aspergillus*)
- frequently associated with IV lines, mucosal or GI infection. Typhilitis (inflammation of cecum) is a rare complication, but can lead to serious infection and poor outcomes

### Investigations

- examine for potential sites of infection: mucositis and line infections are most common
- do NOT perform DRE; examine perianal region for perianal abscess
- blood C&S (x2 sets), urine C&S, culture all indwelling catheter ports,  $\pm$  sputum C&S and nasopharyngeal swab for respiratory viruses, stool for *C. difficile* testing if diarrhea
- CBC and differential, Cr, urea, electrolytes, AST/ALT, total bilirubin, chest imaging (CXR or CT)

### Treatment

- most hospitals have their own specific protocol so check local guidelines first (see *Figure 16*)
- prophylaxis against febrile neutropenia (FN) with granulocyte colony-stimulating factor (G-CSF) and granulocyte-macrophage colony-stimulating factor (GM-CSF) decreases hospitalization without affecting mortality (indicated if risk of FN  $\geq 20\%$  or if FN has occurred in a previous chemotherapy cycle)

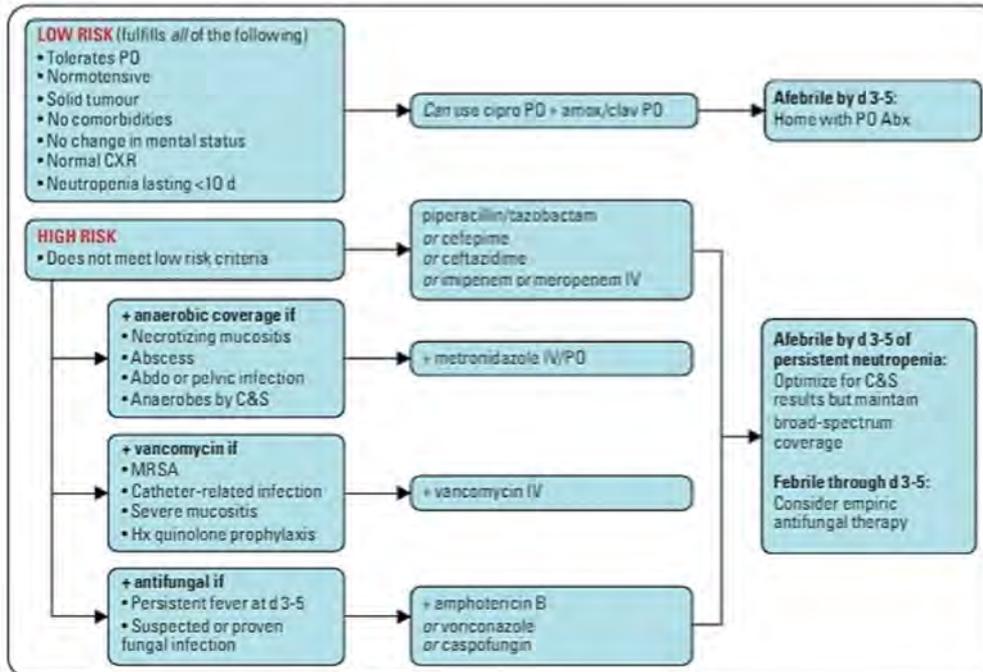

Figure 16. Example of treatment protocol for febrile neutropenia

## Infections in Solid Organ Transplant Recipients

- infection is a leading cause of early morbidity/mortality in transplant recipients
- infection depends on degree of immunosuppression
- common infections <1 mo post-transplant
  - donor-derived infections
  - bacterial infection of wound/lines/lungs, herpetic stomatitis
- common infections >1 mo post-transplant
  - viral (especially CMV, EBV, VZV)
  - fungal (especially *Aspergillus*, *Cryptococcus*, *P. jirovecii*)
  - protozoan (especially *Toxoplasma*)
  - unusual bacterial/mycobacterial infections (especially TB, *Nocardia*, *Listeria*)

### Prophylactic Vaccinations Given Before Transplant

- to all transplant patients: DTaP, pneumococcal, influenza, hepatitis A and B, COVID-19
- in select patients: MMR, varicella, HPV, herpes zoster

## Immune Reconstitution Inflammatory Syndrome

### Definition

- a harmful inflammatory response directed against a previously acquired infection following a recovery of the immune system

### Etiology

- paradoxical worsening of a successfully or partially treated opportunistic infection
- new onset response to a previously unidentified opportunistic infection
- the majority of cases are in patients with advanced HIV or immunosuppressed patients starting anti-retroviral therapy or discontinuing immunosuppressive therapy; sudden recovery from an immunosuppressive state towards a pro-inflammatory state directed towards subclinical infection results in fever and inflammation

- can occur in response to multiple infections
  - *Mycobacteria (tuberculosis, avium complex)*
  - *Cryptococcus*
  - *Pneumocystis*
  - *Toxoplasma*
  - HBV and HCV
  - herpes viruses (VZV reactivation, HSV, CMV)
  - JC virus (progressive multifocal leukoencephalopathy)
  - Molluscum contagiosum
  - COVID-19
- clinical features are dependent on the type and location of the pre-existing infection
- thought to be worse with quick increase in CD4 count and with lower pre-treatment CD4 count
- non-HIV conditions with documented immune reconstitution inflammatory syndrome (IRIS): solid organ transplant recipients, post-partum women, neutropenic patients, anti-TNF therapy

**Epidemiology**

- in HIV-positive patients starting ART, IRIS reported to affect ~10%

**Investigations**

- IRIS is a diagnosis of exclusion
- rule out drug reaction, medication non-adherence, drug resistance

**Treatment**

- continue ARV therapy in HIV-positive patients with mild-moderate symptoms, but consider discontinuation if symptoms are life-threatening or potentially irreversible
- treat underlying infection; initiate treatment for some infections prior to ARV initiation
- consider starting corticosteroids/NSAIDs to decrease inflammatory response

## A Simplified Look at Antibiotics

- general overview, see *Table 33, ID49* for more details

**Table 32. Antibiotics Overview**

Class and Drugs	GP				Anaerobes	GN				Atypicals	Other						
	Streptococcus spp.	Staphylococcus spp.		Enterococcus spp.		<i>C. difficile</i>	<i>H. influenzae</i>	Neisseria spp.			Bacilli (e.g. <i>E. coli</i> , <i>Klebsiella</i> spp.)	<i>Pseudomonas</i>	<i>Legionella</i> , <i>Chlamydia pneumoniae</i> , <i>Mycoplasma</i>	<i>Rickettsia</i>	<i>Chlamydia trachomatis</i>	<i>Syphilis</i>

\* Available in Canada through the Special Access Program

# Antimicrobials

## Antibiotics

- empiric antibiotic therapy
  - choose antibiotic(s) to cover for most likely and lethal organisms for the type of infection prior to obtaining laboratory results (usually reserved for serious infections)
  - adjust antibiotic(s) based on C&S and clinical response
- if causative organism identified, use antibiotic to which organism is susceptible
- if causative organism not identified, re-evaluate need for ongoing antimicrobial therapy (and continue with empiric antibiotic(s) if indicated)

### Reasons for Combination Therapy

- Polymicrobial infection
- Empiric therapy pending culture results
- Synergy for difficult to treat pathogens (e.g. Enterococcus spp. causing endocarditis)
- To prevent emergence of resistance

Bactericidal Antibiotics	Bacteriostatic Antibiotics
"Very Finely Proficient At CCell Murder"	"ECSTaTIC"
Vancomycin	Erythromycin (and other macrolides)
Fluoroquinolones	Clindamycin
Penicillin	Sulfamethoxazole
Aminoglycosides	Trimethoprim
Cephalosporins	Tetracyclines
Carbapenems	Chloramphenicol
Metronidazole	
Daptomycin	

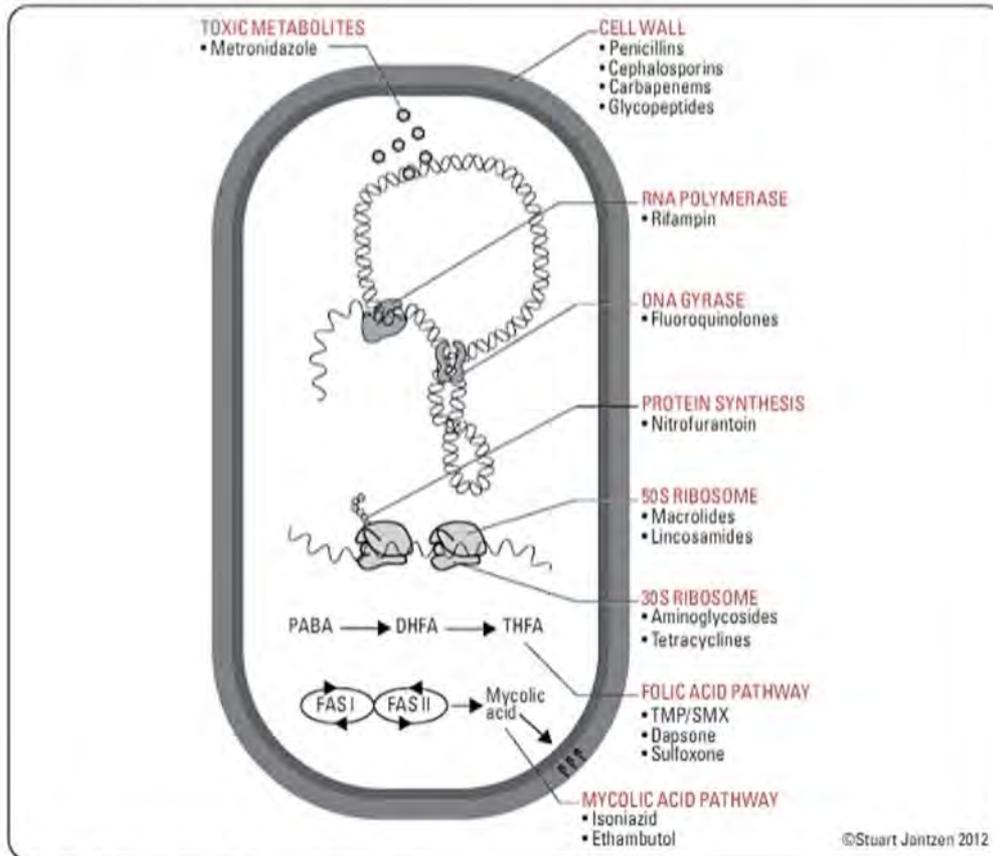

Figure 17. Mechanism of action of antibiotics

Table 33. Antibiotics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications		
<b>CELL WALL INHIBITORS</b>							
<b>Penicillins</b>							
Benzyl penicillin - penicillin G IV/IM - penicillin V PO	GP <u>except</u> <i>Staphylococcus</i> , <i>Enterococcus</i> , <i>N. meningitidis</i> , Oral anaerobes Syphilis	Bactericidal: $\beta$ -lactam inhibits cell wall synthesis by binding penicillin binding protein (PBP) preventing cross-linking of peptidoglycan	Immediate allergy (IgE): anaphylaxis, urticaria Late-onset allergy (IgG): urticaria, rash, serum sickness Interstitial nephritis Dose related toxicity: seizures Diarrhea	Mild to moderately severe infections caused by susceptible organisms including: actinomycosis, streptococcal pharyngitis, streptococcal skin and soft tissue infections, pneumococcal pneumonia, syphilis	Hypersensitivity to penicillin		
Aminopenicillin - ampicillin IV - amoxicillin PO (Amoxil <sup>®</sup> )	Same as penicillin AND <i>Enterococcus</i> <i>Listeria</i> Some strains of: <i>H. influenzae</i> , <i>E. coli</i> , <i>K. pneumoniae</i>	See above	See above	Bacterial meningitis and endocarditis (IV ampicillin), acute otitis media (AOM), streptococcal pharyngitis, sinusitis, acute exacerbations of COPD, part of multidrug therapy for <i>H. pylori</i> treatment, Lyme disease, pneumococcal pneumonia, UTI (amoxicillin and ampicillin) for most enterococci and susceptible GN pathogens	Hypersensitivity to penicillin or $\beta$ -lactam antibiotics		
Isoxazolyl penicillin - cloxacillin - methicillin - nafcillin - oxacillin	Methicillin-sensitive <i>Staphylococcus aureus</i> ; streptococci	See above	See above	Bacterial infections caused by staphylococci and streptococci including skin and soft- tissue infections	Hypersensitivity to cloxacillin or any penicillin		
$\beta$ -lactam combinations - amoxicillin-clavulanate (Clavulin <sup>®</sup> , Augmentin <sup>®</sup> ) - piperacillin/tazobactam (Tazocin <sup>®</sup> ) - ceftolozane/tazobactam	Same as penicillin AND <i>Staphylococcus</i> <i>H. influenzae</i> <i>Enterococcus</i> Anaerobes (oral and gut) <i>P. aeruginosa</i> (piperacillin- tazobactam) Ceftolozane/tazobactam primarily used for resistant GN	$\beta$ -lactamase produced by certain bacteria inactivate $\beta$ -lactams Lactamase inhibitors prevent this process, preserving antibacterial effect of $\beta$ -lactams	See above	Various $\beta$ -lactamase producing bacteria, amoxicillin-clavulanate-sensitive bacteria including URTI, sinusitis, AOM, skin and soft tissue infections, UTI, and severe intra- abdominal and pelvic infections Ceftolozane-tazobactam used to treat resistant GN infections	Hypersensitivity to penicillin or cephalosporin History of amoxicillin- clavulanate-associated jaundice or hepatic dysfunction		
<b>Cephalosporins</b>							
PO 1 <sup>°</sup> cephalexin (Keflex <sup>®</sup> )	IV cefazolin (Ancef <sup>®</sup> )	GP Good with the exception of <i>Enterococcus</i> and MRSA	GN <i>E. coli</i> , <i>Klebsiella</i> , <i>Proteus</i> , <i>H. influenzae</i> (not all isolates)	Bactericidal: $\beta$ -lactam inhibits PBP, prevents cross-linking of peptidoglycan, less susceptible to penicillinases	10% penicillin allergy cross- reactivity	Skin and soft tissue infections, prevention of surgical site infections (cefazolin); infections caused by susceptible organisms (especially <i>Staphylococcus</i> and <i>Streptococcus</i> infections)	Hypersensitivity to cephalosporins or other $\beta$ -lactam antibiotics
2 <sup>°</sup> cefuroxime (Ceftin <sup>®</sup> ) cefprozil (Cefzil <sup>®</sup> )	cefuroxime (Zinacef <sup>®</sup> ) cefoxitin	Weaker activity than 1 <sup>°</sup>	More coverage than 1 <sup>°</sup> (includes anaerobes)	See above	See above	Upper and lower RTI, pneumococcal pneumonia, soft tissue infections	See above
3 <sup>°</sup> cefixime (Suprax <sup>®</sup> )	ceftriaxone (Rocephin <sup>®</sup> ) cefotaxime (Claforan <sup>®</sup> ) ceftazidime (Fortaz <sup>®</sup> )	<i>S. aureus</i> + streptococcal coverage (cefotaxime and ceftriaxone) especially <i>S. pneumoniae</i>	Broad coverage (includes <i>Pseudomonas</i> for ceftazidime only)	See above	~1% penicillin allergy cross- reactivity	Community-acquired pneumonia (cefotaxime, ceftriaxone), gonorrhea (ceftriaxone), community-acquired bacterial meningitis (ceftriaxone, cefotaxime), abdominal and pelvic infections (cefotaxime or ceftriaxone in combination with metronidazole), once-daily administration makes ceftriaxone convenient for outpatient IV therapy	Severe hypersensitivity (Type I) to other $\beta$ -lactam antibiotics
4 <sup>°</sup>	cefepime (Maxipime <sup>®</sup> )	Broad spectrum	Broad coverage including <i>Pseudomonas</i>	See above	See above	Empiric therapy for febrile neutropenia	See above
5 <sup>°</sup>	Ceftobiprole (Zeftara <sup>®</sup> ) ceftaroline (Teflaro <sup>®</sup> ) <sup>*</sup>	Broad coverage including MRSA	Broad coverage (except <i>Pseudomonas</i> )	See above	See above	Acute bacterial skin and skin structure infections, community-acquired pneumonia	See above
<b>Carbapenems</b>							
imipenem (Primaxin <sup>®</sup> )	GP <u>except</u> MRSA GN including <i>Pseudomonas</i> + <i>Enterobacter</i> , extended-spectrum $\beta$ -lactamases (ESBLs), anaerobes	$\beta$ -lactam inhibits PBP and prevents cross-linking of peptidoglycan	Penicillin allergy cross- reactivity Seizures	Treatment of infections caused by GNB producing extended-spectrum $\beta$ -lactamases, serious infections caused by susceptible organisms	Hypersensitivity to imipenem Lowers seizure threshold		
meropenem (Merrem <sup>®</sup> )	See above; does not cover <i>Enterococcus</i>	See above	See above	See above	Hypersensitivity to carbapenems		
ertapenem (Invanz <sup>®</sup> )	GP <u>except</u> <i>Enterococcus</i> , MRSA GN including <i>Enterobacter</i> (but not <i>Pseudomonas</i> ), anaerobes	See above	See above	See above; once-daily administration makes it convenient for outpatient IV therapy	Hypersensitivity to carbapenems		

\*Available in Canada through the Special Access Program

Table 33. Antibiotics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications
<b>CELL WALL INHIBITORS</b>					
<b>Glycopeptides</b>					
vancomycin (Vancocin <sup>®</sup> )	GP including MRSA, not VRE <i>C. difficile</i> if PO	Glycopeptide sterically inhibits cell wall synthesis	Red Man syndrome Nephrotoxicity Ototoxicity Thrombocytopenia	Severe or life-threatening GP infections, patients with $\beta$ -lactam allergy May only be taken orally for severe <i>C. difficile</i> infection	Hypersensitivity to vancomycin
<b>Other</b>					
fosfomicin	GN (some coverage for <i>Pseudomonas</i> but lower compared to <i>Enterobacteriales</i> ) and GP (including <i>Enterococcus</i> )	Inhibiting cell wall synthesis at the initial step involving phosphoenolpyruvate synthase	PO – mild nausea, diarrhea possible IV – hypokalemia, hypernatremia, liver function test abnormalities	PO – uncomplicated urinary tract infections IV – complicated urinary tract infections, nosocomial lower RTI, osteomyelitis; bacterial meningitis	Hypersensitivity to fosfomicin
<b>PROTEIN SYNTHESIS INHIBITORS (50S RIBOSOME)</b>					
<b>Macrolides</b>					
erythromycin (Erybid <sup>®</sup> , Eryc <sup>®</sup> )	GP except <i>Enterococcus</i> GN: <i>Legionella</i> , <i>B. pertussis</i> "Atypicals": <i>Chlamydomydia</i> , <i>Mycoplasma</i>	Binds to 50S ribosomal subunit inhibiting protein synthesis	GI upset Acute cholestatic hepatitis Prolonged QT	Susceptible RTI, pertussis, diphtheria, Legionnaires' disease, skin and soft tissue infections	Hypersensitivity to erythromycin Concurrent therapy with astemizole, terfenadine
*This agent is rarely used due to GI upset					
clarithromycin (Biaxin <sup>®</sup> )	See above, some mycobacteria	See above	See above	Susceptible RTI, skin infections, non-tuberculous mycobacterial infections, part of multidrug therapy for <i>H. pylori</i> treatment	Hypersensitivity to macrolides
azithromycin (Zithromax <sup>®</sup> )	See above, some mycobacteria	See above	See above	Susceptible RTI, acute exacerbations of COPD, community-acquired pneumonia, skin infections, <i>Campylobacter</i> infections if treatment indicated, chlamydia	Hypersensitivity to macrolides
<b>Lincosamides</b>					
clindamycin (Dalacin <sup>®</sup> )	GP except <i>Enterococcus</i> , most community-acquired MRSA anaerobes	Inhibits peptide bond formation at 50S ribosome	Pseudomembranous colitis and <i>C. difficile</i> GI upset	Treatment of suspected or proven infections caused by GP, anaerobes including skin and skin structure infections, oropharyngeal infections, in combination with GN coverage for intra-abdominal and pelvic infections	Hypersensitivity to clindamycin Infants <30 d Concurrent use or within 2 wk of monoamine oxidase (MAO) inhibitors
chloramphenicol	GP GN Anaerobes	Inhibits peptidyl transferase action of tRNA at 50S ribosome	Aplastic anemia Grey Baby syndrome	Serious infections by susceptible organisms when suitable alternatives are not available including meningococcal disease in patients with anaphylaxis to $\beta$ -lactams	Hypersensitivity to chloramphenicol
linezolid (Zyvoxam <sup>®</sup> )	GP including VRE + MRSA	Binds 50S ribosome and prevents functional 70S initiation complex	HTN (acts as MAO inhibitor) Risks with prolonged use: myelosuppression, optic neuropathy, peripheral neuropathy	Vancomycin-resistant <i>Enterococcus faecium</i> infections including intra-abdominal, skin and skin structure, and urinary tract infections, MRSA infections as outpatient therapy	Hypersensitivity to linezolid, concurrent use or within 2 wk of MAO inhibitors
<b>PROTEIN SYNTHESIS INHIBITORS (30S RIBOSOME)</b>					
<b>Aminoglycosides</b>					
gentamicin tobramycin amikacin (Amikin <sup>®</sup> ) plazomicin*	GN (includes <i>Pseudomonas</i> )	Binds 30S subunit of ribosome inhibiting protein synthesis	Nephrotoxicity (reversible) Vestibular and ototoxicity (irreversible) Vestibular toxicity is the most important aminoglycoside toxicity	GN infections when alternatives do not exist, UTIs, used in low doses for synergy with $\beta$ -lactams or with vancomycin for the treatment of serious enterococcal infections	Pre-existing hearing loss and renal dysfunction
<b>Tetracyclines</b>					
tetracycline (Apo-Tetra <sup>®</sup> , Nu-Tetra <sup>®</sup> ) minocycline (Minocin <sup>®</sup> ) doxycycline (Doxycyn <sup>®</sup> ) tigecycline (Tygacil <sup>®</sup> )	GP Anaerobes "Atypicals": <i>Chlamydomydia</i> , <i>Mycoplasma</i> , <i>Rickettsia</i> , <i>Borrelia burgdorferi</i> , <i>Treponema</i> Malaria prophylaxis (doxycycline) Tigecycline has activity against MRSA, VRE, and ESBL-producing <i>E. coli</i> / <i>K. pneumoniae</i>	Binds 30S subunit of ribosome inhibiting protein synthesis	GI upset Hepatotoxicity Fanconi's syndrome Photosensitivity Teratogenic Yellow teeth and stunted bone growth in children	<i>Rickettsial</i> infections, <i>Chlamydomydia</i> , acne (tetracycline, minocycline), Pelvic Inflammatory Disease (PID) (step-down), malaria prophylaxis (doxycycline)	Severe renal or hepatic dysfunction Pregnancy or lactation Children under 12 yr

\*Available in Canada through the Special Access Program

Table 33. Antibiotics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications
<b>TOPOISOMERASE INHIBITORS</b>					
<b>Fluoroquinolones (FQs)</b>					
ciprofloxacin (Cipro <sup>®</sup> ) norfloxacin (Apo-Norflo <sup>®</sup> ) ofloxacin (Floxi <sup>®</sup> ) Respiratory FQs: levofloxacin (Levaquin <sup>®</sup> ) moxifloxacin (Avelox <sup>®</sup> )	Variable GP activity GN (includes <i>Pseudomonas</i> ) "Atypicals" levofloxacin and moxifloxacin cover <i>S. pneumoniae</i> moxifloxacin also has additional anaerobic coverage	Inhibits DNA gyrase	Headache, dizziness Allergy Seizures Prolonged QT Dysglycemia (levofloxacin, moxifloxacin) Tendonitis Tendon rupture	Upper and lower RTI (not ciprofloxacin unless susceptible organism isolated), UTI, prostatitis (not moxifloxacin), bone and joint infections for susceptible organisms, skin and soft tissue infections (levofloxacin, moxifloxacin), infectious diarrhea, meningococcal prophylaxis, intra-abdominal infections (moxifloxacin, ciprofloxacin in combination with metronidazole or clindamycin), febrile neutropenia prophylaxis (ciprofloxacin, levofloxacin) or management of "low-risk" febrile neutropenia (ciprofloxacin in combination with amoxicillin-clavulanate)	Pregnancy or lactation Children under 18 yr Concomitant use of medications that prolong QT interval
<b>OTHER</b>					
rifampin	GP cocci <i>N. meningitidis</i> <i>H. influenzae</i> Mycobacteria	Inhibits RNA polymerase	Hepatic dysfunction, P450 enzyme induction Orange tears/saliva/urine	Part of multidrug treatment for active TB, alone for treatment of latent TB, part of multidrug treatment for other mycobacterial infections, endocarditis involving prosthetic valve or other prosthetic device infections in combination with other antibiotic agents, prophylaxis for those exposed to people with <i>N. meningitidis</i> or Hib meningitis	Jaundice Not to be used as monotherapy (except for prophylaxis)
metronidazole (Flagyl <sup>®</sup> )	Anaerobes, protozoa	Forms toxic metabolites in bacterial cell which damage microbial DNA	Disulfiram-type reaction with EtOH Seizures Peripheral neuropathy	Protozoal infections (trichomoniasis, amebiasis, giardiasis), bacterial vaginosis, anaerobic bacterial infections	Pregnancy with trichomoniasis Disulfiram within 2 wk, alcohol within 3 d Active neurological disorders Hypothyroidism Hypoadrenalism
daptomycin	GP, including MRSA and VRE	Binds to cell wall and forms channels leading to intracellular K <sup>+</sup> depletion	Skeletal muscle injury at high doses (elevated creatine phosphokinase) Peripheral neuropathy	Bacteremia, endocarditis, skin and soft tissue, and other infections due to resistant GP infections including MRSA and VRE	Known hypersensitivity Inactivated by surfactant, therefore not used in MRSA pneumonia Tx
colistin	GN	Disrupts bacterial cell membranes	Renal toxicity	Bacteremia, pneumoniae	Hypersensitivity, renal failure
<b>ANTI-METABOLITE</b>					
trimethoprim-sulfamethoxazole (TMP/SMX) (Septra <sup>®</sup> , Bactrim <sup>®</sup> )	GP, especially <i>S. aureus</i> (including most MRSA) GN: enteric <i>Nocardia</i> Other: <i>Pneumocystis</i> , <i>Toxoplasma</i>	Inhibits folic acid pathway (TMP inhibits dihydrofolate reductase (DHFR) and SMX competes with (para-aminobenzoic acid) PABA)	Hepatitis Stevens-Johnson syndrome Bone marrow suppression Hyperkalemia Drug toxicity (increases free levels of many drugs, including glyburide, warfarin)	Susceptible UTI, RTI, GI infections, skin and soft tissue infections caused by staphylococcal species, treatment and prophylaxis of <i>P. jirovecii</i> pneumonia	Hypersensitivity to TMP-SMX, sulfa drugs Infants <4 wk Hepatic or renal dysfunction Pregnancy and lactation
nitrofurantoin (MacroBID <sup>®</sup> , (Macrochantin <sup>®</sup> ))	<i>Enterococcus</i> , <i>S. saprophyticus</i> GN (coliforms)	Reactive metabolites inhibit ribosomal protein synthesis	Cholestasis, hepatitis Hemolysis if G6PD deficiency Interstitial lung disease with chronic use	Lower UTI; not pyelonephritis or bacteremia	Anuria, oliguria, or significant renal impairment During or imminent labour Infants <1 mo of age
<b>ANTI-MYCOBACTERIALS</b>					
isoniazid (INH)	Mycobacteria	Inhibits mycolic acid synthesis	Hepatotoxicity Hepatitis Drug-induced SLE Peripheral neuropathy	Part of multidrug treatment for active TB, alone for treatment of latent TB	Drug-induced hepatitis or acute liver disease
rifampin (RIF)	Mycobacteria	Inhibits RNA polymerase	Hepatotoxicity P450 enzyme inducer Orange tears, saliva, urine	Part of multidrug treatment for active TB, alone for treatment of latent TB, part of multidrug treatment for other mycobacterial infections, adjunct for treating prosthetic device infection (bacterial biofilm), always use in combination with other antimicrobials to reduce emergence of resistance	Jaundice Not to be used as monotherapy (except for prophylaxis)
ethambutol	Mycobacteria	Inhibits mycolic acid synthesis	Loss of central and colour vision Neuropathy	Part of multidrug treatment for active TB and other mycobacterial infections	Renal failure
pyrazinamide (PZA)	Mycobacteria	Unknown	Hepatotoxicity Gout Gastric irritation	Part of multidrug treatment for active TB	Severe hepatic damage or acute liver disease Patients with acute gout
<b>SULFONES</b>					
dapsone sulfoxone	<i>M. leprae</i> , <i>P. jirovecii</i> , <i>Toxoplasma</i>	Inhibit folic acid synthesis by competition with PABA	Rash Drug fever Agranulocytosis	Part of multidrug treatment for <i>M. leprae</i> , part of treatment for <i>P. jirovecii</i> pneumonia (with TMP), <i>P. jirovecii</i> pneumonia prophylaxis, toxoplasmosis prophylaxis with pyrimethamine	G6PD Deficiency

\*Available in Canada through the Special Access Program

Table 34. Antibiotics for Selected Bacteria

<i>Pseudomonas</i>	<i>S. aureus</i>	<i>Enterococcus</i>	<i>H. influenzae</i>	Anaerobes
ciprofloxacin	cloxacillin (MSSA)	ampicillin	amoxicillin-clavulanate	metronidazole
gentamicin tobramycin amikacin	1° cephalosporin (MSSA)	amoxicillin	2°/3° cephalosporin	clindamycin
piperacillin/ tazobactam	clindamycin	vancomycin	macrolides (clarithromycin, azithromycin)	amoxicillin-clavulanate
ceftazidime	cotrimoxazole (including MRSA)	nitrofurantoin (lower UTI)	levofloxacin	cefoxitin
cefepime	vancomycin (including MRSA)	linezolid for VRE	moxifloxacin	piperacillin/tazobactam
imipenem	linezolid (including MRSA)	daptomycin for VRE		moxifloxacin
	daptomycin (including MRSA)	tigecycline for VRE		ertapenem, imipenem, meropenem
	tigecycline (including MRSA)	penicillin		
	doxycycline (MSSA/MRSA)	imipenem		

## Antivirals

Table 35. Antivirals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
<b>ANTI-HERPESVIRUS</b>				
acyclovir valacyclovir (Valtrex®) (prodrug of acyclovir)	HSV-1,2 VZV	Guanosine analogue inhibits viral DNA polymerase	PO: well-tolerated IV: nephrotoxicity, CNS	Hypersensitivity to acyclovir or valacyclovir
famciclovir (Famvir®) penciclovir	HSV-1,2 VZV	See above	Headache, nausea	Hypersensitivity to famciclovir or penciclovir
ganciclovir (Cytovene®) valganciclovir (prodrug of ganciclovir)	CMV HSV-1,2, VZV, HHV-6, EBV	See above	Hematologic: neutropenia, thrombocytopenia, anemia	Hypersensitivity to ganciclovir or valganciclovir Possible cross-hypersensitivity between acyclovir and valacyclovir
foscarnet	CMV Acyclovir-resistant HSV, VZV	Pyrophosphate analogue inhibits viral DNA polymerase	Nephrotoxicity Anemia Electrolyte disturbance	Hypersensitivity to foscarnet
<b>OTHER ANTIVIRALS</b>				
(pegylated) interferon- $\alpha$ -2a or -2b	Chronic hepatitis B	Inhibits viral protein synthesis	"Flu-like" syndrome Depression Bone marrow suppression	Hypersensitivity to any interferon Cannot use in combination with ribavirin if renal impairment
lamivudine (Epivir®) tenofovir entecavir	Chronic hepatitis B, HIV Chronic hepatitis B, HIV Chronic hepatitis B	See <i>HIV and AIDS, ID27</i> See <i>HIV and AIDS, ID27</i> Deoxyguanosine analogue Inhibits viral DNA polymerase reducing viral DNA synthesis	See <i>HIV and AIDS, ID27</i> See <i>HIV and AIDS, ID27</i> Increased serum ALT, bilirubin Skin rash Glycosuria, hyperglycemia GI Hematuria Fatigue, headache Increased serum Cr	See <i>HIV and AIDS, ID27</i> See <i>HIV and AIDS, ID27</i> Hypersensitivity to entecavir or any component of the formulation HIV co-infection (if monotherapy)
glecaprevir and pibrentasvir	Chronic hepatitis C	glecaprevir: HCV NS3/4A protease inhibitor pibrentasvir: HCV Nonstructural protein 5A inhibitor (NS5A) that is essential for viral RNA replication and virion assembly	Nausea, diarrhea Fatigue, headache Pruritus Increased serum bilirubin	Moderate/severe hepatic impairment or history of hepatic decompensation Coadministration: atazanavir, rifampin, atorvastatin, dabigatran, ethinyl estradiol, or simvastatin
sofosbuvir and velpatasvir	Chronic hepatitis C	velpatasvir: HCV NS5A protein inhibitor sofosbuvir: prodrug, inhibits NS5B RNA-dependent RNA polymerase	Fatigue, headache Increased serum creatine kinase Skin rash Increased serum lipase Nausea Insomnia, irritability Asthenia HBV reactivation (in HBV/HCV coinfection)	Hypersensitivity to sofosbuvir, velpatasvir, or any component of the formulation
ribavirin (Virazole®)	Chronic hepatitis C (in combination with direct-acting antivirals), RSV Lassa fever	Guanosine analog with multiple postulated mechanisms of action	Hemolytic anemia Rash, conjunctivitis Highly teratogenic	Pregnant women and partners Hemoglobinopathies Concomitant $\alpha$ interferon use
cidofovir	Adenovirus CMV retinitis Acyclovir and foscarnet resistant HSV	Deoxycytidine analogue inhibits DNA synthesis	Nephrotoxicity (proximal tubule dysfunction)	Renal failure; probenecid can reduce renal toxicity

Table 35. Antivirals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
Neuraminidase inhibitors: zanamivir (Relenza <sup>®</sup> ) oseltamivir (Tamiflu <sup>®</sup> )	Influenza A and B: treatment and prophylaxis	Inhibits neuraminidase, an enzyme required for release of virus from infected cells leading to prevention of viral aggregation	GI: nausea/vomiting, diarrhea Bronchospasm with zanamivir	Hypersensitivity to the neuraminidase inhibitors
remdesivir	Hospitalized COVID-19	Adenosine triphosphate analog Inhibitor of the SARS-CoV-2 RNA-dependent RNA polymerase Inhibits viral RNA synthesis	Bradycardia, hypotension Increased serum ALT, AST Hypersensitivity reactions (e.g. anaphylaxis, angioedema) Skin rash GI Prolonged prothrombin time Seizure	Hypersensitivity to remdesivir or any component of the formulation
nirmatrelvir/ritonavir (Paxlovid <sup>®</sup> )	COVID-19 infection within 5 days of symptom onset	nirmatrelvir: Peptidomimetic inhibitor of SARS-CoV-2 protease ritonavir: CYP3A inhibitor, increasing concentrations of nirmatrelvir	Hypertension Diarrhea, Dysgeusia Myalgia	Hypersensitivity to nirmatrelvir, ritonavir or any component of the formulation Co-administration of highly dependent CYP3A substrates or potent CYP3A inducers

## Antifungals

Table 36. Antifungals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
<b>POLYENES</b>				
amphotericin B (liposomal formulation is less toxic)	Endemic mycoses: Histoplasmosis Blastomycosis Coccidioidomycosis Pulmonary: Aspergillosis CNS: Cryptococcus	A polyene antimicrobial: inserts into fungal cytoplasmic membrane causing altered membrane permeability and cell death	Nephrotoxicity Hypo/hyperkalemia Infusion reactions: chills, fevers, headache Peripheral phlebitis	Hypersensitivity to amphotericin or any component of the formulation
nystatin (oral, topical)	Candidiasis: mucocutaneous, GI, oral (thrush), vaginal	See above Not absorbed from the GI tract	GI: nausea/vomiting, diarrhea Highly toxic if given IV	Hypersensitivity to nystatin or any component of formulation
<b>IMIDAZOLES</b>				
clotrimazole (Canesten <sup>®</sup> )	Oral and vulvovaginal candidiasis Dermatomycoses	All azoles: inhibit ergosterol synthesis and thereby alter fungal cell membrane permeability	Pruritus, skin irritation	Hypersensitivity to clotrimazole or any component of formulation
miconazole (Monistat <sup>®</sup> , Micozole <sup>®</sup> )	Vulvovaginal candidiasis Dermatomycoses		Vaginal burning Nausea/vomiting	Hypersensitivity to miconazole, milk protein concentrate, or any component of formulation
ketoconazole (Nizoral <sup>®</sup> )	Dermatomycoses Seborrheic dermatitis		Pruritus, skin irritation, GI nonspecific Results in decreased androgen and testosterone synthesis	Cross-sensitivity with other azoles possible Hepatic dysfunction Pregnant women or those that may become pregnant
<b>TRIAZOLES</b>				
fluconazole (Diflucan <sup>®</sup> )	Candida infections (mucosal and invasive) Cryptococcal meningitis (step-down therapy)	All azoles: inhibit ergosterol synthesis and thereby alter fungal cell membrane permeability	Elevated liver enzymes GI nonspecific	Cross-sensitivity with other azoles unknown Terfenadine of multiple doses ≥400 mg CYP3A4 substrates (QTc prolongation risk)
itraconazole (Sporanox <sup>®</sup> )	Sporotrichosis Onychomycoses Endemic mycoses: Histoplasmosis Blastomycosis Coccidioidomycosis		Elevated liver enzymes Rash GI Nonspecific HTN Hyperkalemia Peripheral edema	Cross-sensitivity with other azoles unknown Severe ventricular dysfunction Pregnant women or planning CYP2D6 inhibitors or eliglustat Hepatic and renal impairment
voriconazole (Vfend <sup>®</sup> )	Aspergillosis Candidiasis		Visual disturbance (30%) Hepatotoxicity Cutaneous photosensitivity Cutaneous squamous cell carcinoma with long-term use in immunosuppressed patients Prolonged QT Periostitis Neurologic toxicity	Cross-sensitivity with other azoles unknown May avoid or alter doses if co-administered with other CYP3A4 substrates, rifampin, carbamazepine, long-acting barbiturates, ritonavir, efavirenz, sirolimus, rifabutin, ergot alkaloids, St. John's wort, venetoclax, ivabradine
posaconazole (Posanol <sup>®</sup> , Noxafil <sup>®</sup> )	Candidiasis Aspergillosis Mucormycosis		Elevated liver enzymes Headache Prolonged QT	Coadministration of cisapride, ergot alkaloids, or sirolimus CYP3A4 substrates: HMG-CoA reductase inhibitors (e.g. atorvastatin, lovastatin, simvastatin) QT interval prolonging (e.g. pimozide, quinidine)
isavuconazole	Candidiasis (esophageal) - off label for HIV patients Aspergillosis Mucormycosis		Peripheral edema Headache, fatigue, insomnia Hypokalemia GI Elevated liver enzymes Dyspnea, cough	Hypersensitivity to isavuconazole or any component of the formulation Strong CYP3A4 inhibitors (e.g. ketoconazole, ritonavir) Strong CYP3A4 inducers (e.g. rifampin, carbamazepine, St. John's wort, long acting barbiturates) Moderate CYP3A4/5 inducers (e.g. efavirenz, etravirine) Familial short QT syndrome Pregnant women or planning

**Table 36. Antifungals**

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
<b>ALLYLAMINES</b>				
terbinafine (Lamisil®)	Dermatomycoses Onychomycoses	Inhibits enzyme needed for ergosterol synthesis	Rash, local irritation GI nonspecific Transaminitis	Active liver disease
<b>ECHINOCANDINS</b>				
caspofungin micafungin anidulafungin	Refractory aspergillosis Candidemia (azole-resistant)	Inhibits 1-3 β-D-glucan synthesis (needed for fungal cell wall)	Hepatotoxicity infusion and injection site reactions	

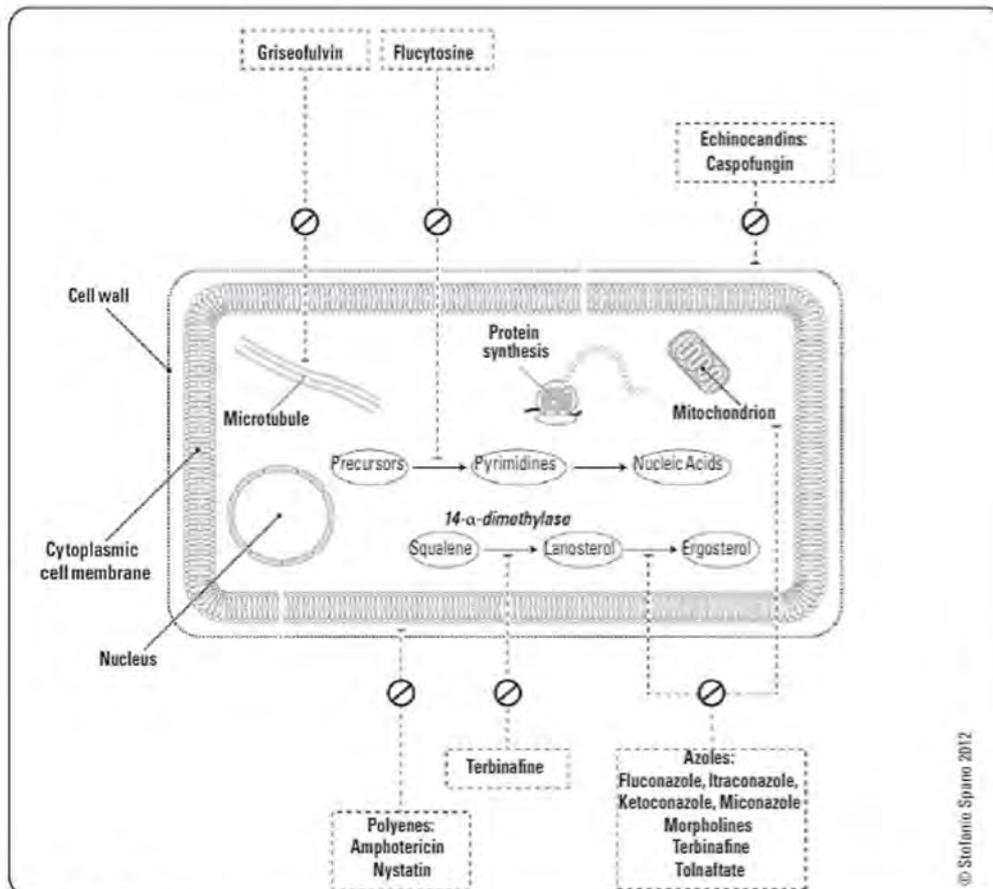

Figure 18. Mechanism of action of antifungals

© Stefano Spano 2012

# Antiparasitics

Table 37. Antiparasitics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
<b>ANTIMALARIALS</b>				
chloroquine	Malaria: treatment of erythrocytic phase of all five species of <i>Plasmodium</i> that infect humans Note: High resistance of <i>P. falciparum</i> and <i>P. vivax</i> in certain geographic areas	Inhibits parasite heme polymerase	CNS: blurred vision, retinopathy, dizziness Nonspecific GI (rare with prophylaxis)	Hypersensitivity to chloroquine or other 4-aminoquinoline Retinal or visual field changes
quinine	Malaria: treatment of all five species of <i>Plasmodium</i> that infect humans, including chloroquine-resistant <i>P. falciparum</i>		Cinchonism: ears (tinnitus, vertigo), eyes (visual disturbance), GI (nausea/vomiting, diarrhea), CNS (headache, fever) Hypoglycemia	Hypersensitivity to quinine, may have cross-sensitivity with quinidine Tinnitus, optic neuritis, hypoglycemia, history of blackwater fever or thrombocytopenic purpura due to quinine use Prolonged QT Myasthenia gravis
mefloquine (Lariam <sup>®</sup> )	Malaria: prophylaxis		CNS/Psych: irritability, nightmares, psychoses, suicide, depression, seizures, headache	History of seizures, psychosis, anxiety, depression, or other mental health diagnoses
primaquine	Malaria: treatment of liver hypnozoites of <i>P. vivax</i> and <i>P. ovale</i> ; prophylaxis of all <i>Plasmodium</i> spp. <i>Pneumocystis jirovecii</i> (with clindamycin)	Interferes with mitochondrial function	Hemolytic anemia in G6PD deficient GI upset (take with food)	G6PD deficiency Concurrent or recent use of quinacrine Pregnancy
atovaquone/proguanil (Malarone <sup>®</sup> )	Malaria: treatment and prophylaxis of <i>P. falciparum</i>	Inhibits mitochondrial electron transport and dihydrofolate reductase	Nausea/vomiting, anorexia, diarrhea, abdominal pain (take with food)	Hypersensitivity to atovaquone or proguanil Severe renal impairment
artemisinin derivatives (artemether, artesunate, etc.) Note: marketed throughout the world in both endemic and non-endemic countries; neither licensed nor marketed in Canada, therefore available only via Health Canada Special Access Program	Malaria: treatment of all <i>Plasmodium</i> spp. Severe malaria (IV artesunate) Typically used in combination with a longer-acting agent from above	Binds iron, leading to formation of free radicals that damage parasite proteins	Transient neurologic deficits (nystagmus, balance disturbance) Transient neutropenia (at high doses of oral artesunate) Delayed hemolysis	Hypersensitivity to artemisinins
<b>OTHER ANTI-PROTOZOAL</b>				
iodoquinol (Diodoquin <sup>®</sup> )	Amebiasis: <i>E. histolytica</i> , <i>Dientamoeba fragilis</i> , <i>Balantidium coli</i> , <i>Blastocystis hominis</i>	Contact amebicide that acts in intestinal lumen by uncertain mechanism	GI: nausea/vomiting, diarrhea, abdominal pain CNS: headache, seizures, encephalitis	Hypersensitivity to any 8-hydroxy-quinoline or iodine Patients with hepatic damage or optic neuropathy Pregnancy
metronidazole	Amebiasis: <i>E. histolytica</i> , <i>T. vaginalis</i> , giardiasis, <i>D. fragilis</i>	See <i>Antibiotics, ID50</i> .		
nitazoxanide	<i>Cryptosporidium</i> , giardiasis, cyclosporiasis	Interferes with parasite anaerobic metabolism	Nausea/vomiting, diarrhea, abdominal pain, headache	Hypersensitivity to nitazoxanide
<b>ANTI-HELMINTHICS</b>				
praziquantel	<i>Schistosomiasis</i> and other flukes Tapeworms	Increases Ca <sup>2+</sup> -permeability of helminth cell membrane, causing paralysis and detachment	Nausea/vomiting, fever, dizziness	Ocular cysticercosis Concomitant use with strong CYP450 inducers
albendazole	Intestinal roundworms <i>Neurocysticercosis</i> <i>Echinococcus</i> Hydatid disease	Inhibits glucose uptake into susceptible parasites Microtubule inhibitor	Elevated liver enzymes Alopecia GI nonspecific Agranulocytosis	Pregnancy Ocular cysticercosis or intraventricular cysticercosis
mebendazole (Vermox <sup>®</sup> )	Intestinal roundworms: pinworm, whipworm, hookworm, roundworm (e.g. <i>Ascaris</i> )	Inhibits microtubule formation and glucose uptake	Nonspecific GI	Pregnancy Infants
ivermectin	<i>Strongyloidiasis</i> <i>Onchocerciasis</i> Scabies	Interferes with polarization of nerve and muscles cells in susceptible parasites leading to paralysis	Nausea, bloating, diarrhea, myalgias, lightheadedness, headache	Hypersensitivity to ivermectin Pregnancy
diethylcarbamazine	<i>Wuchereria bancrofti</i> <i>Loa loa</i>	Thought to immobilize microfilariae and disrupt surface membrane to enhance killing by host immune system	Anorexia, nausea/vomiting, headache, drowsiness, encephalitis, retinal hemorrhage Mazzotti reaction if coinfecting with onchocerciasis	Pregnancy Onchocerciasis High-grade microfilariaemia due to <i>Loa loa</i>

## Landmark Infectious Diseases Trials

Trial Name	Reference	Clinical Trial Details
<b>Respiratory Infections</b>		
EPIC-HR	NEJM 2022;386:1397-1408	<p><b>Title:</b> Oral Nirmatrelvir for High-Risk, Non-hospitalized Adults with COVID-19</p> <p><b>Purpose:</b> To determine whether nirmatrelvir/ritonavir is safe and effective for the treatment of adults who are ill with COVID-19 and do not need to be in the hospital but are at an increased risk of developing severe illness.</p> <p><b>Methods:</b> 2246 participants with confirmed diagnosis of SARS-CoV-2 infection were randomized (1:1) to receive nirmatrelvir/ritonavir or placebo orally every 12 hours for 5 days (10 doses total).</p> <p><b>Results:</b> Primary outcome measure was proportion of participants with COVID-19 related hospitalization or death from any cause; incidence was lower on day 28 by 6.32% in nirmatrelvir group compared to placebo (relative risk reduction of 89.1%; <math>P &lt; 0.0001</math>).</p> <p><b>Conclusions:</b> In early treatment of patients with both symptomatic COVID-19 and at high risk of progressing to severe illness, nirmatrelvir/ritonavir significantly reduces hospitalization and death.</p>
RECOVERY	NEJM 2021;384:693-704	<p><b>Title:</b> Dexamethasone in Hospitalized Patients with COVID-19</p> <p><b>Purpose:</b> To assess if glucocorticoids can protect against inflammation-mediated lung injury and reduce progression to respiratory failure and death.</p> <p><b>Methods:</b> 6425 hospitalized SARS-CoV-2 patients were randomized to receive either (1) dexamethasone (oral or IV, 6 mg daily) for up to 10 d or (2) usual standard of care alone.</p> <p><b>Results:</b> Dexamethasone significantly reduced incidence of death as compared to usual care alone in patients receiving invasive mechanical ventilation (29.3% vs. 41.4%; RR 0.64; 95% CI 0.51-0.81) and among those receiving oxygen (23.3% vs. 26.2%; RR 0.82; 95% CI 0.72-0.94) but not among those without respiratory support (17.8% vs. 14.0%; RR 1.19; 95% CI 0.92-1.55).</p> <p><b>Conclusion:</b> In patients hospitalized with COVID-19, dexamethasone lowers 28-d mortality in those receiving invasive mechanical ventilation or oxygen alone.</p>
PneumA	JAMA 2003;290:2588-98	<p><b>Title:</b> Comparison of 8 vs. 15 Days of Antibiotic Therapy for Ventilator-Associated Pneumonia in Adults: A Randomized Trial</p> <p><b>Purpose:</b> To identify the optimal duration of antimicrobial treatment for ventilator-associated pneumonia (VAP).</p> <p><b>Methods:</b> 401 patients with VAP diagnosed by quantitative culture of bronchoscopic specimens who had received initial empiric antibiotic therapy were randomly assigned to receive either 8 d or 15 d of antibiotic therapy (regimen selected by treating physician).</p> <p><b>Results:</b> As compared to 15-d therapy, 8-d therapy did not result in a significant difference in mortality (18.8% vs. 17.2% in 8-d and 15-d group, respectively; difference, 1.6%; 90% CI, -3.7% to 6.9%) or recurrent infections (28.9% vs. 26.0%; difference, 2.9%; 90% CI, -3.2% to 9.1%). 8-d therapy was associated with more mean antibiotic-free days (13.1 vs. 8.7; <math>P &lt; 0.001</math>).</p> <p><b>Conclusion:</b> 8- and 15-d antibiotic treatment regimens demonstrated comparable clinical efficacy against VAP among patients who had received appropriate initial empiric therapy.</p>
<b>Meningitis</b>		
Dexamethasone in Adults with Bacterial Meningitis. Gans et al. 2002	NEJM 2002;347:1549-56	<p><b>Title:</b> Dexamethasone in Adults with Bacterial Meningitis</p> <p><b>Purpose:</b> To assess the efficacy of corticosteroids as an adjuvant treatment of acute bacterial meningitis in adults.</p> <p><b>Methods:</b> 301 patients were randomly assigned to receive dexamethasone (10 mg) or placebo 15-20 min before or with the first dose of antibiotics and subsequently every 6 h for 4 d.</p> <p><b>Results:</b> Dexamethasone treatment was associated with a significant reduction in the risk of an unfavourable outcome, defined as a score of 1-4 on the Glasgow Outcome Scale at 8 wk (relative risk (RR), 0.59; 95% CI, 0.37-0.94; <math>P = 0.03</math>), as well as a significant reduction in mortality (RR, 0.48, 95% CI, 0.24-0.96; <math>P = 0.04</math>).</p> <p><b>Conclusion:</b> In adults with acute bacterial meningitis, early treatment with dexamethasone significantly improves outcomes and does not increase the risk of GI bleeding.</p>
<b>Infective Endocarditis</b>		
POET	NEJM 2019;380:415-24	<p><b>Title:</b> Partial Oral versus Intravenous Antibiotic Treatment of Endocarditis</p> <p><b>Purpose:</b> To investigate whether a change from IV to oral antibiotics in stable left-sided IE would result in efficacy and safety profiles similar to those with continued IV treatment.</p> <p><b>Methods:</b> 400 adults with IE on the left side of the heart, in stable condition, being treated with IV antibiotics (minimum 10 d) were randomized to continue IV treatment or to switch to oral antibiotics.</p> <p><b>Primary Outcome:</b> Composite of all-cause mortality, embolic events, unplanned cardiac surgery, or relapse of bacteremia with the primary pathogen, from the time of randomization until 6 mo following completion of antibiotics.</p> <p><b>Results:</b> The primary composite outcome occurred in 12.1% in the IV group and 9.0% in the oral group (between-group difference, 3.1 percentage points; 95% CI, -3.4 to 9.6; <math>P = 0.40</math>), thus meeting noninferiority.</p> <p><b>Conclusion:</b> Shifting to oral antibiotics was noninferior to continued IV antibiotics in patients with IE on the left side of the heart in stable condition.</p>
<b>Intraabdominal Infections</b>		
STOP-IT	NEJM 2015;372:1996-2005	<p><b>Title:</b> Trial of Short-Course Antimicrobial Therapy for Intraabdominal Infection</p> <p><b>Purpose:</b> To determine the appropriate duration of antimicrobial therapy for intraabdominal infection.</p> <p><b>Methods:</b> 518 patients with complicated intraabdominal infection and adequate source control were randomly assigned to receive a fixed course of antibiotics for 4-1 d (experimental group) or until 2 d following the resolution of fever, leukocytosis, and ileus, up to maximum 10 d (control group).</p> <p><b>Results:</b> There were no significant differences in the rates of surgical-site infection, recurrent intraabdominal infection, or death between treatment groups (21.8% vs. 22.3% in the experimental and control groups, respectively; absolute difference, -0.5; 95% CI, -7.0 to 8.0; <math>P = 0.92</math>). The experimental group experienced a significantly shorter median duration of antibiotic therapy (4.0 d vs. 8.0 d; absolute difference, -4.0; 95% CI, -4.7 to -3.3; <math>P &lt; 0.001</math>).</p> <p><b>Conclusion:</b> The outcomes after fixed-duration antibiotic therapy were similar to those after a longer course of antibiotics in patients with intraabdominal infections with adequate source control.</p>

Trial Name	Reference	Clinical Trial Details
<b>HIV and AIDS</b>		
iPrEx	NEJM 2010;363:2587-99	<p><b>Title:</b> Preexposure Chemoprophylaxis for HIV Prevention in Men Who Have Sex With Men</p> <p><b>Purpose:</b> To investigate the efficacy and safety of antiretroviral chemoprophylaxis for the prevention of HIV acquisition.</p> <p><b>Methods:</b> 2499 HIV-seronegative men or transgender women who have sex with men were randomly assigned to receive emtricitabine plus tenofovir disoproxil fumarate (FTC-TDF), or placebo daily.</p> <p><b>Results:</b> During median 1.2 yr follow-up, 100 participants became infected (36 in the FTC-TDF group vs. 64 in the placebo group), representing a 44% reduction in the incidence of HIV (95% CI, 15-63; P=0.005). Similar rates of serious adverse events were observed in both groups (P=0.57).</p> <p><b>Conclusion:</b> Preexposure prophylaxis with antiretrovirals significantly reduced HIV infection risk in HIV-negative men and transgender women who have sex with men.</p>
Prevention of HIV-1 Infection With Early Antiretroviral Therapy. Cohen et al. 2011	NEJM 2011;365:493-505	<p><b>Title:</b> Prevention of HIV-1 Infection With Early Antiretroviral Therapy</p> <p><b>Purpose:</b> To investigate if immediate antiretroviral therapy could limit the transmission of HIV in serodiscordant couples.</p> <p><b>Methods:</b> 1763 HIV-1-positive adults with an HIV-negative partner were randomly assigned to receive antiretroviral therapy either immediately or after a decline in the CD4 count or the onset of HIV-1-related symptoms.</p> <p><b>Results:</b> Of the 39 HIV-1 transmissions observed, 28 were virologically linked to the infected partner (incidence rate, 0.9 per 100 person-years, 95% CI, 0.6-1.3). Of the 28 linked transmissions, 1 occurred in the early-therapy group (hazard ratio, 0.04; 95% CI, 0.01-0.27; P&lt;0.001).</p> <p><b>Conclusion:</b> Rates of HIV-1 transmission and clinical events were reduced by early initiation of antiretroviral therapy, suggesting personal and public health benefits.</p>
<b>Sepsis and Septic Shock</b>		
CORTICUS	NEJM 2008;358:111-24	<p><b>Title:</b> Hydrocortisone Therapy for Patients With Septic Shock</p> <p><b>Purpose:</b> To investigate the efficacy of hydrocortisone administration in patients with septic shock who were either responsive or unresponsive to corticotropin.</p> <p><b>Methods:</b> 499 patients were randomly assigned to receive 50 mg IV hydrocortisone or placebo every 6 h for 5 d with dose tapering over the following 6 d.</p> <p><b>Results:</b> No significant difference in mortality at 28 d between patients in groups that did not respond to corticotropin (39.2% in the hydrocortisone group and 36.1% in the placebo group, P=0.69) or between those that did respond to corticotropin (28.8% and 28.7%, P=1.00).</p> <p><b>Conclusion:</b> Survival was not improved by hydrocortisone in patients with septic shock.</p>
Intensive Insulin Therapy and Pentastarch Resuscitation in Severe Sepsis. Brunkhorst et al. 2008	NEJM 2008;358:125-39	<p><b>Title:</b> Intensive Insulin Therapy and Pentastarch Resuscitation in Severe Sepsis</p> <p><b>Purpose:</b> To investigate the role of intensive insulin therapy and the choice of either crystalloids or colloids in patients with severe sepsis.</p> <p><b>Methods:</b> Patients received either intensive insulin therapy to maintain euglycemia or conventional insulin therapy and either 10% pentastarch or modified Ringer's lactate for fluid resuscitation.</p> <p><b>Results:</b> Trial stopped for safety reasons. Intensive insulin therapy was associated with increased rates of hypoglycemia (17.0% vs. 4.1%, P&lt;0.001) and serious adverse events (10.9% vs. 5.2%, P=0.01). Higher rates of acute renal failure and renal-replacement were seen in pentastarch as compared to Ringer's lactate.</p> <p><b>Conclusion:</b> In critically ill patients with sepsis, intensive insulin therapy increased the risk of serious adverse events related to hypoglycemia. Pentastarch was harmful.</p>
<b>Bone and Joint Infections</b>		
OVIVA	NEJM 2019;380:425-36	<p><b>Title:</b> Oral versus Intravenous Antibiotics for Bone and Joint Infection</p> <p><b>Purpose:</b> To assess if oral antibiotics are noninferior to IV antibiotic treatment for managing complex orthopaedic infections.</p> <p><b>Methods:</b> Within 1 wk post-surgery, 1054 patients were randomly assigned to receive IV or oral antibiotics for 6 wk. Both groups were permitted follow-on oral antibiotics.</p> <p><b>Results:</b> There was no significant difference in risk of treatment failure between oral and IV groups (-1.4%; 95% CI, -5.6-2.9), indicating noninferiority. There was no significant difference in the rates of serious adverse events between groups.</p> <p><b>Conclusion:</b> Oral antibiotics were noninferior to IV antibiotics for the treatment of complex orthopaedic infections when used for 6 wk.</p>
DATIPO	NEJM 2021;384:1991-2001	<p><b>Title:</b> Antibiotic Therapy for 6 or 12 Weeks for Prosthetic Joint Infection</p> <p><b>Purpose:</b> To identify the appropriate duration of antimicrobial therapy for the management of prosthetic joint infection.</p> <p><b>Methods:</b> 410 patients with microbiologically confirmed prosthetic joint infection that had been managed with an appropriate surgical procedure were randomly assigned to receive either 6 wk or 12 wk of antibiotic therapy as soon as possible after surgery.</p> <p><b>Results:</b> Rates of persistent infection were significantly higher in the 6-wk group as compared to the 12-wk group (18.1% vs. 9.4%; risk difference, 8.7%; 95% CI, 1.8%-15.6%).</p> <p><b>Conclusion:</b> Antibiotic therapy for 6 wk was not noninferior to 12-wk therapy and resulted in more unfavourable outcomes in patients with prosthetic joint infections managed with standard surgical procedures.</p>
<b>Blood and Tissue Infections</b>		
Seasonal Malaria Vaccination with or without Seasonal Malaria Chemoprevention. Zongo et al. 2021	NEJM 2021; 385:1005-1017	<p><b>Title:</b> Seasonal Malaria Vaccination with or without Seasonal Malaria Chemoprevention</p> <p><b>Purpose:</b> The study compared the efficacy of RTS,S to that of SMC, which is the standard treatment for children in areas with highly seasonal malaria transmission.</p> <p><b>Methods:</b> Randomly assigned 6861 children 5 to 17 months of age to receive sulfadoxine-pyrimethamine and amodiaquine (2287 children [chemoprevention-alone group]), RTS,S/AS01E (2288 children [vaccine-alone group]), or chemoprevention and RTS,S/AS01E (2286 children [combination group]).</p> <p><b>Results:</b> Demonstrated that not only is RTS,S comparable to SMC in preventing malaria, but that combining the two interventions is markedly superior to either intervention alone.</p> <p><b>Conclusion:</b> Use of the two interventions together resulted in an approximately 70 percent further reduction in malaria deaths and hospitalizations, and a 60 percent reduction in uncomplicated malaria over use of SMC alone.</p>
BENEFIT	NEJM 2015;373:1295-306	<p><b>Title:</b> Randomized Trial of Benznidazole for Chronic Chagas' Cardiomyopathy</p> <p><b>Purpose:</b> To investigate the efficacy of trypanocidal therapy in patients with Chagas' cardiomyopathy.</p> <p><b>Methods:</b> 2854 patients with Chagas' cardiomyopathy were randomly assigned to receive benznidazole or placebo for up to 80 d.</p> <p><b>Results:</b> Rates of conversion to negative <i>Trypanosoma cruzi</i> PCR results were 66.2% in the benznidazole group and 33.5% in the placebo group at the end of treatment, 55.4% and 35.3% at 2 yr, and 46.7% and 33.1% at &gt;5 yr (P&lt;0.001 for all). PCR conversion rates did not correspond to clinical outcomes.</p> <p><b>Conclusion:</b> In patients with Chagas' cardiomyopathy, trypanocidal therapy reduced serum parasite levels but did not improve cardiac deterioration.</p>

<b>Fungal Infections</b>		
Voriconazole Versus Amphotericin B for Primary Therapy of Invasive Aspergillosis. Herbrecht et al. 2002	NEJM 2002;347:408-15	<b>Title:</b> Voriconazole Versus Amphotericin B for Primary Therapy of Invasive Aspergillosis <b>Purpose:</b> To compare voriconazole vs. amphotericin B for primary therapy of invasive aspergillosis. <b>Methods:</b> 277 patients randomly assigned to receive IV voriconazole followed by oral voriconazole BID or IV amphotericin B deoxycholate. <b>Results:</b> Successful outcomes occurred in 52.8% of patients on voriconazole and 31.6% on amphotericin B at wk 12 (absolute difference, 21.2%; 95% CI, 10.4-32.9). Rate of survival was 70.8% in the voriconazole group and 57.9% in the amphotericin B group (hazard ratio, 0.59; 95% CI, 0.40-0.88). Voriconazole was associated with significantly fewer severe adverse events. <b>Conclusion:</b> Initial therapy with voriconazole is more clinically effective with fewer side effects than the standard approach with amphotericin B.

## Acronyms

CF	cystic fibrosis	GS	genome sequencing		dehydrogenase deficiency	PKU	phenylketonuria
CNV	copy number variant	GSD	glycogen storage disease	MLPA	multiplex ligation-dependent	SNP	single nucleotide polymorphism
ES	exome sequencing	LCHAD	long chain 3-hydroxyacyl-CoA		probe assay	VLCAD	very long chain acyl-CoA
FISH	fluorescence in situ hybridization		dehydrogenase deficiency	MSUD	maple syrup urine disease		dehydrogenase deficiency
GA	gestational age	MCADD	medium chain acyl-CoA	NGS	next generation sequencing		

## Introduction to Genetics

### Common Terms

- **penetrance**: probability that a gene variant is observably expressed in an individual who carries it
- **expressivity**: extent of gene expression – refers to the range of variation seen in a phenotype for a certain genotype
- **genetic heterogeneity**: when a phenotype/genetic disorder can be caused by different genotypes, due to genetic variation within the same gene (allelic heterogeneity) or in different genes (locus heterogeneity)
- **phenotypic heterogeneity**: pathogenic variants in the same gene result in multiple clinical manifestations and varying degrees of severity
- **mosaicism**: presence of two or more genotypes (e.g. chromosome patterns or gene variants) in the cells of the same person
- **nondisjunction**: a cell division error in which chromosomes fail to segregate, resulting in daughter cells with fewer or more chromosomes than expected
- **uniparental disomy**: the inheritance of two full or partial copies of a chromosome from one parental origin and no corresponding full/partial chromosome from the other parent
- **allele**: one of two or more versions of a gene that is located at a given position on a chromosome

### Genetic Variation

- a variant is a permanent change in the nucleotide sequence that differs from the most common nucleotide sequence (reference sequence)
- variants are classified based on their likelihood of disrupting the function of the gene product. The American College of Medical Genetics and Genomics outlines a commonly used method for classifying variants for single gene disorders:
  - benign: not associated with genetic disease
  - likely benign: probably not associated with genetic disease, but insufficient evidence to classify as benign
  - variant of uncertain significance: insufficient evidence to classify variant as benign or pathogenic
  - likely pathogenic: 90% likely to be pathogenic, and clinically treated as a pathogenic variant
  - pathogenic: known to be associated with genetic disease
- nomenclature no longer used in clinical genetics:
  - mutation: previously synonymous with pathogenic variant. Now this term is only used to describe the actual process of genetic change
  - polymorphism: a variant that is relatively common in the population and not typically associated with a genetic disease. This term is used only in the context of population genetics

### Types of Genetic Variation

- deletions or duplications of a whole gene(s) caused by aneuploidy, unbalanced chromosome rearrangements, or copy number variants (e.g. 22q11.2 deletion, or DiGeorge, syndrome; 17p11.2 duplication, or Potocki-Lupski, syndrome)
- disruption of a gene: inversions, balanced chromosome rearrangements
- variants that cause alteration in the protein coding sequence: missense (encodes for a different amino acid), nonsense (encodes for a premature stop codon), frameshift (deletion/insertion of a number of nucleotides that is not a multiple of 3, thus shifting the reading frame)
- variants that affect the transcription of a gene
- variants that affect splicing

### Single Gene Disorders

- traits or disorders determined by gene(s) at a single locus, which often follow a Mendelian inheritance pattern:
- autosomal inheritance: disorder is caused by pathogenic variants of a gene located on chromosomes 1-22 (the autosomes)
  - autosomal dominant: one copy of a gene with a pathogenic variant is sufficient to cause a trait/disorder
  - autosomal recessive: both copies of a gene must have pathogenic variants to cause a trait/disorder; an individual with one copy of a pathogenic gene variant is a carrier
- sex-linked inheritance: when disease is caused by pathogenic variants in a gene on the X or the Y chromosome. Because the X chromosome contains many more genes than the Y chromosome, almost all sex-linked traits are X-linked. X-linked inheritance generally results in a trait/disorder that is seen more commonly or with greater severity in males than females (e.g. Hemophilia A, Duchenne muscular dystrophy)

**Triplet Repeat Expansions**

- disorders where the number of trinucleotide repeats in certain genes exceeds the normal number and results in altered gene expression or production of an abnormal protein
  - these disorders can demonstrate genetic anticipation, where signs and symptoms are more severe and appear at an earlier age from one generation to the next due to expansion of the triplet repeat number
  - length of expansion segment is often proportional to severity of clinical phenotype
- e.g. Fragile X syndrome, Huntington disease

**Imprinting Disorders**

- imprinted genes are expressed entirely from either the maternal or paternal allele, depending on the gene (parent-of-origin gene expression)
- imprinting is determined by allele-specific epigenetic mechanisms (i.e. modifications to DNA other than a change in the underlying sequence, such as DNA methylation and/or histone modifications)
- disorders occur when a pathogenic variant disrupts the normally expressed allele of an imprinted gene, or through uniparental disomy of the normally silenced allele
- e.g. Prader-Willi syndrome, Angelman syndrome, Beckwith-Wiedemann syndrome

**Mitochondrial Disorders**

- disorders caused by pathogenic variants in mitochondrial DNA or in nuclear genes whose protein products are important for mitochondrial function
- high phenotypic heterogeneity
- mitochondrial disorders caused by pathogenic variants in nuclear genes demonstrate Mendelian inheritance (e.g. Alpers syndrome caused by autosomal recessive pathogenic variants in POLG)
- disorders caused by pathogenic variants in mitochondrial DNA are maternally inherited by all offspring because all mitochondria and associated mitochondrial DNA in the embryo comes from the maternal ovum, with no paternal contribution of mitochondria
- e.g. mitochondrial encephalomyopathy and lactic acidosis with stroke-like episodes syndrome (MELAS)

**Common Indications for Genetic Referrals**

- preconception and prenatal: abnormal prenatal screening test, fetal anomaly, recurrent pregnancy loss, personal or family history of a genetic condition, positive carrier screening test, consanguinity
- paediatric: major and/or multiple minor congenital anomalies, developmental delay, abnormal newborn screen, unusual growth pattern, abnormal pubertal development, connective tissue disorders, congenital hypo- or hypertension
- adult: family history of adult-onset genetic condition (e.g. Huntington Disease), personal or family history of cancer concerning for genetic cause, bleeding or clotting disorder, early onset vision or hearing loss

**Pedigrees**

- diagrams of a family tree that show the pattern/distribution of phenotypes for a genetic disorder within that family, often across multiple generations
- pedigrees generally indicate sex assigned at birth, with or without genetic confirmation of sex chromosomes; when counselling gender diverse patients, including transgender and non-binary patients, physicians should affirm the patient's gender identity while clarifying the role of sex assigned at birth or chromosomal sex in determining genetic features for the pedigree

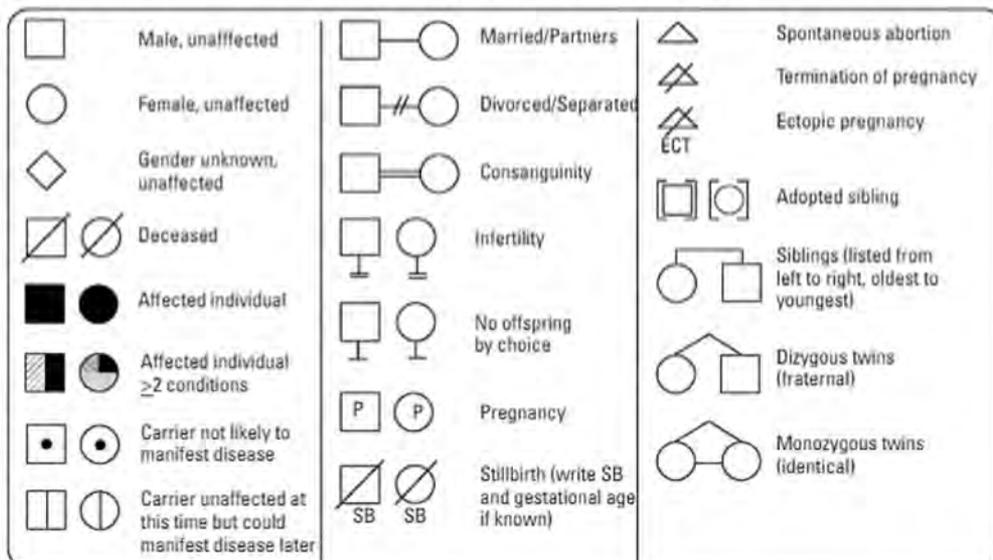

Figure 1. Common pedigree symbols

## Genetic Testing and Counselling

### Common Terms

- **presymptomatic genetic testing:** used to determine whether individuals without current symptoms, but with a known family history of a genetic disease, carry the familial pathogenic variant associated with the disease
- **newborn screening:** performed within the first few days of life to detect treatable and potentially fatal disorders before symptoms arise to allow for early therapy
- **preconception genetic counselling:** pre-pregnancy evaluation to assess the risk of having a child with an inherited condition
- **preimplantation genetic diagnosis:** genetic testing of in-vitro fertilized embryos for specific genetic conditions before uterine transfer

**Table 1. Common Genetic Tests**

Test	Karyotype	FISH	Microarray Analysis	Sanger Sequencing	NGS
<b>Technique</b>	Microscopic analysis of chromosomes with a nucleic acid stain that shows large changes in the number or structure of chromosomes; can detect large CNVs	A fluorescent-tagged DNA probe used to identify a gain, loss, or rearrangement of chromosomal material	SNP array: a collection of DNA probes attached to a solid surface to which test DNA hybridize in order to determine copy number of DNA regions	A method of DNA sequencing which is based on the selective incorporation of chain-terminating nucleotides during replication	High-throughput method used to sequence multiple genes in parallel; NGS is the technology used for panel sequencing, WES, and WGS
<b>Uses/Indications</b>	Useful in identification of major aneuploidies, structural chromosomal rearrangements, chromosomal changes related to hematological conditions, or other genetic diseases related to chromosome structure	Can confirm the presence or absence of specific DNA sequences and localize them. May be used to detect aneuploidies or balanced rearrangements, in gene mapping or identification of oncogenes, and in identification of circulating tumour cells	Microarray analysis can identify small deletions or duplications of genetic material anywhere in the genome. Commonly indicated when there is developmental delay/autism OR two or more congenital anomalies	The "gold-standard" method for identification of single nucleotide variants in the gene(s) known to cause a suspected syndrome	Limited indications vary by province but may include: limiting further invasive diagnostics, facilitating early intervention, when there is multisystem involvement, or when the differential diagnosis includes ≥2 conditions that would require separate genetic tests

- see [Obstetrics, OB7](#) for information on prenatal screening tests

## Differences in Morphology

### Congenital Anomalies

#### Minor and Major Anomalies

- **minor anomaly:** physical difference that is of no serious medical or cosmetic consequence to the patient (e.g. ear pit/tag, single palmar crease)
- **major anomaly:** physical difference that creates significant medical, surgical, or cosmetic problems for the patient (e.g. ventriculoseptal defect, cleft lip)

#### Mechanisms for Anomalies

- **malformation:** results from an intrinsically abnormal developmental process (e.g. polydactyly)
- **disruption:** results from the extrinsic breakdown of, or interference with, an originally normal developmental process (e.g. amniotic band disruption sequence)
- **deformation:** alteration of the final form of a structure by mechanical forces (e.g. Potter deformation sequence)
- **dysplasia:** abnormal development that results in abnormal organization of cells into tissues (e.g. skeletal dysplasia)

#### Multiple Anomalies

- **association:** non-random occurrence of multiple independent anomalies that appear together more often than would be predicted by chance, but are not known to have a single underlying etiology (e.g. VACTERL association)
- **sequence:** related anomalies that originate from a single initial major anomaly or precipitating factor that changes the development of other surrounding or related tissues or structures (e.g. Potter sequence or Pierre-Robin sequence)
- **syndrome:** a pattern of anomalies that occur together and are known or thought to have a single cause (e.g. CHARGE syndrome)

#### Meta-analysis of the Diagnostic and Clinical Utility of Genome and Exome Sequencing and Chromosomal Microarray in Children

Genomic Med 2018;3:16

**Purpose:** To compare the diagnostic and clinical utility of WGS and WES to that of chromosomal microarray.

**Methods:** A systematic review and meta-analysis of the literature.

**Results:** 37 studies were included (20068 children). Diagnostic utility of WGS (0.41, 95% CI 0.34-0.48) and WES (0.36, 95% CI 0.33-0.40) were greater than chromosomal microarray (0.10, 95% CI 0.08-0.12). The clinical utility of WGS (0.27, 95% CI 0.17-0.40) and WES (0.17, 95% CI 0.12-0.24) were higher than chromosomal microarray (0.06, 95% CI 0.05-0.07) and this difference was significant for WGS vs. chromosomal microarray (P<0.0001).

**Conclusion:** The diagnostic and clinical utility of WGS and WES is greater than that of chromosomal microarray.

#### VACTERL Association

Vertebral dysgenesis

Anal atresia (imperforate anus) ± fistula

Cardiac anomalies

TracheoEsophageal fistula ± esophageal atresia

Renal anomalies

Limb anomalies

## Approach to the Patient with Physical Differences

### General Approach

- are the anomalies major or minor?
- what is the mechanism underlying the anomaly?
- do the anomalies fit as part of an association, sequence, or syndrome?
- are the anomalies seen in other family members?

### History

- prenatal/obstetrical history (see [Obstetrics, OB4](#)) with particular attention to potential teratogenic exposures, developmental history (see [Paediatrics, P26](#)), and past medical history
- complete three generation family pedigree: health history, consanguinity, multiple miscarriages/stillbirths, neonatal deaths, congenital defects, developmental delay/autism, ethnicity

### Physical Exam

- compare features with other family members

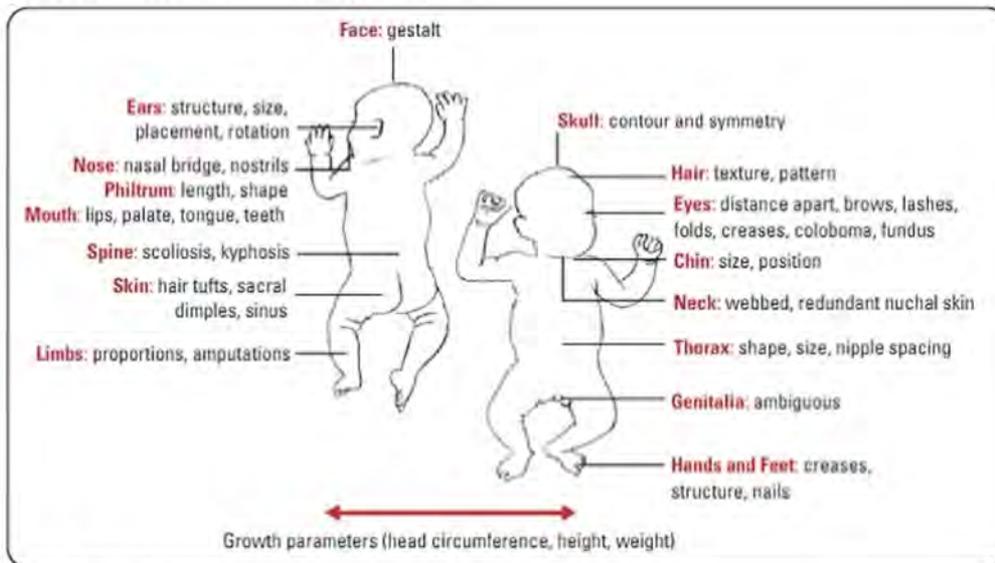

Figure 2. Physical exam in genetic assessment of a child

### Investigations

- screening for TORCH infections (toxoplasmosis, syphilis, varicella-zoster, parvovirus B19, rubella, cytomegalovirus, herpes infection)
- serial photographs if patient is older
- x-rays for bony abnormalities
- abdominal U/S and echocardiography to rule out structural abnormalities of organs
- brain imaging, especially if neurodevelopmental/neurological findings
- cytogenetic studies
  - chromosomal microarray analysis (SNP array) if developmental delay/autism or two or more congenital anomalies
  - FISH if aneuploidy syndrome (e.g. trisomy 13, 18, or 21) suspected
  - consider karyotype if a known aneuploidy syndrome is recognized or if there is a family history of a chromosomal rearrangement such as a translocation
- biochemistry: various biochemical tests, specific enzyme assays (e.g. for lysosomal storage diseases)
- single gene testing, gene panel testing, ES, GS

### Management

- recurrence risk and prenatal counselling
- referral for specialized medical care or genetic care for symptomatic management
- patient education, connect to social and psychological support services

Check the umbilical cord for 2 arteries and 1 vein. The presence of a single umbilical artery may be associated with other congenital anomalies.

# Genetic Conditions

**Table 2. Common Chromosomal Aneuploidy Syndromes**

	Trisomy 21	Trisomy 18	Trisomy 13
<b>Disease</b>	Down syndrome	Edwards syndrome	Patau syndrome
<b>Incidence</b>	1 in 600-800 births Most common abnormality of autosomal chromosomes Rises with advanced maternal age from 1 in 1500 at age 20 to 1 in 20 by age 45	1 in 6000 live births F:M=3:1	1 in 10000 live births
<b>Cranium/Brain</b>	Mild microcephaly, flat occiput, third fontanelle, brachycephaly	Microcephaly, prominent occiput	Microcephaly, sloping forehead, scalp defect, holoprosencephaly
<b>Eyes</b>	Upslanting palpebral fissures, epicanthal folds, speckled iris (Brushfield spots), refractive errors (myopia), acquired cataracts, nystagmus, strabismus	Microphthalmia, hypotelorism, iris coloboma, retinal anomalies	Microphthalmia, corneal abnormalities
<b>Ears</b>	Low-set, small, overfolded upper helix, frequent acute otitis media, hearing loss	Low-set, malformed	Low-set, malformed
<b>Facial Features</b>	Protruding tongue, large cheeks, low flat nasal bridge, small nose	Cleft lip/palate Small mouth, micrognathia	60-80% cleft lip and palate
<b>Musculoskeletal (MSK)</b>	Short stature Excess nuchal skin Joint hyperflexibility (80%) including dysplastic hips, vertebral anomalies, atlantoaxial instability	Intrauterine growth restriction Clenched fist with overlapping digits, hypoplastic nails, clinodactyly	Small head size Polydactyly
<b>Cardiac Defect</b>	50%, particularly atrioventricular septal defect	60% (ventricular septal defect, patent ductus arteriosus, atrial septal defect)	80% (atrial septal defect, patent ductus arteriosus, ventricular septal defect)
<b>Gastrointestinal (GI)</b>	Duodenal/esophageal/anal atresia, tracheoesophageal fistula, Hirschsprung's disease, chronic constipation	Hernia, tracheoesophageal fistula	None known
<b>Genitourinary (GU)</b>	Cryptorchidism, rarely fertile	Polycystic kidneys, cryptorchidism	Polycystic kidneys
<b>Central Nervous System (CNS)</b>	Hypotonia at birth Low IQ, developmental delay, hearing problems Onset of Alzheimer's disease in 40s	Hypertonia	Hypo- or hypertonia Seizures, deafness
<b>Other Features</b>	Single transverse palmar crease, clinodactyly, and absent middle phalanx of the 5th finger 1% lifetime risk of leukemia Polycythemia Hypothyroidism	Small for GA Rocker-bottom feet	Single umbilical artery Midline anomalies: scalp, holoprosencephaly, palate, heart, umbilicus, anus
<b>Prognosis/Management</b>	Long-term management per AAP Guidelines (Health Supervision of Children with Down Syndrome): CBC, echocardiography, yearly thyroid test, atlanto-occipital x-ray at 2 yr, sleep study, hearing test, and ophthalmology assessment	13% 1 yr survival, 10% 10 yr survival Profound intellectual disability in survivors	20% 1 yr survival, 13% 10 yr survival Profound intellectual disability in survivors

**Table 3. Common Genetic Disorders Involving the Sex Chromosomes**

	Fragile X Syndrome	Klinefelter Syndrome	Turner Syndrome
<b>Genotype</b>	CGG trinucleotide repeat expansion in FMR1 gene on X chromosome; ~55-~200 repeats is considered a premutation, whereas >200 repeats is considered a full mutation	47,XXY (most common) 48,XXXY, 49,XXXXY	45,XO (50% of cases), 45,X/46,XX mosaic (15% of cases)
<b>Incidence</b>	1 in 3600 males, 1 in 6000 females Most common heritable cause of intellectual disability in boys	1 in 1000 live male births Increased risk with advanced maternal age	1 in 4000 live female births Risk not increased with advanced maternal age
<b>Phenotype</b>	Overgrowth: macrocephaly, prominent jaw, forehead, and nasal bridge with long and thin face, large protuberant ears, macroorchidism, hyperextensibility, and high arched palate Complications: seizures, scoliosis, mitral valve prolapse Premutation carriers (males more often than females) may demonstrate tremor/ataxia syndrome in later life	Tall, slim, underweight No features pre-puberty Post-puberty: variable learning/behavioural difficulties, long limbs, gynaecomastia, lack of facial hair	Short stature, short webbed neck, low posterior hair line, wide carrying angle Broad chest, widely spaced nipples Lymphedema of hands and/or feet, cystic hygroma in newborn with polyhydramnios, lung hypoplasia Coarctation of aorta, bicuspid aortic valve Renal and cardiovascular abnormalities, increased risk of HTN Less severe spectrum with mosaic
<b>IQ and Behaviour</b>	Mild to moderate intellectual disability, 20% of affected males have normal IQ Attention deficit hyperactivity disorder (ADHD) and/or autism Females with full mutation may show milder intellectual impairment	Mild intellectual disability or learning difficulties Behavioural or psychiatric disorders: anxiety, shyness, aggressive, and impulsive behaviour acts	Typically normal intelligence
<b>Gonad and Reproductive Function</b>	Premutation carrier females at risk of developing premature ovarian failure	Infertility due to hypergonadotropic hypogonadism	Streak ovaries with deficient follicles, infertility, primary amenorrhea, impaired development of secondary sexual characteristics
<b>Diagnosis</b>	Molecular testing of FMR1 gene: PCR and/or Southern blot analysis of trinucleotide repeat length, methylation analysis	Karyotype	Karyotype

**Table 4. Examples of Other Genetic Syndromes**

	<b>22q11.2 Deletion Syndrome (DiGeorge syndrome)</b>	<b>Prader-Willi Syndrome</b>	<b>Angelman Syndrome</b>	<b>Noonan Syndrome</b>	<b>CHARGE Syndrome</b>
<b>Genotype</b>	Autosomal dominant; microdeletions of chromosome region 22q11.2	Lack of gene expression on paternal chromosome 15q11-13 due to deletion, maternal uniparental disomy of chromosome 15, or imprinting defect	Lack of gene expression on maternal chromosome 15q11-13 due to deletion, paternal uniparental disomy of chromosome 15, or an imprinting defect Rarely due to pathogenic variants in UBE3A	Autosomal dominant with variable expression, pathogenic variants in RAS/MAPK pathway genes ("RASopathies"); autosomal recessive with pathogenic variants in LZTR1	2/3 of children with CHARGE have been found to have a pathogenic variant in CHD7
<b>Incidence</b>	1 in 4000; second most common genetic diagnosis (next to Down syndrome)	1 in 15000	1 in 10000	1 in 2000	1 in 10000
<b>Clinical Features</b>	<b>"CATCH 22"</b> Cyanotic suggesting congenital heart disease (CHD) Anomalies: craniofacial anomalies, micrognathia, and low set ears Thymic hypoplasia: immunodeficiency Cognitive impairment Hypoparathyroidism, hypocalcemia 22q11 microdeletions High-risk for schizophrenia and other psychiatric disorders	<b>"H30"</b> Hypotonia and weakness Hypogonadism, obsessive Hyperphagia Obesity Short stature, almond-shaped eyes, small hands and feet with tapering of fingers Hypopigmentation, T2DM	Ataxia with severe intellectual disability, seizures, tremulousness, midface hypoplasia, large mouth, fair hair, inappropriately happy demeanour/laughter, fascination with water	Short stature, webbed neck, hypertelorism, low-set ears, epicanthal folds, ptosis, pectus excavatum Right-sided CHD, pulmonary stenosis Increased risk of hematological cancers, cardiomyopathy, moderate intellectual disability, delayed puberty	<b>"CHARGE"</b> Coloboma congenital Heart disease choanal Atresia mental Retardation GU anomalies Ear anomalies

**Table 5. Examples of Familial Cancer Syndromes**

<b>Syndrome</b>	<b>Gene</b>	<b>Associated Cancers</b>	<b>Screening and Monitoring</b>
<b>Li-Fraumeni Syndrome</b>	<i>TP53</i>	Breast, osteosarcoma, leukemia, soft tissue sarcoma, brain, adrenocortical carcinoma, and numerous other cancers	<b>Children:</b> From birth: abdominal/pelvic U/S every 3-4 mo; annual brain MRI, annual WBMRI <b>Adults:</b> Women age 20-75: annual breast MRI Age 18: annual dermatologic examination, abdominal/pelvic U/S, brain MRI, and WBMRI Age 25: colonoscopy and upper endoscopy every 2-5 yr (Moderate recommendation)
<b>Lynch Syndrome (HNPCC)</b>	<i>MSH2, MLH1, MSH6, PMS2, EPCAM</i>	Colorectal, endometrial, ovarian, renal, pancreatic, liver/biliary duct, stomach, brain, breast	Age 20-25 (or 2-5 yr younger than earliest age of colorectal cancer diagnosis in family): colonoscopy every 1-2 yr Age 30 yr (MSH6) and 35 (PMS2): colonoscopy every 1-2 yr (Strong recommendation)
<b>Familial Adenomatous Polyposis (FAP)</b>	<i>APC</i>	Colorectal, small intestine/stomach tumours	Age 10: sigmoidoscopy or colonoscopy every 1-2 yr, colonoscopy once polyps develop (Strong recommendation)
<b>Hereditary Breast and Ovarian Cancer Syndrome</b>	<i>BRCA1, BRCA2</i>	Female: breast, ovarian, pancreatic Male: prostate, breast, pancreatic	Age 25-65: annual breast MRI Age 30: annual breast MRI and mammograms (Strong recommendation)
<b>Von Hippel-Lindau Syndrome</b>	<i>VHL</i>	Kidney + tumours (e.g. pheochromocytoma)	Age 2: annual physical examination, annual ophthalmologic examination, consider annual catecholamine assessment Consider baseline audiometry at age of school entry Ages 12, 15, and 18: MRI of brain stem, spine, and abdomen, with abdominal U/S in alternating years Age 20: MRI every 2 yr (Expert opinion)
<b>Cowden Syndrome</b>	<i>PTEN</i>	Breast, thyroid, endometrial	<b>Women:</b> Age 30 (or 5-10 yr before earliest breast cancer in the family): annual mammography Age 30: consider random annual endometrial biopsy and/or U/S <b>Men and Women:</b> At diagnosis: annual thyroid U/S Children: evaluation for neurodevelopmental disorders Age 18: annual comprehensive physical exam Age 30-35: colonoscopy every 5 yr (Moderate recommendation)
<b>Neurofibromatosis (NF)</b>			
Type 1	<i>NF1</i>	Astrocytoma, optic glioma, neurofibroma, leukemia	Children: evaluation for neurodevelopmental disorders Annual physical exam including evaluation of growth, blood pressure, skin examination, bone examination, neurological examination, and vision screening (Expert opinion)
Type 2	<i>NF2</i>	Vestibular schwannoma, meningioma, ependymoma, astrocytoma	Annual physical exam including audiology assessment Age 10: annual brain MRI, spinal MRI every 2-3 yr (Expert opinion)

**Table 6. Heritable Connective Tissue Disorders**

	Loeys-Dietz Syndrome	Hypermobile Ehlers-Danlos Syndrome	Classical Ehlers-Danlos Syndrome	Vascular Ehlers-Danlos Syndrome	Marfan Syndrome
<b>Inheritance</b>	Autosomal dominant	Autosomal dominant	Autosomal dominant	Autosomal dominant	Autosomal dominant
<b>Pathophysiology</b>	Pathogenic variants in <i>TGFBR1</i> , <i>TGFBR2</i> , <i>SMAD3</i> , <i>TGF<math>\beta</math>2</i> genes affecting the TGF- $\beta$ pathway	Underlying molecular basis unknown	Pathogenic variants in <i>COL5A1</i> or <i>COL5A2</i> genes affecting Type V collagen	Pathogenic variants in <i>COL3A1</i> gene that affect type III collagen, which is most abundant type of collagen in aortic extracellular matrix	Pathogenic variants in <i>FBN1</i> gene
<b>Incidence</b>	Unknown	1 in 5000-20000	1 in 20000-40000	1 in 100000-250000	1 in 3000-5000
<b>Clinical Features</b>	Vascular findings (aortic aneurysms and dissections, generalized arterial tortuosity), craniofacial features (cleft palate, hypertelorism), skeletal features, easy bruising, allergic/inflammatory disease	Clinical features vary: generalized joint hypermobility, mild skin hyperextensibility, unexplained striae, recurrent abdominal hernias, recurrent joint dislocations in absence of trauma, chronic pain	Clinical features vary: generalized joint hypermobility, skin hyperextensibility and atrophic scarring, fragile skin, easy bruising, subcutaneous spheroids (fat cysts) on forearms and shins	Arterial fragility and/or rupture, aortic dilatation, intestinal rupture, uterine rupture in pregnancy, characteristic facies (translucent skin, thin lips, pinched nose, prominent ears)	Tall and slender build, disproportionately long limbs and digits, aortic dilatation, lens detachment, pneumothoraces

**Table 7. Intracellular/Extracellular Transport Receptor Disorders**

	Hereditary Hemochromatosis	Wilson Disease	CF
<b>Inheritance</b>	Autosomal recessive	Autosomal recessive	Autosomal recessive
<b>Pathophysiology</b>	Pathogenic variants in <i>HFE</i> gene (rarely <i>HJV</i> , <i>HAMP</i> , <i>TFR2</i> , and <i>SLC40A1</i> genes), disrupting regulation of iron	Pathogenic variants in <i>ATP7B</i> gene, leading to the impairment of cellular copper transport	Pathogenic variants in <i>CFTR</i> gene, which predominantly affects the lungs, but also the GI tract
<b>Incidence</b>	1 in 300	1 in 30000	1 in 3200-15000
<b>Clinical Features</b>	Iron overload (elevated transferrin saturation and ferritin), bronze skin, arthralgia, hormone disturbance (DM, hypogonadism), cirrhosis, cardiomyopathy	Liver disease (acute and/or chronic), movement disorders, psychiatric disturbance, Kayser-Fleischer rings	Severe to mild: Malabsorption, failure to thrive, pancreatic insufficiency, Bronchiectasis, male infertility More information found in other chapters*
<b>Management</b>	Phlebotomy for elevated serum ferritin and transferrin saturation	Chelating agents (e.g. penicillamine, trientine)	More information found in other chapters*

\*See *Respirology*, R12 and *Paediatrics*, P92

## Other Single Gene Disorders

### SICKLE CELL DISEASE

- autosomal recessive disease caused by mutation of the HBB gene resulting in the production of an abnormal version of  $\beta$ -globin and subsequently distorted red blood cells
- see [Hematology](#), H21

### DUCHENNE MUSCULAR DYSTROPHY

#### Incidence

- 1 in 4000 males

#### Etiology

- one type of muscular dystrophy characterized by progressive skeletal and cardiac muscle degeneration
- X-linked recessive: 1/3 de novo pathogenic variants, 2/3 inherited pathogenic variants
- missing structural protein (dystrophin)  $\rightarrow$  muscle fibre fragility  $\rightarrow$  fibre breakdown  $\rightarrow$  necrosis and degeneration

#### Clinical Features

- proximal muscle weakness by age 3, positive Gowers' sign, waddling gait, toe walking
- pseudohypertrophy of calf muscles (muscle replaced by fat) and wasting of thigh muscles
- decreased reflexes
- non-progressive delayed motor and cognitive development (dysfunctional dystrophin in brain)
- cardiomyopathy

Incidence of genetic disease vary markedly by ethnic origin; these values have historically been derived from populations of predominantly European ancestry

#### Gowers' Sign

Child uses hands to "climb up" the legs to move from a sitting to a standing position. Observed in individuals with weakness of the pelvic and proximal lower limb muscles.

#### Corticosteroids for the Treatment of Duchenne Muscular Dystrophy (DMD)

Cochrane DB Syst Rev 2016.5:CD003725

**Purpose:** To assess the effects of corticosteroids on prolongation of walking ability, muscle strength, functional ability, and quality of life in DMD and address whether benefit is maintained over long term, assess adverse events, and compare efficacy of different regimens.

**Methods:** Systematic review including RCTs or quasi-RCTs of corticosteroids given to patients with definitive DMD diagnosis for at least 3 mo.

**Results:** 12 studies with 667 participants included. Meta-analyses showed that corticosteroids improved muscle strength and function vs. placebo over 6 mo. Evidence from single trials showed 0.75 mg/kg/d superior to 0.3 mg/kg/d on most strength and function measures, with little evidence of further benefit at 1.5 mg/kg/d. Improvements were seen in time taken to rise from the floor, timed walk, four-stair climbing time, ability to lift weights, leg function grade, and forced vital capacity. Moderate quality evidence of adverse effects: excessive weight gain, behavioural abnormalities, cushingoid appearance, and excessive hair growth.

**Conclusions:** Moderate quality evidence from RCTs indicates that corticosteroid therapy in DMD improves muscle strength and function in the short term (12 mo), and strength (up to 2 yr.) Dose of 0.75 mg/kg/d should be enough. Adverse effects were common but not clinically severe.

**Diagnosis**

- molecular genetic studies of dystrophin gene (*DMD*) (first line)
- genotype-phenotype correlations: different variants in the gene will cause some dystrophin production and a milder muscular dystrophy, Becker muscular dystrophy
- family history (pedigree analysis demonstrating X-linked inheritance)
- increased creatine kinase (50-100x normal) and lactate dehydrogenase
- muscle biopsy, EMG

**Management**

- supportive (e.g. physiotherapy, wheelchairs, braces); prevent obesity
- cardiac health monitoring and early intervention
- bone health monitoring and intervention (vitamin D, bisphosphonates)
- steroids (e.g. prednisone or deflazacort)
- surgical (for scoliosis)
- gene therapy trials underway

**Complications**

- patient usually wheelchair-bound by age 12
- early flexion contractures, scoliosis, osteopenia of immobility, increased risk of fracture
- death due to pneumonia/respiratory failure or CHF in second-third decade

**Metabolic Diseases**

- individually rare but collectively occur in 1 in 1500 births
- inherited disorders of metabolism; most are autosomal recessive
- infants and older children may present with failure to thrive or developmental delay
- organelle disorders can present with dysmorphism
- universal newborn screening in Ontario, Canada includes some treatable metabolic disorders

**Table 8. Metabolic Disorders**

	Protein Metabolism Disorders	Carbohydrate Disorders	Fatty Acid Disorders	Organelle Disorders
<b>Examples of Conditions</b>	PKU* Tyrosinemia* Homocystinuria* MSUD* Alkaptonuria Propionic acidemia* Inborn errors of urea cycle defects (Ornithine transcarbamylase deficiency)	Galactosemia* GSDs: von Gierke, Pompe, Cori, Andersen, McArdle	MCADD* VLCAD* LCHAD*	Congenital disorders of glycosylation Lysosomal storage diseases: mucopolysaccharidosis (Hunter, Hurler*), Niemann-Pick, Tay-Sachs, Gaucher, Fabry, Krabbe Peroxisomal defects: Zellweger syndrome, X-linked adrenoleukodystrophy
<b>Clinical Manifestations</b>	Coma, irritability, lethargy, poor feeding Seizures Intellectual disability Vomiting and acidosis after feeding Irritability Sweet-smelling urine (MSUD)	Hypoglycemia, hepatomegaly, liver failure, cardiomyopathy Growth retardation, failure to thrive	Lethargy, poor feeding Seizures, coma Symptoms triggered by fasting Liver dysfunction Sudden infant death	Progressive neurological problems Developmental regression Chronic encephalopathy Developmental delay Bone crises (Gaucher) Deafness, blindness
<b>Laboratory Findings</b>	Hyperammonemia with normal anion gap (urea cycle defects), hyperammonemia with high anion gap (organic acidemia)	Elevated liver enzymes (galactosemia) Hypoglycemia, lactic acidosis, hyperlipidemia (GSD)	Hypoketotic hypoglycemia Elevated free fatty acids Elevated creatine phosphokinase	Elevated urine oligosaccharides (oligosaccharidoses) and glycosaminoglycans (mucopolysaccharidoses), abnormal transferrin isoelectric focusing (congenital disorders of glycosylation), abnormal very long chain fatty acids (peroxisomal defects)
<b>Physical Exam</b>	Hypotonia/hypertonia Microcephaly, musty odour, eczema, hypopigmentation (PKU) Dark urine, pigmented sclerae, arthralgias (alkaptonuria) Lens subluxation, Marfanoid appearance (homocystinuria)	Infantile cataracts (galactosemia) Hepatomegaly Muscle weakness/cramping	Hepatomegaly Hypotonia	Dysmorphic facial features Macrocephaly (lysosomal storage diseases) Hepatosplenomegaly (Niemann-Pick type A/B/C, not Tay-Sachs) Cherry-red spot on macula (Niemann-Pick type A/B, Tay-Sachs, Gaucher) Corneal clouding (Hurler) Infantile cataract (Fabry) Peripheral neuropathy (Fabry, Krabbe) Spasticity

\* Metabolic disorders included in Newborn Screening Ontario

**Initial Investigations for a Child with Acute Problems Thought to be Due to an Inborn Error of Metabolism**

- important to send lab studies at initial presentation in order to facilitate immediate diagnosis and treatment
- check newborn screening results
- electrolytes, arterial blood gases (calculate anion gap, rule out acidosis)
- CBC with differential and smear
- blood glucose (hypoglycemia seen with organic acidemia, fatty acid oxidation defects, and GSDs)

- lactate, ammonium (hyperammonemia with urea cycle defects or organic acidemias), plasma Ca<sup>2+</sup> and Mg<sup>2+</sup>, plasma amino acid screen
- routine U/A: ketonuria must be investigated in a neonate, urinary organic acids
- carnitine levels with acylcarnitine profile
- others: urate, urine nitroprusside, CSF glycine, free fatty acids (3-β-hydroxybutyrate ratio >4 in fatty acid oxidation defect)

**Treatment**

- varies according to inborn error of metabolism but includes dietary restrictions, toxic metabolite sequestrants, enzyme replacement, etc.
- in the presentation of acute decompensation potentially caused by an inborn error of metabolism, discontinue feeding to prevent further buildup of toxic metabolites

**Table 9. Presentation and Management of Select Metabolic Disorders**

	PKU	Galactosemia	MSUD	GSD Type 1 (Von Gierke Disease)	Tay-Sachs Disease
<b>Inheritance and Incidence</b>	1 in 10000; autosomal recessive disease (mutations in <i>PAH</i> gene)	1 in 60000; autosomal recessive disease	1 in 185000; autosomal recessive disease (pathogenic variants in <i>BCKDHA</i> , <i>BCKDHB</i> , and <i>DBT</i> genes). 1 in 25000 in Ashkenazi Jewish, 1 in 400 in Mennonites	1 in 100000; autosomal recessive disease, 1 in 20000 in Ashkenazi Jewish	1 in 320000; autosomal recessive disease, 1 in 3600 in Ashkenazi Jewish
<b>Pathophysiology</b>	Deficiency of phenylalanine hydroxylase prevents conversion of phenylalanine to tyrosine leading to buildup of phenylalanine and its toxic metabolites Mothers who have PKU may have infants with multiple congenital abnormalities	Most commonly due to deficiency of galactose-1-phosphate uridylyltransferase leading to an inability to process lactose/galactose	Reduction or elimination of protein complex needed for amino acids leucine, isoleucine, and valine breakdown, leading to toxic build-up	Mutations in <i>G6PC</i> (cause of GSD1a) and <i>SLC37A4</i> (cause of GSD1b) genes prevent effective conversion of glucose-6-phosphate to glucose. Glucose-6-phosphate is converted to glycogen and fat which subsequently accumulate in cells, especially in the liver and kidneys	Mutations in <i>HEXA</i> gene, which encodes alpha subunit of hexosaminidase A; leads to intracellular accumulation of GM2 ganglioside, lysosome dysfunction, and neurodegeneration
<b>Clinical Features</b>	Baby is normal at birth, then develops a musty odour, eczema, hypertonia, tremors, and mental retardation Hypopigmentation due to low tyrosine levels (fair hair, blue irises)	Signs of liver and renal failure, jaundice, failure to thrive, and cataracts with ingestion of lactose/galactose  Complications: Increased risk of sepsis, especially <i>E. coli</i> If the diagnosis is not made at birth, liver and brain damage may become irreversible	Feeding intolerance, failure to thrive, vomiting, lethargy, and maple syrup odour in urine and cerumen May progress to irreversible mental retardation, hyperactivity, severe failure to thrive, seizures, coma, cerebral edema, and death if inadequately treated	Typically presents between 3-6 mo of age with hepatomegaly, hypoglycemia, poor fasting tolerance, growth failure, and "doll-like" facies (full cheeks with thin extremities)  Complications: Lactic acidosis, hyperuricemia, hyperlipidemia, delayed puberty, renal disease, hypoglycemic seizures, hepatic adenomas, osteoporosis	Various presentations: infantile form (onset at 3-6 mo), juvenile form (onset at 2-6 yr), and adult or chronic form (onset at >10 yr)  Psychomotor regression, hypotonia, increased startle response, macular cherry red spot, seizures, and hearing impairment
<b>Diagnosis and Management</b>	PKU screening at birth Life-long dietary restriction of phenylalanine starting within the first 10 d of life; especially important during pregnancy to maintain normal phenylalanine levels to prevent maternal PKU effects on fetus Large neutral amino acid (tyrosine) replacement, BH4 enzyme treatment, phenylalanine lyase treatment are other options	Screened for in many newborn screening programs but generally present with liver failure and <i>E. coli</i> sepsis before screening result reported Elimination of galactose from the diet (e.g. dairy, breast milk) Most infants are fed a soy-based diet	MSUD is screened in most newborn screening programs. Serum amino acid evaluation (leucine, isoleucine, alloisoleucine, and valine) and urine organic acid analysis Protein-restricted, high-carbohydrate diet to limit branched amino acid intake A trial of thiamine therapy in addition may be recommended for some infants	Hypoglycemia when interval between feeds are increased (>3-4 h), lactic acidemia, hypertriglyceridemia, and hepatomegaly Treat with nutrition therapy (small frequent feedings, avoid fructose/sucrose/galactose), continuous overnight feedings, raw cornstarch (for slow, sustained glucose release), vitamin supplementation, frequent blood glucose monitoring	Clinical suspicion β-Hexosaminidase enzyme activity (serum) Ashkenazi Jewish carriers often identified by preconception screening Treatment is supportive

## Landmark Medical Genetics Trials

Trial Name	Reference	Clinical Trial Details
<b>PHENYLKETONURIA</b>		
Glycomacropeptide for Nutritional Management of Phenylketonuria: A Randomized, Controlled, Crossover Trial	Am J Clin Nutr 2016; 104(2):334-345	<p><b>Title:</b> Glycomacropeptide for Nutritional Management of Phenylketonuria: A Randomized, Controlled, Crossover Trial</p> <p><b>Purpose:</b> To evaluate the efficacy and safety of a low-phenylalanine (Phe) diet in combination with either glycomacropeptide medical foods (GMP-MFs) or traditional amino acid medical foods (AA-MFs) in individuals with phenylketonuria (PKU).</p> <p><b>Methods:</b> Thirty early-treated individuals aged 15-49 yr with PKU participated in a 2-stage, randomized crossover trial involving consumption of a low-Phe diet with AA-MFs or GMP-MFs for periods of 3 wk each.</p> <p><b>Results:</b> Dietary management of PKU with GMP-MFs compared to AA-MFs resulted in higher intake among participants. GMP-MFs were rated as more acceptable in terms of taste and had less side effects.</p> <p><b>Conclusions:</b> GMP-MFs are safe for dietary management of PKU. GMP-MFs may improve dietary adherence for patients with PKU.</p>
PRISM	Mol Genet Metab 2018; 124(1):27-38	<p><b>Title:</b> Pegvaliase for the Treatment of Phenylketonuria: Results of a Long-Term Phase 3 Clinical Trial Program (PRISM)</p> <p><b>Purpose:</b> Evaluate the efficacy and safety of pegvaliase treatment in adults with phenylketonuria (PKU).</p> <p><b>Methods:</b> Pegvaliase-naive participants with blood Phe &gt;600 µmol/L were randomized to receive 20 mg/d or 40 mg/d of pegvaliase.</p> <p><b>Results:</b> Pegvaliase treatment was given to 261 participants. Within 24 mo, 68.4% of participants achieved blood Phe ≤600 µmol/L. Reductions in blood Phe were associated with neuropsychiatric outcomes, which were maintained with long-term treatment. The vast majority of adverse events (99%) were mild or moderate in severity.</p> <p><b>Conclusions:</b> Results from this trial suggest pegvaliase is safe and efficacious in treating adults with PKU.</p>
<b>CYSTIC FIBROSIS</b>		
NCT03691779	Am J Respir Crit Care Med. 2021;203(12):1522	<p><b>Title:</b> Study of Elexacaftor/Tezacaftor/Ivacaftor in Children 6 through 11 Years of Age with Cystic Fibrosis and at Least One F508del Allele</p> <p><b>Purpose:</b> Elexacaftor/tezacaftor/ivacaftor as a combination therapy was effective in treating patients aged greater than 12 years with CF and an accompanying F508del. This 24-week study served to evaluate the efficacy of treatment in patients less than 12 yr.</p> <p><b>Methods:</b> RCT consisting of 66 children aged between 6 and 11 with CF who were assessed for the primary outcome of interest being safety and tolerability of the proposed treatment of oral Elexacaftor 100 mg once daily, Tezacaftor 50 mg once daily, and Ivacaftor 75 mg q12 h for children weighing ≤30 kg and oral Elexacaftor 200 mg once daily, Tezacaftor 100 mg once daily, and Ivacaftor 150 mg q 12 h for children weighing &gt;30 kg. Additionally, efficacy of the treatment was also assessed (FEV<sub>1</sub> and Cystic Fibrosis Questionnaire-Revised respiratory domain score).</p> <p><b>Results:</b> Commonly reported side effects included cough, headache, and fever. Treatment also resulted in improvements in predicted FEV<sub>1</sub> (10% improvement), and Cystic Fibrosis Questionnaire-Revised respiratory domain score (7.0 points improvement).</p> <p><b>Conclusion:</b> Results show that treatment of CF with accompanying F508del using Elexacaftor/Tezacaftor/Ivacaftor resulted in significant improvements in patients aged under 12.</p>
<b>NON-SMALL CELL LUNG CANCER</b>		
FLAURA	N Engl J Med. 2018;378(2):113. Epub 2017 Nov 18.	<p><b>Title:</b> Osimertinib in Untreated EGFR-Mutated Advanced Non-Small-Cell Lung Cancer (NSCLC)</p> <p><b>Purpose:</b> To compare Osimertinib (a third-generation EGFR inhibitor) against existing standard EGFR inhibitors in patients with previously untreated EGFR mutation-positive NSCLC</p> <p><b>Methods:</b> Double-blind, RCT consisting of 556 previously untreated EGFR mutation positive NSCLC patients. Patients were randomized to receive osimertinib or a standard EGFR-TKI. Outcome of interest included clinician-assessed progression-free survival.</p> <p><b>Results:</b> Median progression-free survival was greater in osimertinib when compared to standard EGFR-TKIs in EGFR mutation positive NSCLC patients (18.9 mo vs. 10.2 mo).</p> <p><b>Conclusion:</b> Results of this study show that osimertinib had superior efficacy when compared to standard EGFR-TKIs.</p>
<b>ALKAPTONURIA</b>		
SONIA-2	Lancet Diabetes Endocrinol. 2020 Sep;8(9):762-772.	<p><b>Title:</b> Using Once-Daily Nitisinone for Treatment of Alkaptonuria</p> <p><b>Purpose:</b> No homogentisic acid (HGA) lowering medications have been for treatment of Alkaptonuria.</p> <p><b>Methods:</b> RCT consisting of 138 patients aged 25 or older with confirmed alkaptonuria were randomized to receive either oral nitisinone 10 mg daily or no treatment. The outcome of interest was daily urinary HGA excretion (u-HGA24) after 12 mo.</p> <p><b>Results:</b> 55 patients in the nitisinone group and 53 in the control group completed the study. u-HGA24 at 12 mo was significantly decreased by 99.7% in the nitisinone group compared with the control group.</p> <p><b>Conclusion:</b> Nitisinone was well tolerated within the treatment group and shows evidence of being an effective treatment for alkaptonuria.</p>
<b>ACHONDROPLASIA</b>		
NCT01603095, NCT02055157, NCT02724228	N Engl J Med. 2019 Jul 4;381(1):25-35.	<p><b>Title:</b> C-Type Natriuretic Peptide Analogue Therapy in Children with Achondroplasia</p> <p><b>Purpose:</b> To assess the efficacy and safety of vosoritide at treating achondroplasia in children</p> <p><b>Methods:</b> RCT consisting of 35 children aged 5 to 14 with achondroplasia. Dosages were stratified based on weight; dose of 2.5 µg per kilogram of body weight (8 patients in cohort 1), 7.5 µg per kilogram (8 patients in cohort 2), 15.0 µg per kilogram (10 patients in cohort 3), or 30.0 µg per kilogram (9 patients in cohort 4). Patients were observed for 24 mo. The outcomes of interest were prevalence of adverse events and growth velocity.</p> <p><b>Results:</b> Each patient experienced minor adverse effects such as pyrexia, hypothermia, erythema, cough, swelling and headaches. 4/35 patients experienced severe adverse effects including grade 3 obstructive sleep apnea, grade 1 tonsillar hypertrophy, grade 3 thyroglossal cyst, and grade 3 syrinx. At 6 mo, there were increases in annualized growth velocity in all cohorts except for that which received 2.5 µg.</p> <p><b>Conclusion:</b> Although associated with mild side effects, with larger scale trials, vosoritide may be used as a treatment for achondroplasia in children.</p>

# Imaging Modalities

## X-Ray Imaging

- x-rays: form of short wavelength electromagnetic energy
- as x-ray photons traverse matter, they can be absorbed (a process known as "attenuation") and/or scattered
- the density of a structure determines its ability to attenuate or "weaken" the x-ray beam
  - air < fat < water < bone < metal
- structures that have high attenuation (e.g. bone) appear white on the resulting images

### Plain Films

- x-rays pass through the patient and interact with a detection device (film) to produce a 2-dimensional projection image
- structures closer to the film appear sharper and less magnified
- contraindications: pregnancy (relative)
- advantages: inexpensive, non-invasive, readily available, portable, reproducible, fast, easily read
- disadvantages: radiation exposure (minimal), generally poor at distinguishing soft tissues

### Fluoroscopy

- continuous x-rays used for guiding angiographic and interventional procedures, in contrast examinations of the GI tract, and in the OR for certain surgical procedures (e.g. orthopaedic, urological)
- on the fluoroscopic image, structures that are radiolucent on plain film appear bright, and structures that are radiopaque on plain film appear dark
- in comparison to continuous fluoroscopy, pulsed fluoroscopy reduces fluoroscopy time and radiation dose
- advantages: real-time visualization of structures
- disadvantages: increased radiation dose compared to plain films

### Computed Tomography

- x-ray beam opposite a detector moves in a continuous 360° arc as patient is advanced through the scanner
  - anatomical structures are then reconstructed
- attenuation is quantified in Hounsfield units:
  - windowing and leveling: adjusting the "window width" (range of Hounsfield units displayed) and "window level" (midpoint value of the window width) to maximally visualize certain anatomical structures (e.g. CT chest can be viewed using "lung", "soft tissue", and "bone" settings)
- contraindications: pregnancy (relative), adverse reactions to contrast agents (e.g. previous anaphylaxis allergy, renal failure)
- advantages: delineates soft tissues, excellent at delineating bones and identifying lung/liver masses, may be used to guide biopsies, helical multidetector CT has fast data acquisition and allows 3D reconstruction, CTA is non-invasive compared to conventional angiography for visualization of vasculature
- disadvantages: high radiation exposure, soft tissue characterization is inferior to MRI, some studies require contrast (e.g. IV, oral, rectal), patient anxiety when going through scanner, increased cost and decreased availability compared to plain film, requires expert interpretation of images

Typical Effective Doses from Diagnostic Medical Exposures (in Adults)\*

Diagnostic Procedure Type	Equivalent Number of Chest X-Rays	Approximate Equivalent Period of Natural Background Radiation** (~3 mSv/yr)
<b>X-Ray</b>		
Skull	5	12 d
Cervical spine	10	3 wk
Thoracic spine	50	4 mo
Lumbar spine	75	6 mo
Chest (single PA film)	1	2 d
Shoulder	0.5	1 d
Mammography	20	7 wk
Abdomen	35	3 mo
Hip	35	3 mo
Pelvis	30	10 wk
Knee	0.25	<1 d
IV urogram	150	1 yr
Dual-energy x-ray absorptiometry (without/with CT)	0.5/2	-1 d/4 d
Upper GI series	300	2 yr
Small bowel series	200	20 mo
Barium enema	400	2.7 yr
<b>CT</b>		
Head	100	8 mo
Neck	150	1 yr
Spine	300	2 yr
Chest	350	2.3 yr
Chest (pulmonary embolism)	750	5 yr
Coronary angiography	800	5.3 yr
Abdomen	400	2.7 yr
Pelvis	300	2 yr
<b>Radionuclide</b>		
Brain ( <sup>18</sup> F)	705	4.7 yr
Bone ( <sup>99m</sup> Tc)	315	2.1 yr
Thyroid ( <sup>99m</sup> Tc)	240	1.6 yr
Thyroid ( <sup>123</sup> I)	95	8 mo
Cardiac rest-stress test		
( <sup>99m</sup> Tc, 1-d)	470	3 yr
( <sup>99m</sup> Tc, 2-d)	640	4 yr
Lung ventilation ( <sup>133</sup> Xe)	25	2 mo
Lung perfusion ( <sup>99m</sup> Tc)	100	8 mo
Renal ( <sup>99m</sup> Tc)	90-165	7-13 mo
Liver-spleen ( <sup>99m</sup> Tc)	105	8.4 yr
Biliary tract ( <sup>99m</sup> Tc)	155	1 yr

\*Source: Radiology 2008;248:254-263

## Ultrasound

- high-frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
- reflection (or "echo") occurs when the sound waves reflect off tissue interfaces of different acoustic impedance
- structures are described based on their echogenicity; hyperechoic (echogenic) structures appear bright (U/S reflected) whereas hypoechoic structures appear dark (U/S waves are relatively less reflected with more waves passing through the structure). A simple cyst is anechoic (pure black) as there are no interfaces to produce any echoes
- a gel is used on the skin surface to reduce the difference of impedance between the skin and transducer
- use of higher frequencies on U/S results in greater resolution but poorer penetrance, thus decreased visualization of deeper structures
- artifacts: acoustic shadowing refers to the echo-free area located behind an interface that strongly reflects (e.g. air) or absorbs (e.g. bone) sound waves; enhancement refers to the increase in reflection amplitude (i.e. increased brightness) from objects that lie below a weakly attenuating structure (e.g. cyst)
- duplex scan: grey-scale imaging that utilizes the Doppler effect (sound reflecting off a moving target) to visualize the velocity of blood moving past the transducer
- colour Doppler: assigns a colour based on the direction of blood flow (i.e. red = toward transducer, blue = away)
- advantages: relatively low cost, excellent spatial and soft tissue contrast resolution, non-invasive, no radiation, portable, real-time imaging, may be used for guided biopsies, many different imaging planes (axial, sagittal), differentiates cystic vs. solid
- disadvantages: highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus, poor for bone evaluation, limited field-of-view

### Attenuation

Bone (= bright) > grey matter > white matter ("fatty" myelin) > CSF > air (= dark)

## Magnetic Resonance Imaging

- imaging technique that uses electromagnetic properties of tissue (mainly water) to produce images in virtually any plane. It does not use ionizing radiation
- patient is placed in a magnetic field generated by electric current; protons, typically from water molecules, align themselves along the direction of magnetization due to their intrinsic polarity. A pulsed radiofrequency beam is subsequently turned on and deflects all the protons off their aligned axes. When the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed. This energy is measured with a detector and interpreted by software to generate MR images
- MR image reflects signal intensity picked up by receiver. Signal intensity is dependent on:
  1. hydrogen density: tissues with low hydrogen density (e.g. cortical bone, lung) generate little to no MR signal compared to tissues with high hydrogen density (e.g. water)
  2. magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment

Remember that water is "white" on T2 as "World War II"

### Methods to Reduce the Risk of Contrast-Induced Nephropathy

- Optimal: 0.9% NaCl at 1 mL/kg/h for 12 h pre-procedure and 12 h post-contrast administration
- For same-day procedure: 0.9% NaCl or NaHCO<sub>3</sub> at 3 mL/kg/h for 1-3 h pre-procedure and for 6 h post-contrast administration

**Table 1. Differences Between Diffusion, T1- and T2-Weighted MR Imaging**

Imaging Techniques	Signal Intensity	Main Application	Advantages
Diffusion-Weighted Imaging	Signal intensity dependent on the free molecular motion of water Decreased diffusion is hyperintense (bright), whereas increased diffusion is hypointense (dark)	Neuroradiology	Sensitive for detection of acute ischemic stroke and differentiating an acute stroke from other neurologic pathologies Acute infarction and abscess collections appear hyperintense due to restricted diffusion
T1-Weighted	Fluid is hypointense (dark) and fat is hyperintense (bright)	Body soft tissues	Often considered an anatomic scan since it provides a reference for functional imaging
T2-Weighted	Fluid is hyperintense (bright) and fat is hypointense (dark)	Body soft tissues	Often considered a pathologic scan since it will highlight edematous areas associated with certain pathologies

## Positron Emission Tomography Scans

- nuclear tracers are employed to produce images of functional processes in the body
- current generation models integrate PET and CT technologies into a single imaging device (PET-CT) that collects both anatomic and functional information during a single acquisition
- positron-producing radioisotopes, such as 18F, are chemically incorporated into a metabolically active molecule (e.g. glucose). These are then injected into the patient, where they travel to and accumulate in the tissues of interest. As the radioactive substance decays,  $\gamma$  rays are produced, and are detected by the PET scanner

### Contraindications to IV Contrast

- MADD Failure
- Multiple myeloma
- Adverse reaction previously
- DM
- Dehydration
- Failure (renal, severe heart)

- contraindications: pregnancy
- advantages: shows metabolism and physiology of tissues (not only anatomic); in oncology, allows for diagnosis, staging, and restaging; has predictive and prognostic value; can evaluate cardiac viability
- disadvantages: cost, ionizing radiation, availability

## Contrast Agents

Table 2. Contrast Agents

Imaging Modality	Types	Advantages	Disadvantages	Contraindications
X-Ray	Barium (e.g. oral or rectal)	Radiopaque substance that helps to delineate intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects		Previous adverse reaction to contrast; barium enema is contraindicated in toxic megacolon, acute colitis, and suspected perforation
CT	Iodinated agents (routes = oral, rectal, IV)	Delineates intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects; under fluoroscopy, may also give information on function of an organ		Previous adverse reaction to contrast, renal failure, DM, pregnancy, multiple myeloma, severe heart failure, and dehydration eGFR < 60 may require preventative measures and follow-up
MRI	Gadolinium Chelates	Shortens T1 relaxation time, thereby increasing signal intensity in T1-weighted sequences; highlights highly vascular structures (e.g. tumours)	Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease	Previous adverse reaction to contrast or end-stage renal disease (relative contraindication)
U/S	Microbubbles (IV)	Tiny gas bubbles create many interfaces and appear very echogenic. The microbubbles allow for echo-enhancement of vascular structures or cavities (i.e. echocardiography)		Contraindicated in individuals with right-to-left cardiac shunts or people with known hypersensitivity reactions

### FDG PET Imaging in Patients with Pathologically Verified Dementia

JNucl Med 2000;41(11):1920-8

**Purpose:** To confirm two beliefs surrounding bilateral temporo-parietal hypometabolism on FDG PET in Alzheimer's disease (AD): (1) it is the metabolic abnormality associated with AD and (2) that sensitivity, specificity, and diagnostic accuracy of this metabolic pattern allows for AD to be differentiated from other degenerative causes of dementia.

**Methods:** FDG PET scans from 22 individuals with pathologic confirmation of AD diagnosis were visually graded by an experienced nuclear medicine physician to identify classic bilateral temporo-parietal hypometabolism.

**Results:** Sensitivity, specificity, and diagnostic accuracy of bilateral temporo-parietal hypometabolism for AD were 93%, 63%, and 82%, respectively.

**Conclusions:** Bilateral temporo-parietal hypometabolism is the classic metabolic abnormality associated with AD. FDG PET may identify this metabolic pattern and can be used clinically to differentiate dementia syndromes.

## Chest Imaging

### Chest X-Ray

#### Standard Views

- PA: anterior chest against film plate to minimize magnification of the cardiac silhouette
- lateral: better visualization of retrocardiac space and thoracic spine; more sensitive at detecting small pleural effusions
  - improves localization of lesions when combined with PA view
- AP: alternative to PA view for admitted or acutely ill patients who are unable to tolerate standing or transport; erect or supine; generally a lower quality film than PA because of magnified cardiac silhouette
- lateral decubitus: can help to assess for pleural effusion and pneumothorax; however, POCUS can also be utilized for both of these purposes
- lordotic: angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs on PA and AP views

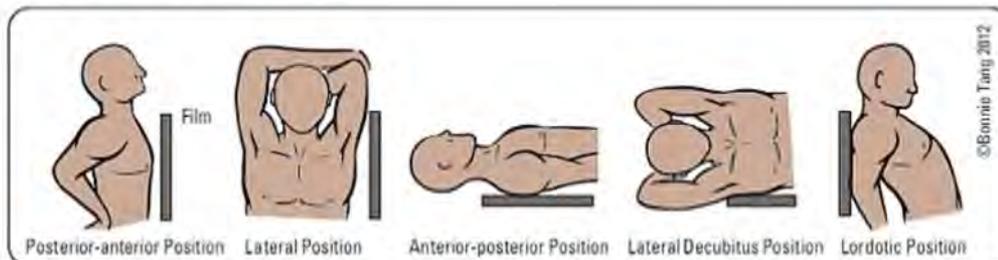

Figure 1. CXR views

**Approach to CXR**

**Basics**

- ID: patient name, medical record number (MRN), sex, age
- date of exam
- markers: right and/or left
- technique: view (e.g. PA, AP, lateral), supine or erect
- indications for the study
- comparison: date of previous study for comparison (if available)
- quality of film: inspiration (10 posterior and 7 anterior ribs should be visible), penetration (thoracic spine should be visible), rotation (spinous processes should be equidistant from medial ends of clavicles), magnification (AP films magnify the heart), angulation (clavicles should be S shaped)

**Analysis**

- tubes and lines: check position and be alert for pneumothorax or pneumomediastinum
- soft tissues: neck, axillae, pectoral muscles, breasts/nipples, chest wall
  - nipple markers can help identify nipples (may mimic lung nodules)
  - amount of soft tissue (check for any asymmetry), presence of masses, presence of air (subcutaneous emphysema)
- abdomen (see *Abdominal Imaging, M111*)
  - free air under the diaphragm, air-fluid levels, distention in small and large bowel
  - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: cervical spine, thoracic spine, scapulae, ribs, sternum, clavicles, proximal humerus
  - lytic and sclerotic lesions, fractures
- mediastinum: trachea, heart, great vessels
  - cardiomegaly (cardiothoracic ratio >0.5 on PA), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem and segmental bronchi, lymph nodes
- lungs: parenchyma, interstitium, pleura, diaphragm
  - abnormal lung opacity, pleural effusions or thickening
  - right hemidiaphragm usually higher than left due to liver
  - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm
- please refer to Toronto Notes website for supplementary material on how to approach a CXR

**Chest X-Ray Interpretation**

**Basics ABCDEF**

- AP, PA or other view
- Body position/rotation
- Confirm name
- Date
- Exposure/quality
- Films for comparison

**Analysis ABCDEF**

- Airways and hilar Adenopathy
- Bones and Breast shadows
- Cardiac silhouette and Costophrenic angle
- Diaphragm and Digestive tract
- Edges of pleura
- Fields (lung fields)

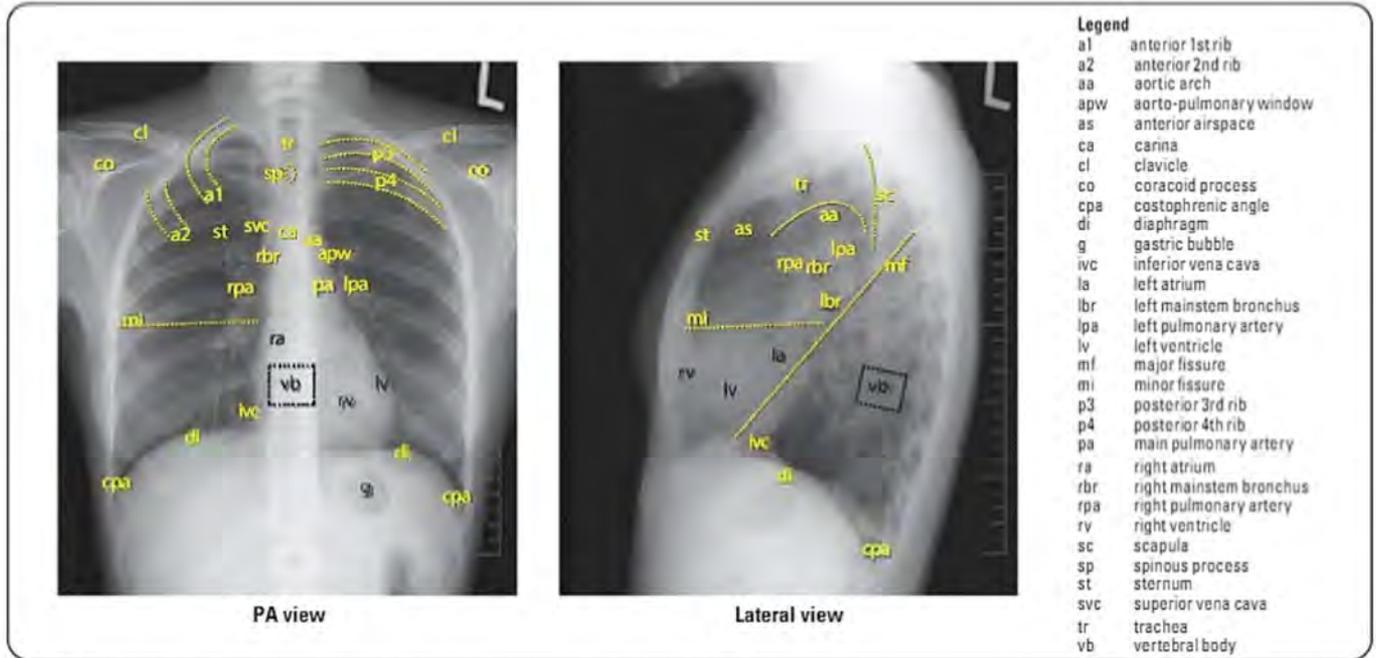

**Anatomy**

**Localizing Lesions for Parenchymal Lung Disease**

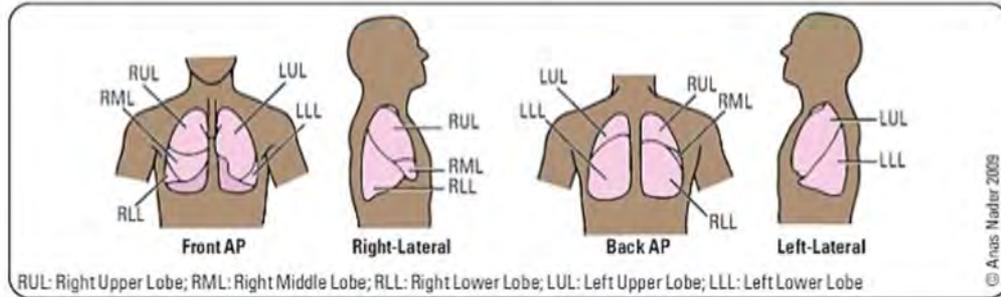

- silhouette sign: when two objects of the same radiodensity abut, they appear indistinguishable on imaging (i.e. the silhouette expected at an anatomical border due to difference in density disappears)
  - can be used to identify lung pathology (consolidation, atelectasis, mass) and localize disease to specific lung segments
  - this sign can be applied to imaging studies throughout the body
- spine sign: on lateral films, vertebral bodies should appear progressively radiolucent (dark) as one moves down the thoracic vertebral column; if they appear more radiopaque, it is an indication of pathology (e.g. consolidation in overlying lower lobe)
- air bronchogram: branching pattern of air-filled bronchi made visible on a background of opacification (i.e. solid or fluid-filled alveoli)

**Table 3. Localization Using the Silhouette Sign**

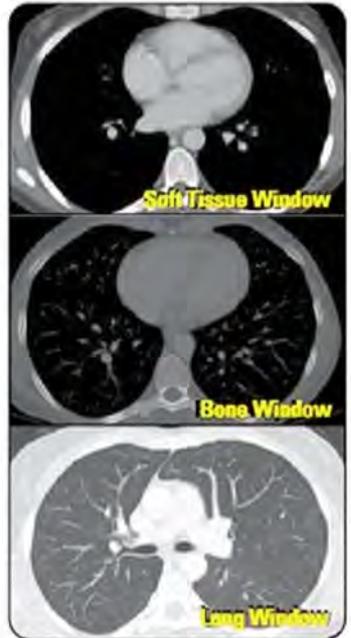

Interface Lost	Location of Lung Pathology
SVC/right superior mediastinum	RUL
Right heart border	RML
Right hemidiaphragm	RLL
Aortic knob/left superior mediastinum	LUL
Left heart border	Lingula
Left hemidiaphragm	LLL

**Figure 2. Location of fissures, mediastinal structures, and bony landmarks on CXR**  
 Note that anterior space is also commonly called retrosternal space

**Figure 3. Location of lobes of the lung**

**Figure 4. CT thorax windows in axial view**

## Chest Computed Tomography

### Approach to CT Chest

- soft tissue window
  - thyroid, chest wall, pleura
  - heart: chambers, coronary artery calcifications, pericardium
  - vessels: aorta, pulmonary artery, smaller vasculature
  - lymph nodes: mediastinal, axillary, hilar
- bone window
  - vertebrae, sternum, ribs: fractures, lytic lesions, sclerosis
- lung window
  - trachea: patency, secretions
  - bronchi: anatomic variants, mucus plugs, airway collapse
  - lung parenchyma: nodules, fibrosis, interstitial changes, consolidation, atelectasis
  - pleural space: effusions, thickening

**Table 4. Types of CT Chest**

	Advantage	Disadvantage	Contrast	Indication
<b>Standard</b>	Scans full lung very quickly (~1 min) ± high resolution reconstructions	Radiation	±	CXR abnormality Pleural and mediastinal abnormality Lung cancer staging Cancer follow-up Empyema vs. abscess
<b>Low Dose</b>	1/5th the radiation	Decreased detail	No	Lung cancer screening Follow-up infections, lung transplant, metastases
<b>CTA</b>	Iodinated contrast highlights vasculature (scan timed for maximum opacification of vessel being studied)	Contrast can cause severe allergic reaction and can cause acute kidney injury	Yes	PE Aortic aneurysms Aortic dissection

## Lung Abnormalities

### Atelectasis

- pathogenesis: collapse of lung tissue due to restricted breathing, blockage of bronchi, external compression, or poor surfactant
- findings
  - increased opacity of involved segment/lobe, vascular crowding, silhouette sign, air bronchograms
  - volume loss: fissure displacement, hilar/mediastinal displacement, diaphragm elevation
  - compensatory hyperinflation of remaining normal lung
- differential diagnosis
  - obstructive (most common): alveolar air distal to obstruction is resorbed causing alveolar collapse
    - post-surgical, endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury), or mucous plug (cystic fibrosis)
  - compressive: tumour, bulla, effusion, enlarged heart, lymphadenopathy
  - traction (cicatriziation): due to scarring, which distorts alveoli and contracts the lung
  - adhesive: due to lack of surfactant
    - hyaline membrane disease, prematurity
  - passive (relaxation): a result of air or fluid in the pleural space preventing full aeration
    - pleural effusion, pneumothorax
- management: in the absence of a known etiology, persisting atelectasis must be investigated (i.e. CT thorax or bronchoscopy) to rule out bronchogenic carcinoma centrally

### Consolidation

- pathogenesis: air in alveoli replaced by fluid (transudate, blood), inflammatory exudates, protein, or tumour
- findings
  - air bronchograms: lucent branching bronchi visible through opacification
  - airspace nodules: fluffy, patchy, poorly defined margins with later tendency to coalesce, may take on lobar or segmental distribution
  - silhouette sign
- differential diagnosis
  - fluid: transudate (pulmonary edema), blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
  - inflammatory exudates: bacterial infections, TB, allergic hypersensitivity alveolitis, COP (cryptogenic organizing pneumonia), allergic bronchopulmonary aspergillosis, aspiration, sarcoidosis
  - protein: pulmonary alveolar proteinosis
  - tumour: adenocarcinoma, lymphoma
- management: varies depending on the pattern of consolidation, which can suggest different etiologies; should also be done in the context of clinical picture

### Interstitial Disease

- pathogenesis: pathological process involving pulmonary interstitium (i.e. "lung scaffolding")
- findings
  - septal thickening: fine lines caused by thickened connective tissue septae (most commonly due to pulmonary edema or lymphangitis carcinomatosa)
    - these manifest on CXR as:
      - Kerley A: long thin lines in upper lobes
      - Kerley B: short horizontal lines extending from lateral lung margin
      - Kerley C: diffuse linear pattern throughout lung
  - nodular pattern: 1-5 mm well-defined or ill-defined nodules distributed throughout lung or with a lung zone predominance
    - seen in metastases, pneumoconiosis, granulomatous disease (e.g. sarcoidosis, miliary TB)
  - reticular pattern: fine curvilinear opacities
    - seen in interstitial lung diseases (pulmonary fibrosis)
    - watch for pneumothorax as a complication
  - reticulonodular: combination of reticular and nodular patterns
  - may also see signs of airspace disease (atelectasis, consolidation)
- differential diagnosis
  - occupational/environmental exposure
    - inorganic: asbestosis, coal miner's pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
    - organic: hypersensitivity pneumonitis, bird fancier's lung, farmer's lung (mouldy hay), and other organic dust
  - autoimmune: connective tissue diseases (e.g. rheumatoid arthritis, scleroderma, SLE, polymyositis, mixed connective tissue disease), IBD, celiac disease, vasculitis
  - drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, phenytoin, carbamazepine, fluoxetine, amiodarone, chemotherapy (e.g. methotrexate), immunotherapy, heroin, cocaine, methadone
  - infections: TB, non-tuberculous mycobacteria, certain fungal infections, viral infections

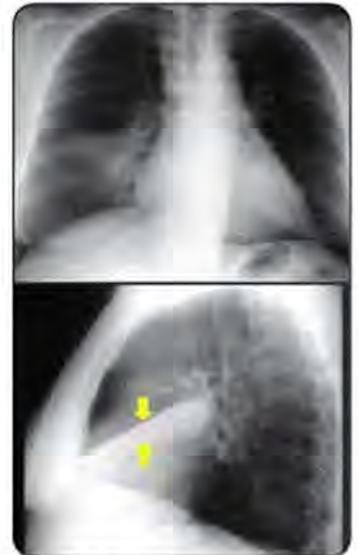

Figure 5. Atelectasis: RML collapse

#### DDx of Airspace Disease

- Pus (e.g. infections such as pneumonia)
- Fluid (e.g. pulmonary edema)
- Blood (e.g. pulmonary hemorrhage)
- Cells (e.g. bronchioalveolar carcinoma, lymphoma)
- Protein (e.g. alveolar proteinosis)

Figure 6. Air bronchograms in right lung

Figure 7. Consolidation: bacterial pneumonia

- idiopathic: IPF, nonspecific interstitial pneumonia (NSIP), organizing pneumonia
- for causes of interstitial lung disease classified by distribution, see [Respirology, R13](#)
- management: high-resolution CT thorax and ± open lung biopsy, multidisciplinary team discussions

**Pulmonary Nodule**

- findings
  - round opacity <3 cm (>3 cm is considered a mass) ± silhouette sign
  - note: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers
- differential diagnosis
  - extrapulmonary density: nipple, skin lesion, electrode, pleural mass, bony lesion
  - solitary nodule
    - tumour: carcinoma, hamartoma, metastasis, bronchial adenoma
    - infection/inflammation: histoplasmosis, tuberculoma, coccidioidomycosis
    - vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, septic embolus
  - multiple nodules: metastases, abscess, granulomatous lung disease (TB, fungal, sarcoid, rheumatoid nodules, silicosis, GPA), septic emboli
- management: clinical information and CT appearance determine level of suspicion of malignancy
  - if high probability of malignancy, invasive testing (transbronchial or CT-guided transthoracic biopsy) ± PET/CT is indicated
  - if low probability of malignancy, follow-up imaging as per Fleischner guidelines 2017

**Table 5. Characteristics of Benign and Malignant Pulmonary Nodules**

	Malignant	Benign
Margin	Ill-defined/spiculated ("corona radiata")	Well-defined
Contour	Lobulated	Smooth
Calcification	Eccentric or stippled	Diffuse, central, popcorn, concentric
Doubling Time	20-460 d	<20 d or >460 d
Other Features	Cavitation, collapse, adenopathy, pleural effusion, lytic bone lesions, smoking history	
Size	>3 cm	<3 cm
Cavitation	Yes, especially with wall thickness >15 mm, eccentric cavity, and shaggy internal margins	No
Satellite Lesions	No	Yes

**Figure 8. Interstitial disease: fine reticular pattern**

**Figure 9. Interstitial disease: medium reticular pattern**

**DDx of Interstitial Lung Disease**

- FASSTEN** (upper lung disease)  
 Farmer's lung (hypersensitivity pneumonitis)  
 Ankylosing spondylitis  
 Sarcoidosis  
 Silicosis  
 TB  
 Eosinophilic granuloma (Langerhans cell histiocytosis)  
 Neurofibromatosis

- BAD RASH** (lower lung disease)  
 Bronchiolitis obliterans organizing pneumonia (BOOP)  
 Asbestos  
 Drugs (nitrofurantoin, hydralazine, isoniazid, amiodarone, many chemotherapy drugs)  
 Rheumatological disease  
 Aspiration  
 Scleroderma  
 Hamman Rich and idiopathic pulmonary fibrosis (IPF)

**DDx for Cavitating Lung Nodule**

- WEIRD HOLES**  
 GP A (Wegener's)  
 Embolic (pulmonary, septic)  
 Infection (anaerobes, pneumocystis, TB)  
 Rheumatoid (necrobiotic nodules)  
 Developmental cysts (sequestration)  
 Histiocytosis  
 Oncological  
 Lymphangioliomyomatosis  
 Environmental, occupational  
 Sarcoidosis

**Pulmonary Vascular Abnormalities**

**Pulmonary Edema**

- pathogenesis: fluid accumulation in the airspaces of the lungs
- findings
  - vascular redistribution/enlargement, cephalization, pleural effusion, cardiomegaly (may be present in cardiogenic edema and fluid overloaded states)
  - fluid initially collects in interstitium
  - loss of definition of pulmonary vasculature
  - peribronchial cuffing
  - Kerley B lines
  - reticulonodular pattern
- thickening of interlobar fissures
  - as pulmonary edema progresses, fluid collects in alveoli and causes diffuse airspace disease, often in a "bat wing" or "butterfly" pattern in perihilar regions (outermost lung fields tend to be spared)
- differential diagnosis: cardiogenic (e.g. CHF), renal failure, volume overload, non-cardiogenic (e.g. ARDS)

**Pulmonary Embolism**

- pathogenesis: blockage in the pulmonary arteries due to emboli from pelvic or leg veins, rarely from central venous catheters, air, fat, or amniotic fluid
- findings
  - generally not possible to definitively diagnose on plain film; diagnosis made by CT pulmonary angiography or ventilation/perfusion scintigraphy (VQ scan)
  - CXR: Westermark sign (localized pulmonary oligemia), Hampton's hump (triangular peripheral infarct), enlarged right ventricle and right atrium, atelectasis, pleural effusion, and rarely pulmonary edema
  - definitive imaging study: CT pulmonary angiography to look for filling defect in contrast-filled pulmonary arteries
  - VQ scan: can be used in patients with impaired renal function or in pregnancy

## Pleural Abnormalities

### Pleural Effusion

**Table 6. Sensitivity of Plain Film Views for Pleural Effusion**

X-Ray Projection	Minimum Volume to Visualize
Lateral decubitus	25 mL: most sensitive
Upright lateral	50 mL: meniscus seen in the posterior costophrenic sulcus
PA	200 mL
Supine	Variable (May appear as diffuse haziness)

- a horizontal fluid level is seen only in a hydropneumothorax (i.e. both fluid and air within pleural cavity)
- effusion may exert mass effect, shift trachea and mediastinum to opposite side, or cause atelectasis of adjacent lung
- U/S is superior to plain film for detection of small effusions and may also aid in thoracentesis; POCUS is now standard of care in acute situations

### Pneumothorax

- pathogenesis: gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
- findings
  - upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air
  - more obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiorly)
  - more difficult to detect on supine film; look for the "deep (costophrenic) sulcus" sign, "double diaphragm" sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
  - contralateral tracheal and mediastinal shift may occur in tension pneumothorax
- differential diagnosis: spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, central venous catheter insertion, thoracentesis), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung
- management: supplemental oxygen and observation, chest tube insertion in 5th ICS anterior axillary line, or emergent needle decompression in 2nd ICS midclavicular line if tension pneumothorax (followed by chest tube insertion); repeat CXR to ensure resolution

### Asbestos

- asbestos exposure may cause various pleural abnormalities including benign plaques (most common; these may calcify), diffuse pleural fibrosis, effusion, and malignant mesothelioma

## Mediastinal Abnormalities

### Mediastinal Mass

- Felson's method of division outlines three compartments, which provides an approach to the differential diagnosis of a mediastinal mass
- anterior compartment is bordered anteriorly by the sternum and posteriorly by the heart and great vessels
  - 4 Ts: thyroid, thymic neoplasm, teratoma, terrible lymphoma
  - cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
- middle compartment extends from the posterior border of anterior mediastinum to a line 1 cm posterior to the anterior edge of thoracic vertebral bodies
  - esophageal carcinoma, esophageal duplication cyst, metastatic disease, lymphadenopathy (all causes), hiatus hernia, bronchogenic cyst
- posterior border (posterior to the middle line described above)
  - neurogenic tumour (e.g. neurofibroma, schwannoma), neuroenteric cyst, thoracic duct cyst, lateral meningocele, Bochdalek hernia, extramedullary hematopoiesis
- any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, or hematoma

### Enlarged Cardiac Silhouette

- heart borders
  - on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
  - on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle

Figure 10. LUL mass: bronchogenic carcinoma

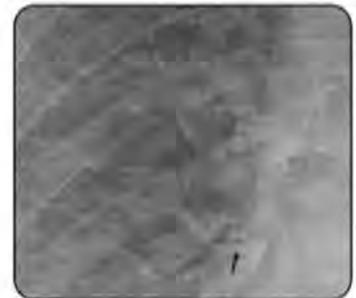

Figure 11. Peribronchial cuffing: interstitial edema

Figure 12. Pleural effusion in lateral view

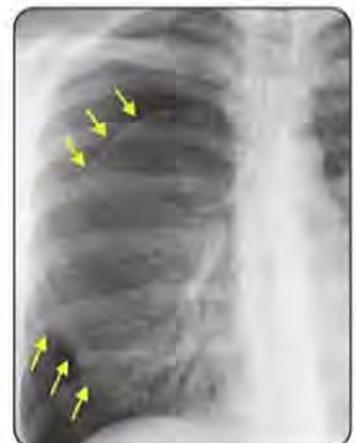

Figure 13. Pneumothorax

- cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
  - using a good quality erect PA chest film in adults, cardiothoracic ratio of  $>0.5$  is abnormal
  - differential of ratio  $>0.5$ 
    - cardiomegaly (myocardial dilatation or hypertrophy)
    - pericardial effusion
    - poor inspiratory effort/low lung volumes
    - pectus excavatum
  - ratio  $<0.5$  does not exclude enlargement
- pericardial effusion: globular heart with loss of indentations on left mediastinal border
- RA enlargement: increase in curvature of right heart border and enlargement of SVC
- LA enlargement: straightening of left heart border; increased opacity of lower right side of cardiovascular shadow (double heart border); elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film); distance between left main bronchus and "double" heart border  $>7$  cm; splayed carina (late sign)
- RV enlargement: elevation of cardiac apex from diaphragm; anterior enlargement leading to loss of retrosternal air space on lateral; increased contact of right ventricle against sternum
- LV enlargement: rounding of the cardiac apex; displacement of left cardiac border leftward, inferiorly, and posteriorly

**Elevated Hemidiaphragm Suggests**  
 PAL DIP  
 Pregnancy  
 Atelectasis  
 Lung resection  
 Diaphragmatic paralysis  
 Intra-abdominal process  
 Pneumonectomy  
 Pleural effusion also may result in apparent elevation

**Depressed Hemidiaphragm Suggests**  
 TALC  
 Tumour  
 Asthma  
 Large pleural effusion  
 COPD

**DDx Anterior Mediastinal Mass**  
 4 Ts  
 Thyroid  
 Thymic neoplasm  
 Teratoma  
 Terrible lymphoma

## Tubes, Lines, and Catheters

- ensure appropriate placement and assess potential complications of lines and tubes
- avoid mistaking a line/tube for pathology (e.g. oxygen rebreather mask for pneumothoraces)

### Central Venous Catheter

- used for fluid and medication administration, vascular access for hemodialysis, and CVP monitoring
- ideally located at the SVC/atrial junction to prevent inducing arrhythmias or perforating wall of atrium
  - if monitoring CVP, catheter tip must be proximal to venous valves
- tip of well-positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib end and clavicle, and inferiorly by top of RA
- course should parallel that of the SVC; if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- complications: pneumothorax, bleeding (mediastinal, pleural), malposition (artery, pleura), air embolism

### Endotracheal Tube

- frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- tip should be located 2-4 cm above tracheal carina (avoids bronchus intubation and vocal cord irritation)
- maximum inflation diameter  $<3$  cm to avoid necrosis of tracheal mucosa and rupture; ensure diameter of balloon is less than tracheal diameter above and below balloon
- complications: aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

### Nasogastric Tube

- tip and side port should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- complications: aspiration (parenchymal opacities), pneumothorax

### Swan-Ganz Catheter

- to monitor pulmonary capillary wedge pressure and estimate diastolic filling of left heart
- tip should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- if tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture/aneurysm
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

### Chest Tube

- in dorsal and caudal portion of pleural space to evacuate fluid
- in ventral and cephalad portions of pleural space to evacuate pneumothoraces
- tube may lie in fissure as long as functioning
- complications: bleeding, infection, lung laceration

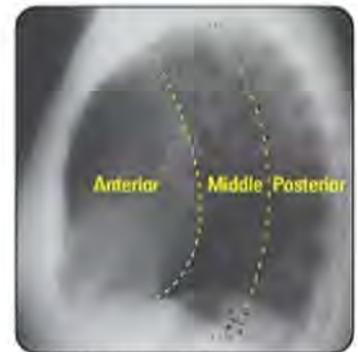

Figure 14. Lateral CXR showing three mediastinal compartments

Figure 15. CXR showing well-positioned central venous catheter

# Abdominal Imaging

## Abdominal X-Ray

### Indications

- acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction, large bowel obstruction
- chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
- not useful in: GI bleeds, chronic anemia, vague GI symptoms

### Anatomy

- the abdomen is divided into 2 cavities:
  - peritoneal cavity: lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
  - retroperitoneal cavity: contains several organs situated posterior to the peritoneal cavity; the contour of these can often be seen on radiographs

**Table 7. Differentiating Small and Large Bowel**

Property	Small Bowel	Large Bowel
Mucosal Folds	Uninterrupted valvulae conniventes (or plicae circulares)	Interrupted haustra extend only partway across lumen
Location	Central	Peripheral (picture frame)
Maximum Diameter	3 cm	6 cm (9 cm at cecum)
Maximum Fold Thickness	3 mm	5 mm
Other	Rarely contains solid fecal material	Commonly contains solid fecal material

### Approach to Abdominal X-Ray

- mnemonic: "Free ABDO"
- "Free": free air and fluid
  - free fluid
    - small amounts of fluid: increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
    - large amounts of fluid: diffuse increased opacification on supine film; bowel floats to centre of anterior abdominal wall
    - ascites and blood (hemoperitoneum) are the same density on the radiograph and cannot be differentiated
  - free intraperitoneal air suggests rupture of a hollow viscus (anterior duodenum, transverse colon, etc.), penetrating trauma, or recent (<7 d) surgery
- "A": air in the bowel (can be normal, ileus, or obstruction)
  - volvulus – twisting of the bowel upon itself resulting in obstruction; from most to least common:
    1. sigmoid: massively dilated sigmoid projects to right or mid-upper abdomen with proximal dilation ("coffee bean" sign)
    2. cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
    3. gastric: rare
    4. transverse colon: rare (usually in younger individuals)
    5. small bowel: "corkscrew" sign (rarely diagnosed on plain films, seen best on CT)
  - toxic megacolon
    - manifestation of fulminant colitis
    - extreme dilatation of colon (>6.5 cm) with mucosal changes (e.g. foci of edema, ulceration, pseudopolyps) and loss of normal haustral pattern
- "B": bowel wall thickening
  - increased soft tissue density in bowel wall, thumb-like indentations in bowel wall ("thumb-printing"), or a picket-fence appearance of the valvulae conniventes ("stacked coin" appearance)
  - may be seen in IBD, infection, ischemia, hypoproteinemic states, and submucosal hemorrhage
- "D": densities
  - bones: look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
  - abnormal calcifications: approach by location
    - RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
    - RLQ: ureteral stone, appendicolith, gallstone ileus
    - LUQ: renal stone, adrenal calcification, tail of pancreas
    - LLQ: ureteral stone
    - central: aorta/aortic aneurysm, pancreas, lymph nodes
    - pelvis: phleboliths (i.e. calcified veins), uterine fibroids, bladder stones
- "O": organs
  - kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
  - outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

### 3 Views of AXR

- Erect/Upright
- Supine
- Left lateral decubitus

### 3-6-9 Rule of Dilation

- Small bowel (>3 cm)
- Large bowel (>6 cm)
- Cecum (>9 cm)

Figure 16. Normal AXRs: (left) supine anteroposterior AXR, (middle) upright anteroposterior AXR, and (right) left lateral decubitus AXR

Table 8. Abnormal Air on Abdominal X-Ray

Air	Appearance	Common Etiologies
Extraluminal Intraperitoneal (pneumoperitoneum)	Upright film: air under diaphragm Left lateral decubitus film: air between liver and abdominal wall Supine film: gas outlines of structures not normally seen: Inner and outer bowel wall ("Rigler's" sign) Falciform ligament Peritoneal cavity ("football" sign)	Perforated viscus Postoperative (up to 10 d to be resorbed)
Retroperitoneal	Gas outlining retroperitoneal structures allowing increased visualization: Psoas shadows Renal shadows	Perforation of retroperitoneal segments of bowel: duodenal ulcer, post-colonoscopy
Intramural (pneumatosis intestinalis)	Lucent air streaks in bowel wall, 2 types: 1. Linear 2. Rounded (cystoides type)	1. Linear: ischemia, necrotizing enterocolitis 2. Rounded/cystoides (generally benign): primary (idiopathic), secondary (COPD)
Intraluminal	Dilated loops of bowel, air-fluid levels	Adynamic (paralytic) ileus, mechanical bowel obstruction
Loculated	Mottled, localized in abnormal position without normal bowel features	Abscess
Biliary	Air centrally over liver	Sphincterotomy, gallstone ileus, erosive peptic ulcer, cholangitis, emphysematous cholecystitis
Portal Venous	Air peripherally over liver in branching pattern	Bowel ischemia/infarction

Table 9. Adynamic Ileus vs. Mechanical Obstruction

Feature	Adynamic Ileus	Mechanical Obstruction
Calibre of Bowel Loops	Normal or dilated	Usually dilated
Air-Fluid Levels (erect and left lateral decubitus films only)	Same level in the same single loop	Multiple air fluid levels giving "step ladder" appearance, dynamic (indicating peristalsis present), "string of pearls" (row of small gas accumulations in the dilated valvulae conniventes)
Distribution of Bowel Gas	Air throughout GI tract is generalized or localized In a localized ileus (e.g. pancreatitis, appendicitis), dilated "sentinel loop" remains in the same location on serial films, usually adjacent to the area of inflammation	Dilated bowel up to the point of obstruction (i.e. transition point) No air distal to obstructed segment "Hairpin" (180°) turns in bowel

**Biliary vs. Portal Venous Air**  
"Go with the flow": air follows the flow of bile or portal venous blood  
Biliary air is most prominent centrally over the liver  
Portal venous air is most prominent peripherally

A

B

C

Rigler's sign courtesy of Dr Jeremy Jones, Radiopaedia.org, rID: 8041, Prof Frank Gaillard <https://radiopaedia.org/cases/8041>  
Football sign courtesy of Dr Maxime St-Amant, Radiopaedia.org, rID: 18597, <https://radiopaedia.org/cases/18597>  
String of pearls courtesy of Dr Maulik S Patel, Radiopaedia.org, rID: 14006, <https://radiopaedia.org/cases/14006>

## Abdominal Computed Tomography

- indications for plain CT: renal colic, hemorrhage
- indications for CT with contrast:
  - IV contrast given immediately before or during CT to allow identification of arteries and veins
    - portal venous phase: indicated for majority of cases
    - biphasic (arterial and portal venous phases): liver, pancreas, bile duct tumours
    - caution: contrast allergy (may pre-medicate with steroids and antihistamine)
    - contraindication: impaired renal function (eGFR <30 mL/min/1.73 m<sup>2</sup>)
  - oral contrast: barium or water-soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
  - rectal contrast: given for investigation of colonic lesions

Figure 18. Sigmoid volvulus on plain film, "coffee bean" sign

Courtesy of Dr Henry Knipe, Radiopaedia.org, rID: 28620, <https://radiopaedia.org/cases/28620>

## Approach to Abdominal Computed Tomography

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ or structure individually, from top to bottom, evaluating the size and shape of each area of increased or decreased density
- evaluate the following:
  - soft tissue window
    - liver, gallbladder, spleen, and pancreas
    - adrenals, kidneys, ureters, and bladder
    - stomach, duodenum, small bowel mesentery, and colon/appendix
    - retroperitoneum (aorta, vena cava, and mesenteric vessels; look for adenopathy in vicinity of vessels)
    - peritoneal cavity for fluid or masses
    - abdominal wall and adjacent soft tissue
  - lung window
    - visible lung (bases)
  - bone window
    - vertebrae, spinal cord, and bony pelvis

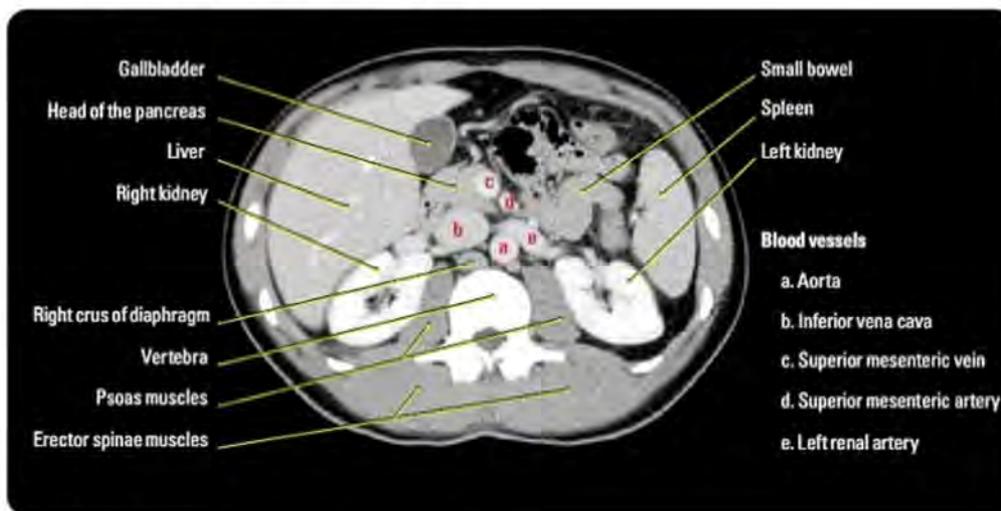

Figure 19. Axial abdominal computed tomography

### CT and Bowel Obstruction

- cause of bowel obstruction is rarely found on plain films; CT is the best imaging modality
- the "3,6,9" rule is a very useful guide for determining when the bowel is dilated; the maximum diameter for the small bowel is 3 cm, for large bowel is 6 cm, and for cecum is 9 cm; this can also be useful to distinguish small and large bowel, and to assess for 'impending' cecal perforation (e.g. post-untreated Ogilvie's syndrome)
- closed-loop obstruction: an obstruction in two locations (usually small bowel) creating a loop of bowel obstructed both proximally and distally; complications (e.g. ischemia, perforation, necrosis) may occur quickly

### CT Colonography (Virtual Colonoscopy)

- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumours)
- two CT scans of the abdomen (prone and supine) after the instillation of carbon dioxide into a prepped colon
- computer reconstruction of 2D CT images into a 3D intraluminal view of the colon
- lesions seen on 3D images correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, or staging of obstructing colonic lesions

## Contrast Studies

Table 10. Types of Contrast Studies

Study	Organ	Procedure Description	Assessment	Findings
Cine Esophagogram	Cervical esophagus	Contrast agent swallowed Recorded for later playback and analysis	Dysphagia, swallowing incoordination, recurrent aspiration, postoperative cleft palate repair	Aspiration, webs (partial occlusion), Zenker's diverticulum, cricopharyngeal bar, laryngeal tumour
Barium Swallow	Thoracic esophagus	Contrast agent swallowed under fluoroscopy, selective images captured	Dysphagia, rule out GERD, post-esophageal surgery	Achalasia, hiatus hernia, esophagitis, cancer, esophageal tear
Upper GI Series	Thoracic esophagus, stomach, and duodenum	Double contrast study: 1. Barium to coat mucosa 2. Gas pills for distention Patient NPO after midnight	Dyspepsia, investigate possible upper GI bleed, weight loss/anemia, post-gastric surgery	Ulcers, neoplasms, filling defects
Enterography and Enteroclysis (MRI or CT)	Entire small bowel	Enterography: patient drinks 1-2 L of sorbitol, psyllium, or barium solution to distend small bowel Enteroclysis: NJ tube used to pump barium, psyllium, or sorbitol contrast media directly into small bowel	IBD, malabsorption, weight loss/anemia, Meckel's diverticulum	Neoplasms, IBD, malabsorption, infection

## Specific Visceral Organ Imaging

- for the management of urgent and emergent peritoneal masses

### Liver

- U/S: assessment of cysts, abscesses, tumours, biliary tree
- CT ± IV: most popular procedure for imaging the liver parenchyma (primary liver tumours, metastases, cysts, abscesses, trauma, cirrhosis)
- MRI: excellent in evaluation of primary liver tumours, liver metastases, other parenchymal conditions; particularly helpful in differentiating common benign hepatic hemangiomas from primary liver tumours and metastases
- elastography: measures shear wave velocity by U/S (FibroScan) or MRI (MR elastography) to non-invasively quantify liver fibrosis
- findings:
  - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
  - porto-systemic shunts: caput medusae, esophageal varices, spontaneous spleno-renal shunt
  - U/S: cirrhosis appears nodular and hyperechoic with irregular areas of atrophy of the right lobe and hypertrophy of the caudate or left lobes
  - CT: fatty infiltration appears hypodense
- some masses require contrast to be visualized
- upon identifying a liver lesion on imaging (e.g. U/S), the follow-up imaging modality should be CT or MRI. CT would be four-phase non-contrast, arterial, venous, and delayed to distinguish the common benign liver lesion hemangioma from other tumours

### Spleen

- U/S, CT, nuclear medicine scan (nuclear medicine only to distinguish ectopic splenic tissue from enhancing tumours)
- CT for splenic trauma (hemorrhage)

### Colorectal Cancer: CT Colonography and Colonoscopy for Detection-Systematic Review and Meta-Analysis

Radiology 2011;259:393-405

**Purpose:** To assess the sensitivity of computed tomography (CT) colonography and optical colonoscopy (OC) for colorectal cancer (CRC) detection.

**Methods:** Systematic review and meta-analysis of diagnostic studies evaluating CT colonography detection of CRC based on a priori eligibility criteria, in particular requiring both OC and histological confirmation of disease. Studies that also assessed true-positive and false-negative diagnoses with OC were used to calculate OC sensitivity. Sensitivity of CTC and OC for CRC was the main outcome.

**Results:** 49 studies on 11,151 patients undergoing diagnostic study for detection of CRC were included. CTC has a sensitivity of 96.1% (95% CI 93.8%, 97.7%) and OC has a sensitivity of 94.7% (95% CI 90.4%, 97.2%) for the detection of CRC.

**Conclusion:** CTC is highly sensitive for the detection of CRC and may be a better modality for the initial investigation of suspected CRC, assuming reasonable specificity.

### Prophylactic Hydration to Protect Renal Function from Intravascular Contrast Material in Patients at High-Risk of Contrast-Induced Nephropathy (AMACING)

Lancet 2017;389:1312-1322

**Purpose:** Determine the clinical-effectiveness and cost-effectiveness of prophylactic hydration (treatment in protecting renal function).

**Methods:** AMACING is a prospective, randomised, non-inferiority trial. High-risk patients (with an eGFR of 30-59) >18 yr, undergoing an elective procedure requiring iodinated contrast were randomly assigned (1:1) to receive IV 0.9% NaCl or no prophylaxis. The primary outcome was incidence of contrast-induced nephropathy, defined as an increase in serum creatinine from baseline of ≥25% or 44 µmol/L within 2-6 d of contrast exposure, and cost-effectiveness of no prophylaxis compared with IV hydration in the prevention of contrast-induced nephropathy. Creatinine was measured before, 2-6 d, and 2-35 d after contrast-material exposure.

**Results:** 660 consecutive patients were randomly assigned to receive no prophylaxis (n=332) or IV hydration (n=328). No hydration and prophylaxis had similar rates of nephropathy. No hydration was cost-saving relative to hydration. No haemodialysis or related deaths occurred within 35 days. 5.5% of patients had complications associated with intravenous hydration.

**Conclusion:** No prophylaxis was found to be non-inferior and cost-saving in preventing contrast-induced nephropathy compared with IV hydration.

Normal liver appears more dense than spleen on CT. If less dense, suspect fatty infiltration

### Liver Mass DDx

- 5 Hs
- HCC
- Hydatid cyst
- Hemangioma
- Hepatic adenoma
- Hyperplasia (focal nodular)

Table 11. Imaging of Liver Masses

	U/S	CT
<b>Benign Mass</b>		
Hepatic Adenoma	Well-defined mass with hyperechoic areas due to hemorrhage	Well-defined hypervascular lesion with enlarged central vessel becoming slightly isoattenuating in venous phase
Hemangioma	Homogeneous hyperechoic mass	Peripheral globular enhancement in arterial phase scans; central filling and persistent enhancement on delayed scans
Focal Nodular Hyperplasia	Well-defined mass, central scar seen in 50% of cases	Hypervascular mass in arterial phase and isoattenuation to liver in portal venous phase
Abscess	Ill-defined, irregular margin, hypoechoic contents	Low attenuation lesion with an irregular enhancing wall
Hydatid Cyst	Simple/multiloculated cyst	Low attenuation simple or multiloculated cyst; calcification
<b>Malignant Mass</b>		
HCC	Single/multiple masses, or diffuse infiltration	Hypervascular; enhances in arterial and washes out in venous phase with portal venous tumour thrombus
Metastases	Multiple masses of variable echotexture	Usually low attenuation on contrast-enhanced scan

### Pancreas

- tumours
  - U/S: mass is more echogenic than normal pancreatic tissue
  - CT: preferred modality for diagnosis/staging
- ductal dilation secondary to stone/tumour
  - MRCP: imaging of ductal system using MRI cholangiography; no therapeutic potential
  - ERCP: endoscopic injection of dye into the biliary tree and x-ray imaging to assess pancreatic and biliary ducts; therapeutic potential (stent placement, stone retrieval)
    - acute pancreatitis is a complication in 5% of diagnostic procedures and 10% of therapeutic procedures

### Biliary Tree

- U/S: bile ducts usually visualized only if dilated, secondary to obstruction (e.g. choledocholithiasis, benign stricture, mass)
- CT: dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- MRCP, ERCP, PTC: further evaluation of obstruction and possible intervention

## “itis” Imaging

### Acute Cholecystitis

- pathogenesis: inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct, or in the case of acalculous cholecystitis, due to gallbladder ischemia or cholestasis (see [General and Thoracic Surgery](#), GS56)
- best imaging modality: U/S (best sensitivity and specificity); nuclear medicine (HIDA scan) can help diagnose cases of acalculous or chronic cholecystitis
- findings: most sensitive findings are presence of gallstones and positive sonographic Murphy's sign (tenderness from pressure of U/S probe over visualized gallbladder). Secondary findings include thickened gallbladder wall (>3 mm), dilated gallbladder, and pericholecystic fluid
- management: admit, NPO, IV fluids, analgesia, cefazolin, and early laparoscopic cholecystectomy

### Acute Appendicitis

- pathogenesis: luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess or peritonitis (see [General and Thoracic Surgery](#), GS35)
- best imaging modality: U/S or CT
- findings:
  - U/S: thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible; may also demonstrate signs of other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
  - CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage
- management: admit, NPO, IV fluids, analgesia, cefazolin + metronidazole, and appendectomy

### Acute Diverticulitis

- pathogenesis: erosion of the intestinal wall (most commonly rectosigmoid) by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro- or macroscopic perforation (see [General and Thoracic Surgery](#), GS39)
- best imaging modality: CT, although U/S is sometimes used
- contrast: oral and rectal contrast given before CT to opacify bowel

### Revised Estimates of Diagnostic Test Sensitivity and Specificity in Suspected Biliary Tract Disease

Arch Intern Med 1998;154:2573-2581

**Purpose:** To assess the sensitivity and specificity of tests used to diagnose cholelithiasis and acute cholecystitis, including U/S, oral cholecystography, radionuclide scanning with Technetium, MRI, or CT.

**Methods:** Meta-analysis of studies evaluating the use of different imaging modalities in the diagnosis of biliary tract disease. Main outcomes were sensitivity and specificity of the different imaging modalities, using the gold standard of surgery, autopsy, or 3 mo clinical follow-up for cholelithiasis. For acute cholecystitis, pathologic findings, confirmation of an alternate disease, or clinical resolution during hospitalization for cholecystitis were used as the standard.

**Results:** Thirty studies were included. For evaluating cholelithiasis, U/S had the best unadjusted sensitivity (0.97; 95% CI 0.95-0.99) and specificity (0.95, 0.88-1.00) and adjusted (for verification bias) sensitivity (0.84; 0.76-0.92) and specificity (0.99; 95% CI 0.97-1.00). For evaluating acute cholecystitis, radionuclide scanning has the best sensitivity (0.97; 0.96-0.98) and specificity (0.90; 0.86-0.95).

**Conclusion:** U/S is the test of choice for diagnosing cholelithiasis and radionuclide scanning is the superior test for diagnosing acute cholecystitis.

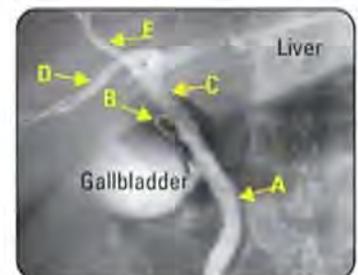

Figure 20. ERCP: biliary tree (A) common bile duct (B) cystic duct (C) common hepatic duct (D) right hepatic duct (E) left hepatic duct

Figure 21. Ultrasound: longitudinal view of an inflamed gallbladder. Arrowheads show thickened walls and pericholecystic fluid

Figure 22. Ultrasound: inflamed appendix

- findings:
  - cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
  - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
  - sometimes difficult to distinguish from perforated cancer (send abscess fluid for cytology and follow up with colonoscopy)
  - if chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)
- management: ranges from antibiotic treatment to surgical intervention; can use imaging to follow progression

### Acute Pancreatitis

- pathogenesis: activation of proteolytic enzymes within pancreatic cells leading to local and systemic inflammatory response (see [Gastroenterology, G48](#)); a clinical/biochemical diagnosis
- best imaging modality: imaging used to support diagnosis and evaluate for complications (diagnosis cannot be excluded by imaging alone)
  - U/S good for screening and follow-up
  - CT is useful in advanced stages and in assessing for complications (1st line imaging test)
- findings:
  - U/S: hypochoic enlarged pancreas (if ileus present, gas obscures pancreas)
  - CT: enlarged pancreas, edema, fat stranding with indistinct fat planes, mesenteric and Gerota's fascia (renal fascia) thickening, pseudocyst in lesser sac, abscess (gas or thick-walled fluid collection), pancreatic necrosis (low attenuation gas-containing non-enhancing pancreatic tissue), hemorrhage
- management: supportive therapy
  - CT-guided needle aspiration and/or drainage of abscess when clinically indicated
  - pseudocyst may be followed by CT and drained if symptomatic

### Chronic Pancreatitis

- pathogenesis: (see [Gastroenterology, G50](#))
- best imaging modality: MRCP (can show calcification and duct obstruction)
- findings: U/S, CT scan, and MRI may show calcifications, ductal dilatation, enlargement of the pancreas, and fluid collections (e.g. pseudocysts) adjacent to the gland

## Angiography of Gastrointestinal Tract

- anatomy of the arterial branches of the GI tract
  - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
  - superior mesenteric artery: jejunal, ileal, ileo-colic, right colic, middle colic
  - inferior mesenteric artery: left colic, superior rectal
- imaging modalities
  - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
    - flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
  - CT angiogram: modality of choice, non-invasive using IV contrast (no catheterization required)

## Genitourinary System and Adrenal

### Urological Imaging

#### Kidney, Ureter, and Bladder (KUB) X-ray

- a frontal supine radiograph of the abdomen
- indication: useful in evaluation of radiopaque renal stones (exceptions: uric acid and indinavir stones), indwelling ureteric stents/catheters, and foreign bodies in abdomen
- findings: addition of IV contrast excreted by the kidney (intravenous urogram) allows better visualization of the urinary tract but has been largely replaced by CT urography

#### Abdominal CT

##### Renal Masses

- Bosniak classification for cystic renal masses
- class I-II: benign and can be disregarded
- class III: should be followed
- class III-IV: suspicious for malignancy, requiring additional workup

#### Computed Tomography and Ultrasonography to Detect Acute Appendicitis in Adults and Adolescents

Ann Intern Med 2004;141:537-546

**Purpose:** To review the diagnostic accuracy of CT and U/S in the diagnosis of acute appendicitis.

**Methods:** Meta-analysis of prospective studies evaluating the use of CT or U/S, followed by surgical or clinical follow-up in patients with suspected appendicitis. Patients >14 yr with a clinical suspicion of appendicitis were eligible. Sensitivity and specificity using surgery or clinical follow-up as the gold standard were the main outcomes studied.

**Results:** Twenty-two studies were included. CT (12 studies) had an overall sensitivity of 0.94 (95% CI 0.91-0.95) and a specificity of 0.95 (0.93-0.96). U/S (14 studies) had an overall sensitivity of 0.86 (0.83-0.88) and a specificity of 0.81 (0.78-0.84).

**Conclusion:** CT is more accurate for diagnosing appendicitis in adults and adolescents, although verification bias and inappropriate blinding of reference standards were noted in the included studies.

#### Ultrasound, Computed Tomography or Magnetic Resonance Imaging for Acute Appendicitis in Children

Pediatr Radiol 2017;47:186-196

**Purpose:** Compare the accuracies of U/S, CT, and MRI for clinically suspected acute appendicitis in children.

**Methods:** Search and meta-analysis. The sensitivity, specificity, and the area under the curve of summary receiver operating characteristics were calculated and compared.

**Results:** 19 studies of U/S, 6 studies of CT, and 4 studies of MRI. The analysis showed that the area under the receiver operator characteristics curve of MRI (0.995) was a little higher than that of US (0.987) and CT (0.982; P=0.05).

**Conclusion:** US, CT, and MRI have high diagnostic accuracies of clinically suspected acute appendicitis in children overall with no significant difference.

**Angiography requires active blood loss 1-1.5 mL/min under optimal conditions for a bleeding site to be visualized in cases of lower GI bleeding**

#### Imaging Modality Based on Presentation

- Acute testicular pain = Doppler, U/S
- Amenorrhea = U/S, MRI (brain)
- Bloating = Plain film/CT (if abnormal)
- Flank pain = U/S, CT
- Hematuria = U/S, Cystoscopy, CT
- Infertility = HSG, MRI
- Lower abdominal mass = U/S, CT
- Lower abdominal pain = U/S, CT
- Renal colic = U/S, KUB, CT
- Testicular mass = U/S
- Urethral stricture = Urethrogram

**Table 12. Bosniak Classification for Cystic Renal Masses**

Classes	Definition
<b>Simple Renal Cysts</b>	
Class I	Fluid-attenuating well-defined lesion, no septation, no calcification, no solid components, hairline-thin wall
Class II	Same as class I + fine calcification or moderately thickened calcification in septae or walls; also includes hyperdense cysts (<3 cm) that do not enhance with contrast *Class IIF: multiple hairline-thin septa with minimal thickening, no enhancing soft tissue components, completely intrarenal non-enhancing high-attenuating renal lesions >3 cm
<b>Complex Renal Cysts</b>	
Class III	Thick irregular walls ± calcifications ± septated, enhancing walls, or septa with contrast
<b>Renal Cell Carcinoma</b>	
Class IV	Same as class III + soft tissue enhancement with contrast (defined as >10 Hounsfield unit increase, characterizing vascularity) with de-enhancement in venous phase ± areas of necrosis

- plain CT KUB indications: general imaging of renal anatomy, renal colic symptoms, assessment of renal calculi (size and location) and potential sequelae (infection and obstruction), and hydronephrosis prior to urological treatment
- CT urography indications: investigation of cause of hematuria, detailed assessment of urinary tracts (excretory phase), high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts, assessment of renal calculi
  - phases: unenhanced, excretory
- renal triphasic CT indications: standard imaging for renal masses, allows accurate assessment of renal arteries and veins, better characterization of suspicious renal masses – especially in differentiating renal cell carcinoma from more benign masses, and preoperative staging
  - phases: unenhanced, arterial and venous (nephrographic), excretory

**Ultrasound**

- indications: initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic masses, simple vs. complicated cysts); modality of choice for screening patients with suspected hydronephrosis (no IV contrast injection, no radiation exposure, and can be used in patients with renal failure); TRUS useful to evaluate prostate gland and guide biopsies; Doppler U/S to assess renal vasculature
- findings: solid renal masses are echogenic (bright on U/S), cystic renal masses have smooth well-defined walls with anechoic interior (dark on U/S), and complicated cysts have internal echoes within a thickened, irregular wall

**Retrograde Pyelography**

- indications: visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium, visualized by radiography or fluoroscopy; ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction, or allergy to IV contrast)
- findings: only yields information about the collecting systems (renal pelvis and associated structures), no information regarding the parenchyma of the kidney

**Voiding Cystourethrogram**

- bladder filled with contrast to the point where voiding is triggered
- fluoroscopy (continuous, real-time x-ray) to visualize bladder during voiding
- indications: males or young females with recurrent UTIs, hydronephrosis, hydroureter, suspected lower urinary tract obstruction, suspected bladder trauma, or vesicoureteral reflux
- findings: evaluation of bladder contractility and evidence of vesicoureteral reflux

**Retrograde Urethrogram**

- a small Foley catheter placed into penile urethral opening, followed by instillation of contrast and radiographic imaging
- indications: used mainly to study strictures or trauma to the male urethra; first-line study if signs of urethral injury are present (i.e. trauma with blood at the urethral meatus, scrotal hematoma, or high-riding prostate)

**MRI**

- advantages: better contrast resolution and tissue discrimination, lack of exposure to ionizing radiation, safer contrast, ability to obtain imaging directly from multiple planes (coronal, sagittal, oblique)
- indications: indicated over CT for depiction of renal masses in patients with previous nephron-sparing surgery, patients requiring serial follow-up (less radiation dosage), patients with reduced renal function, patients with solitary kidneys, clinical staging of prostate cancer (endorectal coil MRI)

**Figure 23. Triphasic CT of an angomyolipoma: showing fat density with non-contrast scan, mildly enhancing with contrast**

**Ultrasonography vs. Computed Tomography for Suspected Nephrolithiasis**

NEJM 2014;371:1100-1110

**Purpose:** Investigate whether the initial imaging method for patients with suspected nephrolithiasis should be CT or US.

**Methods:** Multicenter, pragmatic, comparative effectiveness trial, randomly assigned patients in the ED with suspected nephrolithiasis to undergo initial diagnostic ultrasonography performed by an emergency physician (POCUS), US performed by a radiologist, or abdominal CT. Compensations: 30 d incidence of high-risk diagnoses with complications that could be related to missed or delayed diagnosis and the 6 mo cumulative radiation exposure.

**Results:** A total of 2950 patients underwent randomization. The incidence of high-risk diagnoses with complications in the first 30 d did not vary according to imaging method. The mean 6 mo cumulative radiation exposure was significantly lower in the US groups. Adverse events were similar across groups. Return ED visits, hospitalizations, and diagnostic accuracy did not differ significantly among the groups.

**Conclusions:** Initial ultrasonography was associated with lower cumulative radiation exposure than initial CT, without significant differences in high-risk diagnoses with complications, serious adverse events, pain scores, return ED visits, or hospitalizations.

**Renal Nuclear Scan**

**Table 13. Renal Scan Tests**

Type of Test	Uses	Radionuclide
Renogram	Assess renal function and collecting system: evaluation of renal failure, workup of urinary tract obstruction and renovascular HTN, investigation of renal transplant	IV <sup>99m</sup> Tc-pentetate (DTPA) or mercuric (MAG3), and imaged at 1-3 s intervals with a gamma camera over the first 60 s to assess perfusion
Morphological	Assess renal anatomy: investigation of pyelonephritis and cortical scars	<sup>99m</sup> Tc-DMSA <sup>99m</sup> Tc-glucoheptonate

**Gynaecological Imaging**

**Ultrasound**

- transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
- transabdominal requires a full bladder to push out air-containing loops of bowel
  - indications: good initial investigation for suspected pelvic pathology
- TVUS provides a panoramic pelvic view and enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves due to reduced distances
  - indications: improved assessment of ovaries, first trimester development, and ectopic pregnancy

**Hysterosalpingogram**

- performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent
- indications: useful for assessing pathology of the uterine cavity and fallopian tubes, evaluating uterine abnormalities (e.g. bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)

**CT/MRI**

- indications: evaluating pelvic structures, especially those adjacent to the adnexa and uterus
- invaluable for staging gynaecological malignancies and detecting recurrence

**Sonohysterogram**

- transcervical saline introduction into uterine cavity to provide enhanced endometrial visualization during TVUS examination
- indications: abnormal uterine bleeding, uterine cavity abnormalities that are suspected or noted on TVUS (e.g. leiomyomas, polyps, synechiae), congenital abnormalities of the uterine cavity, infertility, recurrent pregnancy loss
- contraindications: pregnancy, pelvic infection

**Table 14. Typical and Atypical Findings on a Sonohysterogram**

Finding	Typical	Atypical
Polyps	A well-defined, homogeneous, polypoid lesion isoechoic to the endometrium with preservation of the endometrial-myometrial interface	Cystic components, multiple polyps, broad base, hypoechogenicity or heterogeneity
Leiomyoma	Well-defined, broad-based, hypoechoic, solid masses with shadowing. Overlying layer of endometrium is echogenic and distorts the endometrial-myometrial interface	Pedunculation or multilobulated surface
Hyperplasia and Cancer	Diffuse echogenic endometrial thickening without focal abnormality, although focal lesions can occur. Endometrial cancer is typically a diffuse process, but early cases can be focal and appear as a polypoid mass	
Adhesions	Mobile, thin, echogenic bands that cut across the endometrial cavity	Thick, broad-based bands that can completely obliterate the endometrial cavity, as in Asherman's syndrome

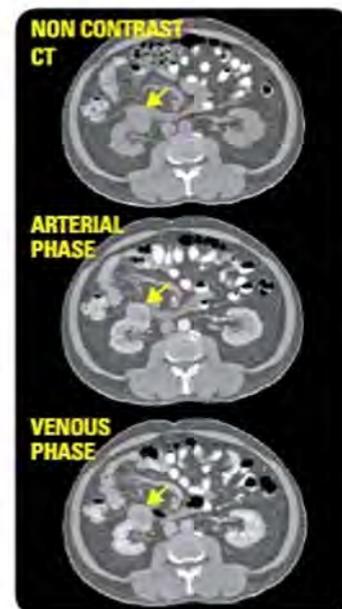

Figure 24. Triphasic CT of a renal cell carcinoma: showing arterial enhancing right renal lesion with venous washout (shunting)

Figure 25. Retrograde urethrogram demonstrating stricture in the membranous urethra

Figure 26. Transabdominal U/S: pregnancy, 18 wk fetus

Figure 27. Hysterosalpingogram: left hydrosalpinx

Pregnancy should always be ruled out by  $\beta$ -hCG before CT of a female pelvis (or any organ system) is performed

## Adrenal Mass

- imaging modality: most often identified on CT scan as 'incidentaloma,' can also use CT/MRI to distinguish benign from malignant masses

Table 15. Adrenal Mass Findings on CT and MRI

Factors	Adrenocortical Adenoma	Adrenocortical Carcinoma	Pheochromocytoma	Metastasis
Diameter (CT)	Usually <3 cm	Usually >4 cm	Usually >3 cm	Variable around <3 cm
Shape (CT)	Smooth margins and round/oval	Irregular with unclear margins	Round/oval with clear margins	Oval/irregular with unclear margins
Texture (CT)	Homogeneous	Heterogeneous with mixed densities	Heterogeneous with cystic areas	Heterogeneous with mixed densities
Vascularity (CT)	Not highly vascular	Usually vascular	Usually vascular	Usually vascular
Washout of Contrast Medium on CT	≥50% at 10 min	<50% at 10 min	<50% at 10 min	<50% at 10 min
Growth	Stable or very slow (<1 cm/yr)	Usually rapid (>2 cm/yr)	Slow (0.5-1 cm/yr)	Variable
Other Findings	Usually low density due to intracellular fat	Necrosis, calcifications, and hemorrhage	Hemorrhage	Occasionally hemorrhage
MRI on T2 Weighted Imaging	Isointense in relation to liver	Hyperintense in relation to liver	Markedly hyperintense in relation to liver	Hyperintense in relation to liver

### Modality Based on Neuropathology Presentation

- Cognitive decline = CT
- Cord compression = MRI
- Decreased level of consciousness = CT
- Fish bone/other swallowed foreign body = CT
- Low back pain, radiculopathy = MRI
- Multiple sclerosis = MRI
- Neck infection = CT
- Orbital infection = CT
- Rule out bleed = CT
- Rule out aneurysm = CTA, MRA
- Seizure = CT
- Sinusitis = CT
- Stroke = CT, MRI
- Trauma = CT
- Weakness, systemically unwell = CT

## Neuroradiology

### Skull Films

- rarely performed, generally not indicated for non-penetrating head trauma
- indications: screening for destructive bony lesions (e.g. metastases), metabolic disease, skull anomalies, postoperative changes and confirmation of hardware placement, skeletal surveys, multiple myeloma

### CT

- CT is often the first line modality for most neuropathology, even in situations where MRI would lead to better characterization
- CT is frequently the initial study performed because of its speed, availability, and lower cost
  - acute craniofacial trauma: CT is best for visualizing "bone and blood;" use MRI when CT fails to detect an abnormality despite strong clinical suspicion
  - acute stroke: MRI ideal, CT most frequently used
  - acute headache with focal neurologic signs
  - suspected hemorrhage (epidural, subdural, subarachnoid, intraparenchymal)
  - suspected hydrocephalus
- vascular structures and areas of blood-brain barrier impairment are bright (e.g. hyperdense or enhancing) with contrast injection
- Danger signs on head CT: space-occupying process, hemorrhage, edema, mass effect, midline shift, uncal and tonsillar herniation, loss of grey-white matter differentiation, hydrocephalus

### Myelography

- introduction of water-soluble, low-osmotic contrast media into subarachnoid space via lumbar puncture followed by x-ray
- largely replaced by MRI or CT myelogram
- indications: excellent study for disc herniation, traumatic nerve root avulsion, patients with contraindication to MRI, extensive hardware from spinal surgery that may create MRI artifacts

### MRI

- indications: finer neuroanatomic definition, better grey-white matter differentiation (especially T1-weighted series), better evaluation of edema extent (better tumour detection), allows evaluation of structures obscured by bony artifacts on CT (posterior fossa structures), multiplanar imaging helpful in preoperative assessment

### Cerebral Angiography/CT Angiography/MR Angiography

- indications: evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissections
- conventional DSA remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (typically femoral) access and catheter manipulation, which confers risk of vessel injury (e.g. dissection, occlusion, vasospasm, emboli)
- MRA methods (phase contrast, time of flight, gadolinium-enhanced) and CTA are much less invasive without risk to intracranial or neck vessels
- MRA and CTA are often used first for the assessment of suspected TIA, subarachnoid hemorrhage, vasospasm, or aneurysms

Figure 28. Epidural hematoma

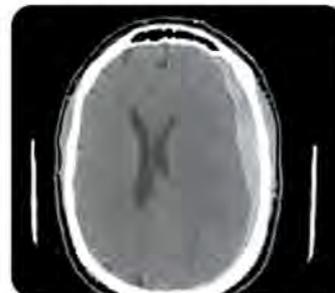

Figure 29. Subdural hematoma

Figure 30. Subarachnoid hemorrhage

Figure 31. Intraparenchymal hemorrhage

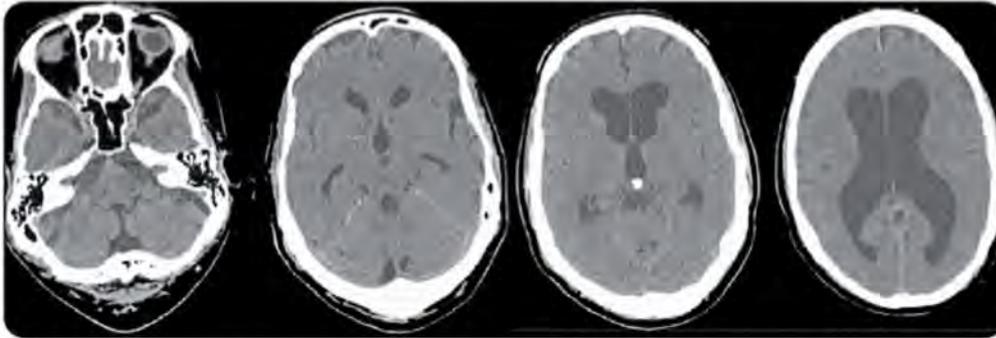

Figure 32. Hydrocephalus: ventricular dilatation (may see periventricular low attenuation due to transependymal CSF flow)

Table 16. Two Types of Hydrocephalus

Type	Cause
Communicating/Extraventricular	Impaired CSF reabsorption with unobstructed flow in ventricular system; imaging shows all ventricles dilated
Non-Communicating	Obstruction within the ventricular system (e.g. mass obstructing the aqueduct or foramen of Monro); imaging shows dilatation of ventricles proximal to the obstruction

**Nuclear Medicine**

- SPECT imaging using <sup>99m</sup>Tc-exametazime (HMPAO) and <sup>99m</sup>Tc-bicisate (ECD) assesses cerebral blood flow, as radionuclides diffuse rapidly across the blood-brain barrier and become trapped within neurons at a magnitude proportional to cerebral blood flow
- <sup>18</sup>F:DG PET imaging assesses cerebral metabolic activity
- indications: differentiation of residual tumour vs. radiation necrosis; localization of epileptic seizure foci, and evaluation of atypical dementia

**Approach to Head Computed Tomography**

- think anatomically, work from superficial to deep
- scan: confirm the time and imaging of the correct patient, whether contrast was used, patient alignment, and presence of artifact
- skin/soft tissue: examine the soft tissue superficial to the skull for thickening suggestive of hematoma or edema; also evaluate the ear, orbital contents (globe, fat, muscles), parotid glands, muscles of mastication (masseter, temporalis, pterygoids), visualize pharynx
- bone and airspace (use the bone window): check calvarium, visualize mandible, visualize C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for fractures or opacity that may suggest fluid, pus, blood, or tumour; status of the orbital floor in cases of facial trauma (coronal series best)
- dura and subdural space: crescent-shaped hyperdensity in the subdural space suggests subdural hematoma; lentiform hyperdensity in the epidural space suggests epidural hematoma; check symmetry of dural thickness, where increased thickness may suggest the presence of blood
- parenchyma: asymmetry of the parenchyma suggests midline shift; poor contrast between grey and white matter suggests possible infarction, tumour, edema, infection, or contusion; a hyperdensity in the parenchyma suggests an enhancing lesions, intracerebral hemorrhage, or calcification; if central grey matter nuclei (e.g. globus pallidus, putamen, internal capsule) are not visible, suspect infarct, tumour, or infection
- ventricles/sulci/cisterns: examine position of ventricles for evidence of midline compression/shift; hyperdensities in the ventricles suggest ventricular/subdural hemorrhage; enlarged ventricles suggest hydrocephalus; obliteration of sulci may suggest presence of edema causing effacement, possible blood filling in the sulci, or tumour; cistern hyperdensities may suggest blood, pus, or tumour

Figure 33. Sagittal (A) and coronal (B) views of the verteobasilar circulation (note the incidental basilar tip aneurysm)

Approach to the CT Head

- Some = Scan
- Sore = Skin/Soft Tissue
- Brains = Bone/Airspace
- Demonstrate = Dura/Subdural space
- Pushed = Parenchyma
- Ventricles = Ventricles/Sulci/Cisterns

TIAs are not associated with radiological findings

Figure 34. Insular ribbon sign (arrow): hypodensity of insular cortex representing early sign of infarction

## Selected Pathology

- see [Neurosurgery](#), NS11 for intracranial mass lesions
- see [Neurosurgery](#), NS35 for head trauma and [Plastic Surgery](#), PL31 for craniofacial injuries
- see [Emergency Medicine](#), ER9 for spinal trauma
- see [Neurosurgery](#), NS28 and [Orthopaedic Surgery](#), OR25 for degenerative spinal abnormalities

### Cerebrovascular Disease (see [Neurosurgery](#), NS21)

- pathogenesis of stroke: see [Neurology](#), N51
- best imaging modality: MRI
- initial imaging modality: CT

Table 17. Temporal Findings of Infarction with CT and MRI

Time from Stroke Onset	CT	MRI
<b>Hyperacute (0-24 h)</b>	Usually normal within 6 h Edema (loss of grey-white matter differentiation – “insular ribbon sign”, effacement of sulci, mass effect) Hyperattenuating artery “hyperdense MCA sign” representing intravascular thrombus/emboli may be seen in ischemic stroke Hyperattenuating acute blood surrounded by edema may be seen in hemorrhagic stroke	Hyperintensity on DWI within minutes of arterial occlusion due to restriction of water movement indicative of cytotoxic edema Hypointensity on ADC within minutes Hyperintensity on T2/FLAIR approximately 6 h after onset due to edema (loss of grey-white matter differentiation, effacement of sulci, mass effect)
<b>Acute (24 h-1 wk)</b>	Increasing edema (seen as hypodensity) may result in significant positive mass effect	Continued hyperintensity on DWI Hypointensity on ADC reaches nadir at 3-5 d and begins to increase Continued hyperintensity on T2/FLAIR
<b>Subacute (1-3 wk)</b>	Resolution of edema leads to increased attenuation of infarcted area that may regain near-normal density and mask stroke “fogging phenomenon”	Continued hyperintensity on DWI due to “T2 shine through” Intensity on ADC continues to rise, pseudo-normalizes at 10-15 d, and then surpasses that of surrounding normal tissue Continued hyperintensity on T2/FLAIR
<b>Chronic (&gt;3 wk)</b>	Encephalomalacia (parenchymal volume loss) appears as hypodensity with negative mass effect	Hyperintensity on DWI/T2/FLAIR progressively decreases ADC intensity remains elevated

- carotid artery disease
  - best imaging modality: Duplex (Doppler U/S)
  - other modalities: MRA or CTA if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)

### Multiple Sclerosis (see [Neurology](#), N55)

- best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
- characteristic lesion locations: juxtacortical (grey-white junction), periventricular, infratentorial, and spinal cord
- cerebral lesions typical of MS:
  - involvement of the brainstem, cerebellum, and corpus callosum
  - “Dawson’s fingers” refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
  - plaques usually hyperintense on T2, and hypointense on T1
  - perivascular and interstitial edema may be prominent; enhances with gadolinium contrast when actively inflamed
- spinal cord lesions typical of MS:
  - little or no cord swelling
  - less likely to enhance with gadolinium contrast
  - incomplete involvement of the cord in cross-section (dorsolateral common)

### CNS Infections

- meningitis
  - pathogenesis: inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via direct seeding of organisms through areas not protected by the blood-brain barrier (choroid plexus or circumventricular organs)
  - pathogens include: *S. pneumoniae*, *H. influenzae*, *N. meningitidis*, *L. monocytogenes*
  - best imaging modality: MRI (T2-weighted/FLAIR)
  - findings:
    - meningeal enhancement (following the gyri/sulci and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
    - a normal MRI does not rule out leptomeningitis
- herpes simplex encephalitis (see [Infectious Diseases](#), ID18)
  - pathogenesis: inflammation of the brain parenchyma secondary to infection with herpes simplex virus, asymmetrically affects the limbic regions of the brain (i.e. temporal lobes, orbitofrontal region, insula, and cingulate gyrus)
  - best imaging modality: MRI (T1- and T2-weighted)

DDx for Ring Enhancing Cerebral Lesion

MAGIC DR  
Metastasis  
Abscess  
Glioblastoma multiforme  
Infarction (subacute/chronic)  
Contusion/hematoma  
Demyelinating disease (e.g. MS)  
Radiation necrosis

Figure 35. CT image of early infarct: hyperdense artery

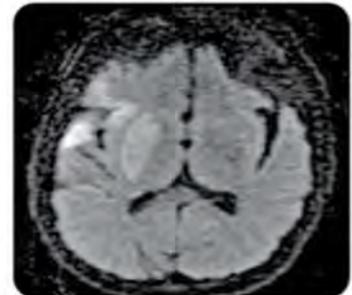

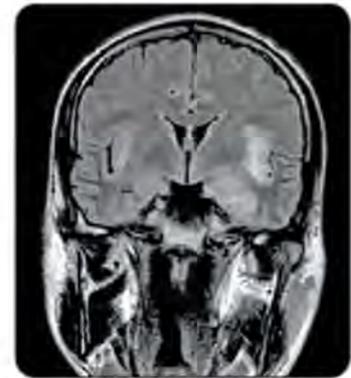

Figure 36. DWI of patient with right frontotemporal infarct

Figure 37. T2-weighted FLAIR (A) sagittal (B) axial images of multiple sclerosis with periventricular “Dawson’s Fingers”

- findings:
  - acute (within 4-5 d): asymmetric high intensity lesions on T2 MRI in temporal and inferior frontal lobes strongly suggestive
  - CT may show hypodensity in temporal lobe and insula; rarely basal ganglia involvement
  - long-term may show parenchymal loss to affected areas
- DDX: infarct, tumour, status epilepticus, limbic encephalitis
- **cerebritis/cerebral abscess**
  - pathogenesis: an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms, commonly located in the distribution of the MCA
  - pathogens include: *S. aureus* (often in IV drug users, nosocomial), *Streptococcus*, Gram negative bacteria, *Bacteroides*
  - best imaging modality: MRI including DWI imaging series (abscess will be DWI positive); CT still used as a viable alternative
  - findings according to one of four stages of abscess formation:
    - early cerebritis (1-3 d): inflammatory infiltrate with necrotic centre, low intensity on T1, high intensity on T2
    - late cerebritis (4-9 d): ring enhancement may be present
    - early capsule (10-13 d): ring enhancement
    - late capsule (>14 d): well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperintensity on T2

**Figure 38. T2-weighted (FLAIR) coronal image of herpes simplex virus encephalitis affecting temporal lobes**

## Musculoskeletal System

### Modalities

- see *Imaging Modalities. M12* for advantages and disadvantages of the following:

#### Plain Film/X-Ray

- usually initial study used in evaluation of bone and joint disorders
- indications: fractures and dislocations, arthritis, assessment of malunion or nonunion, orthopaedic hardware, and bone lesions (initial)
- minimum of two orthogonal views (usually AP and lateral) to rule out a fracture/assess bone lesion
- image the joint proximal and distal to injury site to ensure there is no associated dislocation or second fracture site, particularly important with bony rings (e.g. radius/ulna, tibia/fibula)
- soft tissue assessment limited, but can identify joint effusions (elbow, knee), soft tissue gas (necrotizing fasciitis) and radiodense foreign bodies

#### CT

- evaluation of fine bony detail
- indications: preoperative assessment of complex, comminuted, intra-articular, or detection of radiographically-occult fractures including scaphoid, skull, spine, pelvis, midfoot, and calcaneus
- evaluation of soft tissue calcification/ossification and bone tumours

#### MRI

- indications: evaluation of internal derangement of joints (e.g. ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses, infection of bone (osteomyelitis), occult fracture assessment

#### Ultrasound

- indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection and characterization of soft tissue masses (i.e. cystic or solid), detection of foreign bodies, U/S-guided biopsy and injections, bone/joint evaluation pre-ossification (e.g. DDH in early months), dynamic imaging (i.e. snapping hip, extensor carpi ulnaris subluxation), small joint doppler assessment for arthritis
- Doppler determines vascularity of structures

#### Nuclear Medicine (Primarily Bone Scan/Skeletal Scintigraphy)

- determines the location and extent of bony lesions using radiopharmaceuticals ( $^{99m}\text{Tc}$ -methylene diphosphonate)
- increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
- indications: bone lesion characterization, occult fractures (spine, scaphoid, small bones), bone pain of unknown origin, staging or restaging of cancer with bony metastases (or primary bone cancer), imaging of polyarthritis, imaging of arthroplasty complications like loosening or infection, osteomyelitis imaging
  - when used to assess for osteomyelitis, usually done in combination with gallium or white blood cell scan
- DDX of positive bone scan: bone metastases (primary breast, prostate, lung, thyroid), primary bone tumour, arthritis, fracture, infection, anemia, Paget's disease
- caution: bone tumours that do not elicit osteoblastic response are often occult on bone scan (myeloma, highly vascular tumours such as RCC, or thyroid carcinoma)

#### Characterization of Rotator Cuff Tears: Ultrasound vs. Magnetic Resonance Imaging

*J Orthopaedics* 2017;40:e124-e130

**Purpose:** Determine whether US or MRI is more accurate and precise in evaluating the characteristics of full-thickness rotator cuff tears in a surgical population.

**Methods:** Review of 114 patients who underwent repair of a full-thickness rotator cuff tear over a 1 yr period. Of these patients, 61 had both preoperative MRI and US for review. Three radiologists evaluated each US and MRI in a randomized, blinded fashion on 2 occasions. Tear size, retraction status, muscle atrophy, and fatty infiltration were analyzed and compared between the 2 modalities.

**Results:** US measurements were statistically smaller in both tear size ( $P=0.001$ ) and retraction status ( $P=0.001$ ) compared with MRI. MRI showed greater interobserver reliability in assessment of tear size, retraction status, and atrophy.

**Conclusion:** Independent observers are more likely to agree on measurements of the characteristics of rotator cuff tears when using MRI compared with US. As tear size increases, the 2 image modalities show greater differences in measurement of tear size and retraction status. US may be best used to identify a tear, and MRI is superior for use in surgical planning for larger tears.

## Approach to Bone X-Rays

- identification: name, MRN, age of patient, type of study, region of investigation
- soft tissues: swelling, calcification/ossification
- joints: alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, symmetry of affected joint
- bone: periosteum, cortex, medulla, trabeculae, density, articular surfaces, bone destruction, bone production, appearance of the edges or borders of any lesions

## Trauma

### Fracture/Dislocation

- description of fractures
- site of fracture (bone, region of bone, intra-articular vs. extra-articular)
- pattern of fracture line (simple vs. comminuted)
- displacement (distal fragment with reference to the proximal fragment)
- soft tissue involvement (calcification, gas, foreign bodies)
- type of fracture (stress vs. pathologic)
- for specific fracture descriptions and characteristics of fractures, see [Orthopaedic Surgery, OR5](#)

## Arthritis

- see [Rheumatology](#) for radiographic features of specific arthritides

## Bone and Soft Tissue Tumours

### Bone Tumours

- benign bone lesions (e.g. hemangiomas, enostoses, enchondromas) are more common than malignant bone lesions
- primary bone tumours are rare after 3rd decade; metastases to bone are relatively common after 3rd decade
- MRI is helpful for detection, characterization, staging, soft tissue involvement and surgical planning
- plain film is important for assessing pattern of destruction, mineralization, and aggressiveness
- biopsy may be required if no primary is identified, or suspect primary bone tumour
- may present with pathological fractures or bone pain
- most common metastatic bone tumours: breast, prostate, lung
- for specific bone tumours, see [Orthopaedic Surgery, OR50](#)

### Soft tissue Tumours

- soft tissue masses are most commonly benign
- common benign soft tissue masses include lipomas, benign peripheral nerve sheath tumours, and vascular malformations
- soft tissue sarcomas are uncommon but require urgent workup and specialized treatment
- U/S is helpful for differentiating lipoma from cyst from mass
- MRI is helpful for diagnostic workup
- if the mass is not clearly benign, biopsy or wide excision is required for diagnosis

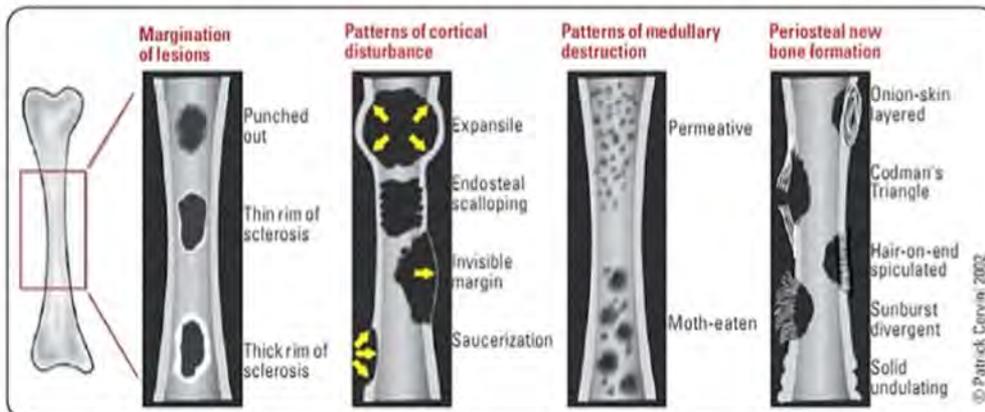

Figure 41. Radiographic appearance of bone remodelling and destruction processes

Figure 39. X-ray findings of first carpometacarpal joint: normal image (left) and osteoarthritis (right) with joint space narrowing and subchondral sclerosis

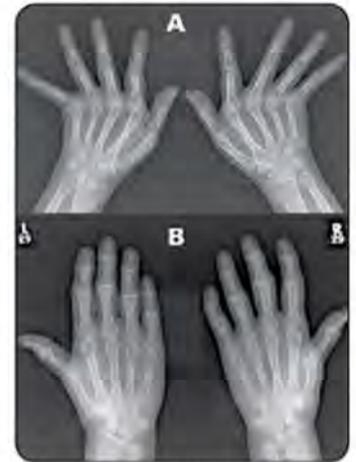

Figure 40. X-ray findings of rheumatoid arthritis (A) compared with osteoarthritis (B)

Lytic = decreased density  
Sclerotic = increased density

**Table 18. Distinguishing Benign from Malignant Bone Lesions on X-Ray**

Benign	Malignant
No periosteal reaction or benign appearing reaction (e.g. uniform smooth periosteal thickening as seen in a healing fracture)	Acute periosteal reaction - Codman's triangle - "Onion skin" - "Sunburst"
Sharp, well-demarcated borders, narrow zone of transition (between lesion and normal bone, suggesting slow-growing lesion)	Poorly defined borders, with a wide zone of transition, or infiltrative (suggesting fast-growing lesion)
Well-developed bone formation	Varied bone formation
Intraosseous and even calcification	Extrasosseous and irregular calcification
No soft tissue mass	Soft tissue mass present
No cortical destruction or uniform cortical destruction in some low grade and locally aggressive benign lesions	Aggressive cortical destruction or tumour infiltration without cortical destruction

Adapted from: Buckholz RW, Heckman JD, Rockwood and Green's Fractures in Adults, Volume 1, Philadelphia: Lippincott Williams & Wilkins, 2001, p558

## Infection

### Osteomyelitis

- modern workup includes MRI or x-ray
  - x-ray can detect osseous destruction seen with subacute osteomyelitis (>1 week) or chronic change, and can detect lucencies surrounding infected orthopedic hardware
  - MRI is more sensitive, with loss of normal fatty T1 marrow signal diagnostic of osteomyelitis, and can also assess for extra-osseous soft tissue involvement or spread
- nuclear medicine (<sup>99m</sup>Tc, followed by <sup>111</sup>In-labeled white cell scan or gallium radioisotope scan) may be used where available, or in the setting of hardware

### Septic Arthritis

- surgical emergency in large joints (i.e. hip)
- x-ray usually normal early
- aspiration required if concern for septic arthritis
- imaging modalities can detect joint fluid in some points, but imaging cannot rule out septic arthritis

### Necrotizing Fasciitis

- surgical emergency
- X-ray can detect gas, but absence does not rule out necrotizing fasciitis
- in the perineum, referred to as Fournier's gangrene
- surgical referral required

## Metabolic Bone Disease

### Osteoporosis

- reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
  - typical sites of fragility fracture: spine, hip, pelvis, wrist, humerus, rib
- DEXA: gold standard for measuring bone mineral density, typically measured hip and lumbar spine
- CAROC guidelines for use of DEXA: diagnosis, determining fracture risk/therapy, and monitoring
  - diagnosis driven by T-score: the number of standard deviations from the young adult mean, most clinically valuable
    - osteopenia: -2.5 < T-score < -1
    - osteoporosis: T-score ≤ -2.5
  - Z-score: the number of standard deviations from the age-matched mean, helpful in diagnosing secondary osteoporosis
  - risk of fracture: patients classified as low, medium or high risk based on bone mineral density, age, history of previous fragility fractures, steroid therapy. Presence of certain criteria such as hip or spine fragility fracture automatically places patients in the high risk category
- see [Endocrinology, E46](#)

### Hyperparathyroidism

- most common cause is renal failure (secondary hyperparathyroidism)
- chondrocalcinosis is a common complication
- calcium crystal deposition in hyaline cartilage or fibrocartilage (including arteries and peri-articular soft tissue)
- resorption of bone typically in hands (subperiosteal and at tufts), sacroiliac joints (subchondral), skull ("salt and pepper" appearance), subligamentous resorption (ischial tuberosity, trochanters, and clavicle), osteoclastoma (brown tumours)
- "rugger jersey spine": band-like osteosclerosis at superior/inferior margins of vertebral bodies

Osteoporosis  
Reduced amount of bone

Osteomalacia  
Normal amount of bone, but reduced  
Mineralization of normal osteoid

**Paget's Disease**

- abnormal remodelling involving single or multiple bones – especially skull, spine, pelvis
- 3 phases: 1st phase = lytic, 2nd phase = mixed (lytic/sclerotic), 3rd phase = sclerotic
- coarsening of the trabeculae with bone expansion
- bone softening/bowing
- bone scintigraphy will reveal high activity
- thickened cortex; widening of diploe in skull, osteoporosis circumscripta (lytic phase in skull); "blade of grass" sign (lytic phase in a long bone like the femur); "picture frame" appearance to vertebra (due to thickening and sclerosis of vertebral cortex)
- see [Endocrinology, E50](#)

## Nuclear Medicine

### Brain

- $^{99m}\text{Tc}$ -exametazime (HMPAO) and  $^{99m}\text{Tc}$ -bicisate (ECD) imaging used in SPECT to assess cerebral blood flow and cellular metabolism
  - taken up predominantly in grey matter
  - used for dementia, traumatic brain injury; and to a lesser extent vasculitis, neuropsychiatric disorders, and occasionally stroke
- PET imaging to assesses metabolic activity
  - used for dementia imaging, grading and staging of brain tumours, occasionally for seizure disorder imaging, and vasculitis
- CSF imaging via intrathecal administration of  $^{111}\text{In}$  DTPA
  - to evaluate CSF leak or to differentiate normal pressure hydrocephalus from brain atrophy
- CSF shunt evaluation for obstruction (most commonly ventriculoperitoneal) with sterile or pyrogen free  $^{99m}\text{Tc}$  (usually) or  $^{111}\text{In}$ -DTPA

### Thyroid

**Radioactive Iodine Uptake (see [Endocrinology, E25](#))**

- index of thyroid function (trapping and organification of iodine)
- radioactive  $^{123}\text{I}$  given PO to fasting patient (small quantity) and percentage of administered iodine taken up by thyroid is measured
- increased RAIU: toxic multinodular goitre, toxic adenoma, Graves' disease
- decreased RAIU: subacute thyroiditis, late Hashimoto's disease, exogenous thyroid hormone or iodine, falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed, taking supplements containing desiccated thyroid)
- important – iodine uptake helps in the differential of hyperthyroidism only, not hypothyroidism

**Thyroid Imaging (Scintiscan)**

- $^{99m}\text{Tc}$ -pertechnetate IV or radioactive iodine ( $^{123}\text{I}$ )
- provides functional anatomic detail
- hot (hyperfunctioning) lesions: usually benign (e.g. adenoma, toxic multinodular goitre), cancer unlikely (<1%) – No FNA
- cold (hypofunctioning) lesions: cancer must be considered until biopsy negative even though only 6-10% are cancerous – decision to biopsy should be based on clinical and sonographic features
- isointense i.e. "warm" lesions: cancer must be considered as an isointense lesion; may represent cold nodules superimposed on normal tissue; if cyst suspected, correlate with U/S

**Radioiodine Ablation**

- $^{131}\text{I}$  for Graves' disease, multinodular goitre, thyroid cancer (in the case of thyroid cancer, ablation performed at higher dose and after thyroidectomy)
- serum thyroglobulin used to detect recurrent thyroid cancer in a patient who has received ablation
- advice should be given for patient-specific precautions to remain away from family members and caregivers to reduce radiation exposure after thyroid ablation, do not initiate pregnancy for 6 mo, small risk of exophthalmos, thyroid storm, secondary malignancy

### Respiratory

**V/Q Scan**

- evaluate areas of lung in which there is a ventilation/perfusion mismatch
- ventilation scan – assess air flow within lungs
  - patient breathes radioactive gas (nebulized  $^{99m}\text{Tc}$ -DTPA,  $^{133}\text{Xe}$ , or most commonly Technegas™) through a closed system, filling alveoli proportionally to ventilation
  - ventilation scan defects indicate: airway obstruction (i.e. air trapping), chronic lung disease, bronchospasm, tumour mass obstruction

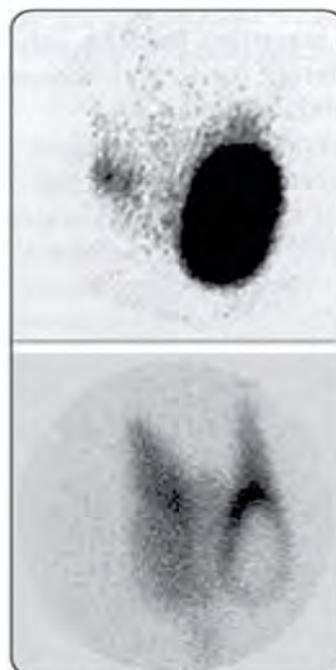

Figure 42. Multinodular goitre (top). Cold nodule (bottom)

**V/Q Scan**  
For PE investigation: normal scan makes PE unlikely  
Probability of PE: high 80-100%, intermediate 20-80%, low <20%, very low <10%

- perfusion scan – assess blood circulation within lungs
  - radiotracer injected IV ( $^{99m}\text{Tc}$ -MAA) → trapped in pulmonary capillaries (0.1% of arterioles occluded) according to blood flow
  - relatively contraindicated in severe pulmonary HTN, right-to-left shunt, previous history of pneumonectomy, and small children
- indicated to rule out PE
  - areas of lung that are well-ventilated but not perfused (unmatched defect) are suspicious for acute infarction
  - defects are wedge-shaped, extend to periphery, usually bilateral and multiple
  - useful in finding clinically important emboli
- modified V/Q scan (perfusion only, lower dose contrast) may be used for pregnant patients if CXR is normal or if there are ventilatory problems

#### Ventilation Scan Defects Indicate...

ABC Tumour  
Airway obstruction  
Bronchospasm  
Chronic lung disease  
Tumour mass obstruction

#### Perfusion Scan Defects Indicate...

Reduced blood flow due to PE  
COPD  
Asthma  
Bronchogenic carcinoma  
Inflammatory lung diseases (pneumonia, sarcoidosis)  
Mediastinitis  
Mucous plug  
Vasculitis

## Cardiac

### Myocardial Perfusion Scan/Nuclear Stress Test

- indications: diagnose and assess treatment of coronary artery disease (CAD), preoperative risk stratification, viability testing before percutaneous intervention or bypass surgery
- $^{99m}\text{Tc}$ -sestamibi or  $^{99m}\text{Tc}$ -tetrofosmin is injected: at peak exercise (85% max predicted heart rate by the Bruce protocol, chest pain, ECG changes), after persantine challenge (vasodilator), or after dobutamine infusion (chronotropic, again to 85% predicted heart rate)
- persistent defect (present at rest and stress) suggests infarction or myocardial scar
- reversible defect (only present during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- COURAGE trial indicates that patients with >10% ischemic myocardium benefit most from revascularization
- see [Cardiology and Cardiac Surgery, C16](#)

### Radionuclide Ventriculography

- $^{99m}\text{Tc}$ -tagged to red blood cells
- non-invasive method of assessing ventricular function and intracardiac hemodynamics (i.e. ejection fraction, presence of shunts, ventricular volume and regional wall motion)
- cardiac MUGA scan sums multiple cardiac cycles, usually at least 200 beats
- indications: most commonly to monitor potential cardiac toxicity with chemotherapy or herceptin, as a gold standard of ejection fraction in defibrillator workup

## Abdomen and Genitourinary System

### HIDA Scan (Cholescintigraphy)

- IV injection of  $^{99m}\text{Tc}$ -disofenin (DISIDA) or  $^{99m}\text{Tc}$ -mebrofenin which is bound to protein, taken up by hepatocytes, and excreted into the biliary system
- indicated for patients who are suspected of having an obstruction in the biliary tract, to assess for bile leaks postoperatively, and for biliary dyskinesia
- indicated in workup of cholecystitis when abdominal U/S result is equivocal:
  - acute cholecystitis: no visualization of gallbladder at 4 h or 1 h after administration of morphine
  - chronic cholecystitis: no visualization of gallbladder at 1 h but seen at 4 h or after morphine administration
- DDX of obstructed cystic duct: acute/chronic cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting <4 h or >24 h

### RBC Scan

- IV injection of radiotracer with sequential images of the abdomen ( $^{99m}\text{Tc}$  RBCs)
- GI bleed evaluation
  - if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed
  - if bleeding acutely at >0.5 mL/min, use angiography (more specific, better for localizing, both diagnostic and therapeutic)
- liver lesion evaluation
  - hemangioma has characteristic appearance: cold early (limited blood flow to lesion), fills in later (accumulation of tagged cells greater than surrounding liver parenchyma)

### Urea Breath Test

- indication: diagnosis of gastric *H. pylori* infection
- patient administered  $^{14}\text{C}$ -labelled urea orally, urea metabolized by *H. pylori* to ammonia and  $^{14}\text{CO}_2$ ,  $^{14}\text{C}$ -labelled  $\text{CO}_2$  is measured via plastic filament detectors or liquid scintillation

Advanced ischemia patients should receive surgery rather than thrombolysis

Chemoembolization delivers chemotherapy directly into the tumour through its feeding blood supply and traps the drug in place by embolization

### Functional Renal Imaging

- evaluation of renal function and anatomy using  $^{99m}\text{Tc}$  DTPA (static imaging) or  $^{99m}\text{Tc}$  MAG3 (dynamic imaging)
- frequently used to provide index of relative function between two kidneys
- in adults, used to assess for UPJ obstruction, renal transplants, or as a nuclear GFR study in patients wanting to donate kidneys
- in children, used to assess for pyelonephritis and reflux

## Interventional Radiology

### Vascular Procedures

#### Angiography

- injection of contrast material through a catheter placed directly into an artery or vein to delineate vascular anatomy
- can be used in the operating room to provide fluoroscopic guidance for exposure of diseased vessel
- indications: diagnosis of primary occlusive or stenotic vascular disease, aneurysms, coronary, carotid and cerebral vascular disease, PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (endovascular aneurysm repair, thrombolysis, stenting, and angioplasties)
- complications (<5% of patients): puncture site hematoma, pseudoaneurysm, dissection, thrombosis, infection, AV fistula, embolic occlusion of a distal vessel
- due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (colour Doppler U/S, CTA, and MRA)
- see *Neuroradiology*, M119

#### Percutaneous Transluminal Angioplasty and Stents

- introduction and inflation of a balloon into a stenosed or occluded vessel to restore distal blood supply
- common alternative to surgical bypass grafting with 5 yr patency rates similar to surgery, depending on site
- renal, iliac, femoral, mesenteric, subclavian, coronary, and carotid artery stenoses are amenable to treatment
- vascular stents may help improve long-term results by keeping the vessel wall patent after angioplasty; also used for angioplasty failure or complications
- stent grafts (metal mesh covered with durable fabric) may provide an alternative treatment option for aneurysms and AV fistulas
- complications: similar to angiography, but also includes vessel rupture

#### Thrombolytic Therapy

- may be systemic (IV) or catheter directed
- infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
- can restore blood flow in a vessel obstructed with a thrombus or embolus
- indications: treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of deep venous thrombosis (DVT) or PE
- complications: bleeding, stroke, distal embolus, reperfusion injury in delayed intervention with myoglobinuria, and renal failure if advanced ischemia present

#### Embolization

- injection of occluding material into vessels
- permanent agents: amplatzer plugs, coils, glue, and onyx
- temporary: gel foam, autologous blood clots
- indications: management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of arteriovenous malformation, preoperative treatment of vascular tumours (bone metastases, renal cell carcinoma), ovarian vein embolization for chronic pelvic pain (pelvic venous disease), varicocele embolization for infertility, symptomatic uterine fibroids
- complications: post-embolization syndrome (pain, fever, leukocytosis), unintentional embolization of a non-target organ with resultant ischemia

#### Inferior Vena Cava Filter

- insertion of temporary or permanent metallic “umbrellas” to mechanically trap DVT emboli to prevent subsequent PE
- inserted via femoral vein, jugular vein, or basilic vein
- usually placed infrarenally to avoid renal vein thrombosis
- indications: contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation therapy necessitating termination of anticoagulation (e.g. life-threatening hemorrhage)

#### Ultrasound vs. Fluoroscopic Guided Femoral Arterial Access in Noncardiac Vascular Patients

*J Vasc Surg* 2019; doi:10.1016

**Purpose:** To compare the procedural outcomes and complication rates of US-guided common femoral artery (CFA) access to fluoroscopic guidance in noncardiac procedures.

**Methods:** A total of 635 patients undergoing femoral access for noncardiac diagnostic or interventional procedures were randomized 1:1 to receive either fluoroscopic or US-guided access. The primary endpoint of the study was successful CFA cannulation.

**Results:** Successful CFA cannulation occurred in 93% of US-guided procedures compared with 86% of fluoroscopy-guided access ( $P=0.002$ ). US guidance was associated with increased rates of first-attempt success, fewer inadvertent venipunctures, and decreased median time to cannulation compared with fluoroscopy. Rates of complications did not differ at 24 h or 30 to 90 d in fluoroscopy vs. US-guided access.

**Conclusions:** In comparison to fluoroscopy, US-guided CFA cannulation had a higher rate of success, faster cannulation, and fewer venipunctures in the absence of increased complications.

#### Thrombolytic Therapy for Pulmonary Embolism

*Cochrane DB Syst Rev* 2015;9:CD004437

**Purpose:** To assess the effects of thrombolytic therapy in patients with acute pulmonary embolism (PE).

**Methods:** Systematic review of RCTs evaluating thrombolytic therapy followed by heparin vs. heparin alone, heparin plus placebo or surgical intervention in patients with acute PE. Studies comparing two different thrombolytic agents or different doses of the same thrombolytic drug were not considered eligible. Main outcomes of interest were death, recurrence of PE, and major and minor hemorrhagic events.

**Results:** Eighteen trials with 2197 participants were included. Thrombolytics plus heparin were associated with a reduction in odds of death relative to heparin alone or heparin plus (OR=0.57, 95% CI, 0.37 to 0.87,  $P=0.02$ ) and recurrence of PE (OR=0.51, 95% CI, 0.29 to 0.89,  $P=0.02$ ). Incidence of major and minor hemorrhagic events was statistically significantly higher in the thrombolytics group than the control group (OR=2.90, 95% CI, 1.95 to 4.31,  $P<0.001$ ). Length of hospital stay (mean difference (MD) -1.35, 95% CI, -4.27 to 1.58) and quality of life were similar between groups. Based on one study, stroke occurred more often in the thrombolytics group (OR=12.10, 95% CI, 1.57 to 93.39).

**Conclusion:** Low-quality evidence suggests thrombolytics reduce death following acute PE compared with heparin and may be helpful in reducing PE recurrence, but may cause more major and minor hemorrhagic events and stroke events.

Figure 43. Retrievable IVC filter

### Central Venous Access

- variety of devices available (PICC, external tunneled catheter (Hickman or dialysis catheters), subcutaneous port (Portacath®))
- indications: chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
- complications: venous thrombosis, central venous stenosis, infection including sepsis, and pneumothorax

#### Indications for Central Venous Access

##### FAT CAB

- Fluids
- Antibiotics
- TPN
- Chemotherapy
- Administration of blood
- Blood sampling

## Nonvascular Interventions

### Percutaneous Biopsy

- alternative to open surgical procedure
- many sites are amenable to biopsy using U/S, fluoroscopy, CT, or MR guidance
- complications: false negative (sampling error or tissue necrosis), hemorrhage (particularly for splenic biopsies), pneumothorax in 30% of lung biopsies (chest tube required in ~5%), needle tract seeding, acute pancreatitis (pancreatic biopsies), bleeding from liver biopsies in patients with uncorrectable coagulopathies or ascites (can be minimized with transjugular approach)

### Abscess Drainage

- placement of a drainage catheter into a deep infected fluid collection
- superficial skin and soft tissue infections are best treated with incision and drainage; needle aspiration and drainage catheter insertion is not recommended for cutaneous abscesses
- administer broad spectrum IV antibiotics prior to procedure
- routes: percutaneous (most common), transgluteal, transvaginal, transrectal
- complications: hemorrhage, injury to intervening and nearby structures (e.g. bowel), bacteremia, sepsis, access failure

### Percutaneous Biliary Drainage/Cholecystostomy

- placement of drainage catheter ± metallic stent into obstructed biliary system (PBD) or gallbladder (cholecystostomy) for relief of obstruction or infection
- percutaneous gallbladder access can be used to crush or remove stones
- indications
  - cholecystostomy: acute cholecystitis
  - PBD: biliary obstruction secondary to stone or tumour, cholangitis, acute biliary pancreatitis
- complications
  - acute: sepsis, hemorrhage
  - long-term: tumour ingrowth and stent occlusion

### Percutaneous Nephrostomy

- placement of catheter into renal collecting system
- indications: hydronephrosis, pyonephrosis, ureteric injury with or without urinary peritonitis (traumatic or iatrogenic)
- complications: bacteremia and septic shock, hematuria due to pseudoaneurysm or AV fistulas, injury to adjacent organs

### Gastrostomy/Gastrojejunostomy

- percutaneous placement of catheter directly into either stomach (gastrostomy) or through stomach into small bowel (transgastric jejunostomy)
- indications: prolonged inadequate oral intake (e.g. impaired swallowing, oromotor dysfunction, dysphagia esophageal obstruction, or decompression in gastric outlet obstruction)
- complications: gastroesophageal reflux with aspiration, peritonitis, hemorrhage, bowel or solid organ injury, death

### Radiofrequency Ablation

- U/S- or CT-guided probe is inserted into tumour, radiofrequency energy delivered through probe causes heat deposition and tissue destruction
- indications: hepatic tumours (HCC and metastases), renal tumours, lung tumours
- complications: destruction of neighbouring tissues and structures, bleeding, periprocedural embolism

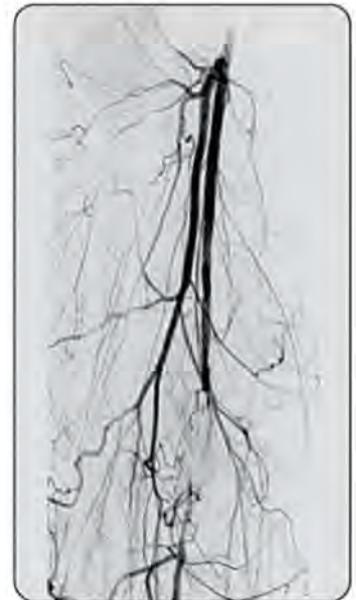

Figure 44. Femoral arteriogram: distal occlusion of superficial femoral artery

# Breast Imaging

## Modalities

### Mammography

#### Description

- x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities (see [General and Thoracic Surgery, GS65](#))
- routine evaluation involves two standard views: cranio-caudal and medial-lateral-oblique

#### Indications

- screening (for guidelines, see [Family Medicine, FM4](#))
  - guidelines may vary by region
- surveillance
  - follow-up of women with previous breast cancer
- diagnostic: includes mammography with special views and/or U/S
  - workup of an abnormality that may be suggestive of breast cancer including a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, overlying skin changes, and spontaneous serous or sanguinous nipple discharge from a single duct
  - women with abnormal screening mammograms
  - suspected complications of breast implants

**Table 19. Breast Imaging Reporting and Data System (BI-RADS®) Mammography Categories**

Assessment Categories	Imaging Findings	Likelihood of Malignancy (%)	Follow-Up Recommendations
BI-RADS 0	Incomplete	N/A	Additional imaging Comparison to prior films
BI-RADS 1	Negative	~0	Routine screening
BI-RADS 2	Benign	~0	Routine screening
BI-RADS 3	Probably benign Likelihood of malignancy is <2%	0-2	Unilateral mammogram at 6 mo
BI-RADS 4	Suspicious abnormality	3-94	Biopsy
BI-RADS 4A	Low suspicion for malignancy	3-10	Biopsy
BI-RADS 4B	Low suspicion for malignancy	11-50	Biopsy
BI-RADS 4C	Low suspicion for malignancy	51-94	Biopsy
BI-RADS 5	Highly suspicious of malignancy	≥95	Biopsy
BI-RADS 6	Malignancy confirmed by biopsy	100	Definitive therapy

### Breast Ultrasound

#### Indications

- characterization of palpable abnormalities
  - U/S is 1st line in <30 yr – denser breast tissue makes mammograms less sensitive in young females
  - first line in lactating and pregnant women
  - >30 yr need mammogram first
- further characterization of mammographic findings
- guidance for interventional procedures

### Breast MRI

#### Description

- contrast-enhanced MRI of the breasts
- sensitive for detecting invasive breast cancer (95-100%) but specificity variable (37-97%)
- for diagnosis, used only after mammography and U/S investigation
- use as a screening modality is limited to high-risk patients, in conjunction with mammography

#### Indications

- “problem-solving” of indeterminate findings following complete mammographic and U/S workup
- evaluation of occult primary in patients presenting with axillary metastases
- evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
- evaluation of previously diagnosed breast cancer: positive margins, recurrence, response to chemotherapy

#### Supplemental MRI Screening for Women with Extremely Dense Breast Tissue

NEJM 2019;381:2091-2102

**Purpose:** Extremely dense breast tissue is a risk factor for breast cancer with poor mammography detection. Data is needed on the use of supplemental MRI to improve early detection and reduce interval breast cancers in such patients.

**Methods:** Multicenter, RCT where 40373 women with extremely dense breast tissue and normal mammography were assigned to a group undergoing supplemental MRI or to a group that received mammography screening only. The primary outcome was the between-group difference in the incidence of interval cancers during a 2 yr screening period.

**Results:** The interval-cancer rate was 2.5 per 1000 screenings in the MRI invitation group and 5.0 per 1000 screenings in the mammography-only group ( $P<0.001$ ). The MRI cancer-detection rate among the women who actually underwent MRI screening was 16.5 per 1000 screenings. The positive predictive value was 17.4% (95% CI, 14.2 to 21.2) for recall for additional testing and 26.3% (95% CI, 21.7 to 31.6) for biopsy. The false positive rate was 79.8 per 1000 screenings.

**Conclusion:** The use of supplemental MRI screening in women with extremely dense breast tissue and normal results on mammography resulted in the diagnosis of significantly fewer interval cancers than mammography alone.

- high-risk screening
  - known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer, or untested first-degree relative of a carrier of such a gene mutation
  - family history consistent with a hereditary breast cancer syndrome and/or estimated personal lifetime cancer risk >25%
  - high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ)
  - radiation therapy to chest (before age 30)

## Breast Interventional Procedures

### Description

- includes core needle biopsy, stereotactic biopsy, MRI-guided biopsy, abscess drainage, and cyst aspiration

### Indications

- cystic mass: complex cyst, symptomatic, suspected abscess
- solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS<sup>®</sup> Category 4 or 5)
- suspicious calcifications: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS<sup>®</sup> Category 4 or 5) – stereotactic biopsy
- initial percutaneous biopsy procedure that was insufficient or discordant with imaging
- presurgical wire localization of a lesion

## Breast Findings

### Breast Masses

- definition: a space-occupying lesion seen in two different projections; if seen in only a single projection it should be called an “asymmetry” until its three-dimensionality is confirmed

**Table 20. Mammographic Features of Benign and Malignant Breast Masses**

	Benign	Malignant
Shape	Oval, round, lobular	Irregular
Margin	Circumscribed, well-defined	Indistinct, microlobulated, spiculated
Density	Radiolucent (oil cyst, lipoma, fibrolipoma, galactocele, hamartoma)	Radiodense
Calcifications (= mass)	Popcorn (hyalinizing fibroadenoma), lucent centred (oil cyst/fat necrosis), layering (milk of calcium), vascular, round, scattered	Pleomorphic (vary in size and shape), amorphous (indistinct), fine linear, coarse heterogeneous, regional, segmental, clustered

### Other Findings

- tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
- intramammary lymph node: typical lymph nodes are well-circumscribed, reniform and often have a fatty notch and centre; usually <1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty centre or notch) are well seen, the lesion is almost always benign and insignificant
- focal asymmetry: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
- if focal compression shows mass-like character – or if the area can be palpated – biopsy generally recommended

### Impact of 18F-FDG PET, PET/CT, and PET/MRI on Staging and Management as an Initial Staging Modality in Breast Cancer

Clin Nucl Med 2021;46(4):271-282

**Purpose:** To review the impact of 18F-FDG PET, PET/CT, and PET/MRI on staging and management during initial staging of breast cancer.

**Methods:** Studies which reported the proportion of breast cancer patients whose clinical stage or management were altered by PET scans were incorporated into a random-effects model.

**Results:** 4216 patients from 29 studies were included in the pooled random-effects model. Pooled proportions of alterations in stage was 25% (95% CI, 21% to 30%) and in management was 18% (95% CI, 14% to 23%).

**Conclusions:** Use of 18F-FDG PET, PET/CT, or PET/MRI leads to significant changes in staging and management for newly diagnosed breast cancer patients. PET should be considered for routine clinical use for initial staging of breast cancer.

# Landmark Radiology Trials

Trial Name	Reference	Clinical Trial Details
<b>VASCULAR PROCEDURES</b>		
PREPIC	NEJM 1998; 338:409-416	<p><b>Purpose:</b> To study the efficacy and safety of vena caval filters in preventing the formation of PEs in patients with proximal DVT.</p> <p><b>Methods:</b> RCT consisting of 400 patients with proximal DVT who were randomized to receive heparin in conjunction with either a caval filter or no filter.</p> <p><b>Results:</b> 2 patients within the treatment group and 9 patients within the control group had experienced a PE within 12 d. 37 patients within the treatment group and 21 patients within the control group experienced recurrent DVT within 2 yr.</p> <p><b>Conclusion:</b> Benefits of vena caval filters were counterbalanced by their risks. Filters resulted in no significant difference in mortality or other outcomes and although they prevented PE within 12 d, they increased the risk of recurrent DVT within 2 yr.</p>
EVAR	NEJM 2010;362:1863-1871	<p><b>Purpose:</b> To understand the long term implications of endovascular repair of abdominal aortic aneurysms.</p> <p><b>Methods:</b> RCT consisting of 1252 patients with abdominal aortic aneurysms were randomized to undergo an endovascular or open repair. The outcomes of interest included mortality, graft-related complications, and re-interventions.</p> <p><b>Results:</b> The 30 d postoperative mortality was lower in the endovascular repair group (1.8% vs. 4.3%). However, due to graft ruptures, the mortality rates equilibrated over time. The rates of graft-related complications and re-interventions were higher in the group that underwent endovascular repair.</p> <p><b>Conclusion:</b> Mortality at 30 d post-operation was significantly lower for endovascular repair compared to open repair. At the end of follow-up (5-10 yr), there was no significant difference in mortality and rates of complication were higher in the endovascular treatment group.</p>
NCT03702413	N Engl J Med 2022; 386:1303-1313	<p><b>Title:</b> Endovascular Therapy for Acute Stroke with a Large Ischemic Region</p> <p><b>Purpose:</b> Endovascular therapy is often avoided for patients with large cerebrovascular infarctions, however the benefits of endovascular therapy in combination with stroke medical care has not been studied.</p> <p><b>Methods:</b> RCT consisting of 203 patients with occlusion of large cerebral vessels and an Alberta Stroke Program Early Computed Tomographic Score between 3-5. Patients were randomized to receive endovascular therapy in conjunction with medical care or medical care alone. The primary outcome is a modified Rankin score between 0 and 3, 90-d post-treatment.</p> <p><b>Results:</b> A larger proportion of patients treated with endovascular therapy in conjunction with medical care achieved a modified Rankin score between 0 and 3 (31%) compared to medical care alone (12.7%).</p> <p><b>Conclusion:</b> In patients with large cerebrovascular occlusions, treatment with endovascular therapy in conjunction with medical care resulted in improved functional outcomes when compared to treatment with medical care alone.</p>
<b>VASCULAR PROCEDURES</b>		
EVAR	N Engl J Med 2022; 386:923-932	<p><b>Title:</b> Thyroidectomy without Radioiodine in Patients with Low-Risk Thyroid Cancer</p> <p><b>Purpose:</b> To assess the clinical benefit of postoperative radioiodine, after thyroidectomy in low-risk thyroid cancer.</p> <p><b>Methods:</b> RCT consisting of 730 patients with low-risk differentiated thyroid cancer undergoing thyroidectomy. Patients were randomized to either receive or not receive radioiodine. The outcomes of interest were the presence of abnormal radioiodine foci, abnormal neck ultrasound, or presence of increased thyroglobulin/thyroglobulin antibodies.</p> <p><b>Results:</b> There was no significant difference in postoperative abnormalities between patients that received (4.1%) and did not receive postoperative radioiodine (4.4%).</p> <p><b>Conclusion:</b> The use of radioiodine is negligible in the prevention of post-thyroidectomy abnormalities.</p>

DI	diabetes insipidus				

## Basic Anatomy Review

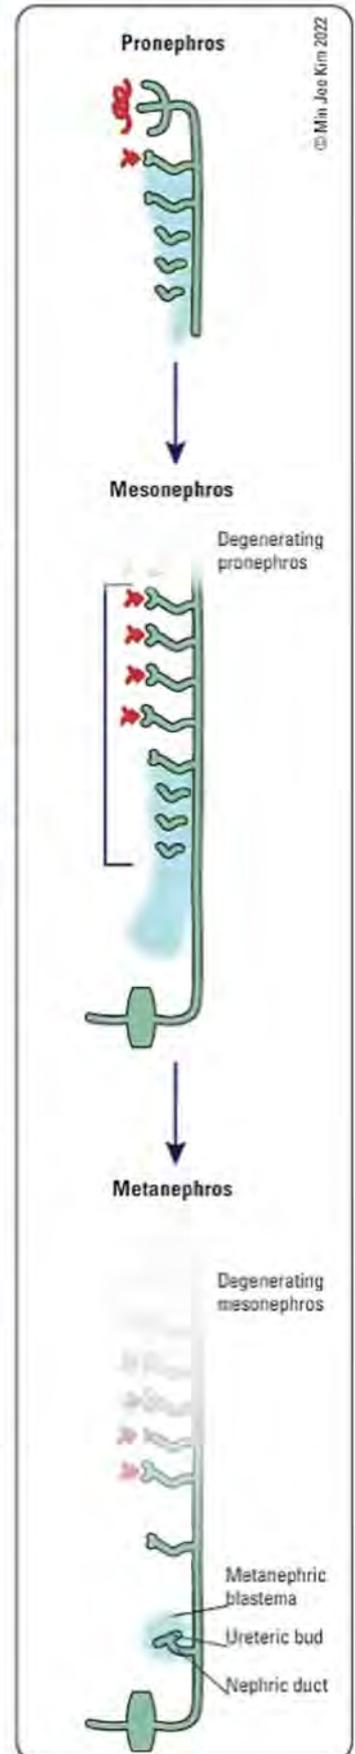

### Embryology of the Kidney

- originates from urogenital ridge of the intermediate mesoderm
- pronephros develops at the end of wk 3, then degenerates along with adjacent pronephric duct, disappearing completely by end of wk 4
- mesonephros develops caudal to the pronephros in wk 4, degenerates, and the remnants form the mesonephric (Wolffian) duct of the male reproductive system
- metanephros develops caudal to the mesonephros in wk 5 from the metanephric blastema and the ureteric bud of the mesonephric duct, forming the definitive kidney
  - excretory system: metanephric blastema → nephrons (i.e. glomeruli, Bowman's capsule, PCT, loop of Henle, DCT)
  - collecting system: ureteric bud → collecting ducts, calyces, renal pelvis, ureters
  - kidneys ascend from the pelvis into the retroperitoneum, gaining a blood supply from the abdominal aorta to form the renal arteries

### Renal Structure and Function

#### The Nephron

- basic structural and functional unit of the kidney, approximately 1 million per kidney
- 2 main components: glomerulus and attached renal tubule
- direction of blood flow: afferent arteriole → glomerular capillaries → efferent arteriole → vasa recta (the capillaries surrounding the tubules) → renal venules

**Figure 1. Kidney embryology**  
The pronephros and mesonephros develop then degenerate in succession. Ultimately, the definitive kidney develops from the metanephric blastema and ureteric bud of the mesonephric duct

**Table 1. Major Kidney Functions**

Function	Mechanism	Affected Elements
1. Waste Excretion	Glomerular filtration	Excretion of nitrogenous products of protein metabolism (urea, Cr)
	Tubular secretion	Excretion of organic acids (urate) and organic bases (Cr)
	Tubular catabolism	Breakdown and excretion of drugs (antibiotics, diuretics) and peptide hormones (most pituitary hormones, insulin, glucagon)
2. Electrolyte Balance and Osmoregulation	Tubular NaCl and water reabsorption	Controls volume status and osmolar balance
	Tubular K <sup>+</sup> secretion	Controls potassium concentration
	Tubular H <sup>+</sup> secretion	Acid-base balance
	HCO <sub>3</sub> <sup>-</sup> synthesis and reabsorption	Acid-base balance
	Tubular Ca <sup>2+</sup> , Mg <sup>2+</sup> , PO <sub>4</sub> <sup>3-</sup> transport	Alters Ca <sup>2+</sup> , Mg <sup>2+</sup> , PO <sub>4</sub> <sup>3-</sup> homeostasis
	Osmolyte synthesis	Increase osmolality of medullary cytoplasm to match medullary concentration gradient
3. Hormonal Synthesis	Erythropoietin production (cortex)	Red blood cell production
	Vitamin D activation: 25(OH)Vitamin D converted to 1,25(OH) <sub>2</sub> Vitamin D (proximal tubule)	Calcium homeostasis
	Renin production (juxtaglomerular apparatus)	Alters vascular resistance and aldosterone secretion
4. Blood Pressure Regulation	Na <sup>+</sup> excretion	Alters ECF volume
	Renin production	Alters vascular resistance
5. Glucose Homeostasis	Gluconeogenesis (from lactate, pyruvate, and amino acids)	Glucose supply maintained in prolonged starvation
	Clearance and degradation of circulating insulin	Maintains glucose homeostasis

### The Glomerulus

- site where blood constituents are filtered through to the kidney tubules for excretion or reabsorption
- filtration occurs across the glomerular filtration barrier (endothelium, GBM, podocytes) into Bowman's space
- there is a filtration barrier to albumin due to its size and negative charge, which is repelled by the negatively-charged GBM
- consists of following cell types:
  1. mesangial cells
    - structural function: support glomerular capillaries; can alter GFR through contractile activity
    - secretory function: matrix components, pro- and anti-inflammatory cytokines, and chemokines
    - secretions are responsible for minimizing the accumulation of macromolecules in the mesangial space and GBM
  2. capillary endothelial cells
    - part of the glomerular filtration barrier; help form the plasma filtration apparatus due to their fenestrated nature and glycocalyx; contribute to the production of the GBM
    - interface with blood – target for antibodies and contact site for neutrophils and lymphocytes
  3. visceral cells (podocytes)
    - part of the glomerular filtration barrier; helps form the plasma filtration apparatus due to their interdigitated foot process forming slit diaphragms; contribute to the production of extracellular matrix proteins (collagen and laminin) making up the GBM
  4. parietal cells
    - lines the interior of Bowman's capsule and contains a podocyte progenitor population
  5. juxtaglomerular cells
    - smooth muscle cells in lining of afferent arteriole; produce, store, and secrete renin

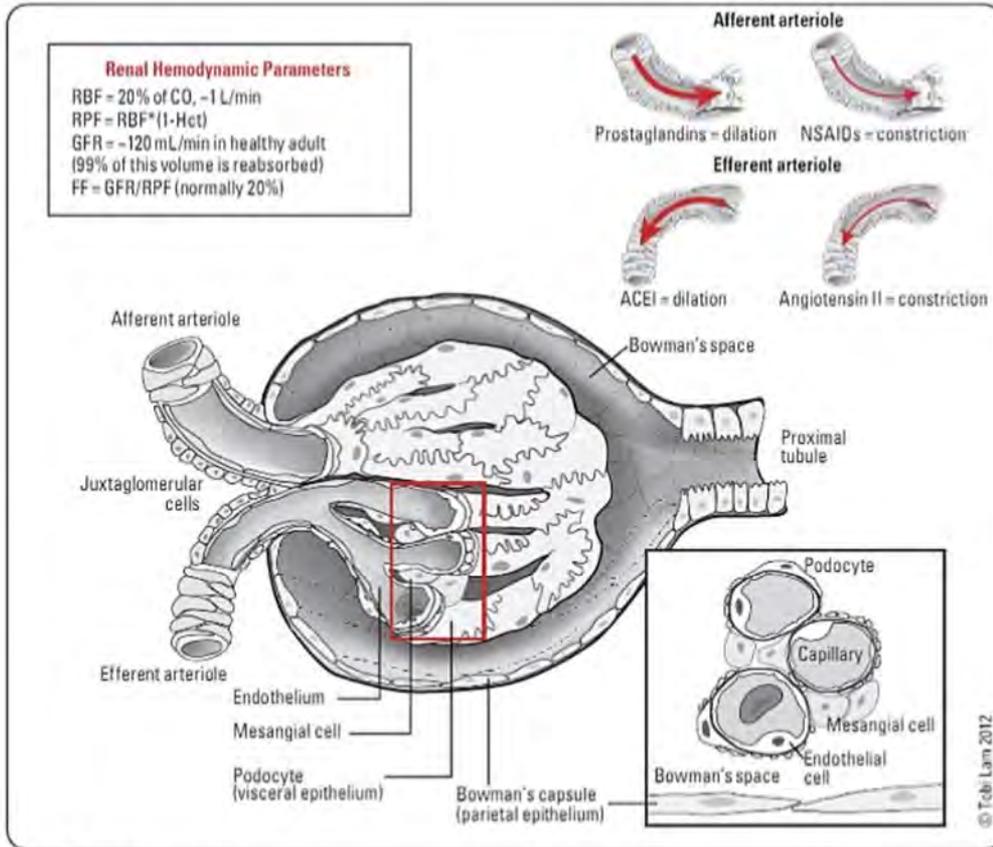

Figure 2. The glomerulus

**The Renal Tubules**

- reabsorption and secretion occur between the renal tubules and vasa recta forming urine for excretion
- each segment of the tubule selectively transports various solutes and water and is targeted by specific diuretics

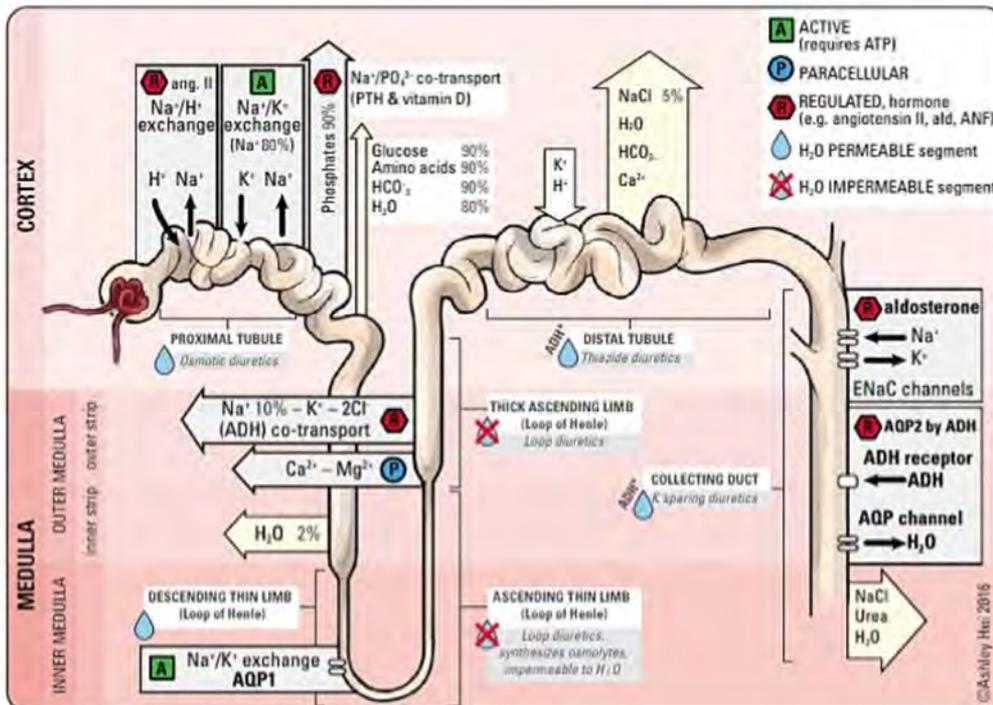

Figure 3. Tubular segments of the nephron

## Renal Hemodynamics

- GFR
  - GFR is the rate of fluid transfer between glomerular capillaries and Bowman's space, expressed as the sum of the filtration across all nephrons
  - average GFR of 180 L/d or 125 mL/min/1.73 m<sup>2</sup>, of which 99% of the filtrate is reabsorbed
  - normal urine output is 0.5-2.0 mL/kg/h in adults
  - GFR is highest in early adulthood, and decreases thereafter starting around age 40
- renal autoregulation maintains constant GFR over mean arterial pressures of 70-180 mmHg
- 2 mechanisms of autoregulation to maintain GFR homeostasis:
  - myogenic mechanism: release of vasoactive factors in response to changes in perfusion pressure (e.g. low GFR → decreased perfusion pressure → release of prostaglandin → afferent arteriolar dilation → increased GFR)
  - tubuloglomerular feedback: changes in Na<sup>+</sup> delivery to macula densa lead to changes in afferent arteriolar tone (e.g. high GFR → increased Na<sup>+</sup> delivery → afferent constriction → decreased GFR)
- filtration fraction
  - percentage of RPF filtered across the glomeruli
  - expressed as a ratio:  $FF = GFR/RPF$ ; normal = 0.2 or 20%
  - angiotensin II constricts renal efferent arterioles which increases FF, thereby maintaining GFR
- renin is released from juxtaglomerular apparatus in response to low Na<sup>+</sup> delivery to the macula densa, which is an indicator of decreased RPF
  - renin is an important enzyme in the RAAS pathway, that converts angiotensinogen to angiotensin I

Glomerular Filtration Rate	
GFR	$Kf (\Delta P - \Delta \Pi)$
Kf	ultrafiltration coefficient
$\Delta P$	hydrostatic pressure difference between glomerular capillaries and Bowman's space
$\Delta \Pi$	osmotic pressure difference between glomerular capillaries and Bowman's space
$\Delta P - \Delta \Pi$	net outward pressure

Considerable variation in GFR is observed based on age, biological sex, ethnicity and BMI

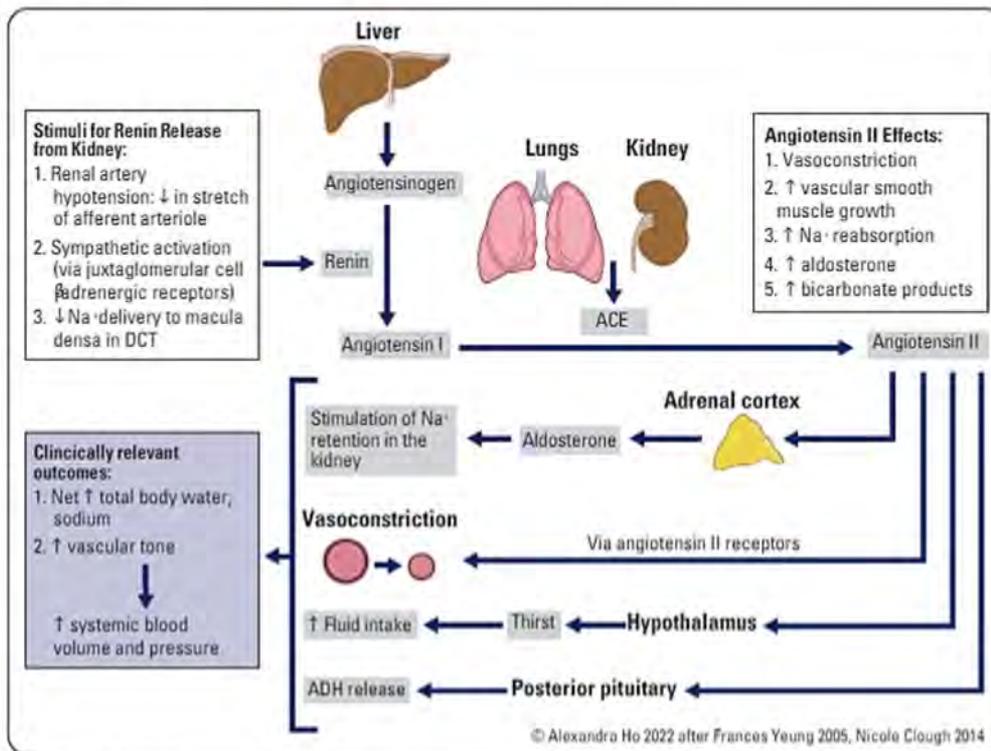

Figure 4. Renin-angiotensin-aldosterone system

## Assessment of Renal Function

### Measurement of Renal Function

- most renal functions decline in parallel with a decrease in GFR
- inulin clearance and iothalamate radiotracer are the gold standard for measuring GFR, but very rarely used clinically
- clinically, GFR is estimated using serum creatinine concentration, [Cr], known as eGFR
  - Cr filtered ≈ Cr excreted (at steady state)
  - Cr reasonably estimates GFR as it is freely filtered at the glomerulus with little tubular reabsorption

Cr<sub>filtered</sub> = Cr<sub>excreted</sub>  
 $[Cr]_{plasma} \times GFR = [Cr]_{urine} \times \text{urine flow rate (mL/min)}$   
 $GFR = \frac{[Cr]_{urine} \times \text{urine flow rate}}{[Cr]_{plasma}}$

- however, Cr is a metabolite of creatine phosphate, and therefore increased muscle mass increases Cr production. Thus, one needs to consider body mass, ethnicity, age, and biological sex when determining eGFR
- there is also 10% to >50% tubular secretion of Cr, depending on renal function
- newly discovered biomarkers such as Cystatin C, which are not affected by muscle mass, may provide more accurate eGFR values

### Ways to Estimate GFR Using Serum Creatinine Concentration

1. estimate GFR using CKD-EPI equation
  - the best current and most accurate equation
  - calculated using serum Cr, age, biological sex, and race
  - overestimates GFR, resulting in lower prevalence of CKD diagnoses when used instead of MDRD formula or Cockcroft-Gault equation
2. measure CrCl – 24 h urine collection
  - calculation provides reasonable estimate of GFR
  - $GFR/d = (\text{urine [Cr]} \times 24 \text{ h urine volume}) / (\text{plasma [Cr]})$
  - must use same units for urine [Cr] and plasma [Cr]
3. estimate GFR with new Cr and cystatin C-based equations
  - serum Cr and cystatin C values used with age and sex to estimate GFR (excludes the race variable)
  - more accurate than CKD-EPI with race omitted

### Limitations of Using Serum Cr Measurements

1. must be in steady state
  - constant GFR and rate of production of Cr from muscles
  - sudden injury (e.g. AKI) may reduce GFR substantially, however, serum Cr will not immediately reflect sudden reduction in GFR until new Cr steady state is reached
2. GFR must fall substantially before plasma [Cr] rises above normal laboratory range
  - with progressive renal failure, remaining nephrons compensate with hyperfiltration
  - GFR is relatively preserved despite significant structural damage
3. plasma [Cr] is influenced by the rate of Cr production
  - lower production with smaller muscle mass (e.g. female, elderly, low weight)
    - e.g. consider plasma [Cr] of 100  $\mu\text{mol/L}$  in both of these patients
      - 20 yr lean man who weighs 100 kg, GFR = 144 mL/min
      - 80 yr woman who weighs 50 kg, GFR = 30.6 mL/min
  - clinical correlation: GFR decreases with age but would not be reflected as a rise in serum Cr due to the age-associated decline in muscle mass
4. tubular secretion of Cr increases as GFR decreases
  - serum Cr and CrCl overestimate low GFR
  - certain drugs (cimetidine, trimethoprim) interfere with Cr secretion
5. errors in Cr measurement
  - very high bilirubin level causes [Cr] to be falsely low
  - acetoacetate (a ketone body) and certain drugs (cefoxitin) create falsely high [Cr]

### Measurement of Urea Concentration

- urea is the major end-product of protein metabolism
- plasma urea concentration reflects renal function but should not be used alone as it is modified by a variety of other factors
- urea production reflects dietary intake of protein and catabolic rate; increased protein intake or catabolism (sepsis, trauma, GI bleed) causes increase in urea level
- ECF volume depletion causes a rise in urea independent of GFR or plasma [Cr]
- in addition to filtration, a significant amount of urea is reabsorbed along the tubule
- reabsorption is increased in hypernatremic states
- typical ratio of urea to [Cr] in serum is 1:12 in SI units (using mmol/L for urea and  $\mu\text{mol/L}$  for Cr)

## Urinalysis

- use dipstick in freshly voided urine specimen to assess the following:

### 1. Specific Gravity

- ratio of the mass of equal volumes of urine/H<sub>2</sub>O
- range is 1.001-1.030
- values <1.010 reflect dilute urine, values >1.020 reflect concentrated urine
- value usually 1.010 (isosthenuria: same specific gravity as plasma) in ESRD

### 2. pH

- urine pH is normally between 4.5-7.0; if persistently alkaline, consider
  - RTA (types I-IV)
  - UTI with urease-producing bacteria (e.g. *Proteus*)

At steady state  $[\text{Cr}]_{\text{serum}} \propto 1/\text{CrCl}$

### CKD-EPI Equation

$eGFR (\text{mL}/\text{min}/1.73 \text{ m}^2) = 141 \times \min(\text{Scr}/\kappa, 1)^{\alpha} \times \max(\text{Scr}/\kappa, 1)^{-1.209} \times 0.993^{\text{age}} \times (1.018 \text{ if female}) \times (1.159 \text{ for Black individuals})$   
 [Scr] measured in mg/dL; 1 mg/dL [Cr] = 88.4  $\mu\text{mol/L}$   
 $\kappa = 0.7$  for females and 0.9 for males  
 $\alpha = -0.329$  for females and -0.411 for males  
 min/max indicates the minimum/maximum of  $\text{Scr}/\kappa$  or 1

### Cystatin C

Cystatin C is a renal biomarker shown to be potentially superior to serum Cr in determining eGFR and detecting impaired filtration rate. However, its clinical use remains limited pending increased adoption and testing availability

### Clinical Settings in which Urea Level is Affected Independent of Renal Function

#### Disproportionately High Urea

- Volume depletion (prerenal azotemia)
- GI hemorrhage
- High protein diet
- Sepsis
- Catabolic state with tissue breakdown
- Corticosteroid or cytotoxic agents

#### Disproportionately Low Urea

- Low protein diet
- Liver disease

### Estimating Urine Osmolality

Last 2 digits of the specific gravity  $\times 30 =$  urine osmolality approximately (e.g. specific gravity of 1.020 = 600 mOsm)

### 3. Glucose

- freely filtered at glomerulus and reabsorbed in proximal tubule
- causes of glycosuria include:
  - hyperglycemia  $>9-11.1$  mmol/L leads to filtration that exceeds tubular resorption capacity
  - increased GFR (e.g. pregnancy: the proximal convoluted tubule is unable to reabsorb the glucose and amino acids)
  - proximal tubule dysfunction (e.g. Fanconi's syndrome)
  - sodium-glucose cotransporter 2 (SGLT2) inhibitors (i.e. -flozin drugs) which are prescribed for DM2; lower the threshold for glucosuria by preventing glucose reabsorption from the filtrate

### 4. Protein

- dipstick only detects albumin; other proteins (e.g. Bence-Jones, Ig, Tamm-Horsfall) may be missed
- microalbuminuria (morning ACR of 2.0 - 20 mg/mmol) is not detected by standard dipstick; greater than these ranges would be macroalbuminuria
- gold standard: 24 h timed urine collection for total protein

### 5. Leukocyte Esterase

- enzyme found in WBC and detected by dipstick
- presence of WBCs indicates infection (e.g. UTI) or inflammation along the urinary tract including prostate, bladder, ureter, pelvis, and interstitium (e.g. AIN)

### 6. Nitrites

- endogenous nitrates in urine are converted to nitrites by some bacteria (most commonly *E. coli*)
- high specificity but low sensitivity for UTI

### 7. Ketones

- positive in alcoholic/diabetic ketoacidosis, prolonged starvation, fasting

### 8. Hemoglobin

- positive in hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis), and true hematuria (RBCs seen on microscopy)

#### 24 h Urine Collection

- Discard first morning specimen
- Collect all subsequent urine for the next 24 h
- Refrigerate between voids
- Collect second morning specimen

Positive dipstick for leukocyte esterase and nitrites is highly specific for diagnosing a UTI

#### Nitrite Negative Bacteria

*Enterococci*  
*Staphylococci*

#### Nitrite Positive Bacteria

*Enterobacteriaceae* (e.g. *E. coli*)

## Urine Microscopy

Table 2. Comparison of Urinary Sediment Findings

	Active Sediment = Suggestive of Parenchymal Kidney Disease	Bland Sediment = Less Likely Parenchymal Kidney Disease
Any one or more of the following seen on microscopy	Red cell casts	Only hyaline casts
	White cell casts	Small quantities of crystals
	Muddy-brown granular or epithelial cell casts	Small amount of bacteria
	$>2$ red cells per HPF	$<2$ red cells per HPF
	$\approx 4$ white cells per HPF	$<4$ white cells per HPF

### 1. CELLS

#### Erythrocytes

- hematuria  $\geq 2$  RBCs per HPF
- dysmorphic RBCs and/or RBC casts suggest glomerular bleeding (e.g. proliferative GN)
- isomorphic RBCs or no casts suggest extraglomerular bleeding (e.g. bladder cancer)

#### Leukocytes

- pyuria = greater than upper limit of normal:  $>4$  WBCs per HPF
- indicates inflammation or infection
- if persistent sterile pyuria present (i.e. negative culture), consider: chronic urethritis, prostatitis, interstitial nephritis, calculi, allergic cystitis, interstitial cystitis, papillary necrosis, renal tuberculosis, viral infections, *N. gonorrhoeae*, *C. trachomatis* infection

#### Eosinophils

- detected using Wright's or Hansel's stain (not affected by urine pH)
- consider AIN, atheroembolic disease

#### Oval Fat Bodies

- renal tubular cells filled with lipid droplets
- seen in heavy proteinuria (e.g. nephrotic syndrome)

### 2. CASTS

- cylindrical structures formed by intratubular precipitation of Tamm-Horsfall mucoprotein; cells may be trapped within the matrix of protein

**Table 3. Interpretation of Casts**

Casts	Interpretation
Hyaline Casts	Physiologic (concentrated urine, fever, exercise)
RBC Casts	Glomerular bleeding (proliferative GN, vasculitis)
WBC Casts	Infection (pyelonephritis) Inflammation (interstitial nephritis)
Pigmented Granular Casts (heme granular casts, muddy brown)	ATN Acute proliferative GN
Fatty Casts	Nephrotic syndrome (proteinuria >3.5 g/d)

**3. CRYSTALS**

- uric acid: consider acidic urine, hyperuricosuria, tumour lysis syndrome
- calcium phosphate: alkaline urine
- calcium oxalate: consider hyperoxaluria, ethylene glycol poisoning, nephrolithiasis
- sulfur: sulfa-containing antibiotics

**Urine Biochemistry**

- commonly measure: Na<sup>+</sup>, K<sup>+</sup>, Cl<sup>-</sup>, osmolality, and pH
- spot urine more useful to assess renal physiology, 24 h urine collection more reflective of mineral balance
- no "normal" values; electrolyte excretion depends on intake and current physiological state
- results must be interpreted in the context of a patient's current state, for example:
  1. ECF volume depletion: expect low urine [Na<sup>+</sup>] (kidneys should be retaining Na<sup>+</sup>)
    - urine [Na<sup>+</sup>] >20 mmol/L suggests a renal problem or the action of a diuretic
    - urine [Na<sup>+</sup>] <20 mmol/L suggests a prerenal problem
  2. daily urinary potassium excretion rate should be decreased (<20 mmol/d) in hypokalemia
    - if higher than 20 mmol/d, suggests renal contribution to hypokalemia
- osmolality is useful to estimate the kidney's concentrating ability
- FENa refers to the fractional excretion of Na<sup>+</sup> (Na excreted in urine/Na filtered through kidney)
  - FENa <1% suggests the pathology is prerenal
- urine pH is useful to grossly assess renal acidification
  - low pH (<5.5) in the presence of low serum pH is an appropriate renal response
  - a high pH in this setting might indicate a renal acidification defect (e.g. RTA Type 1)

**Fractional Excretion of Sodium**  
 $FENa = \frac{[Na^+]_{urine} \times [Cr]_{plasma}}{[Na^+]_{plasma} \times [Cr]_{urine}} \times 100$

**Electrolyte Disorders**

**Sodium Homeostasis**

- hyponatremia and hypernatremia are disorders of water balance
  - hyponatremia usually suggests too much water in the ECF relative to Na<sup>+</sup> content
  - hypernatremia usually suggests too little water in the ECF relative to Na<sup>+</sup> content
- solutes (such as Na<sup>+</sup>, K<sup>+</sup>, glucose) that cannot freely traverse the plasma membrane contribute to effective osmolality and induce transcellular shifts of water
  - water moves out of cells in response to increased ECF osmolality
  - water moves into cells in response to decreased ECF osmolality
- ECF volume is determined by Na<sup>+</sup> content rather than concentration
  - Na<sup>+</sup> deficiency leads to ECF volume contraction
  - Na<sup>+</sup> excess leads to ECF volume expansion
- clinical signs and symptoms of hyponatremia and hypernatremia are secondary to cells (especially brain cells) shrinking (hypernatremia) or swelling (hyponatremia)

**Table 4. Clinical Assessment of ECF Volume\* (Total Body Na<sup>+</sup>)**

Fluid Compartment	Hypovolemic	Hypervolemic
<b>Intravascular</b>		
JVP	Decreased	Increased
Blood pressure	Orthostatic drop	Normal to increased
Auscultation of heart	Tachycardia	S3
Auscultation of lungs	Normal	Inspiratory crackles
<b>Interstitial</b>		
Skin turgor	Decreased	Normal/increased
Edema (dependent)	Absent	Present
<b>Other</b>		
Urine output	Decreased**	Variable
Body weight	Decreased	Increased
Hematocrit, serum protein	Increased	Decreased
Urine sodium	Increased/Decreased***	Decreased
IVC size****	≤2.1 cm	>2.1 cm
IVC collapse on inspiration	>50%	<50%

\*Refers to effective circulating volume (ECV), which is the ECF volume adequately perfusing tissues.  
 \*\*If there is a renal abnormality (e.g. osmotic diuresis), the urine output may be increased despite the presence of hypovolemia  
 \*\*\*In hypovolemia, urine sodium can be increased due to renal losses, or decreased due to extra-renal losses  
 \*\*\*\*IVC ultrasound during respiration assesses central venous pressure/right atrial pressure; lung ultrasound for B-lines can also be used for assessment of pulmonary congestion

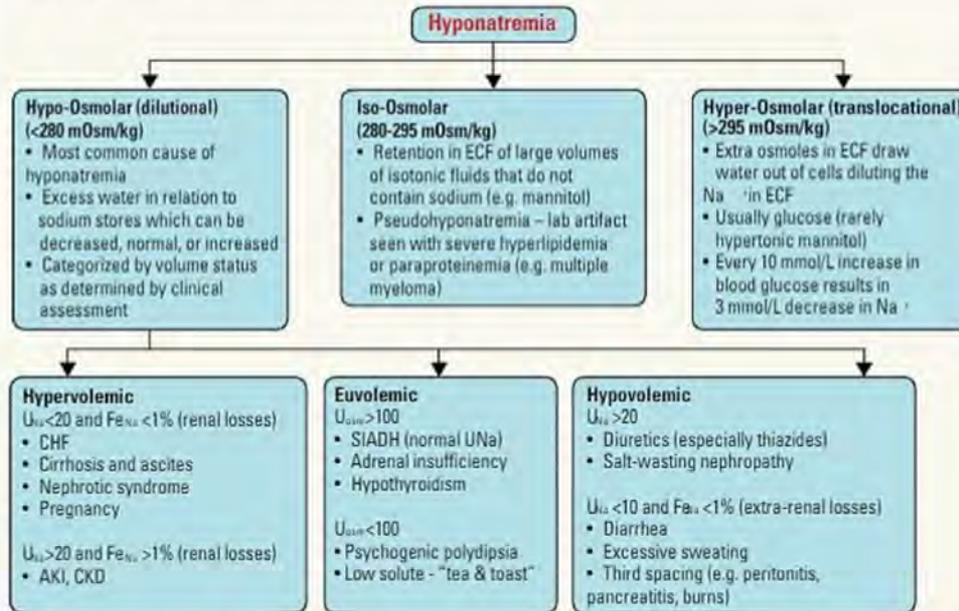

## Hyponatremia

### Definition

- serum [Na<sup>+</sup>] <135 mmol/L
- can be associated with hypo-osmolality (most common), iso-osmolality, or hyperosmolality
- consider if it is associated with “appropriate” (hypovolemia) vs. “inappropriate” (euvolemia) ADH secretion
- if appropriate ADH secretion, is it real vs. effective volume loss?

If the urine osmolality is unknown, assume the urine is hypo-osmolar/dilute

**Figure 5. Approach to hyponatremia**

### Signs and Symptoms

- depend on degree of hyponatremia and, more importantly, velocity of progression from onset
- hyponatremia = swollen cells
- acute hyponatremia (<24-48 h) more likely to be symptomatic
- chronic hyponatremia (>24-48 h) less likely to be symptomatic due to adaptation
  - adaptation: normalization of brain volume through loss of cellular electrolytes (within hours) and organic osmolytes (within days)
- neurologic symptoms predominate (secondary to cerebral edema): headache, nausea, malaise, lethargy, weakness, muscle cramps, anorexia, somnolence, disorientation, personality changes, depressed reflexes, decreased LOC

### Complications

- cerebral edema and increased intracranial pressure resulting in nausea, headaches, decreased LOC, seizures, coma, brain herniation, and death

### Symptoms of Central Pontine Myelinolysis

- Cranial nerve palsies
- Quadriplegia
- Decreased LOC

- risk of brain cell shrinkage with rapid correction of hyponatremia
  - can develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis)
  - symptom onset may be delayed 2-6 d; begins as dysarthria, dysphagia, paresis, movement disorders → later on seizures, lethargy, confusion, disorientation, obtundation, coma

### Risk Factors for Osmotic Demyelination

- low serum  $[Na^+]$  of  $\leq 115$  mmol/L at presentation and/or duration of hyponatremia  $\geq 2$  d
- associated hypokalemia, malnutrition, liver disease, alcoholism
- overly rapid correction of  $[Na^+]$ , i.e. rise in  $[Na^+] > 8$  mmol/L/24 h if chronic hyponatremia, e.g.:
  - inappropriate sodium replacement
  - suppression of ADH by restoring euvoolemia with isotonic fluid, or by stopping a reversible stimulus of SIADH (organic disorders; medications e.g. SSRIs; limbic system activation e.g. nausea, pain, surgical stress; see Table 5, NP11)
  - discontinuation of thiazides; depriving water in patient with psychogenic polydipsia

### Investigations for Hyponatremia

- ECF volume status assessment (see Table 4, NP9)
- serum electrolytes, glucose, Cr
- serum osmolality, urine osmolality
- urine  $Na^+$  (urine  $Na^+ < 10-20$  mmol/L suggests volume depletion as the cause of hyponatremia)
- assess for causes of SIADH (see Table 5)
- TSH, free T4, and cortisol levels
- consider CXR and possibly CT chest if suspect pulmonary cause of SIADH (e.g. paraneoplastic syndrome by small cell lung cancer)
- consider CT head if suspect CNS cause of SIADH (i.e. subarachnoid hemorrhage)

### Treatment of Hyponatremia

- general measures for all patients
  1. treat underlying cause (e.g. restore ECF volume if volume depleted, remove offending drug, treat pain, nausea, etc.)
  2. restrict free water intake in SIADH ( $< 1000$  mL/d)
  3. promote free water loss
  4. carefully monitor serum  $Na^+$ , urine volume, and urine tonicity
  5. monitor frequently that correction is not too rapid
- monitor urine output frequently: high output of dilute urine is the first sign of dangerously rapid correction of hyponatremia as the stimulus for ADH is diminished with the correction of hypovolemia

### A. Known Acute (known to have developed over $< 24-48$ h)

- commonly occurs in hospital (dilute IV fluid, postoperative increased ADH)
- less risk from rapid correction since adaptation has not fully occurred
- if symptomatic
  - correct rapidly with 3% NaCl at 1-2 cc/kg/h up to serum  $[Na^+] = 125-130$  mmol/L
  - may need furosemide to address volume overload
- if asymptomatic, treatment depends on presence of risk factors for ODS
  - goal is to promote a negative balance of free water
  - restrict free water intake
  - promote free water loss by administration of furosemide with salt tablets, oral urea, or vasopressin receptor 2 antagonists (e.g. tolvaptan)
  - if ODS risk factors present, aim to correct serum sodium more slowly
  - do not give 3% NaCl if hyponatremia is autocorrecting due to water diuresis

### B. Chronic or Unknown

1. if severe symptoms (seizures or decreased LOC)
  - must partially correct acutely
  - aim for increase of  $Na^+$  by 0.5-1 mmol/L/h for 4-6 h
  - limit total rise to 8 mmol/L in 24 h
  - IV 3% NaCl at 1-2 cc/kg/h
  - may need furosemide
2. if asymptomatic
  - water restrict to  $< 1$  L/d fluid intake
  - consider IV 0.9% NS + furosemide (reduces urine osmolality, augments excretion of  $H_2O$ )
  - consider NaCl tablets as a source of  $Na^+$
3. refractory
  - furosemide and oral salt tablets
  - oral urea (osmotic aquaresis)
  - vasopressin receptor 2 antagonists (e.g. tolvaptan)
4. always pay attention to patient's ECF volume status – if already volume-expanded, usually don't give NaCl (tablet or IV); if already volume-depleted, almost never appropriate to give furosemide

### C. Options for Treatment of Overly-Rapid Correction

- give water (IV D5W)
- give ADH to stop water diuresis (DDAVP 1-2  $\mu$ g IV)

### Impact of IV Solution on Serum $[Na^+]$

- formula to estimate the change in serum  $[Na^+]$  caused by retention of 1 L of any infusate
- $[TBW = (\text{for men}) 0.6 \times \text{weight(kg)}; (\text{for women}) 0.5 \times \text{weight(kg)}]$

### Beware of Rapid Correction of Hyponatremia

- Rapid correction of hyponatremia can occur inadvertently, commonly after stopping a reversible secondary cause of SIADH, e.g.:
- Patient with SIADH secondary to nausea is given an anti-emetic
- Resolution of nausea causes a rapid cessation of SIADH, leading to renal excretion of excess water and rapid increase in serum  $[Na^+]$
- Patient at risk of osmotic demyelination
- High output dilute urine ( $> 100$  cc/h,  $< 100$  mOsm/L) in the setting of hyponatremia is usually the first sign of dangerously rapid correction of serum sodium

Correction of  $Na^+$  in hyponatremia should not exceed 8 mmol/L/24 h unless definitely known to be  $< 24-48$  h duration; frequent monitoring of serum  $Na^+$  and urine output is essential

### Concentration of $[Na^+]$ in Common Infusates

- $[Na^+]$  in 0.45% NaCl = 77 mmol/L
- $[Na^+]$  in 0.9% NaCl = 154 mmol/L
- $[Na^+]$  in 3% NaCl = 513 mmol/L
- $[Na^+]$  in 5% NaCl = 855 mmol/L
- $[Na^+]$  in Ringer's lactate = 130 mmol/L
- $[Na^+]$  in D5W = 0

**SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION**

1. urine that is inappropriately concentrated for the serum osmolality
2. urine sodium >20-40 mmol/L – likely reflecting euolemia
3. FENa >1%

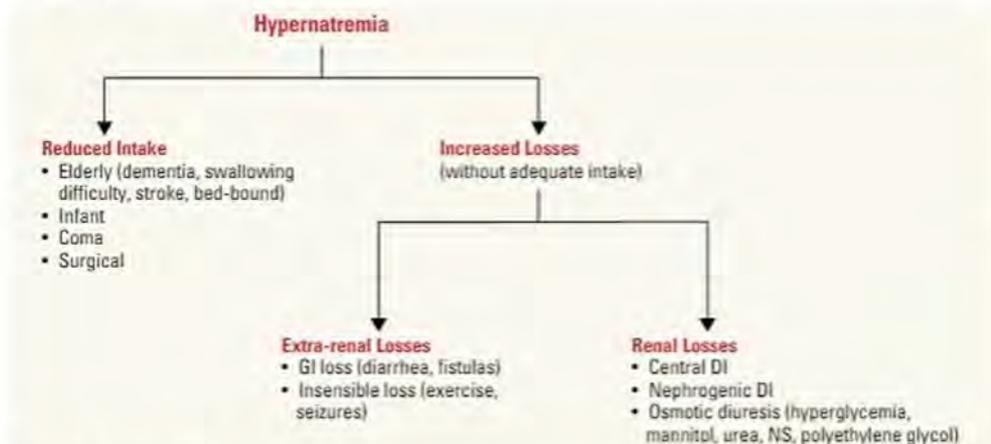

**Table 5. Disorders Associated with SIADH**

Cancer	Pulmonary	CNS	Drugs	Miscellaneous
Small cell cancer	Pneumonia	Mass lesion	Antidepressants	Postoperative state
Bronchogenic carcinoma	Lung abscess	Encephalitis	TcAs	Pain
Pancreatic adenocarcinoma	Tuberculosis	Subarachnoid hemorrhage	SSRIs	Severe nausea
Hodgkin's lymphoma	Acute respiratory failure	Stroke	Antineoplastics	HIV
Thymoma	Asthma	Head trauma	Vincristine	
Leukemia	COPD	Acute psychosis	Cyclophosphamide	
	Positive pressure ventilation	Acute intermittent porphyria	Anti-epileptics	
			Carbamazepine	
			Barbiturates	
			Chlorpropamide	
			ACEI	
			Other	
			DDAVP	
			Oxytocin	
			Nicotine	

**Hypernatremia**

**Definition**

- serum [Na<sup>+</sup>] >145 mmol/L
- too little water relative to total body Na<sup>+</sup>; always a hyperosmolar state
- usually due to NET water loss or insufficient intake, rarely due to hypertonic Na<sup>+</sup> gain
- less common than hyponatremia because patients are protected against hypernatremia by thirst and release of ADH

**Figure 6. Approach to hypernatremia**

**Signs and Symptoms**

- hypernatremia = shrunken cells
  - acute hypernatremia (<24-48 h)
  - chronic hypernatremia (>24-48 h), cells will have achieved adaptive mechanism: can import and generate new osmotically active particles to normalize cell size
  - nearly all cases of hypernatremia will be due to chronic hypernatremia
  - acute hypernatremia primarily presents in patients with diabetes insipidus
  - symptoms due to brain cell shrinkage: altered mental status, weakness, neuromuscular irritability, focal neurologic deficits, seizures, coma, death
- ± polyuria, thirst, signs of hypovolemia

**Complications**

- increased risk of vascular rupture resulting in intracranial hemorrhage
- rapid correction may lead to cerebral edema

**Treatment of Hypernatremia**

- general measures for all patients
  - give free water (oral or IV)
  - treat underlying cause
  - monitor serum Na<sup>+</sup> frequently (q4h) to ensure correction is not occurring too rapidly
- if evidence of hemodynamic instability, then must first correct volume depletion with NS bolus
- loss of water is often accompanied by loss of Na<sup>+</sup>, but a proportionately larger water loss

**H<sub>2</sub>O Deficit and TBW Equations**

TBW = 0.6 x wt (kg) men  
TBW = 0.5 x wt (kg) women

H<sub>2</sub>O deficit = TBW x ([Na<sup>+</sup>]<sub>plasma</sub> - 140) / 140

Correction of serum [Na<sup>+</sup>] in hypernatremia should not exceed 12 mmol/L/24 h

1 L D5W approximately equals 1 L of free water  
1 L 0.45% NS approximately equals 500 mL of free water

**Outcomes in Severe Hyponatremia Treated With and Without Desmopressin**

Am J Med 2018;131:1-317

**Purpose:** Rapid overcorrection of plasma Na<sup>+</sup> in severe hyponatremia can lead to osmotic demyelination syndrome. This study seeks to compare outcomes in hyponatremia based on DDAVP usage in treatment.

**Methods:** Retrospective study including all admissions to internal medicine with hyponatremia (plasma Na<sup>+</sup> < 123 mEq/L) from 2004 to 2014 at 2 Toronto hospitals. The primary outcome was safe Na<sup>+</sup> correction (<12 mEq/L in any 24 h period and <18 mEq/L in any 48 h period), time to reach Na<sup>+</sup> >130 mEq/L or hospital discharge. DDAVP uses were excluded for DI and for bleeding prevention in thrombocytopenia.

**Results:** Among 1450 admissions of 1274 patients for hyponatremia over the 10 yr period, desmopressin was administered in 254 admissions (17.5%). Fewer patients receiving DDAVP achieved safe Na<sup>+</sup> correction within the 24 h time frame (70.9% vs. 85%; P<0.001). The proportion of cases with safe Na<sup>+</sup> correction was highest in the proactive-DDAVP treatment group, followed by reactive then rescue treatment (78.6% for proactive vs. 29.3% for reactive). According to clinical or radiographic findings, 4 of 1450 admissions had suspected osmotic demyelination syndrome, two of which occurred during DDAVP administration (0.79% incidence, 95% CI 0.22-2.32).

**Conclusions:** The rescue strategy of DDAVP administration is not an ideal strategy, while the proactive strategy was effective at slowing Na<sup>+</sup> rate of change. In patients at risk for osmotic demyelination syndrome, a proactive DDAVP strategy more often achieved a more stringent correction limit.

- encourage patient to drink pure water, as PO is preferred for fluid administration
- if unable to replace PO or NG, correct H<sub>2</sub>O deficit with hypotonic IV solution (IV D5W, 0.45% NS [half normal saline], or 3.3% dextrose with 0.3% NaCl ["2/3 and 1/3"])
- chronic hypernatremia: aim to lower serum sodium by 8-10 mEq/L in 24 h (often achieved by giving free water at 1.35 mL/kg/h)
- acute hypernatremia: use formula to calculate water deficit. Replace entire water deficit within 24 h (hourly infusion rate = water deficit in mL/24 h)
- infusion rate may need to be increased in order to account for ongoing losses in addition to initial deficit

## Diabetes Insipidus

### Definition

- collecting tubule is impermeable to water due to absence of ADH or impaired response to ADH
- defect in central release of ADH (central DI) or renal response to ADH (nephrogenic DI)

### Etiology

- central DI: neurosurgery, granulomatous diseases, trauma, vascular events, and malignancy
- nephrogenic DI
  - usually acquired – drugs (e.g. lithium), secondary to amyloidosis, sickle cell disease, Sjogren syndrome, polycystic kidney disease, electrolyte imbalances (i.e. hypercalcemia)
  - congenital/hereditary

### Diagnosis

- urine osmolality inappropriately low in patient with hypernatremia ( $U_{osm} < 300$  mOsm/kg)
- serum vasopressin concentration may be absent/low (central), or elevated (nephrogenic)
- dehydration test: H<sub>2</sub>O deprivation until loss of 3% of body weight or until urine osmolality rises above plasma osmolality; if urine osmolality remains  $< 300$  (fails to concentrate urine), most likely DI

### Management

- central DI: administer exogenous ADH (e.g. DDAVP) 10 µg intranasally or 2 µg SC or IV
- nephrogenic DI: patients may have partial or complete ADH resistance, and DDAVP is generally ineffective
  - maintain fluid intake to match losses, e.g. PO water, IV D5W, IV 0.45% NS
  - treat underlying cause of nephrogenic DI
  - thiazides can help by paradoxically reducing urine output: thiazides induce hypovolemia → stimulate proximal tubular reabsorption of sodium and water → less delivery of glomerular filtrate to the collecting duct → lower urine volume

## Potassium Homeostasis

- ~98% of total body K<sup>+</sup> stores are intracellular
- normal serum K<sup>+</sup> ranges from 3.5-5.0 mEq/L
- in response to K<sup>+</sup> rise, rapid removal from ECF is necessary to prevent life-threatening hyperkalemia (K<sup>+</sup>  $> 6.5$  mEq/L)
- insulin, catecholamines, and acid-base status influence K<sup>+</sup> movement into cells
  - aldosterone has a minor effect
- potassium excretion is regulated at the DCT and collecting ducts
  - K<sup>+</sup> excretion = urine flow rate x urine [K<sup>+</sup>]

### Factors which Increase Renal K<sup>+</sup> Loss

- hyperkalemia
- increased distal tubular urine flow rate and Na<sup>+</sup> delivery (thiazides and loop diuretics)
- increased aldosterone activates epithelial sodium channels in cortical collecting duct, causing Na<sup>+</sup> reabsorption and K<sup>+</sup> excretion
- metabolic alkalosis (increases K<sup>+</sup> secretion)
- hypomagnesemia
- increased non-resorbable anions in tubule lumen: HCO<sub>3</sub><sup>-</sup>, penicillin, salicylate (increased tubular flow rate increases K<sup>+</sup> secretion)

## Hypokalemia

### Definition

- serum [K<sup>+</sup>]  $< 3.5$  mEq/L

### Signs and Symptoms

- usually asymptomatic, particularly when mild (3.0-3.5 mmol/L)
- nausea/vomiting, fatigue, generalized weakness, myalgia, muscle cramps, and constipation
- if severe: arrhythmias, rhabdomyolysis, myoglobinuria, and rarely paralysis with eventual respiratory impairment

### A Copeptin-Based Approach to the Diagnosis of Diabetes Insipidus

NEJM 2018;379:428-39

**Purpose:** Comparison of the indirect water-deprivation test, a technically cumbersome test, with direct detection of plasma copeptin, a precursor-derived surrogate of arginine vasopressin.

**Methods:** From 2013 to 2017, 156 patients with hypotonic polyuria underwent both indirect water-deprivation testing and hypertonic saline infusion tests. In the latter test, plasma copeptin levels were measured when plasma Na<sup>+</sup> increased to  $> 150$  mmol/L after saline infusion. The primary outcome was overall diagnostic accuracy of each test compared with final reference diagnosis, as determined by clinical history, test results and treatment response, with copeptin levels masked.

**Results:** Among the 141 patients included in final analysis, the indirect water-deprivation test showed diagnostic accuracy in 108 patients (76.6%; 95% CI 68.9 to 83.2) and the hypertonic saline infusion (copeptin cutoff  $> 4.9$  mmol/L) showed diagnostic accuracy in 136 patients (96.5%; 95% CI 92.1 to 98.6,  $P < 0.001$ ). The water-deprivation test correctly distinguished primary polydipsia from partial central DI in 77 of 105 patients (73.3%; 95% CI 63.9 to 81.2) while the hypertonic saline test distinguished in 99 of 104 patients (95.2%; 95% CI 88.4 to 98.1,  $P < 0.001$ ).

**Conclusion:** In patients with hypotonic polyuria, direct measurement of hypertonic-saline stimulated plasma copeptin levels showed greater diagnostic accuracy than the water-deprivation test.

- arrhythmias occur at variable levels of  $K^+$ ; more likely if digoxin use, hypomagnesemia, or CAD
- ECG changes are more predictive of clinical picture than serum  $[K^+]$ 
  - U waves most important (low amplitude wave following a T wave)
  - flattened or inverted T waves
  - depressed ST segment
  - prolongation of Q-T interval
  - sinus bradycardia
  - with severe hypokalemia: P-R prolongation, wide QRS, arrhythmias; increases risk of digitalis toxicity
  - common arrhythmias seen with hypokalemia: ventricular fibrillation, ventricular tachycardia

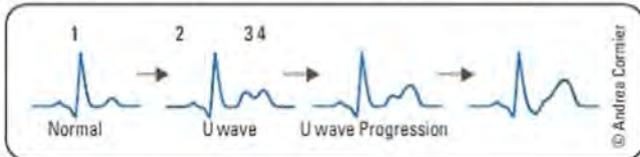

Figure 7. ECG changes in hypokalemia

**Approach to Hypokalemia**

1. emergency measures if  $K^+ < 2.5$  mEq/L: obtain ECG; if potentially life threatening, begin treatment immediately
2. rule out transcellular shifts of  $K^+$  as cause of hypokalemia
3. assess contribution of dietary  $K^+$  intake
4. spot urine  $K:Cr$ 
  - if  $< 1.5$  mEq/mmol consider GI loss
  - if  $> 1.5$  mEq/mmol consider a renal loss
5. consider 24 h  $K^+$  excretion
6. if renal  $K^+$  loss, check BP and acid-base status
7. may also assess plasma renin and aldosterone levels, serum  $[Mg^{2+}]$

**Hypokalemia is often accompanied by metabolic alkalosis:**

- $K^+$  shifts from cells to ECF;  $H^+$  shifts into cells in response
- Plasma  $[HCO_3^-]$  increases, while intracellular pH decreases
- In response to low pH, renal tubular cells secrete  $H^+$  into lumen, and increase renal ammoniogenesis and excretion
- Resultant addition of more  $[HCO_3^-]$  into plasma = metabolic alkalosis

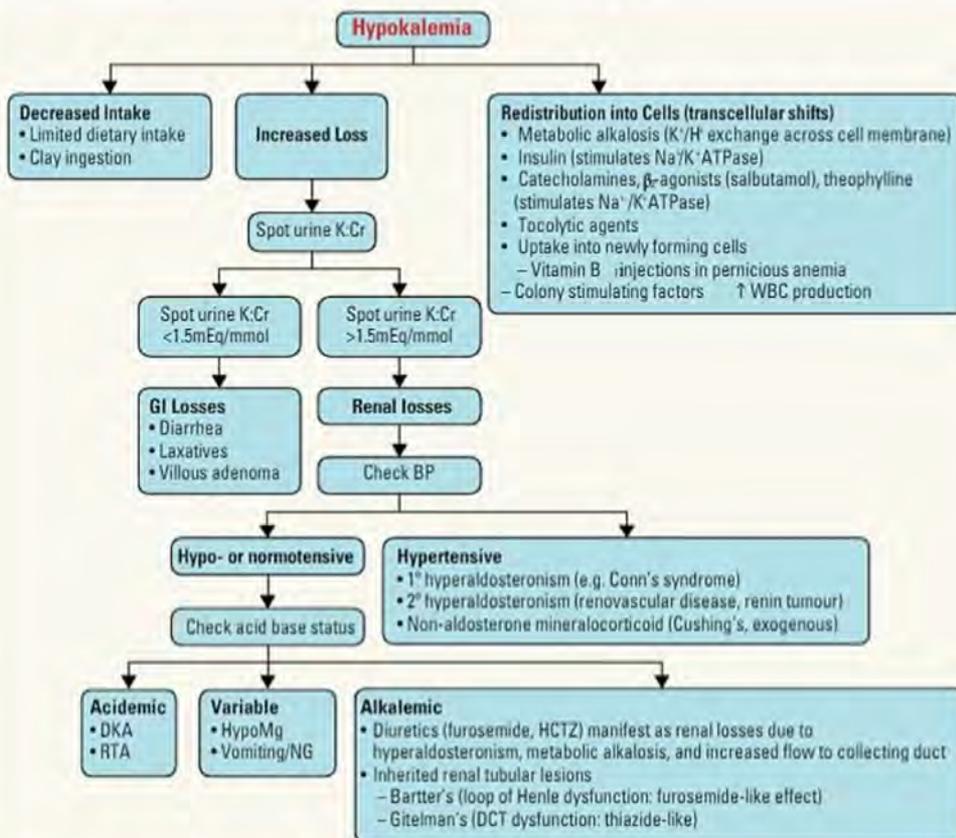

Figure 8. Approach to hypokalemia

**Treatment**

- treat underlying cause
- if true  $K^+$  deficit, potassium repletion
  - oral sources: food, tablets (K-Dur<sup>™</sup>), KCl liquid solutions (preferable route if the patient tolerates PO medications)
  - IV: usually KCl in saline solutions, avoid dextrose solutions (may exacerbate hypokalemia via insulin release)

- max 40 mmol/L via peripheral vein, 60 mmol/L via central vein, max infusion 20 mmol/h
- K<sup>+</sup>-sparing diuretics (triamterene, amiloride, spironolactone) can prevent renal K<sup>+</sup> loss
- restore Mg<sup>2+</sup> before correcting K<sup>+</sup>
- if urine output and renal function are impaired, correct with extreme caution
- risk of hyperkalemia with potassium replacement especially high in elderly, diabetics, and patients with decreased renal function
- use ACE inhibitor or ARB for CHF (reduces angiotensin II action and therefore reduces aldosterone production)
- beware of excessive potassium repletion, especially if hypokalemia secondary to transcellular shift

## Hyperkalemia

### Definition

- serum [K<sup>+</sup>] >5.0 mEq/L

### Signs and Symptoms

- usually asymptomatic but may develop nausea, palpitations, muscle weakness, muscle stiffness, paresthesias, areflexia, ascending paralysis, and hypoventilation
- impaired renal ammoniogenesis and excretion and metabolic acidosis
- ECG changes and cardiotoxicity (do not correlate well with serum [K<sup>+</sup>])
- peaked and narrow T waves
- decreased amplitude and eventual loss of P waves
- prolonged PR interval
- widening of QRS and eventual merging with T wave (sine-wave pattern)
- AV block
- ventricular fibrillation, asystole

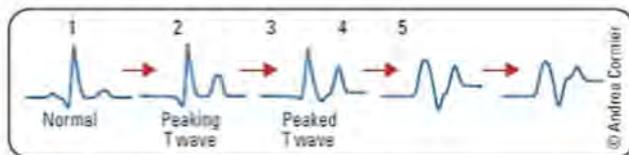

Figure 9. ECG changes in hyperkalemia

Table 6. Causes of Hyperkalemia

Pseudohyperkalemia	Increased Intake	Transcellular Shift	Decreased Excretion
Sample hemolysis*	Diet	Intravascular hemolysis	Decreased GFR
Sample taken from vein where IV KCl is running	KCl tabs	Rhabdomyolysis	Renal failure
Prolonged use of tourniquet	IV KCl	Tumour lysis syndrome	Low effective circulating volume
Leukocytosis (extreme)	Salt substitute	Insulin deficiency	NSAIDs in renal insufficiency
Thrombocytosis** (extreme)		Metabolic Acidosis	Normal GFR but hypoaldosteronism (Table 7)
		Drugs	
		β-blockers	
		Digitalis overdose (blocks Na <sup>+</sup> /K <sup>+</sup> ATPase)	
		Succinylcholine	

\*Most common

\*\*Usually when blood specimen has been sitting out long before being analyzed

Table 7. Causes of Hyperkalemia with Normal GFR Secondary to Hypoaldosteronism

Decreased Aldosterone Stimulus (low renin, low aldosterone)	Decreased Aldosterone Production (normal renin, low aldosterone)	Aldosterone Resistance (decreased tubular response)
Associated with diabetic nephropathy, NSAIDs, chronic interstitial nephritis, HIV	Adrenal insufficiency (e.g. Addison's disease, AIDS, metastatic cancer)	K <sup>+</sup> -sparing diuretics:
	ACEI	Spirolactone
	Angiotensin II receptor blockers	Amiloride
	Heparin	Triamterene
	Congenital adrenal hyperplasia with 21-hydroxylase deficiency	Renal tubulointerstitial disease

### Approach to Hyperkalemia

1. emergency measures: obtain ECG; if life threatening, begin treatment immediately
2. rule out pseudohyperkalemia; repeat blood test
3. hold exogenous K<sup>+</sup> (PO and IV) and any medications that are K<sup>+</sup> retaining e.g. RAAS inhibitors (ACEI, ARBs), aldosterone antagonists, non-selective β-blockers (propranolol/labetalol) or affect K<sup>+</sup> excretion (i.e. NSAIDs)
4. assess potential causes of transcellular shift
5. determine eGFR

In patients with DM and increased [K<sup>+</sup>] and hyperglycemia, often just giving insulin to restore euglycemia is sufficient to correct the hyperkalemia

**Treatment**

- acute therapy is warranted if ECG changes are present or if patient is symptomatic regardless of [K<sup>+</sup>]
- tailor therapy to severity of increase in [K<sup>+</sup>] and ECG changes
  - [K<sup>+</sup>] <6.5 and normal ECG
    - treat underlying cause, stop K<sup>+</sup> intake, increase the loss of K<sup>+</sup> via urine and/or GI tract
  - [K<sup>+</sup>] between 6.5 and 7.0, no ECG changes: add insulin to above regimen
  - [K<sup>+</sup>] >7.0 and/or ECG changes: first priority is to protect the heart, add calcium gluconate to above

**1. Stabilize Myocardium**

- calcium gluconate 1-2 amps (10 mL of 10% solution) IV
- antagonizes hyperkalemia induced membrane depolarization, protects cardiac conduction system, no effect on serum [K<sup>+</sup>]
- onset within minutes, lasts 30-60 min (may require repeat doses during treatment course of hyperkalemia)

**2. Shift K<sup>+</sup> into Cells**

- regular insulin (Insulin R) 10-20 units IV, with 50-100 mL D50W to prevent hypoglycemia
  - onset of action 15-30 min, lasts 4-6 h
  - monitor capillary blood glucose q1h because of risk of hypoglycemia
  - can repeat q4-6 h
  - caution giving D50W before or without insulin if hyperkalemia is severe: hypertonic glucose increases plasma osmolality, promoting extracellular water and shift, and can cause a serious arrhythmia
- β2-agonist (Ventolin<sup>®</sup>) in nebulized form (dose = 2 cc or 10 mg inhaled) or 0.5 mg IV
  - onset of action 30-90 min, stimulates Na<sup>+</sup>/K<sup>+</sup> ATPase
  - caution if patient has heart disease as may result in tachycardia

**3. Enhance K<sup>+</sup> Removal from Body**

- via urine (preferred approach)
  - furosemide (≥40 mg IV), may need IV NS to avoid hypovolemia
  - fludrocortisone (synthetic mineralocorticoid) if suspecting aldosterone deficiency
- via GI (if renal function is severely impaired)
  - cation exchangers: patiromer 8.4 g PO OD (up to 25.2 g/d), zirconium cyclosilicate, or sodium polystyrene sulfonate (Kayexalate<sup>®</sup>)
    - practically, patiromer and zirconium are not currently widely employed due to high cost
    - sodium polystyrene sulfonate (Kayexalate<sup>®</sup>) should be used with caution, as they may lead to the development of colonic necrosis and intestinal perforation
  - osmotic laxatives e.g. lactulose can support GI excretion of K<sup>+</sup> in the form of diarrhea
- dialysis (renal failure, life threatening hyperkalemia unresponsive to therapy)

**Hyperphosphatemia**

**Definition**

- serum phosphate >1.45 mmol/L
  - phosphate binds to serum calcium to create insoluble precipitates in soft tissues and blood vessels, thereby resulting in hypocalcemia
  - hypocalcemia subsequently triggers the development of secondary hyperparathyroidism in patients with advanced CKD on dialysis

**Etiology**

- typically results from decreased renal excretion of phosphate

**Table 8. Etiology of Hyperphosphatemia**

Increased Phosphate Load	Reduced Renal Clearance	Pseudohyperphosphatemia
GI intake (rectal enema, GI bleeding)	Acute/chronic renal failure	Hyperglobulinemia
IV phosphate load (K-Phos <sup>®</sup> , blood transfusion)	Hypoparathyroidism	Hyperlipidemia
Endogenous phosphate (tumour lysis syndrome, rhabdomyolysis, hemolysis, lactic and ketoacidosis)	Acromegaly	Hyperbilirubinemia
	Tumour calcinosis (ability of kidney to specifically clear phosphate is defective)	

**Clinical Features**

- non-specific, include ectopic calcification in soft tissues and vessels, renal osteodystrophy
  - symptoms consistent with hypocalcemia

**Treatment**

- acute: IV saline, hemodialysis if symptomatic;
- chronic: low PO<sub>4</sub><sup>3-</sup>-diet, phosphate binders (e.g. CaCO<sub>3</sub>, lanthanum carbonate, sevelamer with meals)

**Treatment of Hyperkalemia**

**C BIG K DROP**

- C** Calcium gluconate
- BIG** β-agonist, Insulin, Glucose
- K** Kayexalate<sup>®</sup>
- DROP** Diuretics, Dialysis

**Acute Management of Hyperkalemia**

*Curr Heart Failure Rep* 2019;16:67-74

**Purpose:** Outline and review the current evidence behind the acute medical management of hyperkalemia, including the three principal strategies of stabilizing the myocardium, intracellular shifting of serum K<sup>+</sup>, and enhancing elimination via urinary or fecal excretion.

1. **Stabilizing the Myocardium:** The protective effects of Ca<sup>2+</sup> salts on myocardial stabilization should be seen within 5 min of administration. Doses can be repeated in 5 min intervals if life-threatening ECG changes persist. There are concerns regarding calcium use in digoxin toxicity causing irreversible non-contractile states. No life-threatening dysrhythmias occurred within 1 h of calcium administration.
2. **Intracellular Shifting of Potassium:** Regular insulin has shown effectiveness at decreasing serum K<sup>+</sup>, with IV insulin decreasing serum K by 0.8 mmol/L at 1 h. The main side effect of insulin-induced hypoglycemia can be managed with IV dextrose. Albuterol has an onset within 15-30 min of administration, causing maximal decreases by 1 mmol/L at 1 h. There is little evidence to suggest that sodium bicarbonate has a role in the management of hyperkalemia, except in the case of concomitant metabolic acidosis.
3. **Enhanced Excretion:** Though limited evidence for acute management, it is recommended to administer loop diuretics and sodium polystyrene sulfonate to eliminate K<sup>+</sup>. Diuretics may precipitate or worsen AKI in patients with poor volume status, while sodium polystyrene sulfonate should be used with caution due to severe GI side effects such as ulceration, bleeding, colonic ischemia/necrosis, and intestinal perforation.

**Symptoms of Hypocalcemia**

- Tetany
- Seizures
- Hypotension
- QT prolongation
- Papilledema
- Psychiatric manifestations

## Hypophosphatemia

### Definition

- serum phosphate <0.80 mmol/L

### Etiology

- acute hypophosphatemia often caused by intracellular shifts of phosphate superimposed on chronic phosphate depletion
- chronic hypophosphatemia often caused by decreased renal phosphate reabsorption
- severe chronic hypophosphatemia often caused by chronic starvation or malabsorption (e.g. in patients with alcoholism) or chronic use of phosphate binders (e.g. patients with CKD)

Symptoms usually present when phosphate <0.32 mmol/L (1.0 mg/dL)  
Treat asymptomatic patients if phosphate <0.32 mmol/L

Severe burns can cause hypophosphatemia due to PO<sub>4</sub><sup>3-</sup> losses through the skin

Table 9. Etiology of Hypophosphatemia

Inadequate Intake	Renal Losses	Excessive Skeletal Mineralization	Shift into Intracellular Fluid
Starvation	Hyperparathyroidism	Osteoblastic metastases	Recovery from metabolic acidosis
Malabsorption (diarrhea, steatorrhea)	Diuretics	Post parathyroidectomy (referred to as 'hungry bone syndrome')	Respiratory alkalosis
Antacid use	X-linked or autosomal dominant hypophosphatemic Rickets		Starvation refeeding (stimulated by insulin)
Alcoholism	Fanconi syndrome		
	Multiple myeloma		
	Early postrenal transplant		

### Clinical Features

- instability of cell membranes leading to hemolytic anemia or rhabdomyolysis
- MSK weakness, respiratory depression, low cardiac output/CHF from weakened cardiac muscles: symptoms arise due to low ATP production
- neurological symptoms: irritability, encephalopathy, seizures, coma
- hematologic symptoms: hemolytic anemia, decreased release of oxygen from hemoglobin, impaired leukocyte and platelet function (leading to worsening infections/defective clotting)

### Treatment

- treat underlying cause
- initiate when serum [PO<sub>4</sub><sup>3-</sup>] <0.64 mmol/L. Use PO therapy if asymptomatic, or symptomatic and [PO<sub>4</sub><sup>3-</sup>] >0.32 mmol/L. Use IV therapy if symptomatic and [PO<sub>4</sub><sup>3-</sup>] <0.32 mmol/L.
  - PO PO<sub>4</sub><sup>3-</sup>: 2-4 g/d divided BID-QID (start at 1 g/d to minimize diarrhea), encourage PO<sub>4</sub><sup>3-</sup>-rich diet
  - IV PO<sub>4</sub><sup>3-</sup>: only for severely symptomatic patients or inability to tolerate oral therapy

## Hypermagnesemia

### Definition

- serum magnesium >1.05 mmol/L

### Etiology

- AKI/CKD
- Mg<sup>2+</sup>-containing antacids or enemas
- IV administration of large doses of MgSO<sub>4</sub> (e.g. see *Obstetrics, Preclampsia, OB26*)

### Clinical Features

- rarely symptomatic
- drowsiness, hyporeflexia, respiratory depression, heart block, cardiac arrest, hypotension

### Treatment

- discontinue Mg<sup>2+</sup>-containing products
- 10% calcium gluconate 10-20 mL IV (Mg<sup>2+</sup>-antagonist) for acute reversal of magnesium toxicity
- hemodialysis if renal failure, consider peritoneal dialysis in setting of hemodynamic compromise

## Hypomagnesemia

### Definition

- serum magnesium <0.70 mmol/L

You will be unable to correct hypokalemia or hypocalcemia without first supplementing magnesium if patient is hypomagnesemic

### Etiology

GI losses	Excess renal loss
Starvation/malabsorption	2° hyperaldosteronism due to cirrhosis and CHF
Vomiting/diarrhea	Hyperglycemia
Alcoholism	Hypokalemia
Acute pancreatitis	Hypercalcemia
	Loop and thiazide-type diuretics
	Nephrotoxic medications
	Proton-pump inhibitors
	Early postrenal transplant

### Clinical Features

- tremors, nausea and vomiting, lethargy/weakness, seizures, paresis, Chvostek and Trousseau signs, ECG changes (widened QRS, prolonged PR, T-wave abnormalities), and arrhythmias including Torsades de Pointes

### Treatment

- treat underlying cause
- encourage increased dietary intake e.g. fruits
- oral Mg<sup>2+</sup> salts unless patient has seizures or other severe symptoms
- Mg<sup>2+</sup> IM/IV; cellular uptake of Mg<sup>2+</sup> is slow, therefore repletion requires sustained correction
- discontinue diuretics
  - in patients requiring diuretics, use a K<sup>+</sup>-sparing diuretic to minimize magnesuria

## Acid-Base Disorders

- acid-base homeostasis influences protein function and can critically affect tissue and organ function with consequences to cardiovascular, respiratory, metabolic, renal, and CNS function
- normal concentration of [HCO<sub>3</sub><sup>-</sup>] = 24 mEq/L (range: 21–27 mEq/L for arterial blood gas sample)
- normal pCO<sub>2</sub> = 40 mmHg (range: 36–44 mmHg)
- each acid-base disorder has an associated compensation
  - inadequate compensation or overcompensation can indicate the presence of a second acid-base disorder (e.g. in metabolic acidosis, inadequate compensation means there is also respiratory acidosis; overcompensation means there is also respiratory alkalosis)
- most commonly assessed using an arterial blood gas sample
- see [Respirology, R6](#) for more information on respiratory acidosis/alkalosis

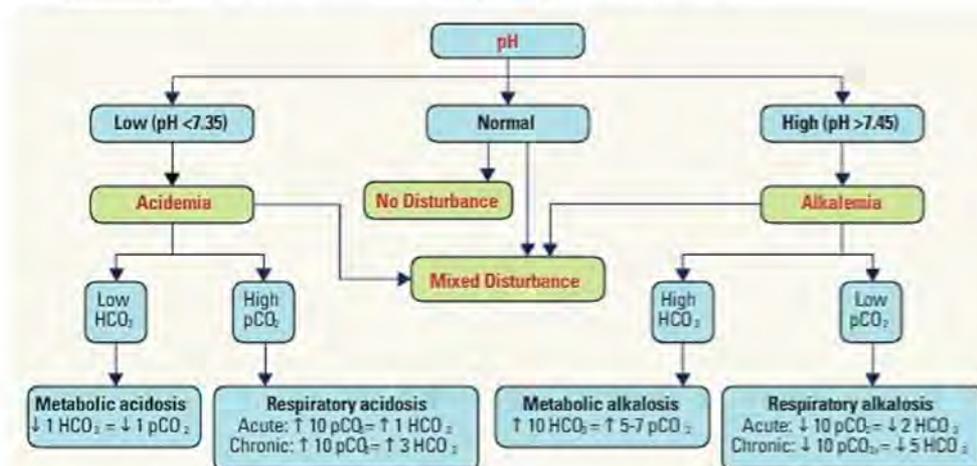

Figure 10. Approach to acid-base disorders. Equalities represent the appropriate compensatory changes in pCO<sub>2</sub> or HCO<sub>3</sub><sup>-</sup> in response to the primary disturbance

### Approach

#### 1. Identify the Primary Disturbance

- respiratory acidosis, metabolic acidosis, respiratory alkalosis, metabolic alkalosis

#### 2. Evaluate Compensation. If compensation is not appropriate, second acid-base disorder is likely present

- compensation occurs in the same direction as the primary disturbance

#### 3. Calculate Plasma AG

- $AG = [Na^+] - ([HCO_3^-] + [Cl^-])$
- baseline = 12, normal range 10–14 mEq/L
- AG can be altered by plasma albumin level: for each 10 g/L fall in albumin, lower baseline AG by 3 mEq/L (e.g. if plasma [albumin] = 20 g/L, expect AG = 6 mEq/L)
  - albumin is an unmeasured polyanion largely responsible for the normal anion gap

#### 4. Calculate Osmolar Gap

- osmolar gap = measured osmolality – calculated osmolality
  - calculated osmolality = (2 x [Na<sup>+</sup>]) + [urea] + [glucose] (all units are in mmol/L)
  - normal osmolar gap < 10
  - If OG > 10, consider methanol poisoning, ethylene glycol poisoning, or another cause of acidosis plus ethanol ingestion

#### Causes of Increased Osmolar Gap

- Methanol
- Ethylene glycol
- Ethanol
- Polyethylene glycol
- Mannitol
- Sorbitol

#### Useful Equations

$AG = [Na^+] - [Cl^-] - [HCO_3^-]$  (normal range = 10–14 mEq/L)

Osmolar Gap = measured serum osmolality – calculated osmolality (normal < 10 mEq/L)  
– “Two Salts and a Sticky BUN”

Calculated Osmolality = 2[Na<sup>+</sup>] + [Urea] + [Glucose] (+1.25[Ethanol])

### 5. If AG elevated, compare increase in AG with decrease in $\text{HCO}_3^-$

- if increase in AG < decrease in  $\text{HCO}_3^-$ , there is a coexisting non-AG metabolic acidosis
- if increase in AG > decrease in  $\text{HCO}_3^-$ , there is a coexisting metabolic alkalosis

## Metabolic Acidosis

- characterized by decreased blood pH (<7.35) and a decreased bicarbonate concentration

### Clinical Features

- hyperventilation (Kussmaul Breathing)
- decreased cardiac output and tissue perfusion (reduced responsiveness to catecholamines)

### Etiology and Pathophysiology

#### 1. increased AG metabolic acidosis (4 types)

- lactic acidosis (2 types)
  - L-lactic acid
    - type A: due to tissue hypoperfusion (any cause of shock), ischemic bowel, profound hypoxemia
    - type B: non-hypoxic - multiple causes; the most common is failure to metabolize normally produced lactic acid in the liver due to severe liver disease; other causes include: excessive alcohol intake, thiamine deficiency, metformin accumulation (metformin interferes with electron transport chain), certain antiretrovirals, large tumours, mitochondrial myopathies
  - D-lactic acid: rare syndrome characterized by episodes of encephalopathy and metabolic acidosis
    - occurs in the setting of carbohydrate malabsorption (e.g. short bowel syndrome), colonic bacteria metabolize carbohydrate load into D-lactic acid, diminished colonic motility, and impaired D-lactate metabolism
- ketoacidosis
  - diabetic
  - starvation
  - alcoholic (decreased carbohydrate intake and vomiting)
- toxins
  - methanol (toxic to brain and retina, can cause blindness and brain death): metabolized to formic acid
  - ethylene glycol (toxic to brain and kidneys): metabolized to oxalic acid (envelope shaped crystals in urine) and multiple other acids
  - salicylate (e.g. ASA) overdose: causes acidosis due to salicylic acid, and also accumulation of lactic acid (salicylate at toxic levels impairs electron transport chain) and ketoacid (salicylate activates fat breakdown)
- advanced renal failure
  - e.g. serum Cr increased at least 5x above baseline - a very low GFR causes retention of  $\text{H}^+$  and decreased  $\text{NH}_4^+$  excretion; the retained acid is buffered by bicarbonate resulting in reduced serum concentrations of bicarbonate

#### 2. non-AG metabolic acidosis (hyperchloremic acidosis; involves increased bicarbonate excretion that is replaced with $\text{Cl}^-$ )

- diarrhea ( $\text{HCO}_3^-$  loss from GI tract)
- RTA
  - type I RTA (distal): inability to secrete  $\text{H}^+$  in collecting duct, leading to impaired excretion of ammonium into urine
  - type II RTA (proximal): impaired  $\text{HCO}_3^-$  reabsorption
  - type III RTA: combination of Types I and II and is extremely rare
  - type IV RTA: defective ammoniogenesis characterized by hyperkalemia, due to decreased or hyporesponsiveness to aldosterone
- to help distinguish renal causes from non-renal causes, use Urine AG =  $(\text{Na}^+ + \text{K}^+) - \text{Cl}^-$
- calculation establishes the presence or absence of unmeasured positive ions (e.g.  $\text{NH}_4^+$ ) in urine
  - if UAG < 0, suggests adequate  $\text{NH}_4^+$  excretion in urine (likely nonrenal cause: diarrhea)
  - if UAG > 0, suggests problem is lack of  $\text{NH}_4^+$  in urine (likely renal cause: distal RTA)

### Treatment of Metabolic Acidosis

#### 1. treat underlying cause, e.g.:

- in DKA: fluid resuscitation,  $\text{K}^+$  supplementation, and insulin
- in Type A lactic acidosis: restore tissue perfusion
- in methanol or ethylene glycol poisoning: ethanol/fomepizole ± dialysis
- in ASA overdose: alkaline diuresis ± dialysis

#### 2. correct coexisting disorders of $\text{K}^+$ (see *Hyperkalemia, NP14*)

#### Causes of Increased AG Metabolic Acidosis

##### MUDPILES CAT

Methanol  
Uremia  
Diabetic ketoacidosis  
Paraldehyde  
Isopropyl alcohol/Iron/Ibuprofen/  
Indomethacin  
Lactic acidosis  
Ethylene glycol  
Salicylates  
Cyanide and Carbon monoxide  
Alcoholic ketoacidosis  
Toluene

#### Causes of Non-AG Metabolic Acidosis

##### HARDUP

Hyperalimentation  
Acetazolamide  
RTA\*  
Diarrhea\*  
Ureteroenteric fistula  
Pancreaticoduodenal fistula

\*Most common

#### 3 Clinical Scenarios that Produce a Mixed Disorder with Near Normal pH (e.g. increased AG metabolic acidosis + respiratory alkalosis)

- Cirrhosis
- ASA overdose
- Sepsis

3. consider treatment with exogenous alkali (e.g.  $\text{NaHCO}_3$ ) if:
- severe reduction in  $[\text{HCO}_3^-]$  e.g.  $<8$  mmol/L, especially with very low pH ( $<7$ )
  - no metabolizable anion (e.g. salicylate, formate, oxalate, or sulphate); note that lactate and ketoacid anions can be metabolized to  $\text{HCO}_3^-$
- note: risks of sodium bicarbonate therapy
- hypokalemia: causes  $\text{K}^+$  to shift into cells (correct  $\text{K}^+$  deficit first)
  - ECF volume overload:  $\text{Na}^+$  load given with  $\text{NaHCO}_3$ , can exacerbate pulmonary edema
  - overshoot alkalosis: abrupt, poorly tolerated transition from overly aggressive alkali loading, partial conversion of accumulated organic anions to  $\text{HCO}_3^-$ , and persisting hyperventilation

## Metabolic Alkalosis

- characterized by increased blood pH ( $>7.45$ ) and an increased bicarbonate concentration

### Pathophysiology

- requires precipitating event and maintenance factors
- precipitating factors
  - GI (vomiting, NG tube) or renal loss of  $\text{H}^+$
  - exogenous alkali (oral or parenteral administration), milk alkali syndrome (hypercalcemia)
  - loop/thiazide diuretics: increased distal  $\text{H}^+$  secretion and proximal  $\text{HCO}_3^-$  reabsorption; ECF volume depletion also contributes to a contraction alkalosis
  - post-hypercapnia: renal compensation for respiratory acidosis is  $\text{HCO}_3^-$  retention, rapid correction of respiratory disorder results in transient excess of  $\text{HCO}_3^-$
- maintenance factors
  - volume depletion: reduced GFR, increased proximal reabsorption of  $\text{Na}^+$  and  $\text{HCO}_3^-$ , and increased aldosterone
  - hyperaldosteronism ( $1^\circ$  or  $2^\circ$ ): distal  $\text{Na}^+$  reabsorption in exchange for  $\text{K}^+$  and  $\text{H}^+$  excretion leads to metabolic alkalosis and hypokalemia
  - hypokalemia: transcellular  $\text{K}^+/\text{H}^+$  exchange, stimulus for ammoniogenesis and  $\text{HCO}_3^-$  generation

### Evaluate Compensation (identify co-existing respiratory acid-base disorders)

- hypoventilation (an upper limit to compensation exists - breathing cannot be stopped)

### Treatment

- correct underlying disease, replenish  $\text{K}^+$  and  $\text{Mg}^{2+}$  deficits, and possibly  $\text{K}^+$ -sparing diuretic
- saline sensitive metabolic alkalosis (most common)
  - urine chloride  $<20$  mEq/L, characterized by ECF contraction and hypokalemia
  - volume repletion  $\pm$  carbonic anhydrase inhibitor (e.g. acetazolamide) to facilitate loss of  $\text{HCO}_3^-$  in urine
- saline resistant metabolic alkalosis
  - urine chloride  $>20$  mEq/L, characterized by ECF expansion and hypertension (increased mineralocorticoids)
  - remove source of aldosterone or glucocorticoid  $\pm$  spironolactone

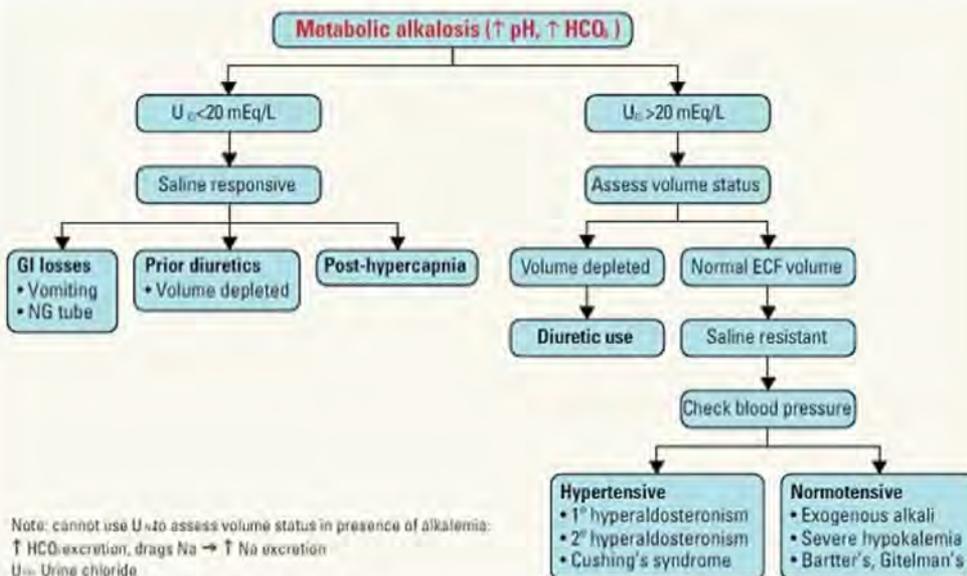

Figure 11. Approach to metabolic alkalosis

## Polyuria

### Definition

- output >3 L/d. Distinguish from urinary frequency, where urination occurs multiple times per day but the total volume over 24 h is <3 L

### Etiology

- drugs (most commonly diuretics)
- excessive caffeine, alcohol intake
- increased water intake (psychogenic polydipsia, IV fluids)
- uncontrolled diabetes mellitus (osmotic diuresis)
- neurological: diabetes insipidus (central and peripheral), cerebral salt-wasting syndrome
- genitourinary: post-obstructive diuresis, cystitis/UTI

### Clinical Features

- must distinguish between true polyuria and urinary frequency
- look for sources of external fluid intake (IV fluids, tube feedings)
- assess for neurological changes (stroke, trauma, postoperative) (for central diabetes insipidus)
- assess for drugs that may cause nephrogenic diabetes insipidus (e.g. lithium)
- abrupt onset suggests central diabetes insipidus (deficient ADH)

### Investigation Findings

- 24 h urine collection >3L
- laboratory findings that may point to specific etiologies:
  - hyperglycemia and/or glucosuria suggests osmotic diuresis secondary to uncontrolled diabetes mellitus
  - hyponatremia may suggest free water intake secondary to polydipsia
  - hypernatremia may suggest free water loss secondary to diabetes insipidus
- check urine osmolality:
  - $U_{osm} < 100$  mOsm/kg, consider causes of water diuresis (DI, psychogenic polydipsia)
  - $U_{osm} 100-300$  mOsm/kg, consider causes of mixed polyuria (partial DI, CKD)
  - $U_{osm} > 300$  mOsm/kg, consider causes of osmotic diuresis (hyperglycemia, azotemia, excess solute intake)
- water deprivation test if suspected DI, see *Diabetes Insipidus, NP12* for complete workup for diabetes insipidus

### Treatment

- specific to etiology

## Acute Kidney Injury

### Definition

- abrupt decline in renal function leading to increased nitrogenous waste products normally excreted by the kidney
- formerly known as acute renal failure

### Clinical Features

- decreased GFR
- weight gain and edema
- azotemia (increased BUN, Cr)
- abnormal urine volume: formally <0.5 mL/kg/h for >6 h but can manifest as anuria, oliguria, or polyuria

Table 10. Classification of Acute Kidney Injury

CRITERIA	RIFLE	AKIN	KDIGO
Serum Creatinine	Increased 2-3 times baseline	Increase of $\geq 26.4$ $\mu\text{mol/L}$ or increase by >50% within 48 h	Increase of $\geq 26.4$ $\mu\text{mol/L}$ within 48 h or increase by >50% within 7 d
GFR	Decreased $\geq 50\%$	N/A	N/A
Urine Output	<0.5 mL/kg/h for >12 h	<0.5 mL/kg/h for >6 h	<0.5 mL/kg/h for >6 h

The 2 most common causes of acute kidney injury in hospitalized patients are prerenal azotemia (decreased perfusion) and ATN; remember that prerenal failure can lead to ATN

### Differentiating Prerenal from ATN

	Prerenal	ATN
Urine Microscopy	Normal	RBC, pigmented granular casts
Urine ( $\text{Na}^+$ )	<20	>40 mEq/L
Urine osmolality	>500	<350 mOsm/kgH <sub>2</sub> O
FENa	<1%	>2%
Plasma (Urea) [Cr]	>20	>10-15
Response of Cr to fluid repletion	Return to baseline 1-3 d	Persistent elevation

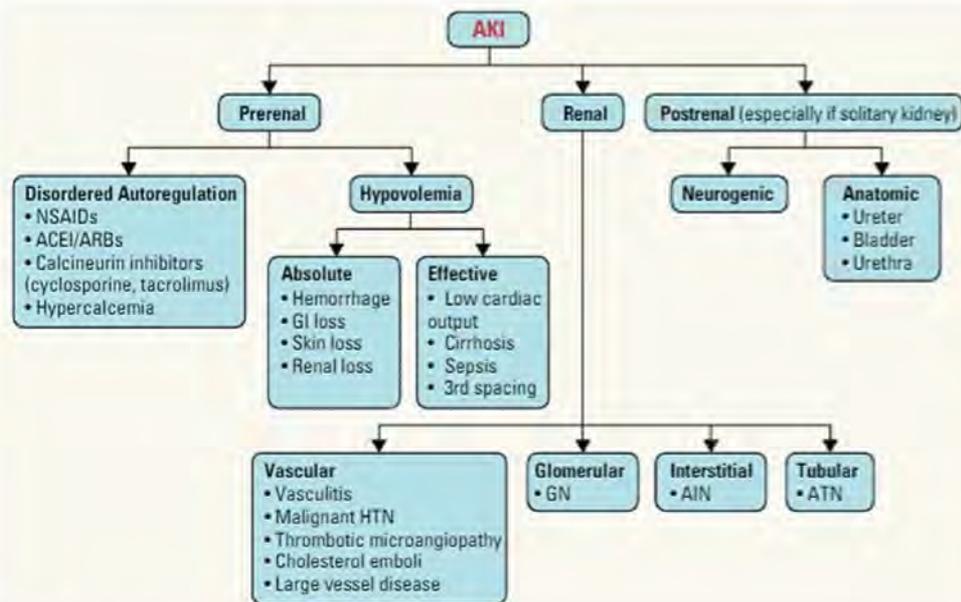

Figure 12. Approach to AKI

**Investigations**

- blood work: CBC, electrolytes, Cr, urea (think prerenal if increase in urea is relatively greater than increase in Cr), Ca<sup>2+</sup>, PO<sub>4</sub><sup>3-</sup>
- urinalysis: albumin, hemoglobin, WBCs, glucose, pH, urobilinogen, specific gravity
- urine volume, C&S, R&M: sediment, casts, crystals
- urinary indices: electrolytes, osmolality
- urine chemistry: urine Na<sup>+</sup> and FENa
- Foley catheterization (rule out bladder outlet obstruction)
- fluid challenge (e.g. fluid bolus to rule out most prerenal causes)
- imaging: abdomen U/S (assess kidney size, hydronephrosis, postrenal obstruction)
- indications for renal biopsy
  - diagnosis is not certain
  - prerenal azotemia or ATN is unlikely
  - oliguria persists >2-4 d
  - RPGN, signs of significant glomerular disease (proteinuria, RBC casts) despite normal kidney size/echogenicity

**Treatment**

1. preliminary measures
  - prerenal
    - correct prerenal factors: optimize volume status and cardiac performance using fluids that will stay in the plasma subcompartment (NS, albumin, blood/plasma), hold ACEI/ARB (gently rehydrate when needed, e.g. CHF), and NSAIDs
  - renal
    - address reversible renal causes: discontinue nephrotoxic drugs, treat infection, and optimize electrolytes
    - correct ECF volume, supportive care, consider corticosteroid or immunosuppressive therapy
  - postrenal
    - consider obstruction: structural (stones, strictures) vs. functional (neuropathy)
    - for obstruction to cause AKI, must have functional solitary kidney or obstruction affecting both kidneys
    - treat with Foley catheter insertion, indwelling bladder catheter, nephrostomy, stenting
2. treat complications
  - fluid overload
    - NaCl restriction
    - high dose loop diuretics
  - electrolyte imbalances (hyperkalemia, hyperphosphatemia, hypocalcemia, hypo/hypermagnesemia, hyperuricemia)
  - acid-base disturbances
  - adjust dosages of medications cleared by kidney (e.g. amiodarone, digoxin, cyclosporine, tacrolimus, some antibiotics, and chemotherapeutic agents)
  - dialysis
3. definitive therapy depends on etiology

**Prognosis**

- high morbidity and mortality in patients with sustained AKI and multi-organ failure

**Clues to Prerenal Etiology**

- Clinical: Decreased BP, increased HR, and orthostatic HR and BP changes, oliguria
- Increased [urea] >> Increased [Cr]
- Urine [Na<sup>+</sup>] <10-20 mmol/L
- Urine osmolality >500 mOsm/kg
- Fractional excretion of Na<sup>+</sup> <1%

**Clues to Renal Etiology**

- Appropriate clinical context
- Urinalysis positive for casts:
  - Pigmented granular – ATN
  - WBC – AIN
  - RBC – GN
- Systemic features, anemia, thrombocytopenia, HTN, mild-moderate ECF volume overload

**Clues to Postrenal Etiology**

- Known solitary kidney
- Older man
- Recent retroperitoneal surgery
- Anuria
- Palpable bladder
- Ultrasound shows hydronephrosis
- Fractional excretion of Na<sup>+</sup> >>2-3 %
- Urine osmolality 250-300 mOsm/kg

**Timing of Initiation of Renal Replacement Therapy in Acute Kidney Injury**  
NEJM 2020;383:240-51

**Purpose:** Elucidate the most effective timing for initiation of renal-replacement therapy in patients with AKI who are critically ill.

**Methods:** Multinational RCT involving critically ill patients with AKI. Patients were randomly assigned to receive an accelerated regimen of renal-replacement therapy (initiated within 12 h after eligibility criteria were met) or a standard strategy (in which renal-replacement therapy was discouraged unless indications developed or AKI >72 h). The primary outcome was all-cause mortality at 90 d.

**Results:** 2927 of the 3019 randomized patients were included in the final intention-to-treat analysis. The 90-day mortality was 43.9% in the accelerated group and 43.7% in the standard strategy group (RR 1.00; 95%CI 0.93 to 2.09, P=0.92). Among 90-day survivors, continued reliance on renal-replacement therapy was 10.4% in the accelerated group and 5.0% in the standard group (RR 1.74; 95% CI 1.24 to 2.43). Adverse events occurred at 23.0% in the accelerated group and 16.5% in the standard group (P<0.001).

**Conclusion:** Among critically ill patients with acute kidney injury, an accelerated renal-replacement strategy was not associated with lower mortality risk than standard strategy at 90 d.

Avoid NSAIDs in patients with diarrhea, heart failure, or renal failure

Renal transplant is not a therapy for AKI

**Drugs Implicated in Prerenal Azotemia**

- Diuretics
- NSAIDs
- ACEI/ARBs

# Parenchymal Kidney Diseases

## Glomerular Diseases

### HISTOLOGICAL TERMS OF GLOMERULAR CHANGES

#### Extent of Changes

- histological terms describing the number of glomeruli affected in a given condition:
  - diffuse: majority of glomeruli abnormal
  - focal: some glomeruli abnormal
- histological terms describing the extent to which individual glomeruli are affected in a given condition
  - global: entire glomerulus abnormal
  - segmental: only part of the glomerulus abnormal

#### Types of Changes

- proliferation: hyperplasia of one of the glomerular cell types (mesangial, endothelial, parietal epithelial), with or without inflammatory cell infiltration
- crescent formation: parietal epithelial cell proliferation and mononuclear cell infiltration form crescent-shape in Bowman's space (hallmark of inflammatory glomerulonephritis)
- membranous changes: capillary wall thickening due to immune deposits or alterations in basement membrane

### CLINICAL FEATURES OF GLOMERULAR DISEASE

#### Important Points to Remember

- glomerular diseases have diverse clinical features including hematuria, proteinuria, HTN, edema, and decreased GFR
  - each glomerulopathy presents as one of four major glomerular syndromes (these are NOT diagnoses)
    1. asymptomatic urinary abnormalities
      - proteinuria
      - hematuria
    2. nephritic syndrome
      - acute GN
      - rapidly progressive GN
    3. nephrotic syndrome
    4. ESRD
- glomerulopathies can be caused by a primary disease or can occur secondary to a systemic disease
- some glomerulopathies can present as more than one syndrome at different times

#### The Nephritic-Nephrotic Spectrum

- glomerular pathology can present with a clinical picture anywhere on a spectrum with pure nephritic (inflammation of glomeruli) and pure nephrotic syndromes (abnormal glomerular permeability) at the extremes

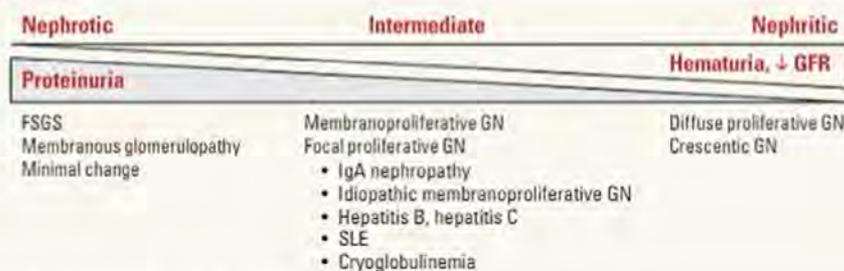

Figure 13. Spectrum of glomerular pathology

#### Proteinuria

- hallmark of nephrotic syndromes
- composition of normal urine protein: albumin, lower molecular proteins (such as immunoglobulin light chain), or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)
- 24 h urine protein: gold standard to assess degree of proteinuria
  - upper limit of normal daily excretion of total protein is 150 mg/d
  - upper limit of normal daily excretion of albumin is 30 mg/d, albuminuria that persists for >3 mo is considered CKD
- spot/random urine ACR: used to screen for diabetic nephropathy and proteinuric renal disease

- microalbuminuria: ACR  $\geq 2.0$  mg/mmol
  - marker of vascular endothelial function
  - an important prognostic marker for CKD (see *Diabetes Insipidus, NP12*)
  - microalbuminuria is the earliest sign of diabetic nephropathy

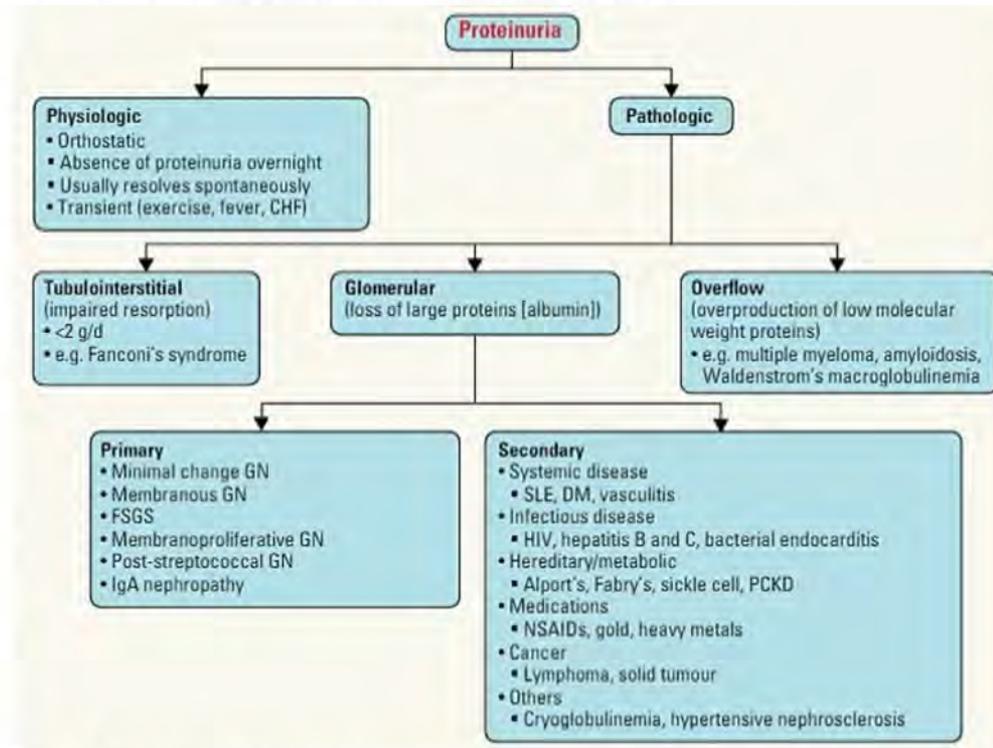

Figure 14. Classification of proteinuria

Table 11. Daily Excretion of Protein

Daily Excretion	Stage of Nephropathy	ACR	PCR
<150 mg total protein (and < 30 mg albumin)	Normal	<2.0 mg/mmol	<15 mg/mmol
30-300 mg albumin	Microalbuminuria	>2.0 mg/mmol	
>3500 mg total protein/1.73 m <sup>2</sup> body surface area	Nephrotic range proteinuria	>220 mg/mmol	>300 mg/mmol
Variable amount of proteinuria	Can be seen with glomerular disease		
Up to 2000 mg per d	Possible tubular disease because of failure to reabsorb filtered proteins		

**Investigations**

- urea, creatinine, ACR, PCR
- urine R&M, C&S, urine dipstick
- further workup (if degree of proteinuria >0.5 g/d, casts, and/or hematuria)
  - CBC, glucose, electrolytes, 24 h urine protein and albumin, and Cr
  - urine and serum immunoelectrophoresis, abdominal/pelvic U/S
  - serology: ANA, RF, p-ANCA (MPO), c-ANCA (PR3), C3, C4, HBV, HCV, HIV, ASOT
- consider urology consult and possible cystoscopy if not clearly a nephrologic source for hematuria or if >50 yr of age

**Pathologic Proteinuria**

**Tubulointerstitial**

- Normally low molecular weight proteins (<60 kDa) pass through glomerular filtration barrier and are reabsorbed in proximal tubule
- Proximal tubule dysfunction causes impaired reabsorption and increased excretion of low molecular weight proteins
- Albumin (>60 kDa) is not affected; thus, edema is partly secondary to salt and water retention

**Glomerular**

- Normally, the filtration barrier is selectively permeable to size (<60 kDa) and charge (repels negative particles); thus, albumin is filtered to a very limited extent through a normal glomerulus
- Damage to any component of the glomerular filtration barrier results in loss of albumin and other high molecular weight proteins; thus, edema is secondary to hypoalbuminemia (low oncotic pressure), but also due to enhanced renal tubular reabsorption of filtered sodium and water (possibly due to filtered proteins stimulating the action of cortical collecting duct epithelial sodium channel)

**Overflow**

- Increased production of low molecular weight proteins which exceeds the reabsorptive capacity of the proximal tubule
- Plasma cell dyscrasias produce light chain Ig (multiple myeloma, Waldenstrom's macroglobulinemia, monoclonal gammopathy of undetermined significance)

# Glomerular Syndromes

## 1. ASYMPTOMATIC URINARY ABNORMALITIES

### Clinical/Lab Features

- often have rapid decline in GFR, anemia, elevated inflammatory markers, ECF volume replete, or mildly overloaded
- proteinuria (usually <2 g/d) and/or microscopic or macroscopic hematuria
  - isolated proteinuria
    - can be postural
    - occasionally can signal beginning of more serious GN (e.g. FSGS, IgA nephropathy, amyloid, diabetic nephropathy)
  - hematuria with or without proteinuria
    - IgA nephropathy (Berger's disease): most common type of primary glomerular disease worldwide, frequently presents after viral upper respiratory tract infection (presents most frequently with gross hematuria)
      - more common in White and Asian populations, and in the 2nd and 3rd decades of life
      - may be associated with cirrhosis, HIV infection, celiac disease
      - mesangial deposition of IgA (more dominant) and C3 seen on immunofluorescence microscopy
      - potential treatment includes: RAAS blockers if proteinuria, steroids, and steroid sparing agents (azathioprine, cyclophosphamide, mycophenolate mofetil, and biologics such as rituximab)
    - hereditary nephritis (Alport Syndrome; Type IV collagen mutation): X-linked nephritis often associated with sensorineural hearing loss; proteinuria <2 g/d
    - thin basement membrane disease: usually autosomal dominant, without proteinuria; benign
    - benign recurrent hematuria: hematuria associated with febrile illness, exercise, or immunization; a diagnosis of exclusion after other possibilities are ruled out

## 2. NEPHRITIC SYNDROME

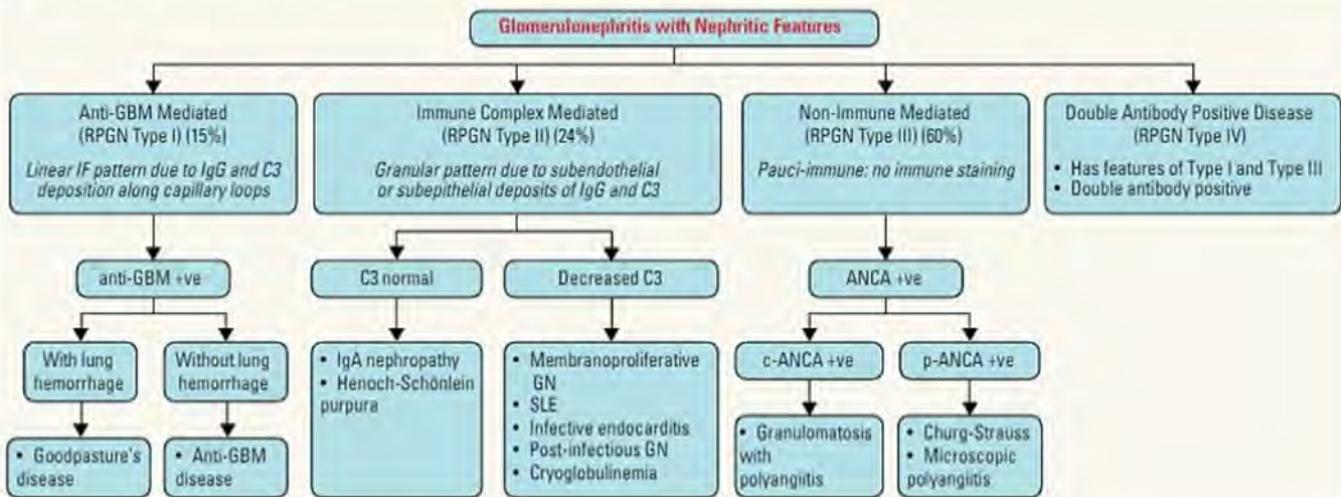

Figure 15. Approach to nephritic syndrome

### ACUTE NEPHRITIC SYNDROME

- a subset of nephritic syndrome in which the clinical course occurs over days
- etiology can be divided into low and normal complement levels
- frequently immune-mediated, with Ig and C3 deposits found in GBM; but may be pauci-immune and caused by an ANCA vasculitis

### Clinical/Lab Features

- proteinuria (less than range for nephrotic syndrome, <3.5 g/1.73 m<sup>2</sup>/d)
- hematuria (microscopic or macroscopic)
- azotemia (increased Cr and urea)
- RBC casts and/or dysmorphic RBCs in urine
- HTN (due to salt and water retention)
- peripheral edema/puffy eyes

### Treatment

- depends on etiology
- pulse steroid therapy and other immunosuppression (steroid sparing agents such as azathioprine and cyclophosphamide, mycophenolate mofetil, and biologics such as rituximab), BP control (with RAAS agents), plasma exchange, monitoring for progression to ESRD

**RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS**

- a subset of nephritic syndrome in which the clinical course occurs over weeks to months
- clinical diagnosis, not histopathological
- any type of GN can present as RPGN (except minimal change disease)
- additional etiologies seen only as RPGN: anti-GBM disease and granulomatosis with polyangiitis (previously called Wegener's granulomatosis)
- crescentic GN (identified by pathology) is frequently seen in RPGN resulting from proliferation of parietal epithelial cells and is the most aggressive form of glomerular disease

**Clinical Features**

- oliguria
- hypertension
- fatigue
- edema

**Investigations**

- fibrous crescents typically present on renal histopathology
- RBC casts and/or dysmorphic RBCs in urine
- classified by immunofluorescence staining
- Type I: anti-GBM mediated (15% of cases)
- Type II: immune complex mediated (24% of cases)
- Type III: Pauci-immune (ANCA associated vasculitis) (60% of cases)
- Type IV: double antibody positive (anti-GBM and ANCA)

**Treatment and Prognosis**

- treatment: underlying cause if post-infectious; corticosteroids and cyclophosphamide or other cytotoxic agent and plasmapheresis to manage cases such as anti-GBM antibody
- prognosis: 50% recovery with early treatment, depends on underlying cause

**3. NEPHROTIC SYNDROME**

**Definition**

- distinct constellation of clinical and laboratory features of renal disease defined by the presence of heavy proteinuria (protein excretion greater than 3.5 g/24 h), hypoalbuminemia (less than 3 g/dL), and peripheral edema

**Clinical/Lab Features**

- heavy proteinuria (>3.5 g/1.73 m<sup>2</sup>/d)
- hypoalbuminemia
- edema
- hyperlipidemia (elevated LDL cholesterol due to increased liver albumin production), lipiduria (fatty casts and oval fat bodies on microscopy)
- hypercoagulable state (due to antithrombin III, Protein C, and Protein S urinary losses)
- patient may report frothy urine
- glomerular pathology on renal biopsy (nephrotic syndrome is always caused by glomerular pathology)
  - minimal change disease (or minimal lesion disease or nil disease): e.g. glomeruli appear normal on light microscopy
  - membranous glomerulopathy
  - FSGS
  - membranoproliferative GN
  - nodular glomerulosclerosis
- each can be idiopathic or secondary to a systemic disease or drug (sirolimus can cause proteinuria without obvious glomerular pathology; sirolimus rarely causes nephrotic syndrome)

**Table 12. Nephrotic Syndrome**

	Minimal Change	Membranous Glomerulopathy	Focal Segmental Glomerulosclerosis	Membranoproliferative Glomerulonephritis	Nodular Glomerulosclerosis
<b>Secondary Causes</b>	Hodgkin's Lymphoma (primarily) and Non-Hodgkin Lymphoma	HBV, SLE, solid tumours (lung, breast, GI)	Reflux nephropathy, HIV, HBV, obesity, sickle cell disease	HCV, malaria, SLE, leukemia, lymphoma, shunt nephritis	DM, amyloidosis
<b>Drug Causes</b>	NSAIDs	Gold, penicillamine	Heroin		
<b>Therapy</b>	Steroids	Reduce BP, ACEI, steroids	Steroids, cytotoxic agents (cyclophosphamide), immunosuppressive agents (calcineurin inhibitors, cyclosporine), ACEI/ARB for proteinuria	Aspirin <sup>®</sup> , ACEI, dipyridamole (Persantine <sup>®</sup> ) – controversial	Treat underlying cause

Note: the most common secondary causes are diabetes mellitus and amyloidosis

**Interventions for Renal Vasculitis in Adults**

Cochrane DB Syst Rev 2015;CD003232

**Purpose:** To assess benefits and harms of any intervention used for the treatment of renal vasculitis in adults.

**Methods:** RCTs in Cochrane Kidney and Transplant Specialized Register investigating any intervention for the treatment of renal vasculitis in adults.

**Conclusions:** Plasma exchange was effective in patients with severe AKI secondary to vasculitis.

Pulse cyclophosphamide resulted in an increased risk of relapse (compared to continuous oral) but required reduced dose. Rituximab and mycophenolate mofetil were comparable in efficacy to cyclophosphamide. Azathioprine, methotrexate and leflunomide were effective as maintenance therapy.

See Landmark Nephrology Trials table for more information on BLISS-LN which details the efficacy and safety of IV belimumab as an add-on therapy in the management of lupus nephritis.

**4. END STAGE RENAL DISEASE**

• see *End Stage Renal Disease, NP39*

**Investigations for Glomerular Disease**

- blood work
  - first presentation: electrolytes, Cr, urea, albumin, fasting lipids, ACR
  - determining etiology: CBC, ESR, serum immunoelectrophoresis (for amyloidosis or multiple myeloma), C3, C4, ANA, p-ANCA, c-ANCA, cryoglobulins, HBV and HCV serology, ASOT, VDRL, HIV, anti-GBM antibodies
- urinalysis: RBCs, WBCs, casts, protein
- 24 h urine for protein and CrCl
- radiology
  - CXR (infiltrates, CHF, pleural effusion)
  - renal U/S
- renal biopsy (percutaneous or open) if heavy proteinuria or renal insufficiency and cause is not obviously diabetic nephropathy
- urine immunoelectrophoresis
  - for Bence-Jones protein if proteinuria present
- renal pathology (light microscopy, immunofluorescence, electron microscope)
- serum protein electrophoresis

**SECONDARY CAUSES OF GLOMERULAR DISEASE**

**Amyloidosis**

- nodular deposits of amyloid in mesangium, usually related to amyloid light chain (AL)
- presents as nephrotic range proteinuria with progressive renal insufficiency
- can be primary or secondary to multiple myeloma, TB, rheumatoid arthritis, or malignancy

**Systemic Lupus Erythematosus**

- see [Rheumatology, RH11](#)
- lupus nephritis can present as any of the glomerular syndromes
- nephrotic syndrome with an active sediment is most common presentation
- GN caused by immune complex deposition in capillary loops and mesangium with resulting renal injury
- serum complement, ANA, anti-DNA levels are usually low during periods of active renal disease
- children and males with SLE are more likely to develop nephritis

**EULAR Recommendations for the Management of Systemic Lupus Erythematosus (SLE)**

*Ann Rheum Dis* 2008;87:195-205

**Lupus Nephritis Recommendations**

**Monitoring:** Renal biopsy, urine sediment analysis, proteinuria, and kidney function may have independent predictive ability for clinical outcome in therapy of lupus nephritis but need to be interpreted in conjunction. Changes in immunological tests (anti-dsDNA, serum C3) have limited ability to predict response to treatment and may be used only as supplemental information.

**Treatment:** In patients with proliferative lupus nephritis, glucocorticoids in combination with immunosuppressive agents are effective against progression to end-stage renal disease. Long-term efficacy has been demonstrated only for cyclophosphamide-based regimens, which are associated with considerable adverse effects. In short- and medium-term trials, mycophenolate mofetil has demonstrated at least similar efficacy compared with pulse cyclophosphamide and has a more favourable toxicity profile. If failure to respond by 6 mo consider intensifying therapy. Flares following remission are not uncommon and require diligent follow-up.

**End-Stage Renal Disease:** Dialysis and transplantation in SLE have long-term patient and graft-survival rates comparable with those observed in non-diabetic non-SLE patients. Transplantation is the method of choice.

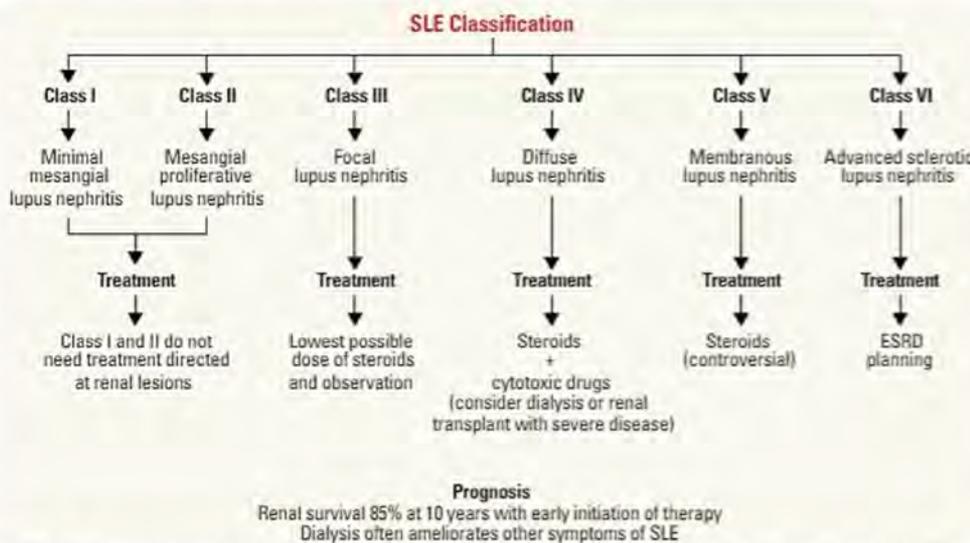

Figure 16. International Society of Nephrology/Renal Pathology Society classification of lupus nephritis 2003

**IgA Vasculitis (Henoch-Schönlein Purpura)**

- Systemic IgA vasculitis, tissue deposition of IgA1-dominant immune complexes affecting mostly small vessels
- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia, and fever
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD

**ANCA-Associated Vasculitis**

- c-ANCA most commonly associated with the clinical picture of granulomatosis with polyangiitis
- p-ANCA most commonly associated with the clinical picture of microscopic polyangiitis
- focal segmental necrotizing RPGN with no immune staining

- may be indolent or fulminant in progression
- vasculitis and granulomas rarely seen on renal biopsy
- treatment typically involves cyclophosphamide and prednisone

### Cryoglobulinemic Vasculitis

- cryoglobulins: monoclonal IgM and polyclonal IgG which precipitate at reduced temperatures, deposit in walls of small vessels
- presents as purpura, fever, Raynaud's phenomenon, and arthralgias
- at least 50% of patients have HCV
- renal disease seen in 40% of patients (isolated proteinuria/hematuria progressing to nephritic syndrome)
- most patients have decreased serum complement (C4 initially)
- treat HCV, plasmapheresis
- overall prognosis: 75% renal recovery

### Shunt Nephritis

- immune-complex mediated nephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus
- commonly caused by *S. epidermidis*
- presents as acute nephritic syndrome with decreased serum complement
- nephrotic range proteinuria in 25% of patients
- treat by removing shunt and administering appropriate antibiotics; can consider a ventriculoperitoneal shunt

### HIV-Associated Renal Disease

1. direct nephrotoxic effect of HIV infection, anti-retroviral drugs (e.g. tenofovir, indinavir), and other drugs used to treat HIV-associated infections
2. HIV-associated nephropathy
  - histology: focal and segmental glomerular collapse with mesangial sclerosis; "collapsing FSGS"
  - tubular cystic dilation and tubulo-reticular inclusions
  - clinical features: predominant in African American men, heavy proteinuria, progressive renal insufficiency (Apo-L-1 risk genotypes)
  - prognosis: kidney failure within 1 yr without treatment
  - therapy: short-term, high dose steroids, ACEI, HAART

### Infective Endocarditis

- manifests as mild form of acute nephritic syndrome with decreased serum complement
- *S. aureus* is most common infecting agent
- treatment with appropriate antibiotics usually resolves GN

### Hepatitis B

- can result in membranous nephropathy, membranoproliferative GN, and polyarteritis nodosa

### Hepatitis C

- can result in membranous nephropathy, membranoproliferative GN, and cryoglobulinemia

### Syphilis

- can result in membranous GN

## Tubulointerstitial Disease

### TUBULOINTERSTITIAL NEPHRITIS

#### Definition

- cellular infiltrates affecting primarily the renal interstitium and tubular cells
- functional tubule defects are disproportionately greater than the decrease in GFR
- classified as acute or chronic

#### Signs and Symptoms

- manifestation of disease depends on site of tubule affected
  1. proximal tubule (e.g. multiple myeloma, heavy metals)
    - Fanconi syndrome: decreased reabsorption in proximal tubule causing glycosuria, aminoaciduria, phosphaturia, and hyperuricosuria
    - proximal RTA (decreased bicarbonate absorption): Type II RTA
  2. distal tubule (e.g. amyloidosis, obstruction)
    - distal RTA (decreased hydrogen secretion, usually hypokalemic): Type I RTA
    - Na<sup>+</sup>-wasting nephropathy
    - ± hyperkalemia leading to Type IV RTA (where reduced renal bicarbonate production is caused by hyperkalemia)

IgA nephropathy is the most common type of primary glomerular disease worldwide

Features of Nephritic Syndrome

**PHAROH**  
 Proteinuria  
 Hematuria  
 Azotemia  
 RBC casts  
 Oliguria  
 HTN

Presentation of Nephrotic Syndrome

**HELP**  
 Hypoalbuminemia  
 Edema  
 Lipid abnormalities  
 Proteinuria

3. collecting duct (e.g. sickle cell anemia, analgesics, primary ciliary dyskinesia)
  - ◆ urinary concentrating defect leading to mild nephrogenic DI
  - ◆ polyuria

## 1. ACUTE TUBULOINTERSTITIAL NEPHRITIS

### Definition

- rapid (d to wk) decline in renal function
- 10-20% of all AKI

### Etiology

- hypersensitivity
  1. antibiotics:  $\beta$ -lactams, sulfonamides, rifampin, quinolones, cephalosporins, fluoroquinolones
  2. other: NSAIDs, allopurinol, furosemide, thiazides, triamterene, PPIs, acyclovir, phenytoin, cimetidine
- infections
  - bacterial pyelonephritis, *Streptococcus*, brucellosis, *Legionella*, CMV, EBV, toxoplasmosis, leptospirosis, HIV, *Mycoplasma*
- immune
  - SLE, acute allograft rejection, Sjögren's syndrome, sarcoidosis, mixed essential cryoglobulinemia
- idiopathic (renal-ocular syndrome – acute TIN plus uveitis)

### Pathophysiology

- acute inflammatory cell infiltrates into renal interstitium

### Clinical Features

- AKI
- if hypersensitivity reaction (common with antibiotics): may see fever, eosinophilia, skin rash, arthralgia, serum sickness-like syndrome (particularly rifampin)
- if pyelonephritis: flank pain and costovertebral angle tenderness
- if drug reaction, AKI usually occurs 7-10 d after exposure
- other signs and symptoms based on underlying etiology
- HTN and edema are uncommon

### Findings

- urine
  - mild, non-nephrotic range proteinuria and microscopic hematuria
  - sterile pyuria, WBC casts
  - eosinophils if AIN
- blood work
  - increased Cr and urea
  - eosinophilia if drug reaction (high negative predictive value, common in  $\beta$ -lactam reactions)
  - normal AG metabolic acidosis (RTA)
  - hypophosphatemia, hypo- OR hyperkalemia, hyponatremia
- gallium scan often shows intense signal due to inflammatory infiltrate
- renal biopsy definitive – shows interstitial infiltrates and edema on biopsy

### Treatment

- treat underlying cause (e.g. stop offending medications, treat infection with antibiotics if present i.e. pyelonephritis)
- corticosteroids (may be indicated in allergic or immune disease)

### Prognosis

- recovery within 2 wk if underlying insult can be eliminated
- the longer the patient is in renal failure, the less likely they will have a full renal recovery

## 2. CHRONIC TUBULOINTERSTITIAL NEPHRITIS

### Definition

- characterized by slowly progressive renal failure, moderate proteinuria, and signs of abnormal tubule function

### Etiology

- persistence or progression of acute TIN
  - may also involve concurrent glomerular manifestations
- urinary tract obstruction: most important cause of chronic TIN (tumours, stones, bladder outlet obstruction, vesicoureteral reflux)
- chronic pyelonephritis due to vesicoureteral reflux or UTI with obstruction
- nephrotoxins
  - exogenous
    - ◆ analgesics: NSAIDs (common), acetaminophen
    - ◆ cisplatin, lithium, cyclosporine, tacrolimus

- heavy metals (lead, cadmium, copper, lithium, mercury, arsenic)
- Chinese herbs (aristolochic acid)
- endogenous
  - hypercalcemia, hypokalemia, oxalate, uric acid
- vascular disease: ischemic nephrosclerosis, atheroembolic disease
- malignancies: multiple myeloma, lymphoma
- granulomatous: TB, sarcoidosis, granulomatosis with polyangiitis
- immune: SLE, Sjögren's, cryoglobulinemia, anti-GBM disease, amyloidosis, renal graft rejection, vasculitis
- hereditary: cystic diseases of the kidney, sickle cell disease
- others: radiation, Balkan (endemic) nephropathy

### Pathophysiology

- fibrosis of interstitium with atrophy of tubules, mononuclear cell inflammation

### Signs and Symptoms

- dependent on underlying etiology

### Findings

- non-AG metabolic acidosis
- hyperkalemia (out of proportion to degree of renal insufficiency)
- polyuria, nocturia
- partial or complete Fanconi's syndrome
- progressive renal failure with azotemia and uremia
- urine: mild proteinuria, few RBCs and WBCs, no RBC casts
- U/S: shrunken kidneys with irregular contours (differentiates acute from chronic etiology)

### Treatment

- stop offending agent or treat underlying disease
- supportive measures: correct metabolic disorders ( $\text{Ca}^{2+}$ ,  $\text{PO}_4^{3-}$ ) and anemia

## 3. ACUTE TUBULAR NECROSIS

### Definition

- abrupt and sustained decline in GFR within minutes to days after ischemic/nephrotoxic insult
- GFR reduced (this serves the purpose of avoiding life-threatening urinary loss of fluid and electrolytes from non-functioning tubules)

### Etiology

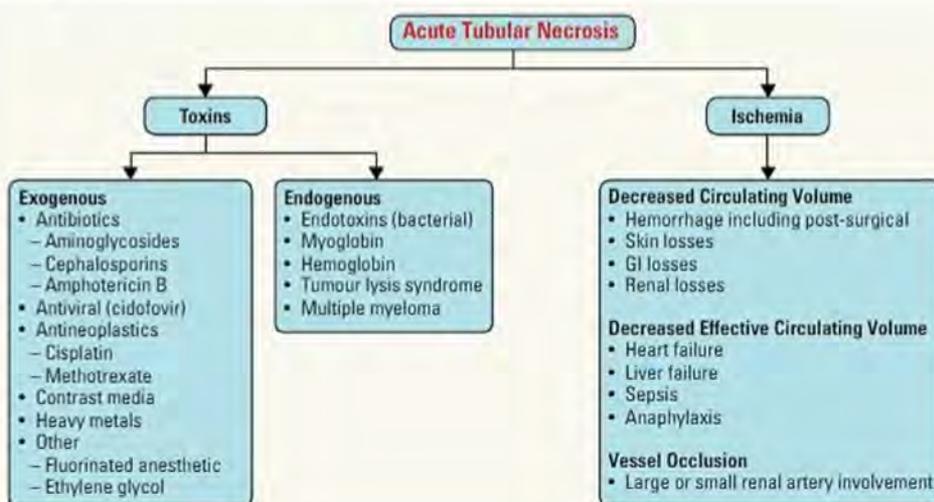

Figure 17. Etiology of ATN

### Clinical Features

- typically presents as an abrupt rise in urea and Cr after a hypotensive episode, sepsis, rhabdomyolysis, or administration of nephrotoxic drug
  - pre-renal AKI can eventually progress to ATN
  - consists of three phases:
    - oliguric: decreased urinary output from renal damage, azotemia, and uremia; lasts 10-14 d
    - diuretic: urinary output >500 mL/day (result of retained water, salt, and solutes during oliguric phase) and tubular cell damage
    - recovery: tubular function recovers

### Effectiveness of Prevention Strategies for Contrast-Induced Nephropathy: A Systematic Review and Meta-Analysis

Ann Intern Med 2016;164(5):406-416

**Purpose:** To evaluate the comparative effectiveness of interventions to reduce contrast-induced nephropathy in adults receiving contrast media.

**Methods:** Meta-analysis of RCTs N-acetylcysteine, sodium bicarbonate, statins, or ascorbic acid that used IV or intra-arterial contrast media.

**Results:** Low dose N-acetylcysteine+IV saline vs. IV saline (RR 0.75, 95% CI 0.63-0.89). N-acetylcysteine+IV saline vs. IV saline (RR 0.69, 95% CI 0.58-0.84). Statins+N-acetylcysteine+IV saline vs. N-acetylcysteine+IV saline (RR 0.52, 95% CI 0.29-0.93). Clinically important, but not statistically significant, reductions were observed in sodium bicarbonate vs. IV saline, statins+IV saline vs. IV saline, and ascorbic acid vs. IV saline.

**Conclusions:** Greatest reduction in contrast-induced nephropathy was seen with N-acetylcysteine plus IV saline and statins plus N-acetylcysteine plus IV saline.

- physical exam may show signs of true or effective ECF volume depletion
- most common cause of non-prerenal AKI in hospitalized patients
- urine: high FE<sub>Na</sub> (>2%), pigmented-granular casts

### Risk Factors

- pre-existing CKD, pre-existing cardiovascular disease, ECF volume depletion, multiple renal insults

### Complications

- hyperkalemia: can occur rapidly and cause serious arrhythmias
- metabolic acidosis, decreased Ca<sup>2+</sup>, increased PO<sub>4</sub><sup>3-</sup>, hypoalbuminemia

### Investigations

- blood work: CBC, electrolytes, Cr, urea, Ca<sup>2+</sup>, PO<sub>4</sub><sup>3-</sup>, blood gasses
- urine: R&M, electrolytes, osmolality, microscopic urinalysis searching for heme granular/muddy brown casts
- ECG (monitor for arrhythmias due to hyperkalemia)
- abdominal U/S
- rule out other causes of prerenal/postrenal azotemia and intrinsic AKI (GN, AIN, vasculitis)
  - IV fluid challenge will not increase urine output or normalize serum creatinine in ATN, helps to differentiate ATN from pre-renal AKI
  - if diagnosis is uncertain, biopsy

### Treatment

- largely supportive once underlying problem is corrected
- consideration for early dialysis in severe/rapidly progressing cases to prevent uremic syndrome (the STARRT-AKI study addressing this is ongoing)

### Prevention

- correct fluid balance before surgical procedures
- for patients with chronic renal disease requiring radiographic contrast:
  - isotonic saline
  - avoid giving diuretics, NSAIDs, ACEI, cyclosporine on morning of procedure if possible
- use renal-adjusted doses of nephrotoxic drugs in patients with renal insufficiency
- use low dose non-ionic, iso- or low-osmolal contrast agents

## Vascular Diseases of the Kidney

### LARGE VESSEL DISEASE

Table 13. Summary of Vascular Diseases

Large Vessel Disease	Medium Vessel Disease	Small Vessel Disease
Acute renal artery occlusion (infarct)	Kawasaki disease	Hypertensive nephrosclerosis
Renal artery stenosis (ischemia)	Polyarteritis nodosa	Atheroembolic renal disease
Renal vein thrombosis	ANCA-associated vasculitis	Thrombotic microangiopathy
		Scleroderma
		Calcineurin inhibitor nephropathy
		HUS
		ANCA-associated vasculitis

### 1. RENAL INFARCTION (ACUTE RENAL ARTERY OCCLUSION)

- important, potentially reversible cause of renal failure

#### Etiology

- abdominal trauma, surgery, embolism, vasculitis, extrarenal compression, hypercoagulable state, aortic dissection
- kidney transplant recipients more vulnerable

#### Signs and Symptoms (depend on presence of collateral circulation)

- fever, N/V, flank pain
- leukocytosis, elevated AST, ALP
- marked elevated LDH (LDH >4x upper limit of normal with minimal elevations in AST/ALT strongly suggestive)
- acute onset HTN (activation of RAAS) or sudden worsening of long-standing HTN
- renal dysfunction, e.g. elevated Cr (if bilateral, or solitary functioning kidney)

#### Investigations

- renal arteriography (more reliable but risk of atheroembolic renal disease)
- contrast-enhanced CT or MR angiography, duplex Doppler studies (operator dependent)

**Treatment**

- prompt localization of occlusion and restoration of blood flow
- anticoagulation, thrombolysis, percutaneous angioplasty or clot extraction, surgical thrombectomy
- medical therapy in the long-term to reduce risk (e.g. antihypertensives)

**2. ISCHEMIC RENAL DISEASE (RENAL ARTERY STENOSIS)**

- chronic renal impairment secondary to hemodynamically significant renal artery stenosis or microvascular disease
- significant cause of ESRD: 15% in patients >50 yr (higher prevalence if significant vascular disease)
- usually associated with large vessel disease elsewhere
- causes of renal artery stenosis
  - atherosclerotic plaques (90%): proximal 1/3 renal artery, usually males >55 yr, smokers
  - fibromuscular dysplasia (10%): distal 2/3 renal artery or segmental branches, usually young females (typical onset <30 yr)
- when there is decreased RBF, GFR is dependent on angiotensin II-induced efferent arteriolar constriction which raises the FF (GFR/RBF)
- most common cause of secondary HTN ("renovascular HTN"), 1-2% of all hypertensive patients
  - etiology
    - decreased renal perfusion of one or both kidneys leads to increased renin release and subsequent angiotensin production
    - increased angiotensin raises blood pressure in two ways
      1. causes generalized arteriolar constriction
      2. release of aldosterone increases Na<sup>+</sup> and water retention
        - elevated blood pressure can in turn lead to further damage of kidneys and worsening HTN

**Risk Factors**

- age >50 yr
- smoking
- other atherosclerotic disease (dyslipidemia, DM, diffuse atherosclerosis)

**Signs and Symptoms**

- severe/refractory HTN and/or hypertensive crises, with negative family history of HTN
- asymmetric renal size
- epigastric or flank bruits
- spontaneous hypokalemia (renin activation in under-perfused kidney)
- increasing Cr with ACEI/ARB
- flash pulmonary edema with normal LV function

**Investigations**

- must establish presence of renal artery stenosis and prove it is responsible for renal dysfunction
- duplex Doppler U/S (kidney size, blood flow): good screening test (operator dependent)
- digital subtraction angiography (risk of contrast nephropathy)
- CT or MR angiography (effective noninvasive tests to establish presence of stenosis, for MR avoid gadolinium contrast if eGFR <30 mL/min because of risk of systemic dermal fibrosis)
- ACEI renography (e.g. captopril renal scan)
- renal arteriography (gold standard, but risk of contrast nephropathy)

**Treatment**

- treatment of renal artery stenosis is performed for select cases of blood pressure control, treatment of heart failure, pulmonary edema, and prevention of nephropathy
- medical therapy includes potential use of ACEI, statins, and platelet inhibitors
- revascularization using stenting is used to treat or prevent development of ischemic nephropathy, although there is debate surrounding its efficacy
- surgical bypass or reconstruction is an option but benefit over angioplasty is debated

**3. RENAL VEIN THROMBOSIS****Etiology**

- endothelial damage: blunt trauma, tumour infiltration (e.g. RCC), vasculitis, renal transplant, and acute rejection
- stasis: severe volume loss (i.e. GI fluid loss, hemorrhage, dehydration), renal vein compression
- hypercoagulability: nephrotic syndrome, sepsis, oral contraceptives, disseminated malignancy, intrinsic hypercoagulability, sickle cell disease
- hypercoagulable states (e.g. nephrotic syndrome, especially membranous), ECF volume depletion, extrinsic compression of renal vein, significant trauma, malignancy (e.g. RCC), sickle cell disease
- clinical features determined by rapidity of occlusion and formation of collateral circulation

**Signs and Symptoms**

- acute: N/V, flank pain, hematuria, elevated plasma LDH, ± rise in Cr, sudden rise in proteinuria
- chronic: PE (typical first presenting symptom), increasing proteinuria, and/or tubule dysfunction

**Treatment of Hypertension in Association with Renovascular Disease**

Can J Cardiol 2017;33(5):557-576

**Guidelines:**

1. Recommend medical management as renal angioplasty and stenting offers no benefit over optimal medical therapy alone.
2. In patients with uncontrolled HTN resistant to maximally tolerated pharmacotherapy, progressive renal function loss and acute pulmonary edema, renal artery angioplasty and stenting for atherosclerotic hemodynamically significant stenosis could be considered.
3. Patients with confirmed renal fibromuscular dysplasia should be referred to HTN specialist and considered for revascularization.

**Stenting and Medical Therapy for Atherosclerotic Renal Artery Stenosis**

NEJM 2014;370:13-22

**Study:** Multicentre, unblinded RCT, median follow-up of 43 mo.

**Patients:** 947 patients with atherosclerotic renal-artery stenosis who also have significant systolic HTN or CKD.

**Intervention:** 947 patients with atherosclerotic renal-artery stenosis who also have significant systolic HTN or CKD.

**Intervention:** Percutaneous revascularization (stenting) with medical therapy (statins, ARB, calcium channel blockers, HCTZ, and BP control) vs. medical therapy alone.

**Outcomes:** Occurrence of adverse CV or renal event (composite of death from CV or renal cause, MI, stroke, hospitalization for CHF, progressive renal insufficiency, or need for renal replacement therapy) and all-cause mortality.

**Outcomes:** Occurrence of adverse CV or renal event (composite of death from CV or renal cause, MI, stroke, hospitalization for CHF, progressive renal insufficiency, or need for renal replacement therapy) and all-cause mortality.

**Results:** No significant difference in primary composite endpoint between participants who received stenting or those on medical therapy alone. No significant differences between the treatment groups in the rates of the individual components of the primary endpoint or in all-cause mortality.

**Conclusion:** Renal artery stenting did not confer a significant benefit with respect to the prevention of clinical events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal artery stenosis and HTN or CKD.

**Investigations**

- renal venography (gold standard), CT or MR angiography, duplex Doppler U/S

**Treatment**

- anticoagulation therapy to aid in recanalisation, improve renal function, and reduce risk of thromboembolism. Initial treatment using IV heparin, followed by warfarin (target INR 2.3) within 3-10 d continued for minimum 1 yr
- certain cases are suitable for thrombectomy or thrombolysis (local or systemic). Commonly used agents include streptokinase, urokinase, and tissue plasminogen activators

**MEDIUM VESSEL DISEASE****1. KAWASAKI DISEASE**

- see [Paediatrics](#), P98

**2. POLYARTERITIS NODOSA**

- see [Rheumatology](#), RH21
- kidneys most commonly involved organ
- heterogenous impact on renal function
- pathologically can cause glomerular ischemia which manifests as mild proteinuria and hypertension

**SMALL VESSEL DISEASE****1. HYPERTENSIVE NEPHROSCLEROSIS**

- see [Hypertension](#), NP37

**2. ATHEROEMBOLIC RENAL DISEASE**

- progressive renal insufficiency due to embolic obstruction of small- and medium-sized renal vessels by atheromatous emboli
- spontaneous or after renal artery manipulation (surgery, angiography, percutaneous angioplasty)
- anticoagulants and thrombolytics interfere with ulcerated plaque healing and can worsen disease
- investigations
  - eosinophilia, eosinophiluria, and hypocomplementemia
  - renal biopsy: needle-shaped cholesterol clefts (due to tissue-processing artifacts) with surrounding tissue reaction in small-/medium-sized vessels

**treatment**

- no effective treatment; avoid angiographic and surgical procedures in patients with diffuse atherosclerosis, medical therapy for concomitant cardiovascular disease
- prognosis: poor overall, at least one third will develop ESRD

**3. THROMBOTIC MICROANGIOPATHY**

- see [Hematology](#), H23
- etiologies include the spectrum of TTP-HUS, DIC, severe preeclampsia, drug-induced, complement mediated, metabolism-mediated, and coagulation-mediated
- the enzyme ADAMTS13 is reduced in TTP, and ADAMTS13 autoantibodies are useful for diagnosing TTP
- events leading to HUS often begin with the ingestion of Shiga toxin-producing *E. coli*
- renal involvement more common in HUS than TTP
- renal involvement characterized by fibrin thrombi in glomerular capillary loops ± arterioles
- treatment
  - depends on cause
  - supportive therapy
  - TTP-HUS: plasma exchange, corticosteroids (splenectomy and rituximab if refractory)
- avoid platelet transfusions and ASA

**4. CALCINEURIN INHIBITOR NEPHROPATHY**

- secondary to the use of cyclosporine and tacrolimus
- causes both acute reversible and chronic, largely irreversible nephrotoxicity
- major cause of kidney failure in other solid organ transplants (e.g. heart)
- acute: due to afferent and efferent glomerular capillary constriction leading to decreased GFR (tubular vacuolization)
  - prerenal azotemia
  - treatment: calcium channel blockers or prostaglandin analogs, reduce dose of cyclosporine or switch to another immunosuppressive drug
- chronic: result of obliterative arteriolopathy causing interstitial nephritis and CKD (striped fibrosis), less frequent now due to lower doses of calcineurin inhibitors

**Reduced Exposure to Calcineurin Inhibitors in Renal Transplantation (ELITE-Symphony Trial)**

N. EJM 2007;257:2562-2575

**Study:** Multicentre, RCT with 12 mo follow-up. Patients: 1645 patients scheduled to receive a single organ kidney transplant.

**Intervention:** Mycophenolate mofetil, corticosteroids, and either: 1) standard dose cyclosporine; 2) low dose cyclosporine with daclizumab induction; 3) low dose tacrolimus with daclizumab induction; 4) low dose sirolimus with daclizumab induction.

**Primary Outcome:** Estimated Cockcroft-Gault GFR 12 mo after transplantation.

**Results:** The tacrolimus arm showed significantly higher eGFR at 12 mo compared to all other arms (85.4 mL/min vs. 57.1, 59.4, 56.7 for arms 1, 2, 4 respectively,  $P < 0.001$ ). The tacrolimus arm also showed decreased rates of acute rejection at 6 mo and 12 mo vs. all arms ( $P < 0.001$ ), improved allograft survival against standard dose cyclosporine and sirolimus, and decreased treatment failure against all other arms. There was no difference in overall patient survival between groups. Sirolimus had the highest incidence of lymphocele, delayed wound healing, and serious adverse events; tacrolimus had significantly higher rates of new-onset DM; and cyclosporine regimens had the lowest incidence of diarrhea but highest opportunistic infection rates.

**Conclusion:** Immunosuppression regimens using low dose tacrolimus and daclizumab induction (decrease nephrotoxicity while maintaining therapeutic immunosuppression in renal transplant patients).

## Analgesic Nephropathies

### 1. Vasomotor AKI

- clinically: develop prerenal azotemia days after NSAID initiations
- normally prostaglandins vasodilate afferent renal arteriole to maintain blood flow
- NSAIDs act by inhibiting cyclooxygenase activity, thereby preventing prostaglandin synthesis and causing renal ischemia
- more common in elderly, underlying renal disease, hypovolemia (diuretics, CHF, cirrhosis, nephrotic syndrome)
- treatment: discontinue NSAID, dialysis rarely needed

### 2. Acute Interstitial Nephritis

- caused by fenoprofen (60%), ibuprofen, naproxen
- may be associated with minimal change glomerulopathy and nephrotic range proteinuria
- resolves eventually with discontinuation of NSAID, may require interval dialysis
- short-term high dose steroids (1 mg/kg/d of prednisone) may hasten recovery

### 3. Chronic Interstitial Nephritis

- due to excessive consumption of antipyretics (phenacetin or acetaminophen) in combination with NSAIDs
- seen in patients who also have emotional stress, psychiatric symptoms, and GI disturbance
- papillary necrosis occurs
  - gross hematuria, flank pain, declining renal function
  - calyceal filling defect seen with IVP – “ring sign”
- increased risk of transitional cell carcinoma of renal pelvis
- good prognosis if discontinue analgesics

### 4. Acute Tubular Necrosis

- can be caused by acetaminophen
  - incidence of renal dysfunction is related to the severity of acetaminophen ingestion
- vascular endothelial damage can also occur
- both direct toxicity and ischemia contribute to the tubular damage
- renal function spontaneously returns to baseline within 1-4 wk
- dialysis may be required during the acute episode of ingestion

### 5. Other Effects of NSAIDs

- sodium retention (2° to reduced GFR)
- hyperkalemia, HTN (2° to hyporeninemic hypoaldosteronism)
- excess water retention (2° to loss of antagonistic effect of prostaglandins on ADH)

## Systemic Disease with Renal Manifestation

### Diabetes

- diabetic nephropathy is a slow, progressive increase in albuminuria, followed by a decrease in eGFR <60 later in disease course
- key risk factors include:
  - long duration of diabetes
  - non-optimal glycemic control, blood pressure, and plasma lipid control
  - obesity
  - cigarette smoking
- most common cause of end-stage renal failure in North America
- 50% of patients with diabetes will develop nephropathy
- greater burden in Indigenous communities
  - in Indigenous youth diagnosed with diabetes before age 20, risk of developing ESRD was 2.59 times higher than non-Indigenous people with diabetes
  - 55.1% of Indigenous individuals diagnosed with diabetes had chronic kidney disease
- at diagnosis up to 30% of patients with type 2 DM have albuminuria (75% microalbuminuria, 25% overt nephropathy)
- microalbuminuria is a risk factor for progression to overt nephropathy and cardiovascular disease
- once macroalbuminuria is established, renal function declines, 50% of patients reach ESRD within 7-10 yr
- associated with HTN and diabetic retinopathy (especially type 1 DM) and/or neuropathy (especially type 2 DM)

DM is one of the causes of ESRD that does not result in small kidneys at presentation of ESRD; the others are amyloidosis, HIV nephropathy, PKD, and multiple myeloma

Abnormal Urine ACR Values from 2018 Diabetes Canada CPG  
≥2.0 mg/mmol in males and females

ACEI can cause hyperkalemia; therefore, be sure to watch serum K<sup>+</sup>, especially if patient has DM and renal insufficiency

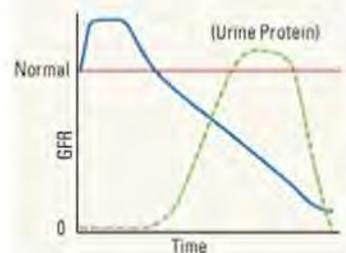

Figure 18. GFR and urine protein over time in DM

Protein Restriction for Diabetic Renal Disease  
Cochrane DB Syst Rev 2007;4:CD002181

**Purpose:** To review the effects of dietary protein restriction on the progression of diabetic nephropathy.

**Study Selection:** RCTs and before and after studies of the effects of restricted protein diet on renal function in subjects with DM. 12 studies were reviewed.

**Results:** The risk of ESRD or death was lower in patients on low-protein diet. In patients with type 1 DM no effect on GFR was noted in the low-protein diet group.

See Landmark Nephrology Trials table for more information on ONTARGET, which details the efficacy of ACEI/ARB combination therapy on renal outcomes in patients with atherosclerotic vascular disease or T2DM. + slightly + mesangial matrix

See Landmark Nephrology Trials table for more information on CREDENCE which details the efficacy of canagliflozin (SGLT2 inhibitor) on renal outcomes in patients with T2DM and diabetic nephropathy

- indication of possible non-diabetic cause of renal disease in patients with DM
  - rising Cr with little/no proteinuria
  - lack of retinopathy or neuropathy (microvascular complications)
  - persistent hematuria (microscopic or macroscopic)
  - signs or symptoms of systemic disease
  - inappropriate time course; rapidly rising Cr, renal disease in a patient with short duration of DM
  - family history of non-diabetic renal disease (e.g. PKD, Alport's)

## DIABETIC RENAL COMPLICATIONS

### 1. Progressive Glomerulosclerosis

- classic diabetic glomerular lesion: Kimmelstiel-Wilson nodular glomerulosclerosis (15-20%)
- more common lesion is diffuse glomerulosclerosis with a uniform increase in mesangial matrix

Table 14. Stages of Diabetic Progressive Glomerulosclerosis

	Stage 1	Stage 2	Stage 3	Stage 4
Clinical	↑ GFR (120-150%) – compensatory hyperfiltration	Detectable microalbuminuria (0-300 mg/24 h)  ACR 2.0-20 mg/mmol (18-180 mg/d)	Macroalbuminuria (>300 mg/24 h)  ACR >20 mg/mmol, (>180 mg/d)  Proteinuria (positive urine dipstick)  Normal GFR	↑ proteinuria (>500 mg/24 h)  ↓ GFR
Pathological	± slightly ↑ mesangial matrix		↑↑↑ mesangial matrix	Sclerosed glomeruli  <20% glomerular filtration surface area present

### 2. Accelerated Atherosclerosis

- common
- leads to decreased GFR
- may increase angiotensin II production resulting in increased BP
- increased risk of ATN secondary to contrast media

### 3. Autonomic Neuropathy

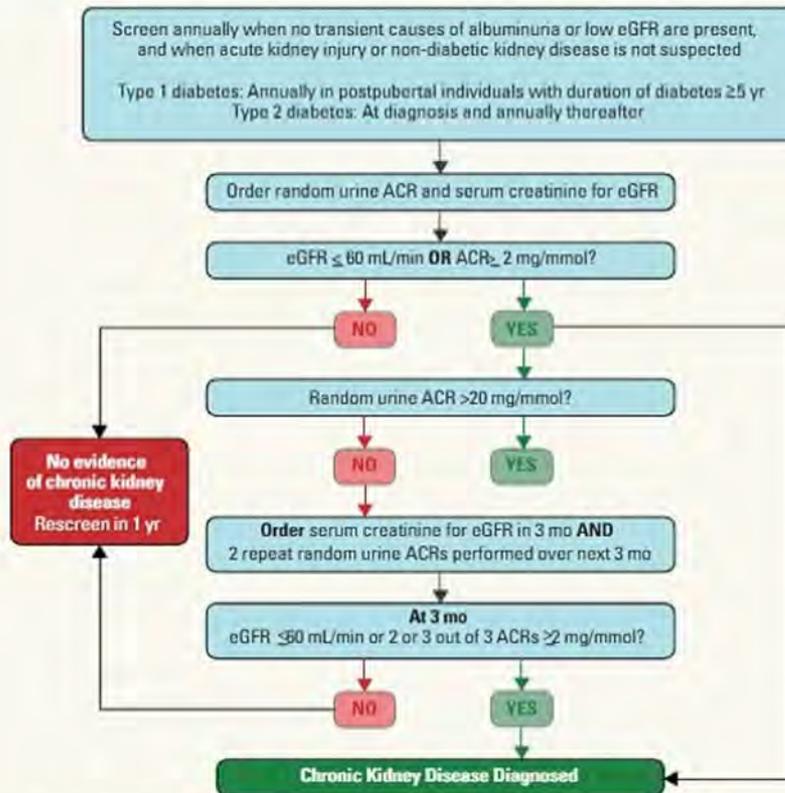

- causes atonic bladder, which leads to functional obstruction and urinary retention
- residual urine promotes infection
- obstructive nephropathy

### 4. Papillary Necrosis

- type 1 DM susceptible to ischemic necrosis of medullary papillae
- sloughed papillae may obstruct ureter
- can present as renal colic or with obstructive features ± hydronephrosis

## Priorities in the Management of Patients with DM

1. vascular protection for all patients with DM
  - ACEI, antiplatelet therapy (as indicated)
  - BP control, glycemic control, lifestyle modification, lipid control
  - SGLT2 inhibition (i.e. canagliflozin, dapagliflozin, and empagliflozin) provides renoprotection independent of glycemic effects
  - mineralocorticoid receptor antagonists (i.e. finerenone) provide renoprotection of top of RAAS blockade
2. optimization of BP in patients who are hypertensive
  - treat according to HTN guidelines
3. renal protection for DM patients with nephropathy (even in absence of HTN)
  - type 1 DM: ACEI or ARB
  - type 2 DM: CrCl >60 mL/min: ACEI or ARB; CrCl <60 mL/min: ARB
  - 2nd line agents: nondihydropyridine calcium channel blockers (diltiazem, verapamil)
  - combination of ACEI and ARB not recommended
4. smoking cessation
  - check serum Cr and K<sup>+</sup> levels within 1 wk of initiating ACEI or ARB and at time of acute illness
  - serum Cr can safely be allowed to rise up to 30% with initiation of ACEI or ARB, usually stabilizes after 2-4 wk, monitor for significant worsening of renal function or hyperkalemia
  - if >30% rise in serum Cr or hyperkalemia, discontinue medication and consider 2nd line agent
  - consider holding ACEI, ARB, and/or diuretic with acute illness and in women before pregnancy
  - consider referral to nephrologist if ACR >60 mg/mmol, eGFR <30 mL/min, progressive loss of kidney function, inability to achieve BP targets, or inability to stay on ACEI or ARB

**Figure 19. Clinical practice guidelines on chronic kidney disease in diabetes**

Diabetes Canada Clinical Practice Guidelines Expert Committee. Diabetes Canada 2018 Clinical Practice Guidelines for the Prevention and Management of Diabetes in Canada. Can J Diabetes 2018;42(Suppl 1):S1-S325

## Scleroderma

- see [Rheumatology, RH14](#)
- 50% of patients with scleroderma have renal involvement (mild proteinuria, high Cr, HTN)
- renal involvement usually occurs early in the course of illness
- histology: media thickened, "onion skin" hypertrophy of small renal arteries, fibrinoid necrosis of afferent arterioles and glomeruli
- 10-15% of scleroderma patients have a "scleroderma renal crisis" (occurs in first few years of disease): malignant HTN, ARF, microangiopathy, volume overload, visual changes, HTN encephalopathy
- treatment: BP control with ACEI slows progression of renal disease

## Multiple Myeloma

- see [Hematology, H51](#)
- malignant proliferation of plasma cells in the bone marrow with the production of immunoglobulins
- patients may present with severe bone disease and renal failure
- light chains are filtered at the glomerulus and appear as Bence-Jones proteins in the urine (monoclonal light chains)
- kidney damage can occur by several mechanisms
  - hypercalcemia
  - light chain cast nephropathy or "myeloma kidney"
  - hyperuricemia
  - infection
  - secondary amyloidosis
  - monoclonal Ig deposition disease
  - diffuse tubular obstruction
- light chain cast nephropathy
  - large tubular casts in urine sediment (light chains + Tamm-Horsfall protein)
  - proteinuria and renal insufficiency can progress rapidly to kidney failure
- monoclonal immunoglobulin deposition disease
  - deposits of monoclonal Ig in kidney, liver, heart, and other organs
  - mostly light chains (85-90%)
  - causes nodular glomerulosclerosis (similar to diabetic nephropathy)
- lab features: increased BUN, increased Cr, urine protein immunoelectrophoresis positive for Bence-Jones protein (not detected on urine dipstick)
- poor candidates for kidney transplantation

## Malignancy

- cancer can have many different renal manifestations
- kidney transplantation cannot be performed if there is a malignancy. Nephrology considerations for malignant presentations include:
  - solid tumours: mild proteinuria or membranous GN
  - lymphoma: minimal change GN (Hodgkin's) or membranous GN (non-Hodgkin's)
  - renal cell carcinoma
  - tumour lysis syndrome: hyperuricemia, diffuse tubular obstruction, hyperkalemia, hyperphosphatemia, hypocalcemia, lactic acidosis
  - chemotherapy (especially cisplatin): ATN or chronic TIN
  - pelvic tumours/metastases: postrenal failure secondary to obstruction
  - 2° amyloidosis
  - radiotherapy (radiation nephritis)

## Chronic Kidney Disease

### Definition

- progressive abnormalities of kidney function for ≥3 mo, with either
  - GFR <60 mL/min/1.73 m<sup>2</sup>; or
  - markers of kidney damage, including:
    - hematuria, proteinuria, or anatomic abnormalities

### Clinical Features

- cardiovascular: HTN, CHF (volume overload, HTN, and anemia), pericarditis (uremia)
- GI: N/V, anorexia
- neurologic: lethargy, confusion, neuropathy, seizures, asterixis, hyperreflexia, restless leg syndrome, encephalopathy (uremia)
- hematologic: normocytic normochromic anemia (reduced EPO), bleeding due to platelet dysfunction (uremia)
- endocrine/metabolic: Ca<sup>2+</sup>, PO<sub>4</sub><sup>3-</sup> disturbances, hyperphosphatemia, hypocalcaemia, secondary hyperparathyroidism, reduced renal production of 1,25-dihydroxy vitamin D, osteopenia/osteoporosis
- sexual/reproductive: hypothalamic pituitary disturbances, infertility
- pruritus: multifactorial etiology

Table 15. Stages of CKD (KDIGO, 2013)

GFR Categories (mL/min/1.73 m <sup>2</sup> )	GFR (mL/min/1.73 m <sup>2</sup> )	Persistent Albuminuria Categories		
		A1 <30 mg/g <3 mg/mmol	A2 30-300 mg/g 3-30 mg/mmol	A3 >300 mg/g >30 mg/mmol
G1	≥90	1 if CKD	1	2
G2	60-89	1 if CKD	1	2
G3a	45-59	1	2	3
G3b	30-44	2	3	3
G4	15-29	3	3	4+
G5	<15 (kidney failure)	4+	4+	4+

The numbers in the boxes are a reflection of the risk of progression and are a guide to the frequency of monitoring/year

\*D\* is added to G5 for patients requiring dialysis

Classification is based on cause, GFR, and amount of albuminuria

Rate of progression and risk of complications are determined by the cause of CKD

## Management of Complications of CKD

### Management of Chronic Kidney Disease

- diet
  - preventing HTN and volume overload
  - low-protein diet with adequate caloric intake in order to limit endogenous protein catabolism. Not recommended in children as protein is needed for growth. Literature is conflicted regarding use of protein restriction in certain other populations
  - Na<sup>+</sup> restriction (<2 g/d) if HTN, CHF, or oliguria are present
  - K<sup>+</sup> restriction (40-60 mmol/d), phosphate (1 g/d) and magnesium (avoid antacids; preventing uremia and potentially delaying decline in GFR) intake
- medical
  - adjust dosages of renally excreted medications
  - HTN: ACEI (target 140/90 mmHg without DM and 130/80 mmHg with DM), loop diuretics when GFR <25 mL/min
  - dyslipidemia: statins (target LDL <2 mmol/L)

### 2016 CCS Guidelines for the Management of Dyslipidemia for the Prevention of CVD in the Adult - Chronic Kidney Disease

Can J Cardiol 2016;32:1263-82

#### Recommendations:

- Adults >50 yr with CKD (GFR <60 mL/min/1.73 m<sup>2</sup>) should receive treatment with a statin or a statin/ezetimibe combination.
- Initiation of lipid-lowering therapy is not recommended for adults with dialysis-dependent CKD however, if already receiving it at the time of dialysis initiation, it should be continued.
- Statin therapy should be used in adults with kidney transplantation.

### Incidence of Etiologies of CKD

DM	42.9%
HTN	26.4%
Glomerulonephritis	9.9%
Other/Unknown	7.7%
Interstitial nephritis/ Pyelonephritis	4.0%
Cystic/Hereditary/Congenital	3.1%
Secondary GN/Vasculitis	2.4%

### Management of Complications of CKD

#### NEPHRON

Low-Nitrogen diet

Electrolytes: monitor K<sup>+</sup>

pH: metabolic acidosis

HTN

RBCs: manage anemia with erythropoietin

Osteodystrophy: give calcium between meals (to increase Ca<sup>2+</sup>) and calcium with meals (to bind and decrease PO<sub>4</sub><sup>3-</sup>)

Nephrotoxins: avoid nephrotoxic drugs (ASA, gentamicin) and adjust doses of renally excreted medications

### Effects of Lowering LDL Cholesterol with Simvastatin and Ezetimibe in Patients with Chronic Kidney Disease

Lancet 2011;377:2181-2192

**Purpose:** To assess the efficacy and safety of the combination of simvastatin and ezetimibe in patients with moderate to severe CKD.

**Study:** Randomized, double-blind trial with 9270 patients with CKD with no known history of myocardial infarction or coronary vascularization. Patients were randomized to simvastatin 20 mg plus ezetimibe 10 mg daily vs. matching placebo.

**Primary Outcome:** First major atherosclerotic event (non-fatal myocardial infarction or coronary death, non-hemorrhagic stroke, or any arterial revascularization procedure).

**Results:** The simvastatin plus ezetimibe group was associated with an average LDL cholesterol difference of 0.85 mmol/L during a median follow-up of 4.9 yr. There was a 17% proportional reduction in major atherosclerotic events in the simvastatin plus ezetimibe group compared to placebo.

**Conclusions:** Reducing LDL cholesterol with a treatment regimen of simvastatin plus ezetimibe safely reduced the incidence of major atherosclerotic events in patients with moderate to severe CKD.

- calcium and phosphate disorders
  - consider vitamin D and calcitriol (1,25-dihydroxy-vitamin D) if hypocalcemic, but hold if hyperphosphatemic (reduces PTH)
  - sevelamer (phosphate binder) if both hypercalcemic and hyperphosphatemic
  - cinacalcet for hyperparathyroidism (sensitizes parathyroid to  $Ca^{2+}$ , decreasing PTH)
- metabolic acidosis: sodium bicarbonate
- anemia: erythropoietin injections for Hb <90 g/L (9 g/dL) and target Hb between 90-115g/L (9-10.5 g/dL). IV iron administration often required for iron deficiency
- clotting abnormalities: DDAVP if patient has clinical bleeding or invasive procedures (acts to reverse platelet dysfunction)
- dialysis (see Indications for *Dialysis in Chronic Kidney Disease, NP41*)
- renal transplantation for end stage kidney disease

### Prevention of Progression

- as above
- control of HTN, DM (HbA1c <7%), cardiovascular risk factors (e.g. smoking cessation, physical activity, weight loss)
- avoid nephrotoxins such as NSAIDs, COXIBs, IV contrast in patients with eGFR <60 mL/min/1.73 m<sup>2</sup>
- address reversible causes of AKI

## Hypertension

- see [Family Medicine, FM37](#)
- HTN occurs in about 20% of population
- etiology classified as primary ("essential;" makes up 90% of cases) or secondary
- primary HTN can cause kidney disease (hypertensive nephrosclerosis), which may in turn exacerbate the HTN
- secondary HTN can be caused by renal parenchymal or renal vascular disease

## Hypertensive Nephrosclerosis

Table 16. Chronic vs. Malignant Nephrosclerosis

	Chronic Nephrosclerosis	Malignant Nephrosclerosis
<b>Histology</b>	Slow vascular sclerosis with ischemic changes affecting intralobular and afferent arterioles	Fibrinoid necrosis of arterioles, disruption of vascular endothelium
<b>Clinical Picture</b>	Black race, underlying CKD, chronic hypertensive disease	Acute elevation in BP (dBP >120 mmHg) HTN encephalopathy
<b>Urinalysis</b>	Mild proteinuria, normal urine sediment	Proteinuria and hematuria (RBC casts)
<b>Therapy</b>	Blood pressure control, (target <140/90) with frequent follow-up	Lower dBP to 100-110 mmHg within 6-24 h More aggressive treatment can cause ischemic event Identify and treat underlying cause of HTN
<b>Prognosis</b>	Can progress to renal failure despite patient adherence	Lower survival if renal insufficiency develops

## Renovascular Hypertension

- see [Vascular Diseases of the Kidney, NP30](#)

## Renal Parenchymal Hypertension

- HTN secondary to GN, AIN, diabetic nephropathy, or any other chronic renal disease
- mechanism of HTN not fully understood but may include:
  - excess RAAS activation due to inflammation and fibrosis in multiple small intra-renal vessels
  - production of unknown vasopressors, lack of production of unknown vasodilators, or lack of clearance of endogenous vasopressor
  - ineffective sodium excretion with fluid overload

### Investigations

- as well as investigations for renovascular HTN, additional tests may include
  - 24 h urinary estimations of CrCl and protein excretion
  - imaging (U/S, CT)
  - serology for collagen-vascular disease
  - renal biopsy (very rarely if at all)

### Treatment

- most chronic renal disease is irreversible; however, treatment of HTN can slow the progression of renal insufficiency
- control ECF volume: Na<sup>+</sup> restriction (2 g/d intake), diuretic, dialysis with end-stage disease
- ACEI or ARB may provide added benefit (monitor K<sup>+</sup> and Cr) if there is significant proteinuria (>300 mg/d)

### Renin Angiotensin System Blockade and Cardiovascular Outcomes in Patients with Chronic Kidney Disease and Proteinuria: A Meta-Analysis

Am Heart J 2008;155:791-805

**Purpose:** To evaluate the role of RAS blockade in improving cardiovascular CV outcomes in patients with CKD.

**Study Selection:** RCT that analyzed CV outcomes in patients with CKD/proteinuria treated with RAS blockade (ACEI/ARB). RAS blockade-based therapy was compared with placebo and control therapy (β-blocker, calcium-channel blockers, and other antihypertensive-based therapy) in the study.

**Results:** Twenty-five trials (n=45758) were included. Compared to placebo, RAS blockade reduced the risk of heart failure in patients with diabetic nephropathy. In patients with non-diabetic CKD, RAS blockade decreased CV outcome compared to control therapy.

**Conclusions:** RAS blockade reduced CV outcomes in diabetic nephropathy as well as non-diabetic CKD.

### Effects of Intensive BP Control in CKD

J Am Soc Nephrol 2017;28(9):2812-2823

**Purpose:** To evaluate appropriate target for BP in patients with CKD and HTN.

**Methods:** RCT subgroup analyses of participants in the Systolic Blood Pressure Intervention Trial (SPRINT). Participants were randomly assigned to intensive group (sBP <120 mmHg) or standard group (sBP <140 mmHg).

**Results:** The intensive group had a lower rate of all-cause death (HR 0.72, 95% CI 0.63-1.05) and major CV events (HR 0.81, 95% CI 0.63-1.05). Decreases in eGFR were comparable between treatment groups (HR 0.90, 95% CI 0.44-1.83). Treatment effects did not differ between participants with and without CKD.

**Conclusions:** In patients with CKD and HTN without diabetes, target sBP of 120 mmHg vs. 140 mmHg reduced rates of major CV events and all-cause death.

## Cystic Diseases of the Kidney

- characterized by epithelium-lined cavities filled with fluid or semisolid debris within the kidneys
- includes: simple cysts (present in 50% of population >50), medullary cystic kidney, medullary sponge kidney, polycystic kidney disease (autosomal dominant and recessive), and acquired cystic kidney disease (in chronic hemodialysis patients)

### Adult Polycystic Kidney Disease

- autosomal dominant; at least 2 genes: *PKD1* (chr 16p) and *PKD2* (chr 4q)
- *PKD1* (1:400), *PKD2* (1:1000) accounts for about 10% of cases of renal failure
- patients generally heterozygous for mutant *PKD* gene but accumulate a series of second 'somatic hits' precipitating the condition
- *PKD* gene defect leads to abnormal proliferation and apoptosis of tubular epithelial cells leading to cyst growth
- most common extrarenal manifestations: multiple asymptomatic hepatic cysts (33%), mitral valve prolapse (25%), intracranial arterial aneurysm (10%), diverticulosis, hernias (abdominal/inguinal)
- polycystic liver disease rarely causes liver failure, but may form the indication of liver transplant due to space occupying impact which can lead to reduced oral intake and malnutrition
- less common extrarenal manifestations: cysts in pancreas, spleen, thyroid, ovary, seminal vesicles, and aorta

#### Signs and Symptoms

- often asymptomatic; discovered incidentally on imaging or by screening those with FHx
- acute abdominal flank pain/dull lumbar back pain (source: infection of renal cysts, hemorrhaging into cysts, kidney stones)
- hematuria (frequently initial sign is microscopic hematuria, otherwise gross hematuria)
- nocturia (urinary concentrating defect)
- extrarenal presentation (e.g. ruptured berry aneurysm, diverticulitis, mitral valve prolapse, aortic regurgitation, tricuspid valve prolapse)
- HTN (increased renin due to focal compression of intrarenal arteries by cysts) (60-75%)
- ± palpable kidneys

#### Common Complications

- urinary tract and cyst infections, HTN, chronic renal failure, nephrolithiasis (5-15%), flank and chronic back pain

#### Clinical Course

- polycystic changes are always bilateral and can present at any age
- clinical manifestations rare before age 20-25
- kidneys are normal at birth but may enlarge to 10x normal size
- variable progression to renal functional impairment (ESRD in up to 50% by age 60)

#### Investigations

- U/S is confirmatory (enlarged kidneys, multiple cysts throughout renal parenchyma, increased cortical thickness, splaying of renal calyces)
- CT abdomen with contrast (for equivocal cases, occasionally reveals more cystic involvement)
- MRI for kidney volume measurement
- gene linkage analysis for *PKD1* for asymptomatic carriers
- Cr, BUN, urine R&M (to assess for hematuria)

#### Treatment

- goal: to preserve renal function by prevention and treatment of complications
- tolvaptan has been used to slow decline of renal function, however its use has been limited by side effects
- educate patient and family about disease, its manifestations, and inheritance pattern
- genetic counselling: transmission rate 50% from affected parent
- prevention and early treatment of urinary tract and cyst infections (avoid instrumentation of GU tract)
- TMP/SMX, ciprofloxacin: able to penetrate cyst walls, achieve therapeutic levels
- adequate hydration to prevent stone formation
- avoid contact sports due to greater risk of injury to enlarged kidneys
- screen for cerebral aneurysms if family history of aneurysmal hemorrhages
- monitor blood pressure and treat HTN with ACEI
- dialysis or transplant for ESRD (disease does not recur in transplanted kidney)
- may require nephrectomy for symptomatic relief of pain or due to recurrent infections

Hypercalcemia complicates many cancers and can cause multiple kinds of renal disorders (renal vasoconstriction with reduced GFR, salt-wasting with volume depletion, risk of calcium kidney stones)

#### Extrarenal Manifestations of PKD

- Hepatic cysts
- Mitral valve prolapse
- Cerebral aneurysms
- Diverticulosis

#### Tolvaptan in Later-Stage Autosomal Dominant Polycystic Kidney Disease

NEJM 2017;377:1930-1942

**Purpose:** To evaluate the efficacy and safety of the vasopressin V2-receptor antagonist tolvaptan in patients with later-stage autosomal dominant polycystic kidney disease.

**Methods:** Phase III, randomized withdrawal, multicentre, placebo-controlled, double-blind trial.

**Results:** Change in estimated GFR from baseline was -2.34 mL/min/1.732 in the tolvaptan group (95% CI, -2.81 to -1.87) vs. -3.61 mL/min/1.732 in the placebo group (95% CI, -4.08 to -3.14).

**Conclusions:** Tolvaptan resulted in a slower decline than placebo in the estimated GFR over a 1 yr period.

## Autosomal Recessive Polycystic Kidney Disease

- 1 in 20000 incidence
- prenatal diagnosis by enlarged kidneys (due to cystic dilatation of the collecting ducts); if significant *in utero* can result in Potter sequence
- perinatal death from respiratory failure
- associated with hepatic fibrosis
- patients who survive perinatal period develop CHF, HTN, CKD, portal hypertension
- treated with dialysis, kidney, and/or liver transplant

## Medullary Sponge Kidney

- common, autosomal dominant, usually diagnosed in 4th-5th decades
- multiple cystic dilatations in the collecting ducts of the medulla
- renal stones, hematuria, and recurrent UTIs are common features
- an estimated 10% of patients who present with renal stones have medullary sponge kidney
- nephrocalcinosis on abdominal x-ray in 50% patients, often detect asymptomatic patients incidentally
- diagnosis: contrast filled medullary cysts on IVP leading to characteristic radial pattern ("bouquet of flowers"), "Swiss cheese" appearance on histological cross-section
- treat UTIs and stone formation as indicated
- does not result in renal failure

## End Stage Renal Disease

### Definition

- ESRD represents an irreversible decline in kidney function requiring renal replacement therapy
- no definite definition, but glomerular filtration rate less than 15 mL/min/1.73 m<sup>2</sup> body surface area, or those requiring dialysis irrespective of glomerular filtration rate

### Risk Factors

- amount of daily proteinuria (strongest predictor of progression to ESRD)
- hypertension, age, history of chronic renal insufficiency, DM, heroin use, tobacco, analgesic use, ethnicity (increased incidence in Black individuals), lower socioeconomic status, obesity, hyperuricemia, and family history of kidney disease

## Presentation of End Stage Renal Disease

### 1. Volume Overload

- due to increase in total body Na<sup>+</sup> content
- signs: weight gain, HTN, pulmonary, or peripheral edema

### 2. Electrolyte Abnormalities

- high
  - K<sup>+</sup> (decreased renal excretion, increased tissue breakdown)
  - PO<sub>4</sub><sup>3-</sup> (decreased renal excretion, increased tissue breakdown)
  - Ca<sup>2+</sup> (rare; happens during recovery phase after rhabdomyolysis-induced AKI or in settings where hypercalcemia contributes to renal failure, such as in multiple myeloma or sarcoidosis)
  - uric acid
- low
  - Na<sup>+</sup> (failure to excrete excessive water intake)
  - Ca<sup>2+</sup> (decreased vitamin D activation, hyperphosphatemia, hypoalbuminemia)
  - HCO<sub>3</sub><sup>-</sup> (especially with sepsis or severe heart failure)

### 3. Uremic Syndrome

- manifestations result from retention of uremic toxins as well as hormone deficiencies

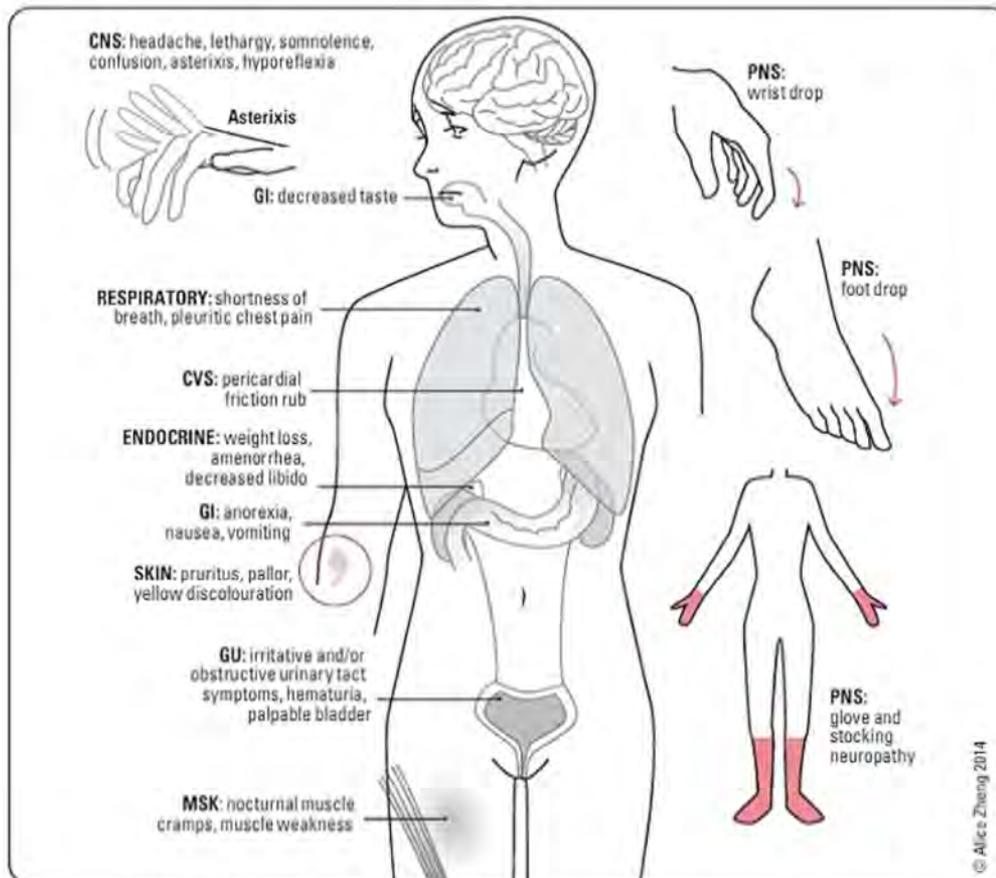

Figure 20. Signs and symptoms of end stage renal disease

### Complications

- CNS: decreased LOC, stupor, seizure
- cardiovascular system: cardiomyopathy, CHF, arrhythmia, pericarditis, atherosclerosis
- GI: peptic ulcer disease, gastroduodenitis, AVM
- hematologic: anemia, bleeding tendency (platelet dysfunction), infections
- endocrine
  - decreased testosterone, estrogen, progesterone
  - increased FSH, LH
- metabolic
- renal osteodystrophy: secondary increased PTH due to decreased  $\text{Ca}^{2+}$ , high  $\text{PO}_4^{3-}$ , and low active vitamin D
  - osteitis fibrosa cystica
  - hypertriglyceridemia, accelerated atherogenesis
  - decreased insulin requirements, increased insulin resistance
- dermatologic: pruritus, ecchymosis, hematoma, calciphylaxis (vascular  $\text{Ca}^{2+}$  deposition)

### Treatment

- dialysis is the preferred treatment for ESRD
- initiation of chronic dialysis has major implications on patients and healthcare system

# Renal Replacement Therapy

## Dialysis

### Indications for Dialysis in Chronic Kidney Disease

**Table 17. Indications for Dialysis**

Absolute Indications	Relative Indications
Volume overload*	Anorexia
Hyperkalemia*	Decreased cognitive functioning
Severe metabolic acidosis*	Profound fatigue and weakness
Neurologic signs or symptoms of uremia (encephalopathy, neuropathy, seizures)	Severe anemia unresponsive to erythropoietin
Uremic pericarditis	Persistent severe pruritus
Refractory accelerated HTN	Restless leg syndrome
Clinically significant bleeding diathesis	
Persistent severe N/V	

\*Unresponsive to medications

- decision to start dialysis in ESRD should be symptom driven or when GFR reaches approximately  $\leq 10$  mL/min
  - hemodialysis: blood is filtered across a semipermeable membrane removing accumulated toxic waste products, solutes, excess fluid (ultrafiltration), and restoring buffering agents to the bloodstream
  - available as intermittent (e.g. 3-6x/wk), CVVHD, or SLED which are in-hospital treatments
  - can be delivered at home or in-centre, nocturnal
  - vascular access can be achieved through a central line, an artificial AV graft, or an AV fistula
- patients with CKD should be referred for surgery to attempt construction of a primary AV fistula when their eGFR is  $< 20$  mL/min, the serum Cr level quoted as  $> 350$   $\mu\text{mol/L}$ , or within 1 yr of an anticipated need
- check Kidney Failure Risk Equation, which provides the 2 and 5 year probability of treated kidney failure for a potential patient with CKD stage 3 to 5
- peritoneal dialysis: peritoneum acts as a semipermeable membrane similar to hemodialysis filter
  - advantages: independence, fewer stringent dietary restrictions, better rehabilitation rates
  - available as continuous ambulatory (CAPD; 4-5 exchanges/d) or cyclic (CCPD; machine carries out exchanges overnight)
- refer patients with chronic renal disease to a nephrologist early on to facilitate treatment and plan in advance for renal replacement therapy (RRT)

**Table 18. Peritoneal Dialysis vs. Hemodialysis**

	Peritoneal Dialysis	Hemodialysis
Rate	Slow	Fast
Location	Home	Hospital (usually)
Ultrafiltration	Osmotic pressure via dextrose dialysate	Hydrostatic pressure
Solute Removal	Concentration gradient and convection	Concentration gradient and convection
Membrane	Peritoneum	Semi-permeable artificial membrane
Method	Indwelling catheter in peritoneal cavity	Line from vessel to artificial kidney
Complications	Infection at catheter site Bacterial peritonitis Metabolic effects of glucose Difficult to achieve adequate clearance in patients with large body mass	Vascular access (clots, collapse) Bacteremia Bleeding due to heparin Hemodynamic stress of extracorporeal circuit Disequilibrium syndrome (headache, cerebral edema, hypotension, nausea, muscle cramps related to solute/water flux over short time)
Preferred When	Residual renal function Success depends on presence of residual renal function Hemodynamic instability	Comorbidities, no renal function Residual renal function not as important History of abdominal surgery

#### How to Write Dialysis Orders (MUST BE INDIVIDUALIZED)

- Filter Type (e.g. F80)
- Length (e.g. 4 h 3x/wk or 2 h daily)
- Q Blood Flow (max 500 cc/min)
- Ultrafiltration (e.g. 2 L or to target dry weight)
- Na<sup>+</sup> 140 (can be adjusted by starting at 155 and "ramping" down to minimize cramping)
- K<sup>+</sup> (based on serum K<sup>+</sup>)  
Serum K<sup>+</sup>/Dialysate  
4-6    1.5  
3.5-4    2.5  
<3.5    3.5
- Ca<sup>2+</sup> 1.25
- HCO<sub>3</sub><sup>-</sup> = 40
- Heparin (none, tight [500 U/h] or full [1000 U/h])
- IV fluid to support BP (e.g. NS)

#### When to Initiate Dialysis

- CrCl  $< 20$  mL/min
- Educate patient regarding dialysis; if not a candidate for peritoneal dialysis, make arrangements for AV fistula
- CrCl  $< 15$  mL/min
- Weigh risk and benefits for initiating dialysis
- CrCl  $< 10$  mL/min
- Dialysis should be initiated

#### NOTE

- Cockcroft-Gault equation (or MDRD equation) should be used to measure kidney function
- Monitor for uremic complications
- Significant benefits in quality of life can occur if dialysis started before CrCl  $< 15$  mL/min
- It is unclear whether patients who start dialysis early have increased survival
- A preemptive transplant can be considered if patient is stable, in order to avoid dialysis

Source: National Kidney Foundation Kidney Disease Outcomes Quality Initiative

#### Commonly Used Immunosuppressive Drugs

- Calcineurin inhibitors
  - Cyclosporine
  - Tacrolimus
- Antiproliferative medications
  - Mycophenolate mofetil
  - Azathioprine
- Other agents
  - Sirolimus
  - Prednisone
- Anti-lymphocyte antibodies
  - Thymoglobulin
  - Basiliximab

#### Indications for Dialysis (Refractory to Medical Therapy)

- AE IOU
- Acidosis
- Electrolyte imbalance (K<sup>+</sup>)
- Intoxication (AKI)
- Overload (fluid)
- Uremia (encephalopathy, pericarditis, urea  $> 35-50$  mM)

## Renal Transplantation

- provides maximum replacement of GFR
- preferred modality of RRT in CKD, not AKI
- best way to reverse uremic signs and symptoms
  - renal transplantation has been shown to have improved long-term patient survival and greater quality of life over dialysis
- native kidneys usually left in situ
- 2 types: deceased donor, living donor (related or unrelated)
- living donor transplants have been shown to have better short- and long-term outcomes than deceased donor transplants
- kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
- induction immunosuppression with IV thymoglobulin or basiliximab, followed by maintenance oral immunosuppression with an oral immunosuppression cocktail (usually corticosteroids, calcineurin inhibitor, anti-metabolite)
- long-term monitoring of cyclosporine and tacrolimus levels are required
- 1 yr renal allograft survival rates  $\geq 90\%$

### Complications

- #1 cause of mortality in transplanted patients is cardiovascular disease
- increased risk of infections (bacterial, viral, fungal, opportunistic)
- new-onset DM (often due to prednisone and calcineurin inhibitors, especially tacrolimus)
- graft rejection (cellular or humoral)
- acute rejection: rise in Cr, fever, hematuria, graft site tenderness, oliguria, although symptoms are very uncommon
- early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
- transplant glomerulopathy from antibody injury
- cyclosporine or tacrolimus nephropathy (see *Small Vessel Disease, NP32*)
- *de novo* GN (membranous, IgA, MPGN)
- BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss
- leading causes of late allograft loss: interstitial fibrosis/tubular atrophy and death with functioning graft
- depends on immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset DM)
- infections (CMV, PJP, and other opportunistic infections usually occur between 1 and 6 mo post-transplant)
- malignancy (skin cancer, Kaposi's sarcoma, non-Hodgkin's lymphoma)

### Intravenous Iron in Patients Undergoing Maintenance Hemodialysis

NEJM 2019;380:447-458

**Purpose:** To assess the use of high doses of iron in patients undergoing hemodialysis.

**Study:** Multi-centre, open-label trial with blinded endpoint evaluation.

**Population:** 2141 adults with ESRD in whom maintenance hemodialysis was initiated no more than 12 mo prior were randomized to high-dose IV iron (median 264 mg monthly) administered proactively (1,093) or low-dose IV iron (median 145 mg monthly) administered reactively (1,048).

**Outcome:** Primary endpoint was nonfatal myocardial infarction, nonfatal stroke, hospitalization for heart failure, or death.

**Results:** 29.3% of patients in the high-dose group had a primary endpoint event, compared to 32.3% in the low-dose group. Patients in the high-dose group had a lower median monthly dose of an erythropoiesis-stimulating agent compared to the low-dose group (29,757 IU vs. 38,805 IU).

**Conclusions:** A high-dose IV iron regimen administered proactively in patients undergoing hemodialysis is superior to a low-dose regimen administered reactively.

### Survival Benefit with Kidney Transplants from HLA-Incompatible Live Donors

NEJM 2016;374:940-950

**Purpose:** To assess whether there is a survival advantage to receiving a kidney from HLA-incompatible donors compared to remaining on the waiting list for a possible matched deceased donor kidney.

**Study:** Retrospective, multi-centre analysis

**Population:** 1025 individuals who received HLA-incompatible live donor kidneys compared to two different controls: individuals waiting and possibly receiving a deceased donor kidney (N=5125), or individuals ultimately not receiving a kidney transplant (N=5125).

**Outcome:** Survival, tracked for up to 8 years.

**Results:** Individuals who received HLA incompatible kidneys had increased survival compared to either control group for time points at 1 year, 5 years, and 8 years post-transplant (P<0.001). After 8 years non-matched kidney recipients had 76.5% survival compared to 43.9% for individuals who ultimately did not receive a kidney transplant. Survival advantage was significant regardless of how the recipient anti-HLA antibodies were detected.

**Conclusions:** Individuals who received HLA incompatible kidneys had significantly improved long-term survival compared to individuals who waited for compatible deceased donor kidneys.

## Common Medications

**Table 19. Common Medications in Nephrology**

Classification	Examples	Site of Action	Mechanism of Action (Secondary Effect)	Indication	Dosing	Adverse Effects
<b>Loop Diuretics</b>	furosemide (Lasix <sup>®</sup> ) bumetanide (Bumex <sup>®</sup> / Buinex <sup>®</sup> ) ethacrynate (Edecrin <sup>®</sup> ) torsemide (Demadex <sup>®</sup> )	Thick ascending limb of Loop of Henle	↓ Na <sup>+</sup> /K <sup>+</sup> /2Cl <sup>-</sup> transport ± renal and peripheral vasodilatory effects (K <sup>+</sup> loss; ↑ H <sup>+</sup> secretion; ↑ Ca <sup>2+</sup> excretion)	Management of edema secondary to CHF, nephrotic syndrome, cirrhotic ascites; ↑ free water clearance (e.g. in SIADH-induced hyponatremia), ↓ BP (less effective due to short action)	furosemide: edema: 20-80 mg IV/IM/PO q6-8h (max 600 mg/d) until desired response HTN: 20-80 mg/d PO once daily/BID dosing	Allergy in sulfa-sensitive individuals Electrolyte abnormalities: hypokalemia, hyponatremia, hypocalcemia, hypercalciuria (with stone formation) Volume depletion with metabolic alkalosis Precipitates gout attacks
<b>Thiazide Diuretics</b>	hydrochlorothiazide (HCTZ) chlorothiazide (Diuril <sup>®</sup> ) indapamide (Lozol <sup>®</sup> , Lozide <sup>®</sup> ) metolazone (Zaroxolyn <sup>®</sup> ) chlorthalidone (Hygroton <sup>®</sup> )	Distal convoluted tubule	Inhibit Na <sup>+</sup> /Cl <sup>-</sup> transporter (K <sup>+</sup> loss; ↑ H <sup>+</sup> secretion; ↓ Ca <sup>2+</sup> excretion)	1st line for essential HTN Treatment of edema Idiopathic hypercalciuria and stones Diabetes insipidus (nephrogenic)	HCTZ: edema: 25-100 mg PO once daily HTN: 12.5-25 mg PO once daily (max 50 mg/d) nephrolithiasis/hypercalciuria: 25-100 mg once daily	Hypokalemia Increased serum urate levels Precipitates gout attacks, hypercalcemia Elevated lipids Glucose intolerance
<b>Potassium-Sparing Diuretics</b>	spironolactone (Aldactone <sup>®</sup> ) triamterene (Dyrenium <sup>®</sup> ) amiloride (Midamor <sup>®</sup> )	Cortical collecting duct (↓ Na <sup>+</sup> reabsorption)	Aldosterone antagonist (spironolactone) Block Na <sup>+</sup> channels (triamterene and amiloride)	Reduces K <sup>+</sup> loss caused by other diuretics Edema/hypovolemia Severe CHF, ascites (spironolactone), cystic fibrosis (amiloride ↓ viscosity of secretions)	spironolactone: 25-200 mg/d once daily/BID dosing HTN: 50-200 mg/d once daily/BID dosing Hyperaldosteronism: 100-400 mg/d once daily/BID dosing amiloride: edema/HTN: 5-10 mg PO once daily	Hyperkalemia (caution with ACEI) Triamterene can be nephrotoxic (rare) Nephrolithiasis Gynecomastia (estrogenic effect of spironolactone)
<b>Combination Agents</b>	Dyazide <sup>®</sup> (triamterene + HCTZ) Aldactazide <sup>®</sup> (spironolactone + HCTZ) Moduretic <sup>®</sup> (amiloride + HCTZ) Vaseretic <sup>®</sup> (enalapril + HCTZ) Zestoretic <sup>®</sup> (lisinopril + HCTZ)		Combination of ACEI and thiazide have a synergistic effect	Combine K <sup>+</sup> -sparing drug with thiazide to reduce hypokalemia		
<b>Osmotic Diuretics</b>	mannitol (Osmitol <sup>®</sup> ) glycerol urea	Renal tubules (proximal and collecting duct)	Non-reabsorbable solutes increase osmotic pressure of glomerular filtrate → inhibits reabsorption of water and ↑ urinary excretion of toxic material	To ↑ intracranial or intraocular pressure Mobilization of excess fluid in renal failure or edematous states	mannitol: ↓ ICP: 0.25-2 g/kg IV over 30-60 min	Transient volume expansion Electrolyte abnormalities (↓ Na <sup>+</sup> , ↓ K <sup>+</sup> )
<b>ACEI</b>	ramipril (Altace <sup>®</sup> ) enalapril (Vasotec <sup>®</sup> ) lisinopril (Prinivil <sup>®</sup> ) trandolapril (Mavik <sup>®</sup> ) captopril (Capoten <sup>®</sup> )	Lungs Tissues diffusely	Inhibits angiotensin converting enzyme, preventing formation of angiotensin II Prevents angiotensin II vasoconstricting vascular smooth muscle → net vasodilation → ↓ BP Prevents angiotensin II mediated aldosterone release from adrenal cortex and action on proximal renal tubules → ↑ Na <sup>+</sup> and H <sub>2</sub> O excretion → ↓ BP Reduces fibrosis and atherogenesis	HTN Cardioprotective effects Renoprotective effects	ramipril: HTN: 2.5-20 mg PO once daily/BID dosing renoprotective use: 10 mg PO once daily trandolapril: HTN: 1-4 mg PO once daily	Cough Asthma Hyperkalemia Angioedema Agranulocytosis (captopril) AKI Teratogenic
<b>ARB</b>	losartan (Cozaar <sup>®</sup> ) candesartan (Atacand <sup>®</sup> ) irbesartan (Avapro <sup>®</sup> ) valsartan (Diovan <sup>®</sup> ) telmisartan (Micardis <sup>®</sup> ) eprosartan (Teveten <sup>®</sup> ) olmesartan (Olmetec <sup>®</sup> )	Vascular smooth muscle, adrenal cortex, proximal tubules	Competitive inhibitor at the angiotensin II receptor: prevents angiotensin II vasoconstricting action on vascular smooth muscle → ↓ BP Prevents angiotensin II mediated aldosterone release from adrenal cortex and action on proximal renal tubules → ↑ Na <sup>+</sup> and H <sub>2</sub> O excretion	HTN Cardioprotective effects Renoprotective effects	HTN: losartan 25-100 mg PO once daily candesartan 8-32 mg PO once daily irbesartan 150-300 mg PO once daily valsartan 80-320 mg PO once daily telmisartan 20-80 mg PO once daily eprosartan 400-800 mg PO once daily olmesartan 20-40 mg PO once daily	Hyperkalemia Caution – reduce dose in hepatic impairment AKI Teratogenic
<b>Renin Antagonists</b>	aliskiren (Rasilez <sup>®</sup> )	Direct renin antagonist	Inhibits renin production and activity Cardioprotective and renoprotective abilities being evaluated	HTN	aliskiren 150-300 mg PO once daily	Hyperkalemia

# Landmark Nephrology Trials

Trial Name	Reference	Clinical Trial Details
<b>ELECTROLYTE DISTURBANCES</b>		
SALT-1	NEJM 2006;16:2099-112	<p><b>Title:</b> Tolvaptan, a Selective Oral Vasopressin V2-Receptor Antagonist, for Hyponatremia</p> <p><b>Purpose:</b> Investigate whether tolvaptan might be of benefit in hyponatremia.</p> <p><b>Methods:</b> Patients with euvolemic or hypovolemic hyponatremia were randomized to oral tolvaptan 15 mg daily or oral matched placebo. The primary endpoints were changes in daily area-under-the-curve for serum Na<sup>+</sup> concentrations.</p> <p><b>Results:</b> Serum Na<sup>+</sup> concentrations increased more in the tolvaptan group than placebo during the first 4 d (P&lt;0.001) and after 30 d (P&lt;0.001). Side effects included dry mouth, thirst, and increased urination.</p> <p><b>Conclusions:</b> In patients with euvolemic or hypovolemic hyponatremia, tolvaptan, an oral vasopressin V2-receptor antagonist, was effective in increasing serum Na<sup>+</sup> concentrations.</p>
OPAL-HK	NEJM 2015;372:211-21	<p><b>Title:</b> Patiromer in Patients with Kidney Disease and Hyperkalemia Receiving RAAS Inhibitors</p> <p><b>Purpose:</b> Assess the safety and efficacy of patiromer, a K<sup>+</sup> binder, in treating hyperkalemia.</p> <p><b>Methods:</b> Patients with CKD receiving RAAS inhibitors with serum K<sup>+</sup> levels of 5.1 to 6.5 mmol/L received patiromer for 4 wk. The primary efficacy endpoint was the mean change in serum K<sup>+</sup> levels from baseline to week 4. Subsequently, 107 patients were randomly assigned to patiromer or placebo for the randomized withdrawal phase.</p> <p><b>Results:</b> The median increase in K<sup>+</sup> levels from baseline was greater with placebo than with patiromer (P&lt;0.001). A recurrence of hyperkalemia occurred in 60% of placebo patients compared with 15% in the patiromer group.</p> <p><b>Conclusions:</b> In CKD patients receiving RAAS inhibitors and who had hyperkalemia, patiromer treatment was associated with a decrease in serum K<sup>+</sup> levels and a reduction in hyperkalemia recurrence.</p>
<b>DIABETIC NEPHROPATHY</b>		
ACEI and Diabetic	NEJM 1993;329:1456-62	<p><b>Title:</b> The Effect of Angiotensin-Converting-Enzyme Inhibition on Diabetic Nephropathy</p> <p><b>Purpose:</b> Determine whether captopril has kidney-protecting properties independent of BP control in patients with diabetic nephropathy.</p> <p><b>Methods:</b> Patients with insulin-dependent DM were randomized to captopril or placebo. The primary endpoint was a doubling of the baseline serum Cr.</p> <p><b>Results:</b> The associated risk reductions of the primary endpoint was 48% in the captopril group. Serum Cr concentrations doubled in 25 patients in the captopril group compared to 43 patients in the placebo group. The mean rate of decline in Cr clearance was 11% per yr in the captopril group and 17% in the placebo group.</p> <p><b>Conclusions:</b> Captopril protects against deterioration in renal function in insulin-dependent diabetic nephropathy and is significantly more effective than BP control alone.</p>
ALTITUDE	NEJM 2012;367:2204-13	<p><b>Title:</b> Cardiorenal End Points in a Trial of Alikiren for Type 2 Diabetes</p> <p><b>Purpose:</b> Determine whether aliskiren would reduce CV events in patients with T2DM and CKD.</p> <p><b>Methods:</b> 8561 patients were randomized to aliskiren 300 mg daily or placebo as an adjunct to ACEI or ARB. The primary endpoint was a composite of time to CV death, cardiac arrest with resuscitation, nonfatal MI, nonfatal stroke, or UA hospitalization.</p> <p><b>Results:</b> The primary endpoint occurred in 18.3% of patients assigned to aliskiren, compared with 17.1% in the placebo group (hazard ratio 1.08; 95% CI 0.98 to 1.20; P=0.12). Effects on secondary renal outcomes were similar between groups. The proportion of patients with hyperkalemia (11.2% vs. 7.2%) and hypotension (12.1% vs. 8.3%) were higher in the aliskiren group.</p> <p><b>Conclusions:</b> Combining aliskiren with ACEI or ARB in high-risk patients with T2DM leads to increased incidence of nonfatal stroke, hyperkalemia, and hypotension.</p>
BENEDICT	NEJM 2004;351:1941-51	<p><b>Title:</b> Preventing Microalbuminuria in Type 2 Diabetes</p> <p><b>Purpose:</b> Assess whether ACEI and non-dihydropyridine calcium channel blockers (CCBs), alone or in combination, prevent microalbuminuria in patients with HTN and T2DM.</p> <p><b>Methods:</b> 1204 patients were randomized to 3 yr of treatment with trandolapril 2 mg daily plus verapamil SR 180 mg daily, trandolapril alone, verapamil alone, or placebo. The primary endpoint was the development of persistent microalbuminuria.</p> <p><b>Results:</b> The primary outcome was reached in 5.7% of combination patients, 6% of trandolapril patients, 11.9% of verapamil patients, and 10% of placebo patients. Serious adverse events were similar among all treatment groups.</p> <p><b>Conclusions:</b> Treatment with ACEI trandolapril alone or trandolapril combined with verapamil decreased the incidence of microalbuminuria in patients with T2DM and HTN with normoalbuminuria.</p>
DETAIL	NEJM 2004;351:1952-61	<p><b>Title:</b> Angiotensin-Receptor Blockade versus Converting-Enzyme Inhibition in Type 2 Diabetes and Nephropathy</p> <p><b>Purpose:</b> Compare renoprotective effects of ARBs and ACEIs in patients with T2DM.</p> <p><b>Methods:</b> 250 patients with T2DM and early nephropathy were randomized to either telmisartan 80 mg daily or enalapril 20 mg daily. The primary endpoint was a change in GFR between baseline and last available value, during the 5 yr study period.</p> <p><b>Results:</b> At 5 yr, the change in GFR was -17.9 mL/min/1.73 m<sup>2</sup> with telmisartan, compared with 14.9 mL/min/1.73 m<sup>2</sup> with enalapril (difference -3.0 mL/min/1.73 m<sup>2</sup>; 95% CI -7.6 to 1.6).</p> <p><b>Conclusions:</b> The ARB telmisartan and the ACEI enalapril are equally effective in slowing renal function deterioration in T2DM with mild to moderate HTN and early nephropathy.</p>
IDNT	NEJM 2001;345:851-60	<p><b>Title:</b> Renoprotective Effect of the Angiotensin-Receptor Antagonist Irbesartan in Patients with Nephropathy Due to Type 2 Diabetes</p> <p><b>Purpose:</b> Assess whether the ARB irbesartan or the CCB amlodipine slow progression of nephropathy in patients with T2DM independently of BP effects.</p> <p><b>Methods:</b> 1715 hypertensive patients with nephropathy due to T2DM were randomized to irbesartan 300 mg daily, amlodipine 10 mg daily, or placebo. The primary endpoint was a composite of the doubling of baseline serum Cr, development of ESRD, or all-cause mortality.</p> <p><b>Results:</b> Treatment with irbesartan was associated with a rate of primary endpoints 20% lower than placebo (P=0.02) and 23% lower than amlodipine (P=0.006). Treatment with irbesartan was associated with a RR of ESRD 23% lower than that in both other groups (P=0.07 for both comparisons). These differences were not explained by BP changes.</p> <p><b>Conclusions:</b> Treatment with irbesartan reduced the risk of developing ESRD and worsening renal function in patients with T2DM and diabetic nephropathy.</p>
RENAAL	NEJM 2001;345:861-69	<p><b>Title:</b> Effects of Losartan on Renal and Cardiovascular Outcomes in Patients with Type 2 Diabetes and Nephropathy</p> <p><b>Purpose:</b> Assess the role of ARB losartan in slowing progression of renal disease, in patients with T2DM and nephropathy.</p> <p><b>Methods:</b> 1513 patients were randomized to losartan 50-100 mg daily or placebo, in addition to conventional antihypertensive treatments. The primary outcome was a composite of the doubling of serum Cr, ESRD, or mortality.</p> <p><b>Results:</b> 327 patients in the losartan group, compared with 359 in the placebo group, achieved the primary endpoint (risk reduction 16%; P=0.02). Losartan reduced the incidence of the doubling of serum Cr (risk reduction 25%; P=0.006) and ESRD (risk reduction 28%; P=0.002), with no effect on mortality.</p> <p><b>Conclusions:</b> Losartan conferred significant renal benefits in patients with T2DM and nephropathy, and was generally well-tolerated.</p>

Trial Name	Reference	Clinical Trial Details
ROADMAP	NEJM 2011;364:907-17	<p><b>Title:</b> Olmesartan for the Delay or Prevention of Microalbuminuria in Type 2 Diabetes</p> <p><b>Purpose:</b> Assess whether treatment with an ARB would prevent the occurrence of microalbuminuria in T2DM patients with normoalbuminuria.</p> <p><b>Methods:</b> 4447 patients with T2DM were randomized to receive olmesartan 40 mg OD or placebo. Additional hypertensives were used as needed to meet the target BP of &lt;130/80 mmHg. The primary outcome was the time until the first onset of microalbuminuria.</p> <p><b>Results:</b> Microalbuminuria developed in 8.2% of olmesartan-treated patients, and 9.8% in the placebo group. The time to onset of this increase was increased by 23% with olmesartan (hazard ratio 0.77; 95% CI 0.63 to 0.94; P=0.01).</p> <p><b>Conclusions:</b> The use of the ARB olmesartan was more effective than placebo in delaying the onset of microalbuminuria in patients with T2DM, normoalbuminuria, and good BP control.</p>
Canagliflozin Slows Progression of Renal Function Decline Independently of Glycemic Effects	JASN 2017; 28:368-75	<p><b>Title:</b> Canagliflozin Slows Progression of Renal Function Decline Independently of Glycemic Effects</p> <p><b>Purpose:</b> Determine whether canagliflozin decreases albuminuria and reduces renal function decline independently of its glycemic effects.</p> <p><b>Methods:</b> 1450 patients with T2DM receiving metformin were randomized to canagliflozin 100 mg, canagliflozin 300 mg, or glimepiride at 6-8 mg. Primary endpoints were annual change in eGFR and albuminuria over 2 yr follow-up.</p> <p><b>Results:</b> Glimepiride, canagliflozin 100 mg and canagliflozin 300 mg had eGFR declines of 3.3 mL/min/1.73 m<sup>2</sup> per yr (95% CI 2.8 to 3.8), 0.5 mL/min/1.73 m<sup>2</sup> (95% CI 0.0 to 1.0), and 0.9 mL/min/1.73 m<sup>2</sup> (95% CI 0.4 to 1.4), respectively. Patients receiving these treatments had reductions in HbA1c of 0.81%, 0.83% and 0.93%, respectively.</p> <p><b>Conclusions:</b> Canagliflozin, an SGLT2 inhibitor, slowed the progression of renal disease over 2 yr in patients with T2DM, and may confer renoprotective effects independently of glycemic control.</p>
<b>PARENCHYMAL KIDNEY DISEASES</b>		
AASK	JAMA 2001;285:2719-28	<p><b>Title:</b> Effect of Ramipril vs. Amlodipine on Renal Outcomes in Hypertensive Nephrosclerosis</p> <p><b>Purpose:</b> Compare the effects of an ACEI, a dihydropyridine CCB and <math>\beta</math>-blocker on hypertensive renal disease progression.</p> <p><b>Methods:</b> 1094 patients with hypertensive renal disease were randomized to amlodipine 5-10 mg/d, metoprolol 50-200 mg/d or ramipril 2.5-10 mg/d, with other agents. The primary outcome was the rate of change of GFR.</p> <p><b>Results:</b> The ramipril group had a 36% slower mean decline in GFR (P=0.006) vs. the amlodipine group (95% CI 20% to 66%). There were no significant differences in the mean GFR decline from baseline to 3 yr between treatment groups.</p> <p><b>Conclusions:</b> Ramipril, compared with amlodipine, slows progression of hypertensive renal disease and proteinuria, and may benefit patients without proteinuria as well.</p>
AURORA 1	Lancet 2021; 397(10289): 2070-80	<p><b>Title:</b> Efficacy and safety of voclosporin versus placebo for lupus nephritis (AURORA 1): a double-blind, randomised, multicentre, placebo-controlled, phase 3 trial</p> <p><b>Purpose:</b> Evaluate the safety and efficacy of voclosporin in the treatment of lupus nephritis.</p> <p><b>Methods:</b> Adults diagnosed with systemic lupus erythematosus with lupus nephritis (biopsy class III-V) were randomized (1:1 ratio) to receive oral voclosporin or placebo, in addition to standard therapy. The primary outcome at wk 52 was a complete renal response (urine protein: Cr ratio <math>\leq</math>0.5 mg/mg, stable renal function (eGFR <math>\geq</math>60 mL/min/1.73 m<sup>2</sup> or &lt;20% decrease from baseline eGFR), and no rescue therapy).</p> <p><b>Results:</b> At endpoint wk 52, significantly more patients in the voclosporin group had a complete renal response, as compared to the placebo group (41% vs. 23%; OR 2.65; 95% CI 11.64-4.27; P&lt;0.0001). The adverse event profile was similar between groups (21% vs. 21%) with no deaths attributable to study-related treatments.</p> <p><b>Conclusions:</b> Patients who received voclosporin in addition to standard therapy had a higher rate of complete renal response than those receiving standard therapy alone.</p>
BLISS-LN	NEJM 2020;383:1117-28	<p><b>Title:</b> Two Year, Randomized, Controlled Trial of Belimumab in Lupus Nephritis</p> <p><b>Purpose:</b> Elucidate the efficacy and safety of IV belimumab as compared with placebo, when added to standard therapy of mycophenolate mofetil or cyclophosphamide-azathioprine.</p> <p><b>Methods:</b> Adults with biopsy-proven, active lupus nephritis were randomized (1:1 ratio) to receive IV belimumab (10 mg/kg) or matching placebo, in addition to standard therapy. The primary outcome at week 104 was a primary efficacy renal response (urinary protein: Cr ratio <math>\leq</math>0.7, eGFR no &lt;20% pre-flare value, or <math>\geq</math>60 mL/min and no use of rescue therapy).</p> <p><b>Results:</b> At endpoint wk104, significantly more patients in the belimumab group had a primary efficacy response, as compared to the placebo group (43% vs. 32%; OR 1.65; 95% CI 1.1 to 2.5; P=0.02). The risk of a renal-related event or death was lower among patients who received belimumab than placebo (hazard ratio 0.51; 95% CI 0.34 to 0.77; P=0.001).</p> <p><b>Conclusions:</b> Patients who received belimumab in addition to standard therapy had a higher rate of primary efficacy response than those who received standard therapy alone.</p>
CORAL	NEJM 2014;370:13-22	<p><b>Title:</b> Stenting and Medical Therapy for Atherosclerotic Renal-Artery Stenosis</p> <p><b>Purpose:</b> Study the usefulness of renal artery stenting for the prevention of major adverse renal and CV events in patients with atherosclerotic renal artery stenosis.</p> <p><b>Methods:</b> 947 patients with atherosclerotic renal artery stenosis and either systolic HTN or CKD were randomized to medical therapy plus stenting, or to medical therapy alone. The primary outcomes were occurrence of adverse CV and renal events.</p> <p><b>Results:</b> The rate of primary events did not differ significantly between participants who underwent stenting or medical therapy alone (35.1% vs. 35.8%; hazard ratio 0.94; 95% CI 0.76 to 1.17; P=0.58). There were no significant differences in other components of the primary endpoint.</p> <p><b>Conclusions:</b> Renal-artery stenting did not confer a significant benefit with respect to the prevention of renal or cardiac events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal-artery stenosis and hypertension or chronic kidney disease.</p>
MAINRITSAN	NEJM 2014;371:1771-80	<p><b>Title:</b> Rituximab versus Azathioprine for Maintenance in ANCA-Associated Vasculitis</p> <p><b>Purpose:</b> Assess whether rituximab helps maintain remission of ANCA-associated vasculitis.</p> <p><b>Methods:</b> Patients with newly diagnosed ANCA-associated vasculitides in complete remission were randomized to either rituximab 500 mg or daily azathioprine. The primary endpoint at 28 mo was the rate of major relapse.</p> <p><b>Results:</b> At 28 mo, major relapse occurred in 29% of patients in the azathioprine group, compared to 5% of patients in the rituximab group (hazard ratio 6.61; 95% CI 1.56 to 27.96; P=0.002). The frequency of serious adverse events was comparable between groups.</p> <p><b>Conclusions:</b> More patients with ANCA-associated vasculitis had sustained remission at 28 mo with rituximab than with azathioprine.</p>
ONTARGET	Lancet 2008;372:547-53	<p><b>Title:</b> Renal Outcomes with Telmisartan, Ramipril, or Both, in People at High Vascular Risk</p> <p><b>Purpose:</b> Investigate the renal effects of ACEI, ARB and combination, in patients with atherosclerotic vascular disease for the reduction of proteinuria.</p> <p><b>Methods:</b> 25 620 patients were randomized to ramipril 10 mg daily, telmisartan 80 mg daily, or a combination. The primary renal outcome was a composite of dialysis, doubling of serum Cr, and mortality.</p> <p><b>Results:</b> The number of primary events were similar for telmisartan (13.4%) and ramipril (13.5%), (hazard ratio 1.00; 95% CI 0.92 to 1.09) but were increased with combination therapy (14.5%; hazard ratio 1.09; 95% CI 1.01 to 1.18, P=0.037).</p> <p><b>Conclusions:</b> Telmisartan and ramipril monotherapy reduced proteinuria and Cr increase in patients with high vascular risk.</p>
REIN	Lancet 1999;354:359-64	<p><b>Title:</b> Renoprotective Properties of ACE-inhibition in Non-diabetic Nephropathies with Non-Nephrotic Proteinuria</p> <p><b>Purpose:</b> Assess the renoprotective effects of ACE inhibition in non-diabetic nephropathies with non-nephrotic proteinuria.</p> <p><b>Methods:</b> 186 patients were randomized to ramipril or control (placebo plus conventional antihypertensive). The primary endpoints were change in GFR and time to overt proteinuria.</p> <p><b>Results:</b> The decline in monthly GFR was not significantly different (0.26 mL/min/1.73 m<sup>2</sup> in ramipril group vs. 0.29 mL/min/1.73 m<sup>2</sup> in the control group). Progression to ESRD was significantly less common with ramipril than control, for a RR of 2.72 (95% CI 1.22 to 6.08), likewise for progression to overt proteinuria (RR 2.40; 95% CI 1.27 to 4.52).</p> <p><b>Conclusions:</b> In non-diabetic nephropathy, ACEI were renoprotective in patients with non-nephrotic range proteinuria.</p>

Trial Name	Reference	Clinical Trial Details
REIN2	Lancet 2005;365:939-46	<p><b>Title:</b> Blood-Pressure Control for Renoprotection in Patients with Non-diabetic Chronic Renal Disease</p> <p><b>Purpose:</b> Assess effects of intensified vs. conventional BP control with ACEI on progression to ESRD.</p> <p><b>Methods:</b> Patients with non-diabetic nephropathies receiving background treatment were randomized to either conventional (diastolic &lt;90 mmHg) or intensified (&lt;130 mmHg) BP control. The primary outcome was time to ESRD over 36 mo.</p> <p><b>Results:</b> Patients assigned to intensified BP control progressed to ESRD at a rate of 23% compared to 20% in the control group.</p> <p><b>Conclusions:</b> In patients with non-diabetic nephropathy already on ACEI, there was no further benefit from intensified BP control by adding CCB vs. conventional BP control on ACEI alone.</p>
ROAD	JASN 2007;18:1889-98	<p><b>Title:</b> Renoprotection of Optimal Antiproteinuric Doses</p> <p><b>Purpose:</b> Determine whether titration of benazepril or losartan would improve renal outcomes in chronic renal insufficiency.</p> <p><b>Methods:</b> 360 patients without DM, who had proteinuria and chronic renal insufficiency were randomized to benazepril 10 mg/d, benazepril 20 mg/d, losartan 50 mg/d, or losartan 100 mg/d. The primary endpoint was time to a composite of doubling serum Cr, ESRD, or mortality.</p> <p><b>Results:</b> Up-titration of benazepril and losartan were associated with a 51% and 53% reduction in the primary endpoint risk (P=0.028 and 0.022 respectively). There was no significant difference in the rates of major adverse events between treatment groups.</p> <p><b>Conclusions:</b> Up-titration of either ACEI benazepril or ARB losartan to optimal anti-proteinuria doses conferred benefit on renal outcome in patients without DM who had proteinuria and renal insufficiency.</p>
AMACING	Lancet 2017;389:1312-22	<p><b>Title:</b> Prophylactic Hydration to Protect Renal Function from Intravascular Iodinated Contrast Material in Patients at High Risk of Contrast-Induced Nephropathy</p> <p><b>Purpose:</b> Assess clinical effectiveness of prophylactic hydration in preventing contrast-induced nephropathy in patients with compromised renal function.</p> <p><b>Methods:</b> High-risk adult patients undergoing an elective procedure requiring iodinated contrast were randomized to IV NaCl 0.9% or no prophylaxis. The primary outcome was incidence of contrast-induced nephropathy.</p> <p><b>Results:</b> Contrast-induced nephropathy was recorded in 2.6% of non-hydrated patients and 2.7% of hydrated patients.</p> <p><b>Conclusions:</b> No-hydration prophylaxis was non-inferior and cost-saving in preventing contrast-induced nephropathy compared with IV hydration.</p>
<b>CHRONIC KIDNEY DISEASE</b>		
CHOIR	NEJM 2006;355:2085-98	<p><b>Title:</b> Correction of Anemia with Epoetin Alfa in Chronic Kidney Disease</p> <p><b>Purpose:</b> Determine the optimal level of Hb correction in CKD with erythropoietin (EPO) deficiency as a complication.</p> <p><b>Methods:</b> 1432 patients with CKD were randomized to receive epoetin alfa (human recombinant EPO) targeted to Hb 13.5 g/dL, or those receiving epoetin alfa targeted to Hb 11.3 g/dL. The primary endpoint was a composite of death, MI, hospitalization for CHF, and stroke.</p> <p><b>Results:</b> 125 primary events occurred in the high-Hb group compared to 97 events in the low-Hb group (hazard ratio 1.34; 95% CI 1.03 to 1.74; P=0.03). More patients in the high-Hb group had at least one serious adverse event.</p> <p><b>Conclusions:</b> A higher Hb correction target resulted in increased rates of infarction, hospitalization for CHF, and stroke.</p>
CLICK	NEJM 2021; 385:2507-19	<p><b>Title:</b> Chlorthalidone for Hypertension in Advanced Chronic Kidney Disease</p> <p><b>Purpose:</b> Understand the safety and efficacy of thiazide diuretic chlorthalidone for the treatment of HTN in patients with advanced CKD.</p> <p><b>Methods:</b> 160 patients with stage 4 CKD and poorly controlled HTN were randomized (1:1 ratio) to receive chlorthalidone or placebo. The primary outcome measure was the change in 24-h ambulatory sBP from baseline to 12 wk post-treatment.</p> <p><b>Results:</b> Patients with advanced CKD and poorly controlled CKD receiving chlorthalidone experienced a greater reduction in sBP than those receiving placebo therapy (-11.0 mmHg vs. -0.5 mmHg; P&lt;0.001). Adverse events, including hypokalemia, hyperglycemia, dizziness, and hyperuricemia occurred more frequently in patients receiving chlorthalidone.</p> <p><b>Conclusions:</b> In patients with advanced CKD and poorly controlled HTN, chlorthalidone more effectively reduces sBP than placebo, however, adverse events must be carefully considered.</p>
CREATE	NEJM 2006;355:2071-84	<p><b>Title:</b> Normalization of Hemoglobin Level in Patients with Chronic Kidney Disease and Anemia</p> <p><b>Purpose:</b> Establish whether correction of anemia in stage 3 or 4 CKD improves CV outcomes.</p> <p><b>Methods:</b> 603 patients with eGFR 15.0 to 35.0 mL/min/1.73 m<sup>2</sup> and mild-moderate anemia were randomized to a normal target Hb (13-15 g/dL) or a subnormal target range (10.5-11.5 g/dL). The primary endpoint was a composite of 8 CV events.</p> <p><b>Results:</b> Complete correction of anemia did not affect the likelihood of a first CV event (hazard ratio 0.78; 95% CI 0.53 to 1.14; P=0.20). The mean eGFR was 24.9 mL/min/1.73 m<sup>2</sup> in the complete group, and 24.2 mL/min/1.73 m<sup>2</sup> in the incomplete group, decreasing by 3.6 and 3.1 mL/min/1.73 m<sup>2</sup>/yr, respectively.</p> <p><b>Conclusions:</b> In patients with CKD, complete correction of Hb did not reduce the risk of CV events or incidence of hypertensive episodes.</p>
CREDENCE	NEJM 2019;380:2295-306	<p><b>Title:</b> Canagliflozin and Renal Outcomes in Type 2 Diabetes and Nephropathy (CREDENCE)</p> <p><b>Purpose:</b> Since few effective treatments are available for diabetic nephropathy, this study aims to assess renal outcomes in patients treated with SGLT2 inhibitor canagliflozin.</p> <p><b>Methods:</b> Patients with type 2 diabetes and albuminuric CKD were randomized to receive canagliflozin 100 mg daily, or placebo. All patients had an estimated GFR of 30 to &lt;90 mL/min/1.73 m<sup>2</sup> and albuminuria &gt;300 to 5000, and were treated with RAAS blockade. The primary outcome was a composite of ESRD (dialysis, transplantation, or sustained eGFR &lt;15 mL/min/1.73 m<sup>2</sup>), a doubling of serum Cr, or death from renal or CV (CV) causes.</p> <p><b>Results:</b> Of 4401 randomized patients with a median follow-up of 2.62 yr, the RR of primary outcome was 30% lower in the canagliflozin group than in the placebo group (hazard ratio 0.70; 95% CI 0.59 to 0.82; P=0.00001). The canagliflozin group also had a lower risk of CV death, MI or stroke (hazard ratio 0.85; 95% CI 0.67 to 0.95; P=0.01).</p> <p><b>Conclusions:</b> In patients with T2DM and kidney disease, the risk of kidney failure and CV events was lower in the canagliflozin group than in the placebo group.</p>
DAPA-CKD	NEJM 2020; 383:1436-46	<p><b>Title:</b> Dapagliflozin in Patients with Chronic Kidney Disease</p> <p><b>Purpose:</b> Elucidate the safety of dapagliflozin in patients with CKD with or without T2DM.</p> <p><b>Methods:</b> 4304 patients with CKD (eGFR 25-73 mL/min/1.73 m<sup>2</sup> and ACR 200-5000) were randomized to receive dapagliflozin or placebo. The primary outcome was a composite of ≥50% reduction in eGFR, ESRD, and death from cardiorenal causes.</p> <p><b>Results:</b> The primary outcome occurred less frequently in patients receiving dapagliflozin compared to those receiving placebo (9.2% vs. 14.5%; HR 0.61; 95% CI 0.51-0.72; P&lt;0.001; NNT to prevent one primary outcome event 19; 95% CI 15-27). This trial was stopped early because of efficacy.</p> <p><b>Conclusions:</b> Patients receiving dapagliflozin are less likely to experience a composite of ≥50% reduction in eGFR, ESRD, or death from cardiorenal causes compared to those receiving placebo. Dapagliflozin is safe in patients with CKD.</p>
FIDELIO-DKD	NEJM 2020;383:2219-29.	<p><b>Title:</b> Effect of Finerenone on Chronic Kidney Disease Outcomes in Type 2 Diabetes</p> <p><b>Purpose:</b> Understand the effects of finerenone on kidney and cardiovascular outcomes in patients with CKD and T2DM.</p> <p><b>Methods:</b> 5734 patients with CKD (diabetic retinopathy + urine ACR 30-300 + eGFR 25-60 mL/min/1.73 m<sup>2</sup> or urine ACR 300-5000 + eGFR 25-75 mL/min/1.73 m<sup>2</sup>) and T2DM were randomized (1:1 ratio) to receive finerenone or placebo. The primary outcome measure was a composite of kidney failure, ≥40% reduction in eGFR, and death from renal causes.</p> <p><b>Results:</b> The primary outcome occurred less frequently in patients receiving finerenone compared to those receiving placebo (17.8% vs. 21.1%; HR 0.82; 95% CI 0.73-0.93; P=0.001). The frequency of adverse events was comparable between groups, though hyperkalemia-related discontinuation of therapy occurred more frequently in patients receiving finerenone.</p> <p><b>Conclusions:</b> Patients receiving finerenone are less likely to experience a composite of kidney failure, ≥40% reduction in eGFR, and death from renal causes compared to those receiving placebo.</p>

Trial Name	Reference	Clinical Trial Details
SHARP	Lancet 2011;377:2181-92	<p><b>Title:</b> The Effects of Lowering LDL Cholesterol with Simvastatin plus Ezetimibe in Patients with Chronic Kidney Disease</p> <p><b>Purpose:</b> Assess safety and efficacy of low-density lipoprotein (LDL)-lowering with simvastatin plus ezetimibe in patients with CKD.</p> <p><b>Methods:</b> 9270 patients with moderate-severe CKD with no history of MI or coronary revascularization were randomized to simvastatin 20 mg plus ezetimibe 10 mg daily, or to matching placebo. The primary outcome was the first major atherosclerotic event.</p> <p><b>Results:</b> Combination therapy resulted in a 17% reduction in first major atherosclerotic events (11.3% vs. 13.4%; RR 0.83; 95% CI 0.74 to 0.94; P=0.0021). There were significant reductions in non-hemorrhagic strokes (2.8% vs. 3.8%; RR 0.75; 95% CI 0.60 to 0.94; P=0.01) and arterial revascularization (6.1% vs. 7.6%; RR 0.79; 95% CI 0.68 to 0.93; P=0.0036).</p> <p><b>Conclusions:</b> In patients with CKD and no history of MI or coronary revascularization, 20 mg simvastatin plus 10 mg ezetimibe daily, compared to matching placebo, reduced the incidence of major atherosclerotic events.</p>
TREAT	NEJM 2009;361:2019-32	<p><b>Title:</b> A Trial of Darbepoetin Alfa in Type 2 Diabetes and Chronic Kidney Disease</p> <p><b>Purpose:</b> Assess clinical outcomes with darbepoetin alfa among patients with T2DM and CKD.</p> <p><b>Methods:</b> 4038 patients with diabetes, CKD and anemia were randomized to darbepoetin alfa at 13 g/dL, or to placebo. The primary endpoints were the composite outcomes of death, CV event, death, or ESRD.</p> <p><b>Results:</b> Death or CV events occurred in 632 patients treated with darbepoetin alfa and 602 placebo-matched patients (hazard ratio 1.05; 95% CI 0.94 to 1.17; P=0.41). Death or ESRD occurred in 652 patients treated with darbepoetin alfa and 618 placebo-matched patients (hazard ratio 1.06; 95% CI 0.95 to 1.19; P=0.29).</p> <p><b>Conclusions:</b> Darbepoetin alfa did not reduce the risk of death, a CV event, or a renal event, and was associated with an increased risk of stroke.</p>
EVOLVE	NEJM 2012; 367:2482-94	<p><b>Title:</b> Effect of Cinacalcet on Cardiovascular Disease in Patients Undergoing Dialysis</p> <p><b>Purpose:</b> Assess the effects of calcimimetic agent cinacalcet in reducing mortality risk and nonfatal CV events in patients with CKD.</p> <p><b>Methods:</b> 3383 patients with moderate-severe hyperparathyroidism undergoing hemodialysis were randomized to cinacalcet or placebo. The primary composite endpoint was time until death, MI, hospitalization for unstable angina (UA), HF, or a peripheral vascular event.</p> <p><b>Results:</b> The primary endpoint was reached in 48.3% of cinacalcet-treated patients and 49.2% of placebo-matched patients (hazard ratio 0.93; 95% CI 0.85 to 1.02; P=0.11).</p> <p><b>Conclusions:</b> Cinacalcet did not significantly reduce the risk of death or major CV events in patients with moderate-to-severe secondary hyperparathyroidism who were undergoing dialysis.</p>
<b>CYSTIC DISEASES OF THE KIDNEY</b>		
REPRISE	NEJM 2017;377:1930-42	<p><b>Title:</b> Tolvaptan in Later-Stage Autosomal Dominant Polycystic Kidney Disease</p> <p><b>Purpose:</b> Assess the efficacy and safety of tolvaptan in patients with later-stage autosomal dominant polycystic kidney disease (ADPKD).</p> <p><b>Methods:</b> 1370 patients with ADPKD with eGFR 25 to 44 mL/min/1.73 m<sup>2</sup> were randomized (1:1 ratio) to tolvaptan or placebo for 12 mo. The primary endpoint was a change in eGFR from baseline to follow-up.</p> <p><b>Results:</b> The change from baseline eGFR was -2.34 mL/min/1.73 m<sup>2</sup> in the tolvaptan group (95% CI -2.81 to -1.87) compared with -3.61 mL/min/1.73 m<sup>2</sup> in the placebo group (95% CI -4.08 to -3.14); (difference 1.27; 95% CI 0.86 to 1.86; P&lt;0.001).</p> <p><b>Conclusions:</b> Tolvaptan treatment in patients with later-stage ADPKD resulted in a slower decline in eGFR over a 1 yr period, compared to the placebo group.</p>
<b>RENAL REPLACEMENT THERAPY</b>		
ALERT	Lancet 2003;361:2024-31	<p><b>Title:</b> Effect of Fluvastatin on Cardiac Outcomes in Renal Transplant Recipients</p> <p><b>Purpose:</b> Evaluate the safety and efficacy of fluvastatin on cardiac and renal endpoints in renal transplant recipients.</p> <p><b>Methods:</b> 2102 renal transplant patients were randomized to fluvastatin or placebo. The primary endpoint was the occurrence of a major CV event, including cardiac death, nonfatal MI, or coronary intervention.</p> <p><b>Results:</b> Risk reduction in primary events was not significant with fluvastatin (risk ratio 0.83; 95% CI 0.64 to 1.06; P=0.139). There were fewer cardiac deaths and nonfatal MI in the fluvastatin group than in the placebo group (risk ratio 0.60; 95% CI 0.48 to 0.88; P=0.005).</p> <p><b>Conclusions:</b> The use of fluvastatin in renal transplant recipients did not significantly decrease the risk of occurrence of a major adverse cardiac event, however, there was a significant reduction in cardiac deaths or nonfatal MI.</p>
AURORA	NEJM 2009;360:1395-407	<p><b>Title:</b> Rosuvastatin and Cardiovascular Events in Patients Undergoing Hemodialysis</p> <p><b>Purpose:</b> Assess the benefit of statin therapy in patients undergoing hemodialysis for reduction of CV risk.</p> <p><b>Methods:</b> 2776 patients undergoing maintenance hemodialysis were randomized to rosuvastatin 10 mg daily or placebo. The primary endpoint was death from CV causes, nonfatal MI, or stroke.</p> <p><b>Results:</b> 9.2% and 9.5% of patients reached the primary endpoint, in the rosuvastatin and placebo groups, respectively (hazard ratio 0.96; 95% CI 0.84 to 1.11; P=0.59). Rosuvastatin had no effect on individual components of the primary endpoint.</p> <p><b>Conclusions:</b> In patients receiving maintenance hemodialysis, rosuvastatin had no significant effect on CV risk.</p>
ELITE-SYMPHONY	NEJM 2007;357:2562-75	<p><b>Title:</b> Reduced Exposure to Calcineurin Inhibitors in Renal Transplantation</p> <p><b>Purpose:</b> Evaluate the efficacy and relative toxic effects of four immunosuppressive agents in renal transplant recipients.</p> <p><b>Methods:</b> 1645 renal-transplant recipients were randomized to receive standard-dose cyclosporine plus mycophenolate mofetil plus corticosteroids, or daclizumab induction plus mycophenolate mofetil plus corticosteroids, both groups in combination with either low-dose cyclosporine, low-dose tacrolimus, or low-dose sirolimus. The primary endpoint was eGFR 12 mo after transplantation.</p> <p><b>Results:</b> The mean eGFR was higher in patients receiving low-dose tacrolimus (65.4 mL/min/1.73 m<sup>2</sup>) than in the 3 other groups (ranging from 56.7 mL/min/1.73 m<sup>2</sup> to 59.5 mL/min/1.73 m<sup>2</sup>). Serious adverse events were more common in low dose sirolimus than the other groups (53.2% vs. a range of 43.4% to 44.3%).</p> <p><b>Conclusions:</b> Daclizumab induction, mycophenolate mofetil, corticosteroids, and low-dose tacrolimus effectively maintain stable renal function following renal transplantation, without the negative effects on renal function commonly reported for standard calcineurin inhibitor (CNI) regimens.</p>
FHN	NEJM 2010;363:2287-300	<p><b>Title:</b> Hemodialysis Six Times per Week versus Three Times per Week</p> <p><b>Purpose:</b> Determine whether increasing the frequency of in-center hemodialysis would be beneficial.</p> <p><b>Methods:</b> Patients were randomized to undergo hemodialysis 6x/wk or 3x/wk. The primary composite outcomes were death or change in left ventricular (LV) mass, and death or change in physical health scores.</p> <p><b>Results:</b> Frequent hemodialysis was associated with significant benefits with respect to both primary outcomes (hazard ratio for LV mass 0.61; 95% CI 0.46 to 0.83; hazard ratio for physical health 0.70; 95% CI 0.53 to 0.92). Frequent hemodialysis was also associated with improved HTN and hyperphosphatemia control.</p> <p><b>Conclusions:</b> Frequent hemodialysis, versus conventional hemodialysis, is associated with favourable patient outcomes.</p>
HEMO	NEJM 2002;347:2010-19	<p><b>Title:</b> Effect of Dialysis Dose and Membrane Flux in Maintenance Hemodialysis</p> <p><b>Purpose:</b> Assess the effects on morbidity and mortality of dialysis dose and level of flux, in patients undergoing maintenance hemodialysis.</p> <p><b>Methods:</b> 1846 patients undergoing thrice-weekly dialysis were randomized to high-dose dialysis and to a low- or high-flux dialyzer. The primary outcome was all-cause mortality.</p> <p><b>Results:</b> The primary outcome was not influenced by the dose or flux assignment; (RR 0.96; 95% CI 0.84 to 1.10; P=0.53) for a comparison of the high-dose group with standard-dose, and (RR 0.96; 95% CI 0.81 to 1.05; P=0.23) for a comparison of high- and low-flux dialyzer assignments.</p> <p><b>Conclusions:</b> Use of high dose dialysis or high flux membranes vs. standard dose or low flux in 3x/wk dialysis does not improve survival or outcomes.</p>

Trial Name	Reference	Clinical Trial Details
IDEAL	NEJM 2010;363:609-19	<p><b>Title:</b> A Randomized, Controlled Trial of Early versus Late Initiation of Dialysis</p> <p><b>Purpose:</b> Examine effects of timing dialysis initiation on survival in patients with CKD.</p> <p><b>Methods:</b> Patients with CKD and eGFR 10 to 15 mL/min/1.73 m<sup>2</sup> were randomized to early initiation (eGFR 10.0 to 14.0 mL/min/1.73 m<sup>2</sup>) or late initiation (eGFR 5.0 to 7.0 mL/min/1.73 m<sup>2</sup>). The primary outcome was all-cause mortality.</p> <p><b>Results:</b> A total of 37.6% of patients in the early initiation group and 36.6% of patients in the late-initiation group died within 3.59 yr (hazard ratio 1.04; 95% CI 0.83 to 1.30; P=0.75). There were no significant differences in the frequency of adverse events.</p> <p><b>Conclusions:</b> In patients with progressive CKD, early initiation of dialysis was not associated with an improvement in survival or clinical outcomes.</p>
CONVERT	Transplantation 2009;87:233-42	<p><b>Title:</b> Conversion from Calcineurin Inhibitors to Sirolimus Maintenance Therapy in Renal Allograft Recipients</p> <p><b>Purpose:</b> Evaluate the efficacy and safety of converting maintenance renal transplant patients from CNIs to sirolimus.</p> <p><b>Methods:</b> 830 renal allograft recipients were randomized to continue CNI or convert from CNI to sirolimus. Primary endpoints were GFR and the rates of biopsy-confirmed acute rejection (BCAR), graft loss, or death at 12 mo.</p> <p><b>Results:</b> Intention-to-treat analysis showed no significant difference in GFR, while on-therapy analysis showed higher GFR at 12 and 24 months after sirolimus conversion. Rates of other primary endpoints were similar between groups. Malignancy rates were significantly lower at 12 and 24 months in patients who underwent sirolimus conversion.</p> <p><b>Conclusions:</b> At 2 years, conversion of maintenance therapy in renal transplant patients from CNIs to sirolimus was associated with excellent patient and graft survival.</p>

## Acronyms

aPTT	activated partial thromboplastin time	FDG-PET	18-F fluorodeoxyglucose positron emission tomography	LR	lateral rectus	PPRF	paramedian pontine reticular formation
ACA	anterior cerebral artery	FEF	frontal eye field	MAOI	monoamine oxidase inhibitors	PSP	progressive supranuclear palsy
ACEI	angiotensin converting enzyme inhibitor	FTD	frontotemporal dementia	MCA	middle cerebral artery	PSG	polysomnogram
ACh	acetylcholine	GBS	Guillain-Barré syndrome	MG	myasthenia gravis	RAPD	relative afferent pupillary defect
AD	Alzheimer's disease	GCA	giant cell arteritis	MMSE	mini mental status examination	REM	rapid eye movement
ADL	activities of daily living	GCS	Glasgow coma scale	MoCA	Montreal cognitive assessment	RLS	restless legs syndrome
AED	antiepileptic drugs	GPe	globus pallidus pars externa	MR	medial rectus	ROM	range of motion
AION	acute ischemic optic neuropathy	GPI	globus pallidus pars interna	MRA	magnetic resonance angiography	rtPA	recombinant tissue plasminogen activator
ALS	amyotrophic lateral sclerosis	H/A	headache	MRV	magnetic resonance venography	SAH	subarachnoid hemorrhage
ARI	absolute risk increase	HD	Huntington's disease	MS	multiple sclerosis	SDH	subdural hematoma
AVM	arteriovenous malformation	HTT	Huntingtin gene	MSA	multiple systems atrophy	SNc	substantia nigra pars compacta
AVPU	alert, verbal, pain, unresponsive	IADL	instrumental activities of daily living	MuSK	muscle specific kinase	SNr	substantia nigra pars reticulata
BPPV	benign paroxysmal positional vertigo	ICH	intracranial hemorrhage	NCD	neurocognitive dementia	SNRI	serotonin and norepinephrine reuptake inhibitors
CIDP	chronic inflammatory demyelinating polyneuropathy	IIH	idiopathic intracranial hypertension	NCS	nerve conduction studies	SO	superior oblique
CJD	Creutzfeldt-Jakob disease	INO	internuclear ophthalmoplegia	NMJ	neuromuscular junction	SR	superior rectus
CN	cranial nerve	IO	inferior oblique	NPH	normal pressure hydrocephalus	SSRIs	selective serotonin receptor inhibitors
CNS	central nervous system	IR	inferior rectus	OA	osteoarthritis	STN	subthalamic nucleus
CRPS	complex regional pain syndrome	IVIG	intravenous immunoglobulin	PComm	posterior communicating artery	TBI	traumatic brain injury
CRVO	central retinal vein occlusion	JCV	John Cunningham virus	PD	Parkinson's disease	TCA	tricyclic antidepressant
CTV	cerebral CT venography	LEMS	Lambert-Eaton myasthenic syndrome	PHN	postherpetic neuralgia	TIA	transient ischemic attack
CVD	cerebrovascular disease	LGB	lateral geniculate body	PICA	posterior inferior cerebral artery	UMN	upper motor neuron
DBS	deep brain stimulation	LMN	lower motor neuron	PLMS	periodic limb movement in sleep	VEGF	vascular endothelial growth factor
DLB	dementia with Lewy bodies	LOC	level of consciousness	PML	progressive multifocal leukoencephalopathy	VZV	varicella zoster virus
EOM	extraocular movement	LP	lumbar puncture	PPA	primary progressive aphasia		

## Approach to the Neurological Complaint

### Lesion Localization

- **CNS vs. PNS lesion**
  - CNS: cortical, subcortical, brainstem/bulbar (midbrain, pons, medulla), cerebellum, spinal cord, anterior horn cells
  - PNS: anterior horn cells, nerve root, plexus, peripheral nerve, NMJ, muscle
  - see *Table 3, N5* for UMN (motor neurons originating in cerebral cortex and travelling to brainstem or spinal cord) and LMN (motor neurons originating in spinal cord and travelling to muscles or glands) signs
- **cortical**
  - contralateral hemiparesis (with differential effect on face and arm vs. leg)
  - cortical sensory loss: hemisensory loss, position sense, two-point discrimination, graphesthesia, stereognosis
  - dominant hemisphere: aphasia, alexia, agraphia, acalculia, left-right disorientation
  - non-dominant hemisphere: hemineglect, dysprosody, amusia, constructional apraxia, alien hand syndrome
  - homonymous hemianopia/quadrantanopia
  - gaze deviation
  - seizure
  - agnosia (visual, auditory)
  - ideomotor and ideational apraxia
- **subcortical**
  - internal capsule: contralateral hemiparesis with equal face, arm, and leg involvement without sensory/cortical deficits (pure motor); contralateral hemiparesis and sensory deficit (sensorimotor); contralateral dysmetria/clumsiness and paresis (ataxic hemiparesis); dysarthria and ataxia of the hand (clumsy hand-dysarthria syndrome)
  - basal ganglia: pill-rolling tremor, bradykinesia, festinating gait, hemiballismus, chorea, dystonic posture
  - thalamus: dense sensory loss, contralateral severe pain, visual field cut, cognitive impairment, altered level of awareness
- **brainstem/bulbar (midbrain, pons, and medulla)**
  - crossed hemiplegia or sensory loss (i.e. ipsilateral face, contralateral body)
  - ipsilateral ataxia (dysmetria, rapid alternating movements)
  - nystagmus, diplopia, INO (impaired adduction on contralateral gaze), pupillary abnormalities, gaze impairment
  - dysphagia, dysarthria
  - hearing loss, vertigo
  - hiccups
  - ipsilateral Horner's syndrome

- **cerebellum**
  - ipsilateral ataxia (unsteadiness, incoordination)
  - dysmetria, intention tremor
  - dysidiadochokinesia
  - head/truncal titubation, wide-based gait (staggering, reeling, lurching)
  - scanning speech (explosive speech with noticeable pauses and accentuated syllables)
  - nystagmus, distorted smooth pursuit, oscillopsia
  - pendular reflexes, hypotonia
- **spinal cord**
  - bilateral motor and/or sensory deficits below the lesion without facial involvement
  - sensory level (line below which there is decreased sensation); suspended "cape-like" sensory level (in central cord lesions)
  - LMN signs at level of lesion; UMN signs below lesion
  - bowel, bladder, sexual dysfunction
  - saddle anesthesia (i.e. conus medullaris)
  - sensory ataxia
- **nerve root**
  - multiple peripheral nerve involvement
  - myotomal/dermatomal deficits
  - back/neck pain radiating to leg/arm
  - saddle anesthesia (i.e. cauda equina)
- **peripheral nerve**
  - length dependent ("stocking-glove distribution") or non-length dependent sensory loss (see *Peripheral Neuropathies, N38*)
  - weakness or sensory loss respecting the distribution of a specific nerve (e.g. median nerve, ulnar nerve, radial nerve)
- **neuromuscular junction**
  - fluctuating/fatiguable symptoms
  - facial and limb weakness, bulbar (dysarthria/dysphonia/dysphagia), ocular (diplopia/ptosis), respiratory distress (see *Neuromuscular Diseases, N5*)
  - reflexes usually preserved unless severe/advanced or LEMS
- **muscle**
  - usually symmetric proximal weakness (e.g. climbing stairs, getting up from chair) without sensory deficits
  - asymmetric myopathic weakness seen in distal myopathies, myositis, glycogen storage diseases, and facioscapulohumeral dystrophy
  - muscle tenderness
  - muscle atrophy

See Online Atlas for Cranial Nerves Exam, Motor Exam, and Sensory Exam Techniques

Battle's sign = mastoid ecchymosis  
Raccoon eyes = periorbital ecchymosis

If patient has not brought their glasses, have them look through a pinhole for best corrected vision

When testing CN I, avoid noxious smells like ammonia, as this tests CN V

**Screening Neurologic Exam**

- Mental status: orientation (person, place, time), obeys commands, GCS
- Head and neck: examine for lacerations, contusions, deformities, signs of basal skull fracture, flex neck for meningismus if c-spine injury has been ruled out
- CN exam: visual fields ± fundoscopy, pupil size and reactivity, EOM, facial strength, hearing to finger rub
- Motor: tone, power in deltoids, biceps, triceps, wrist extensors, hand interossei, iliopsoas, hamstrings, ankle dorsiflexors, pronator drift
- Coordination: finger tapping, finger-to-nose, heel-knee-shin
- Gait: tandem gait, heel walking
- Reflexes: biceps, triceps, patellar, ankle, plantar (Babinski)
- Sensation: pain/temperature, vibration

# The Neurological Exam

## General Exam and Mental Status

- **vitals:** pulse (especially rhythm), BP, RR, temperature
- **H&N:** meningismus (nuchal rigidity/Brudzinski sign/Kernig sign), head injury/bruises (signs of basal skull fracture: Battle's sign, raccoon eyes, hemotympanum, CSF rhinorrhea/otorrhea), tongue biting
- **CVS:** carotid bruits, heart murmurs
- **mental status:** orientation (person, place, time), LOC (GCS) (see [Emergency Medicine, ER4](#))
  - GCS/15 - Motor/6, Verbal/5 (T= intubated), Eyes/4

**Table 1. Glasgow Coma Scale**

Points	Eyes	Verbal	Motor
1	No eye opening	No verbal response	No motor response
2	Eye opening to pain	Incomprehensible sounds	Extension to pain
3	Eye opening to verbal stimulus	Inappropriate words	Flexion to pain
4	Eye opening spontaneously	Confused	Withdraws from pain
5		Oriented	Localizes pain
6			Obeys commands

- **mental status examination**
  - Folstein MMSE - /30 (normal: ≥24, mild impairment: 19-23, moderate impairment: 10-18, severe impairment: <10 (note: dementia is not diagnosed by cognitive testing alone))
  - MoCA - /30 (normal: ≥26)
  - frontal lobe testing: test for executive function (e.g. go/no-go test, Luria's test, F-word list generation, trails test, and frontal release signs e.g. grasp, pout-and-snout, rooting, palmomental, glabellar tap)
  - clock drawing (note: no single scoring system is clearly superior, and simple subjective assessment as "normal" or "abnormal" is sufficient)

## Cranial Nerve Exam

Table 2. Cranial Nerve Examination and Associated Deficits

Cranial Nerve	Recommended Physical Exams	Signs/Symptoms of Deficit
<b>Olfactory (CN I)</b>	Odour sensation: test each nostril separately	Anosmia (can be associated with loss of taste)
<b>Optic (CN II)</b>	Visual acuity: test each eye individually; best corrected vision Test visual fields: peripheral visual fields (counting fingers, white pin), central visual field, and blind spot (red pin) Assess pupils: direct and consensual pupillary reaction (afferent component), swinging flashlight test (for RAPD) Fundoscopy: optic disc edema and pallor, venous pulsations, hemorrhages Colour vision testing (Ishihara plates)	Central vision loss, peripheral vision loss, absence of light reflexes, RAPD, enlarged blind spot, colour desaturation (especially red)
<b>Oculomotor (CN III)</b>	Assess EOM and nystagmus Assess pupils: direct and consensual pupillary reaction (efferent component), size and shape Accommodation reflex and saccadic eye movements Test for ptosis (levator palpebrae superioris)	Eye deviation (e.g. one eye deviated down and out), ophthalmoparesis, ptosis, can demonstrate mydriasis
<b>Trochlear (CN IV)</b>	Test movement of SO muscle	Vertical diplopia, may tilt head towards unaffected side (Bielschowsky head tilt test), affected eye cannot turn inward and downward
<b>Trigeminal (CN V)</b>	Test sensation above supraorbital ridge (V1), maxilla or cheeks (V2), mandible (V3) Test corneal reflex (afferent limb) Assess motor function: temporalis, masseter, pterygoids, jaw jerk reflex	Ipsilateral facial sensory abnormality and absent corneal reflex on stimulation ipsilaterally, weakness and wasting of muscles of mastication, deviation of open jaw to ipsilateral side, trigeminal neuralgia
<b>Abducens (CN VI)</b>	Test movement of LR muscle	Horizontal diplopia, esotropia (convergent strabismus), and abductor paralysis of ipsilateral eye, leading to difficulty looking laterally with diplopia
<b>Facial (CN VII)</b>	Test muscles of facial expression Test corneal reflex (efferent limb) Assess taste in anterior 2/3 of the tongue Visceral motor nerve function to salivary and lacrimal glands	LMN lesion = ipsilateral facial weakness, involving forehead. Loss of lacrimation, decreased salivation, dry mouth, loss of taste in anterior 2/3 of the tongue ipsilaterally, hyperacusis UMN lesion = contralateral facial weakness, sparing the forehead
<b>Vestibulocochlear (CN VIII)</b>	Vestibular function: nystagmus, caloric reflexes Cochlear function: whisper test, Rinne test, Weber test	Vertigo, disequilibrium, nystagmus, sensorineural hearing loss
<b>Glossopharyngeal (CN IX)</b>	Assess vocal cord function (phonation) and gag reflex (afferent limb) Assess taste in posterior 1/3 of the tongue (bitter and sour taste)	Dysarthria, dysphonia Loss of taste in posterior 1/3 of ipsilateral tongue, loss of gag reflex, dysphagia Unilateral lesion is rare
<b>Vagus (CN X)</b>	Assess vocal cord function: guttural ("ga") and palatal ("ka") articulation Assess gag reflex (efferent limb) Observe uvula deviation and palatal elevation Assess swallowing	Loss of gag reflex, dysphagia, hoarse voice, paralysis of soft palate (failed elevation), deviation of uvula to contralateral side of lesion, anesthesia of pharynx and larynx ipsilaterally
<b>Accessory (CN XI)</b>	Assess strength of trapezius (shoulder shrug) and sternocleidomastoid muscles (head turn)	Ipsilateral shoulder shrug weakness and turning head to opposite side
<b>Hypoglossal (CN XII)</b>	Inspect tongue for signs of atrophy, fasciculations, asymmetry of movement and strength, lateral deviation with protrusion	Wasting of ipsilateral tongue muscles and deviation to ipsilateral side on protrusion

**CN Innervation of EOM**  
LR: CN VI, SO: CN IV, Other: CN III

Contraction of the left sternocleidomastoid turns the head right

Calorics: Brainstem Test  
Describe nystagmus by direction of fast component

COWS  
Cold  
Opposite  
Warm  
Same

**UMN Tests**  
**Plantar (Babinski) reflex:** 'Up-going' big toe ± fanning of toes indicates an UMN lesion  
**Hoffmann's reflex:** Involuntary flexion of the thumb or index finger when tapping/flicking the nail of the middle finger downwards may indicate an UMN lesion and corticospinal pathway dysfunction, potentially due to cervical spine cord compression, if asymmetrical  
**Pronator drift:** Unable to maintain full arm extension and supination; side of forearm pronation reflects contralateral pyramidal tract lesion; closing eyes accentuates effect

**Pyramidal Pattern of Muscle Weakness (i.e. UMN)**  
**Weaker arm extensors:** shoulder abduction, elbow extension, wrist extension, finger extension, finger abduction  
**Weaker leg flexors:** hip flexion, knee flexion, ankle dorsiflexion

**Primitive Reflexes**  
Grasp, palmomental, root, glabellar tap, snout

## Motor Exam

- bulk: atrophy, asymmetry
- tone: hypotonia (flaccid), hypertonia (spasticity, rigidity, paratonia), cogwheeling
- power: Medical Research Council muscle strength scale, pronator drift, forearm rolling test (satellite sign)
- reflexes: deep tendon reflexes, abdominal reflexes, primitive reflexes, Babinski sign, Hoffmann's sign, clonus
- abnormal movements: tremors, chorea, dystonia, dyskinesia, hemiballism, myoclonus, athetosis, tics, fasciculations, myokymia
- abnormal posturing: decorticate (upper extremity flexion, lower extremity extension), decerebrate (extremity extension)

**Table 3. Localization of Motor Deficits**

	LMN	UMN	Extrapyramidal
Muscle Tone	Flaccid	Spastic	Rigid
Involuntary Movements	Fasciculations	None	Tremor, chorea, ballism, myoclonus
Reflexes	Decreased	Increased	Normal
Plantar Reflex	Down-going (flexor)	Up-going (extensor, i.e. Babinski sign)	Down-going (flexor)
Pattern of Muscle Weakness	Proximal, distal, or focal	Pyramidal pattern: look for hemiparetic gait (flexed arm, extended legs) Upper extremities: extensors weaker than flexors Lower extremities: flexors weaker than extensors	None

**Table 4. Overview of Neuromuscular Diseases**

	Motor Neuron Disease (e.g. ALS)	Peripheral Neuropathy	Neuromuscular Junction	Myopathy
<b>SIGNS AND SYMPTOMS</b>				
Weakness	Segmental and asymmetrical, distal to proximal	Distal (except GBS) but may be asymmetrical	Proximal and fatigable (e.g. MG), or weak then recovers (e.g. LEMS)	Proximal (with some exceptions)
Fasciculations	Yes	Yes	No	No
Reflexes	Mixture of hyperreflexia and decreased/absent reflexes	Decreased/absent	Normal	Normal (until late)
Sensory	No	Yes	No	No
Autonomic*	No	Yes	No (except LEMS)	No
<b>TESTS</b>				
EMG	Denervation and reinnervation	Signs of demyelination and/or axonal loss	Decremental response on repetitive nerve stimulation, jitter on single fibre EMG	Small, short motor potentials
Routine NCS	Normal or abnormal	Abnormal	Normal	Normal
Muscle Enzyme	Normal or mildly elevated	Normal	Normal	Increased (early/mid stage) Normal/decreased (late stage)

\*e.g. orthostatic hypotension, anhidrosis, visual blurring, urinary hesitancy or incontinence, constipation, erectile dysfunction

**Table 5. Approach to Strength Testing of Radiculopathies vs. Peripheral Neuropathies**

How to use this table: For each nerve root, learn two (or more) peripheral nerves (and their associated muscles/movements). In radiculopathies, all associated peripheral nerves (and their movements) will be impaired, whereas in peripheral neuropathies, only one of the nerves (and its movement) will be impaired, sparing the other nerve. Particularly useful peripheral nerve "pairs" are bolded for emphasis

Root	Peripheral Nerve	Movement	Muscle
C5	Axillary	Shoulder abduction	Deltoid
C6	Musculocutaneous (C5/6) Radial (C6)	Elbow flexion Wrist extension	Biceps brachii Brachioradialis Extensor carpi radialis longus
C7	Radial Posterior interosseus Median	Elbow extension Finger extension Forearm pronation Wrist flexion	Triceps brachii Extensor digitorum communis Pronator teres Flexor carpi radialis
C8, T1	<b>Median</b>	Thumb flexion Thumb abduction Opposition	Flexor pollicis longus Abductor pollicis brevis (look for thenar wasting) Opponens pollicis (look for thenar wasting)
	<b>Ulnar</b>	Finger abduction	First dorsal interosseus (look for wasting in first dorsal webbed space)
L2, 3, 4	<b>Femoral Obturator</b>	Hip flexion Hip adduction	Iliopsoas Adductor muscles
L3, 4	Femoral (L3/4) Deep peroneal (L4/5)	Knee extension Dorsiflexion	Quadriceps Tibialis anterior
L5	Superior gluteal nerve (L5, S1) Sciatic (L5, S1) Tibial Superficial peroneal Deep peroneal	Hip abduction Knee flexion Ankle inversion Ankle eversion Big toe extension	Tensor fascia lata Hamstring Tibialis posterior Peroneus muscles Tibialis anterior Extensor hallucis longus
S1	Inferior gluteal nerve Sciatic Tibial	Hip extension Knee flexion Plantar flexion	Gluteus maximus Hamstring muscles Gastrocnemius and soleus

**Medical Research Council Muscle**

**Strength Scale**

5	Full power
4	Submaximal power against resistance (ranging 4+, 4, 4-)
3	Full ROM against gravity without resistance
2	Full ROM with gravity removed
1	Muscle flicker
0	No muscle contraction

**Deep Tendon Reflexes**

Root	Muscle/Tendon
C5/6	Biceps brachii
C6	Brachioradialis
C7	Triceps brachii
C8	Finger flexors
L2/3	Hip adductors
L3/4	Knee extensors
S1/2	Ankle (Achilles)

**Deep Tendon Reflex Scoring**

0	Absent
1+	Depressed – elicited with reinforcement only
2+	Normal
3+	Increased
4+	Increased with clonus (≥4 beats)

**Interpreting a Slow or Uncoordinated Rapid Alternating Movement (RAM)**

- Slow RAMs without fatiguing is suggestive of weakness (especially if it is asymmetric)
- Slow RAMs with fatiguing (i.e. decreasing amplitude over time) is suggestive of Parkinsonism
- Uncoordinated RAM is suggestive of cerebellar disorder (i.e. ataxia and irregularly irregular rhythm) or ideomotor apraxia

**Common Cerebellar Findings**

Frontal executive dysfunction/disinhibition, scanning speech, nystagmus, hypermetric saccades, hypotonia, pendular reflexes, intention tremor, ataxic finger-nose/heel-shin/tandem, wide based stance and gait, positive rebound  
Midline cerebellar diseases: truncal ataxia  
Lateral cerebellar hemisphere diseases: limb ataxia

**Romberg Test**

Stable with eyes open and closed = normal  
Stable with eyes open, falls with eyes closed = positive Romberg, suggesting loss of joint position sense

## Sensory Exam

- **primary sensation**
    - spinothalamic tract: crude touch, pain, temperature
    - dorsal column-medial lemniscus pathway: fine touch, vibration, proprioception
  - **cortical sensation**
    - graphesthesia, stereognosis, extinction (tactile, visual, auditory), 2-point discrimination
- Note:** If primary sensation is not intact, this precludes the testing of cortical sensation. Deficits in cortical sensation are typically a sign of contralateral parietal lobe lesions

## Coordination Exam and Gait

- coordination exam
  - finger-to-nose, heel-to-shin, knee taps, rapid alternating movements
- stance and gait
  - Romberg test
  - pull test or push and release test for postural instability
  - gait: antalgic, hemiplegic, ataxic, apraxic, Parkinsonian, steppage, broad-based
  - tandem gait (heel-to-toe test)

## Basic Anatomy Review

Figure 8. Sympathetic and parasympathetic pathways

© Glen Bonnen 2002

Figure 9. Dermatome map

**Myotomes**

- C5 – Shoulder abduction and elbow flexion
- C6 – Elbow flexion and wrist extension
- C7 – Elbow extension and finger extension
- C8 – Finger flexion
- T1 – Finger abduction
- T2-9 – Intercostal (abdominal reflexes)
- T9-10 – Upper abdominals
- T11-12 – Lower abdominals
- L2 – Hip flexion
- L3 – Hip adduction
- L4 – Knee extension and ankle dorsiflexion
- L5 – Ankle dorsiflexion and big toe extension
- S1 – Plantar flexion

## Lumbar Puncture

### Indications

- diagnostic: CNS infection (meningitis, encephalitis), inflammatory disorder (MS, GBS, vasculitis), SAH (if CT negative), CNS neoplasm (neoplastic meningitis), IHH
- therapeutic: to administer anesthesia, chemotherapy, contrast media
  - to decrease ICP (IHH, NPH, cryptococcus meningitis)

### Contraindications

- mass lesion causing increased ICP could lead to cerebral herniation; CT first if suspect mass lesion or any neurologic deficit
  - LP causes acute pressure gradient that can result in downward displacement of brain
- infection over LP site/suspected epidural abscess
- moderate thrombocytopenia ( $<50 \times 10^9/L$ ), ongoing anticoagulant therapy (high INR or aPTT), or coagulopathy (e.g. hemophilia)
- uncooperative patient
- acute confirmed/suspected spinal trauma or congenital spinal abnormalities

### Complications

- tonsillar herniation (rare)
- SDH (rare)
- transient 6th nerve palsy (rare)
- post-LP headache (5-40%): worse when upright, better supine; generally, onset within 24 h
  - prevention: smaller gauge (i.e. 22) needle, reinsert stylet prior to needle removal, blunt-ended needle
  - symptomatic treatment: oral analgesics, antiemetics, caffeine and sodium benzoate injection
  - definitive treatment: epidural blood patch (autologous)
- spinal epidural hematoma
- infection

### LP Tubes

- tube #1: cell count and differential: RBCs, WBCs, and differential
  - xanthochromia (yellow bilirubin pigmentation implies recent bleed into CSF, diagnostic of SAH)
- tube #2: chemistry: glucose (compare to serum glucose) and protein
- tube #3: microbiology: Gram stain and C&S
  - specific tests depending on clinical situation/suspicion
    - viral: PCR for herpes simplex virus (HSV) and other viruses
    - bacterial: polysaccharide antigens of *H. influenzae*, *N. meningitidis*, *S. pneumoniae*
    - fungal: cryptococcal antigen, culture
    - TB: acid-fast stain, TB culture, TB PCR
- tube #4: cytology: for evidence of malignant cells. If clinical suspicion is low for neoplasm and concerned about SAH, send final tube for cell count

The needle for a LP is inserted into one of L3-4, L4-5, or L5-S1 interspaces

Do not delay antibiotics while waiting for a LP if infection is suspected

RBCs in tube #1->#5 → traumatic tap  
RBCs in tube #1->#5 and elevated → SAH

**Table 6. Lumbar Puncture Interpretation (Normal vs. Various Infectious Causes)**

Condition	Colour	Protein	Glucose	White Blood Cells
Normal	Clear	$<0.45$ g/L	60% of serum glucose or $\sim 3.0$ mmol/L	$0-5 \times 10^6/L$
Viral Infection	Clear or opalescent	Normal or slightly increased $\sim 0.45-1$ g/L	Normal	$<1000 \times 10^6/L$ Lymphocytes mostly, some PMNs
Bacterial Infection	Opalescent yellow, may clot	$>1$ g/L	Decreased ( $\sim 25\%$ serum glucose or $<2.0$ mmol/L)	$>1000 \times 10^6/L$ PMNs
Granulomatous Infection (tuberculosis, fungal)	Clear or opalescent	Increased but usually $<5$ g/L	Decreased (usually $<2.0-4.0$ mmol/L)	$<1000 \times 10^6/L$ Lymphocytes

## Approach to Common Presentations

### Weakness

#### Approach

- **mode of onset:** abrupt (vascular, toxic, metabolic), subacute (neoplastic, infective, inflammatory), insidious (genetic, degenerative, endocrine, neoplastic)
- **course:** worse at onset (vascular), progressive (neoplastic, degenerative, infective, genetic), episodic (vascular, inflammatory), activity dependent (NMJ), muscular)
- **pattern:** objective vs. subjective, generalized vs. localized, asymmetric vs. symmetric, proximal vs. distal, UMN vs. LMN, peripheral vs. myotomal
- **associated symptoms:** sensory, cortical, autonomic, spinal (i.e. bowel/bladder dysfunction), signs/symptoms specific to various etiologies
- **history:** family history, developmental history, medications, risk factors, recent/preceding exposures

- **investigations for LMN:** NCS/EMG
- **investigations for UMN:** imaging (brain and/or spinal cord)
- **investigations for suspected myopathy:** muscle biopsy, CK level, NCS/EMG
- **investigations for suspected neuromuscular junction disorder:** NCS/EMG (with repetitive nerve stimulation and single fiber EMG), antibodies (e.g. anti-acetylcholine receptor (AChR) antibodies and anti-MuSK antibodies for MG, voltage-gated calcium channel antibodies for LEMS)

### Differential Diagnosis

- objective muscle weakness; also, differentiate between true muscle weakness vs. fatigue
  - generalized
    - myopathy (proximal > distal weakness)
      - endocrine: hypothyroidism, hyperthyroidism, Cushing's syndrome
      - rheumatologic: dermatomyositis, polymyositis, vasculitis
      - infectious: HIV, influenza
      - other: collagen vascular disorders, steroids, statins, alcohol, electrolyte disorders
    - NMJ (MG, botulism, LEMS, organophosphate poisoning)
    - polyradiculopathy (infection, malignancy, GBS, CIDP)
    - cachexia
  - localized
    - UMN (vasculitis, abscess, brain tumour, vitamin B12 deficiency, MS, stroke)
    - radicular pain (i.e. nerve root)
    - anterior horn cell (spinal muscular atrophy, ALS, polio, paraneoplastic)
    - peripheral neuropathy (peroneal muscle atrophy, GBS, leprosy, amyloid, myeloma, DM, lead toxicity)
- no objective muscle weakness
  - chronic illness (cardiac, pulmonary, anemia, infection, malignancy)
  - depression
  - deconditioning

## Numbness/Altered Sensation

### Approach

- positive sensory symptoms: paresthesia/dysesthesia = tingling, pins and needles, prickling, burning, stabbing
- negative sensory symptoms: hypoesthesia/anesthesia = numbness, reduction/absence of feeling
- determine distribution of sensory loss:
  - nerve root vs. peripheral nerve
  - symmetric stocking-glove pattern (indicative of distal symmetric polyneuropathy)
  - dissociated sensory loss: dorsal column (fine touch, proprioception, vibration) vs. spinothalamic tract (pain and temperature)
- investigations: NCS, blood glucose, vitamin B12 levels, imaging based on associated findings

### Differential Diagnosis

- cerebral: stroke, demyelination, tumour
  - symptoms: hemiplegia, aphasia, apraxia
- brainstem: stroke, demyelination, tumour
  - symptoms: diplopia, vertigo, dysarthria, dysphagia, crossed sensory and/or motor findings
- spinal cord/radiculopathy: cord infarction, tumour, MS, syringomyelia, vitamin B12 deficiency, disc lesion
  - symptoms: back/neck pain, weakness (paraparesis or Brown-Séquard pattern), bowel and bladder dysfunction
- neuropathy: focal compressive neuropathy (based on location and distribution), DM, uremia, vasculitis, vitamin B12 deficiency, HIV, Lyme disease, alcohol, paraneoplastic, amyloid
  - polyneuropathy (length-dependent neuropathy) will have a stocking-glove distribution of sensory abnormalities
- other: dermatological (e.g. herpes zoster, angioedema), psychiatric disorders (e.g. panic attacks)

## Gait Disturbance

### Approach

1. **Characterize the gait disturbance**
  - posture, stride length, width between feet, height of step, stability of pelvis, symmetry, arm swing, difficulty turning, tremor, elaborate/inconsistent movements, standing from sitting
2. **Identify accompanying neurologic signs**
  - full neurological exam required (diagnosis often can be made by physical exam alone)
3. **Identify red flags**
  - sudden onset, cerebellar ataxia, paresis (hemi-, para-, or quadri-), bowel/bladder incontinence
4. **Workup**
  - based on etiology – requires blood work, neuroimaging, and urgent neurologist referral

Table 7. Types of Gait Disturbance

Location	Description	Disorder
Visual Loss	Broad based gait with tentative steps	Cataract surgery without lens replacement
Proprioceptive Loss	Sensory ataxia: wide-based with high stepping posture and positive Romberg	Demyelinating neuropathies, paraneoplastic syndrome, tabes dorsalis, MS, compressive myelopathy, B12 deficiency
Peripheral Vestibular Lesion	1. Vestibular ataxia 2. Disequilibrium	1. Tumour, trauma, infectious, Ménière's disease 2. Ototoxic drugs
Peripheral Nerve Disorder	Steppage gait	Acquired/hereditary peripheral neuropathy, compressive peroneal neuropathy, L4-5 radiculopathy
Myopathies	Waddling gait: broad based, short stepped gait with pronounced lumbar lordosis, rotation of pelvis	Muscular dystrophy, inflammatory myopathy
Pyramidal/Corticospinal Tract Lesion	Spastic gait: spastic foot drop, circumduction, scissoring of legs or toe walking with bilateral circumduction	Unilateral: stroke (ischemic/hemorrhagic) Bilateral: cervical spondylosis, cerebral palsy, spinal cord tumour, combined spinal cord degeneration, MS, motor neuron disease
Basal Ganglia	1. Parkinsonian gait: small paces, stooped posture, reduced arm swing 2. Choreic/hemiballistic/dystonic gait	Infarct, PD, PSP, MSA, Huntington's, Sydenham's chorea, Wilson's disease, SLE, neuroleptic medications, polycythemia vera, genetic dystonia
Cerebellar Disorder	Cerebellar ataxic gait, wide-based without high stepping; veers to side of lesion Alcoholic gait	Primary and secondary neoplasm, toxins (alcohol), vitamin E deficiency, hypothyroid, hypoxia, hypoglycemia, paraneoplastic syndrome, vascular lesion

## Cranial Nerve Deficits

### CN I: Olfactory Nerve

#### Clinical Features

- anosmia associated with a loss of taste

#### Differential Diagnosis

- nasal: physical obstruction
  - heavy smoking, chronic rhinitis, sinusitis, neoplasms, septal deformity, choanal atresia, vestibular stenosis, foreign body
- olfactory neuroepithelial: destruction of receptors or their axon filaments
  - influenza, herpes simplex, interferon treatment of hepatitis C virus, atrophic rhinitis (leprosy), COVID-19
- central: lesion of olfactory pathway
  - Kallmann syndrome, albinism, head injury, cranial surgery, SAH, chronic meningeal inflammation, meningioma, aneurysm, PD, MS

### CN II: Optic Nerve

- see *Neuro-Ophthalmology, N14*

### CN III: Oculomotor Nerve

#### Clinical Features

- ptosis, resting eye position is "down and out" (depressed and abducted), pupil dilated (mydriasis)
- vertical and horizontal diplopia; paralysis of adduction, elevation, and depression

#### Differential Diagnosis

- PComm aneurysm: early mydriasis, then CN III palsy
- cavernous sinus (internal carotid aneurysm, meningioma, sinus thrombosis): associated with deficits in other CNs within the cavernous sinus
- midbrain lesion: complete unilateral CN III palsy with bilateral weakness of the SR and ptosis with contralateral pyramidal signs ± mydriasis
- orbital lesion: associated with optic neuropathy, chemosis, proptosis
- other: inflammatory (e.g. MS with brainstem lesion), infection, ischemia, neoplasia, uncal herniation, trauma

If anosmia is not associated with loss of taste, consider conversion disorder

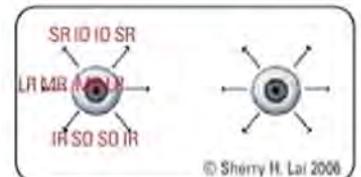

Figure 10. Diagnostic positions of gaze to isolate the primary action of each muscle

Kallmann syndrome is a congenital disorder of anosmia and hypogonadotropic hypogonadism

Pupillary constrictor fibres run along outside of nerve, whereas vasculature is contained within nerve  
For CN III palsy with a reactive pupil, think ischemic cause ("pupil sparing")  
For CN III palsy with mydriasis, think compressive lesion

Lesions involving the cavernous sinus can lead to cranial nerve palsies of III, IV, VI, V1, and V2 as well as orbital pain and proptosis

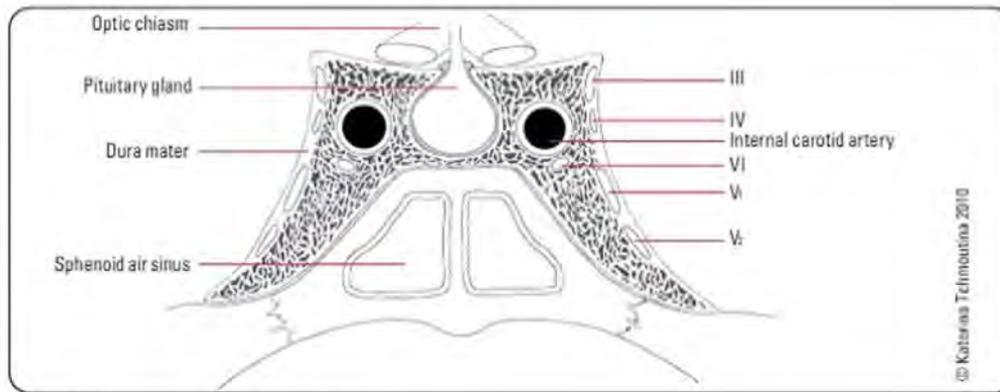

Figure 11. Cavernous sinus (coronal view)

**DDx of CN III Palsy**

- iCAM
- ischemic
- Cavernous sinus
- Aneurysm (PComm, internal carotid)
- Midbrain lesion

CN IV is the only cranial nerve that decussates at midline and exits posteriorly  
A CN IV lesion may cause a contralateral deficit if lesion affects the nucleus

CN IV is at risk of trauma during neurosurgical procedures involving the midbrain because of its long intracranial course

**Distinguishing CN III, IV, and VI Lesions**

	III	IV	VI
<b>Diplopia</b>	Oblique	Vertical	Horizontal
<b>Exacerbating</b>	Near target	Looking down	Far target
<b>Head Tilt</b>	Up and rotated away	Down and flexed away	Rotated towards

Jaw deviation is towards the side of a LMN CN V lesion

CN VI has the longest intracranial course and is vulnerable to increased ICP, creating a false localizing sign

Forehead is spared in a UMN CN VII lesion due to bilateral innervation of CN VII nuclei from cerebral hemispheres to the frontalis

When screening for dysphagia and assessing aspiration risk, the presence of a gag reflex is insufficient; the correct screening test is to observe the patient drinking water from a cup while observing for any coughing, choking, or "wetness" of voice

**CN IV: Trochlear Nerve**

**Clinical Features**

- vertical and torsional diplopia; defect of intorsion and depression
- patient may complain of difficulty going down stairs or reading

**Differential Diagnosis**

- common: ischemic (DM, HTN), idiopathic, trauma (TBI or surgical), congenital
- other: cavernous sinus lesion, superior orbital fissure (tumour, granuloma)

**CN V: Trigeminal Nerve**

**Clinical Features**

- ipsilateral loss of facial sensation and corneal reflex, weakness of muscles of mastication (V3 only) with pterygoid deviation towards the side of the lesion

**Differential Diagnosis**

- brainstem: ischemia, tumour, syringobulbia, demyelination
- peripheral: tumour, aneurysm, chronic meningitis, metastatic infiltration of nerve
- trigeminal ganglion: acoustic neuroma, meningioma, fracture of middle fossa
- cavernous sinus: carotid aneurysm, meningioma, sinus thrombosis
- trauma
- note: other CN V lesions that cause facial pain = trigeminal neuralgia, herpes zoster

**CN VI: Abducens Nerve**

**Clinical Features**

- resting inward deviation (esotropia)
- horizontal diplopia; defect of lateral gaze

**Differential Diagnosis**

- pons (infarction, hemorrhage, demyelination, tumour): facial weakness and contralateral pyramidal signs
- tentorial orifice (compression, meningioma, trauma): false localizing sign of increased ICP
- cavernous sinus: carotid aneurysm, meningioma, sinus thrombosis
- ischemia of CN VI: DM, temporal arteritis, HTN, atherosclerosis
- congenital: Duane's syndrome

**CN VII: Facial Nerve**

**Clinical Features**

- LMN lesion: ipsilateral facial weakness (facial droop, flattening of forehead, inability to close eyes, flattening of nasolabial fold)
- UMN lesion: contralateral facial weakness with forehead sparing (due to bilateral frontalis innervation)
- impaired lacrimation, decreased salivation, numbness behind auricle, hyperacusis, taste dysfunction of anterior 2/3 of tongue

**Differential Diagnosis**

- idiopathic: Bell's palsy, 80-90% of cases (see Otolaryngology, OT23)
  - most often related to HSV, but other viruses may be implicated (CMV, herpes zoster, EBV)
- other: temporal bone fracture, EBV, Ramsay Hunt (VZV), otitis media/mastoiditis, sarcoidosis, DM mononeuropathy, parotid gland disease, Lyme meningitis, HIV

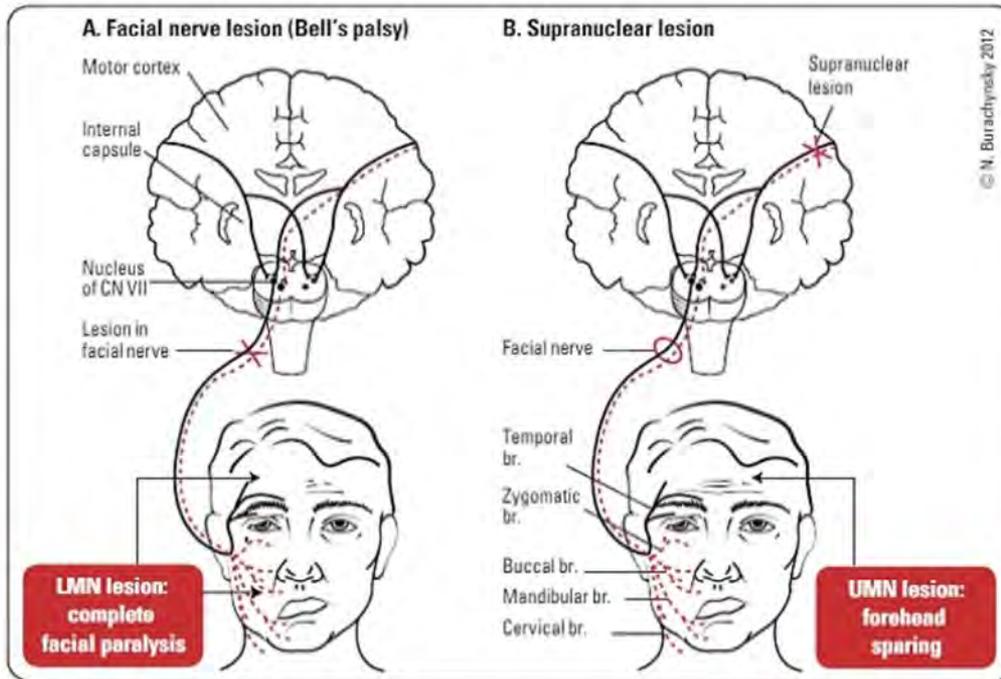

Figure 12. LMN vs. UMN facial nerve palsy

## CN VIII: Vestibulocochlear Nerve

- see [Otolaryngology, OT14](#)

## CN IX: Glossopharyngeal Nerve

### Clinical Features

- unilateral lesion is rare
- taste dysfunction in posterior 1/3 of tongue, absent gag reflex, and dysphagia

### Disorders

- glossopharyngeal neuralgia: sharp paroxysmal pain of posterior pharynx radiating to ear, triggered by swallowing
  - treated with carbamazepine or surgical ablation of CN IX

## CN X: Vagus Nerve

### Clinical Features

- oropharyngeal dysphagia (transfer dysphagia) due to palatal and pharyngeal weakness
- bulbar dysphagia (brainstem)
  - other causes of dysphagia: see [Gastroenterology, G8](#)
- dysarthria: inability to produce understandable speech due to impaired phonation and/or resonance

## CN XI: Accessory Nerve

### Clinical Features

- LMN lesion: paralysis of ipsilateral trapezius and sternocleidomastoid (ipsilateral shoulder drop, weakness on turning head to contralateral side)
- UMN lesion: paralysis of ipsilateral sternocleidomastoid and contralateral trapezius

## CN XII: Hypoglossal Nerve

### Clinical Features

- LMN lesion: tongue deviation towards lesion, ipsilateral tongue atrophy, and fasciculations (if chronic)
- UMN lesion: tongue deviation away from lesion, absence of atrophy and fasciculations, and slowed tongue movement

### Facial Nerve Branch Memory Aid

To Zanzibar By Motor Car  
 Temporal  
 Zygomatic  
 Buccal  
 Mandibular  
 Cervical

### Differential Diagnosis of Lower Cranial Nerve Deficits (CN IX, X, XI, XII)

**Intracranial/Skull Base:** meningioma, neurofibroma, metastases, osteomyelitis, meningitis  
**Brainstem:** stroke, demyelination, syringobulbia, poliomyelitis, astrocytoma  
**Neck:** trauma, surgery, tumours

Normal swallowing is initiated when the tongue moves a bolus back into the palatal archway. Tongue movements are innervated exclusively by CN XII. The bolus stimulates the soft palate to elevate, and the bolus is deflected into the oropharynx. Next the pharyngeal constrictors contract, the larynx elevates, and the vocal cords close. Swallowing depends on afferent information via CN V, IX, and X and motor action via CN V, VII, IX, X, and XII. Connections in the nucleus of the tractus solitarius in the medulla (in proximity to the respiratory centre) act as the swallowing centre. Swallowing and breathing are coordinated to prevent aspiration.

Uvula deviation is away from the side of a LMN CN X lesion due to impaired ipsilateral palatal elevation

CN XI is vulnerable to damage during neck surgery

# Neuro-Ophthalmology

## Optic Neuritis

- see *Optic Disc Edema*, below and *Multiple Sclerosis, N55*

## Anterior Ischemic Optic Neuropathy

- see *Optic Disc Edema* and *Multiple Sclerosis, N55*
- non-arteritic (NAION): due to atherosclerosis, diabetes, hyperlipidemia, hypertension
- arteritic (AAION): due to GCA (see [Rheumatology, RH22](#))

NAION can be caused by use of sildenafil (Viagra®) in rare case

## Amaurosis Fugax

- see [Ophthalmology, OP36](#) and *Stroke, N51*

## Optic Disc Edema

Table 8. Common Causes of Optic Disc Edema

	Optic Neuritis	Papilledema	AION	CRVO
Age	<50 yr	Any	>50 yr but usually >70 yr	>50 yr
Vision	Acute to subacute monocular/binocular central vision loss (± acuity and colour vision) with recovery	Late visual loss	Painless unilateral acute field defect over h to d with ↓ colour vision	Painless unilateral variable vision loss
Symptoms	Pain with EOM	H/A, N/V, focal neurological deficits	GCA: H/A, scalp tenderness, jaw claudication, systemic (weight loss, fatigue, fever), polymyalgia rheumatica	Painless, monocular, blurry vision, with sudden onset
Pupil	RAPD	No RAPD	RAPD	+ RAPD
Fundus	Disc swelling if anterior (1/3) Normal disc in acute stage if retrobulbar (2/3) Will go on to develop optic disc pallor in the chronic phase in both	Bilateral disc swelling, retinal hemorrhage, no venous pulsations (only true if combined with other fundal findings)	Pale segmental disc edema, retinal dot, flame hemorrhages	Swollen disc, venous engorgement, retinal hemorrhage
Etiologies	MS, neuromyelitis optica, other inflammatory and infectious diseases	Increased ICP see <i>Table 24, Headaches, N47</i> , IIH if CT/V rules out space-occupying lesion and venous thrombosis	Arteritic: GCA Non-arteritic: atherosclerosis, DM, hyperlipidemia, hypertension	Associated with vasculopathy, thrombus. Cardiovascular risk factors, DM, glaucoma, SLE
Investigations	MRI brain and orbits with gadolinium	Emergent CT and CT-venogram; LP if CT is normal to measure opening pressure	CBC, ESR, CRP, temporal artery biopsy, MRI orbits with gadolinium	Fluorescein angiogram and coherence tomography; thrombophilia work-up if no cause for CRVO identified (younger patients)
Treatment	High-dose IV or PO corticosteroids (accelerates recovery of vision, does not improve long-term outcome)	Treat cause (acetazolamide for IIH)	Arteritic: steroids Non-arteritic: no proven treatment	Optimize risk factors, reduce IOP, ± laser, ± VEGF inhibitors

If you suspect the diagnosis of GCA, do not wait for biopsy results; begin treatment immediately

## Optic Disc Atrophy

- etiologies: glaucoma, AION, compressive tumour, optic neuritis, Leber's hereditary optic neuropathy, congenital
- presentation: disc pallor, low visual acuity, vision defect, decreased colour vision
- treatment: none (irreversible), aim to prevent

# Abnormalities of Visual Field

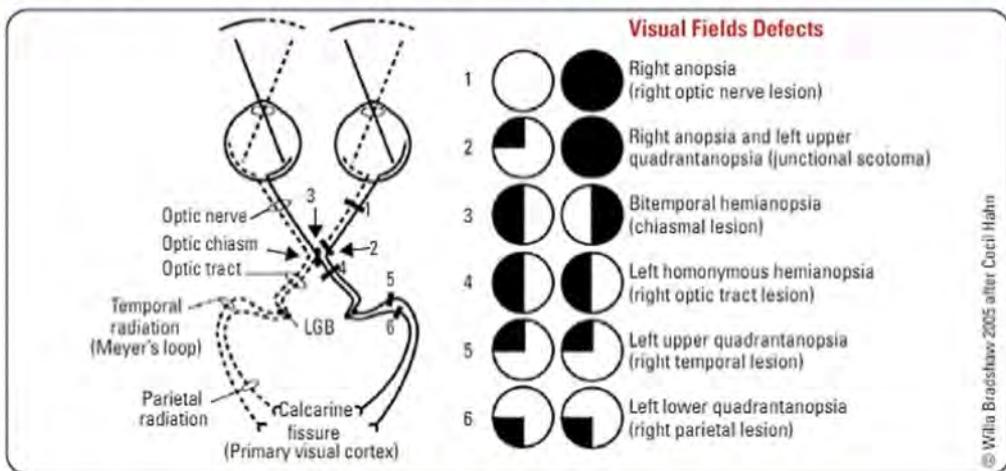

Figure 13. Characteristic visual field defects with lesions along the visual pathway

# Abnormalities of Eye Movements

## Disorders of Gaze

### Pathophysiology

- horizontal gaze: FEF → contralateral PPRF (pons) → eyes saccade away from FEF
- vertical gaze: cortex → rostral interstitial nucleus in the MLF (midbrain)

### Clinical Features

- unilateral lesion in one FEF → eyes deviate toward the side of the lesion
  - can sometimes be overcome with doll's eye maneuver
- unilateral lesion in the PPRF → eyes cannot look toward side of lesion, thus producing a pseudo-deviation to the contralateral side
  - cannot be overcome with doll's eye maneuver if CN VI nucleus lesion as well
- seizure involving a FEF: eyes deviate away from the focus

### Etiology

- common: infarcts (frontal or brainstem), MS, tumours

## Internuclear Ophthalmoplegia

### Pathophysiology

- results from a lesion in the MLF which disrupts coordination between the CN VI nucleus in the pons and the contralateral CN III nucleus in the midbrain → disrupts conjugate horizontal gaze

### Clinical Features

- horizontal diplopia on lateral gaze, oscillopsia (objects in visual field appear to oscillate)
- ipsilateral adduction defect and horizontal abducting nystagmus in the contralateral, abducted eye
- cannot be overcome by caloric testing
- accommodation reflex intact
- may be bilateral (especially in MS)

### Etiology

- common: MS, brainstem infarct or tumour

### Investigations

- MRI

### Bitemporal Hemianopsia DDx by Age

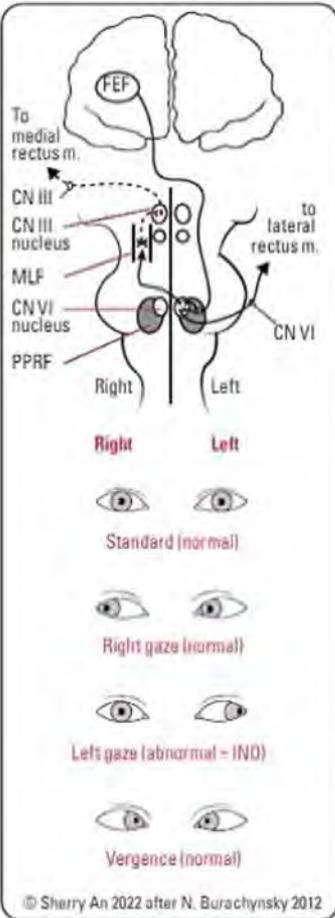

- Children: craniopharyngioma
- Middle aged (20s to 50s): pituitary mass
- Elderly (>60 yr): meningioma

In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions; macular sparing may occur with occipital lesions

A destructive lesion (e.g. stroke) in a cerebral hemisphere causes eyes to "look away" from the hemiplegia, and to look towards the lesion  
A destructive lesion (eg. stroke) in the brainstem causes the eyes to "look toward" the side of the hemiplegia, and to look away from the lesion

Check all hemiplegic patients for homonymous hemianopsia (ipsilateral to side of hemiplegia)

"Negative lesions" that eliminate function/cause malfunction of FEF (i.e. stroke/tumour) cause the eyes to deviate to the side of the lesion; "positive lesions" that cause overactive function of FEF (i.e. seizure) focus cause the eyes to deviate away from the focus

© Sherry An 2022 after N. Burachynsky 2012

## Diplopia

### Etiology – Monocular

- mostly due to benign optical problems (refractive error, cataract, dry eye) or functional causes

### Etiology – Binocular (due to ocular misalignment)

- muscle: Graves' ophthalmopathy, EOM restriction/entrapment
- neuromuscular junction: MG (see *Myasthenia Gravis, N40*)
- cranial nerve palsy (see *Cranial Nerve Deficits, N11*)
- INO (see *Internuclear Ophthalmoplegia, N15*)
- other
  - orbital trauma (orbital floor fracture), tumour, infection, inflammation
  - Miller-Fisher variant of GBS
  - Wernicke's encephalopathy
  - leptomeningeal disease

### Approach to Diplopia

- monocular (diplopia when one eye open) vs. binocular (diplopia when both eyes open)
- horizontal (CN VI palsy if worse at distance, convergence insufficiency if worse when near) vs. vertical vs. oblique diplopia
- direction of gaze that exacerbates diplopia
- corrective head movements

### Workup

- may observe isolated CN IV or CN VI palsy for a few weeks, but workup if persistent or other symptoms develop
- consider ESR/CRP if symptoms of GCA and diplopia
- indications for neuroimaging
  - bilateral or multiple nerve involvement
  - progressive worsening
  - severe sudden onset headache (rule out aneurysm)
  - other neurological deficits on examination
  - any findings of CN III palsy (e.g. unequal pupils with mydriasis +/- down and out)
  - any findings of Horner's syndrome: ptosis, miosis, anhidrosis

## Nystagmus

- rapid, involuntary, small amplitude movements of the eyes that are rhythmic in nature
- begins with a slow phase movement, followed by a quick more obvious phase
- nystagmus is described in relation to the quick phase of the eye movement
- can be categorized by movement type (pendular, jerking, rotatory, coarse) or as physiological vs. pathological

Table 9. Nystagmus Features

	Peripheral (Vestibular)	Central (Brainstem)
Direction	Unidirectional, fast phase away from the lesion	May be bilateral/unidirectional
Nystagmus	Usually horizontal = rotary	Can be any type; usually vertical, horizontal, pendular or jerk; may change direction
Gaze Fixation	Suppresses nystagmus	Does not suppress nystagmus
Vertigo	Severe	Mild
Auditory Symptoms	Common	Extremely rare
Other Neurological Signs	Absent	Often present
DDx	BPPV, vestibular neuritis, Ménière's disease, toxicity, trauma, Ramsay Hunt syndrome	MS, vascular (brainstem/cerebellar), neoplastic/paraneoplastic, medications

## Abnormalities of Pupils

- see [Ophthalmology, OP30](#)

Diplopia worse at the end of the day suggests MG (i.e. fatigable), in addition to mixed (horizontal and vertical diplopia) that resolves when one eye is closed

If diplopia is only on extremes of gaze, cover each eye in isolation during extremes of gaze. The covered eye that makes the lateral image disappear is the pathological one

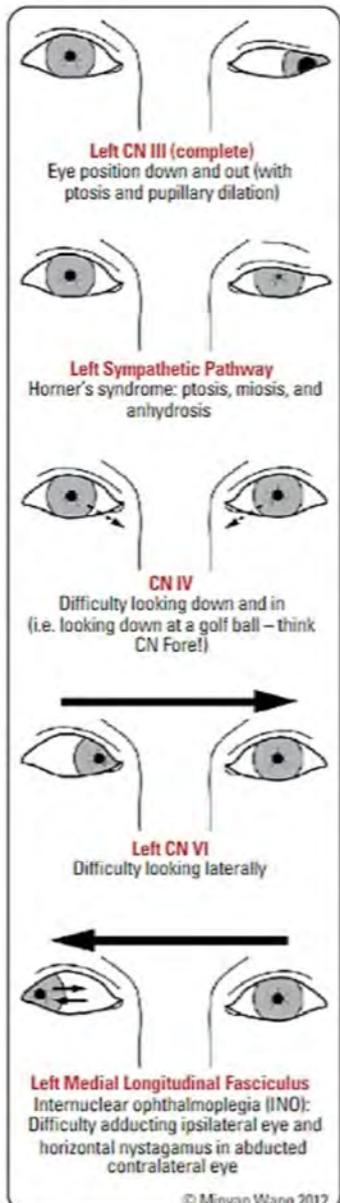

Figure 15. Abnormal eye movement

## Nutritional Deficiencies and Toxic Injuries

- sufficient nutritional intake is required for optimal functioning of the nervous system; deficiencies in the following nutrients may result in central and peripheral nervous system abnormalities (potential neurological symptoms are provided)

**Table 10. Nutritional Deficiency Features and Management**

Vitamin Deficiency	Neurological Clinical Manifestation	Investigation	Treatment*
Vitamin B12	Paresthesias and sensory ataxia are the most common initial symptoms Myelopathy (subacute combined degeneration), peripheral neuropathy Neuropsychiatric: memory impairment, change in personality, delirium, and psychosis Optic neuropathy	Serum cobalamin Serum methylmalonic acid Serum homocysteine MRI spine, EMG/NCS	Vitamin B12 1000 µg IM for 5 d, then 1/mo or PO B12 1000 µg/d
Folate	Myelopathy, peripheral neuropathy May be clinically indistinguishable from vitamin B12 deficiency Neuropsychiatric symptoms	Serum folate Homocysteine	Folate 1 mg TID PO initially, 1 mg once daily thereafter
Copper	Myelopathy, myeloneuropathy, sensory ataxia, spastic gait (similar to vitamin B12 deficiency) Severe sensory loss	Serum copper and ceruloplasmin; urinary copper; MRI spine; EMG/NCS	Discontinue zinc; copper 8 mg/d PO for 1 wk, 6 mg/d for 1 wk, 4 mg/d for 1 wk, 2 mg/d thereafter
Vitamin E	Ophthalmoplegia, retinopathy, spinocerebellar syndrome with peripheral neuropathy (with signs of cerebellar ataxia), psychomotor impairment	Serum vitamin E; ratio serum vitamin E to sum of cholesterol and triglycerides; EMG/NCS	Vitamin E 2200 mg/kg/d PO or IM
Thiamine	Three manifestations include: beriberi (dry and wet), infantile beriberi, Wernicke-Korsakoff syndrome, see <i>Cerebellar Disorders, N36</i>	Clinical diagnosis; brain MRI	Thiamine 100 mg IV followed by 50-100 mg IV or IM until nutritional status stable
Pyridoxine (Vitamin B6)	Painful sensorimotor peripheral neuropathy, intractable epilepsy in infants, confusion	Serum pyridoxal phosphate; EEG in infants and children; EMG/NCS	Pyridoxine 50-100 mg daily
Niacin (Vitamin B3)	Pellagra: encephalopathy, dementia, and peripheral neuropathy		Nicotinic acid 25-50 mg daily PO or IM. When supplementing, be aware of "niacin flush" in some patients

- also consider occupational neurotoxic syndromes secondary to exposure to pesticides, solvents, and metals. Encephalopathy, extrapyramidal features, neurodegenerative diseases, and peripheral neuropathy are commonly encountered. Onset and progression of neurological diseases should be temporally related to neurotoxin exposure. Main toxins associated with neurotoxicity are listed below

**Table 11. Selected Occupational Neurotoxic Syndromes**

Toxin	Associated Occupations	Characteristic Neurological Findings
Organic Solvents	Printer, spray painters, industrial cleaners, paint or glue manufacturers, graphic industry, electronic industry, plastic industry	Nausea, H/A, concentration difficulty Long-term exposure may lead to "chronic solvent-induced encephalopathy," characterized by mild-to-severe cognitive impairment
Pesticides (e.g. insecticides, fungicides, rodenticides, fumigants, herbicides)	Agricultural work, pesticide manufacturing and formulating, highway and railway workers, green house, forestry and nursery workers	Pesticide exposure may increase the risk of PD
Heavy Metals (e.g. lead, mercury, manganese, aluminum, arsenic, tin, thallium)	Battery and metal production (e.g. solder, pipes), chemical and electronic application industries, steel manufacturing, welders, alloy workers, transportation, packaging, construction	<b>Lead:</b> delayed/reversed development, permanent learning disabilities, peripheral neuropathy (commonly presenting with radial neuropathy resulting in wrist drop), seizures, coma, death from encephalopathy (rare) <b>Mercury:</b> psychiatric disturbances, ataxia, tremor, visual loss, hearing loss, tiredness, memory disturbances, peripheral neuropathy <b>Manganese:</b> psychiatric symptoms, hallucinations ("manganese madness"), extrapyramidal features, dystonia, parkinsonism (manganism) <b>Aluminum:</b> implicated in Alzheimer's pathogenesis, ALS <b>Arsenic:</b> sleeplessness/sleepiness, irritability, H/A, spasms in muscle extremities and muscle fatigue, peripheral neuropathy <b>Thallium:</b> ataxia, seizures, motor neuropathy, brain edema <b>Tin:</b> mental status changes with persistent neuropsychological abnormalities
Gases (e.g. carbon dioxide, nitrous oxide, formaldehyde)	Anesthesia, disinfection, manufacture of illuminating gas and water-gas	Cognitive/behavioural and emotional symptoms, parkinsonian syndromes Nitrous oxide misuse may result in a functional B12 deficiency and thus symptoms of subacute combined degeneration

### Neurologic Complications due to Toxic Injuries Related to Bariatric Surgery

- deficiencies of both fat- and water-soluble vitamins may occur following malabsorptive bariatric surgery
- patients who have undergone malabsorptive surgery should be monitored for late metabolic complications (e.g. B<sub>12</sub> and copper deficiency) and neurological manifestations (e.g. peripheral neuropathy)

## Seizure Disorders and Epilepsy

### Seizure

#### Definitions

- seizure: transient occurrence of signs and/or symptoms due to abnormal hyper-synchronization of neurons
  - can be a symptom of acute insult to the brain such as: alcohol and illicit drug use/withdrawal; brain injury/abnormality (tumour, trauma, vascular); CNS infection; fever (children); metabolic (hypoglycemia, electrolyte abnormalities, liver/renal failure); medications; or be a genetic or inherited cause
- epilepsy: disorder of the brain characterized by an enduring predisposition to generate epileptic seizures, and by the neurobiologic, cognitive, psychological, and social consequences of this condition
  - diagnosis of epilepsy requires:
    1. at least two unprovoked seizures occurring more than 24 h apart
    2. one unprovoked seizure and a probability of further seizures similar to the general recurrence risk (at least 60%) of two unprovoked seizures, occurring over the next 10 yr
    3. diagnosis of an epilepsy syndrome
  - etiologies: genetic; structural (e.g. prior stroke, tumour, meningo/encephalitis, perinatal insult, vascular malformation, malformation of cortical development, neurodegenerative); or unknown

#### Classification

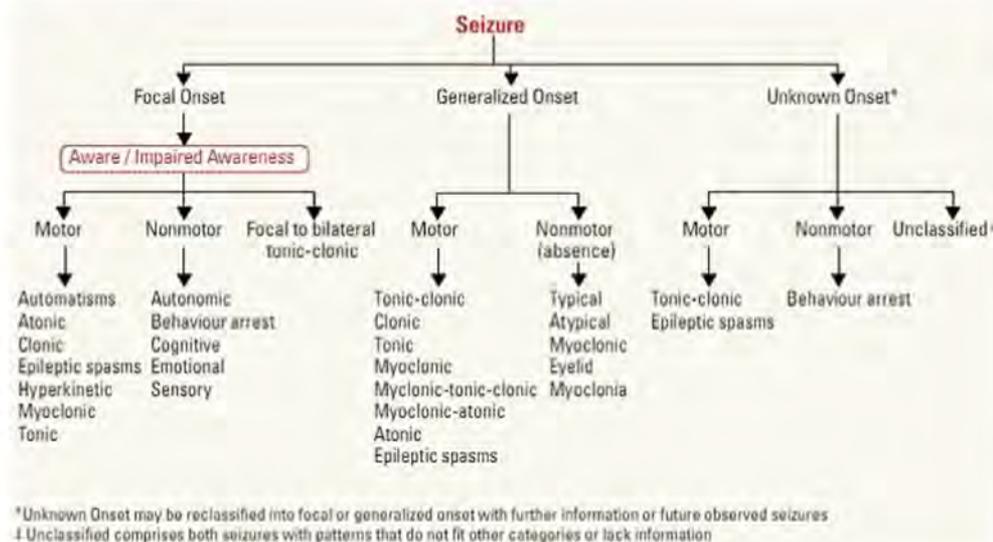

Figure 16. International League Against Epilepsy (ILAE) 2017 seizure classification

#### Clinical Features

- focal (partial) seizures
  - focal can secondarily generalize or remain focal
  - focal without impaired awareness (i.e. "simple partial seizures") → focal with impaired awareness (i.e. "complex partial seizures") → secondarily generalized seizures
  - focal aware (formerly simple partial)
    - motor: dystonic posturing, clonic movements, forceful turning of eyes and/or head, focal muscle rigidity/jerking ± Jacksonian march (spreading to adjacent muscle groups)
    - sensory: unusual sensations affecting vision, hearing, smell, taste or touch
    - autonomic: epigastric discomfort, pallor, sweating, flushing, piloerection, pupillary dilatation
  - focal impaired awareness (formerly complex partial)
    - patient may appear to be awake but with impairment of awareness
    - classic complex seizure is characterized by automatisms such as chewing, swallowing, lip-smacking, scratching, fumbling, running, disrobing, and other stereotypic movements
    - other forms: dysphasic, dysmnestic (déjà vu), cognitive (disorientation of time sense), affective (fear, anger), illusions, structured hallucinations (music, scenes, taste, smells), epigastric fullness

Stroke is the most common cause of late-onset (>50 yr) seizures, accounting for 50-80% of cases

Seizures and Dementia  
Neurodegenerative diseases can underlie seizures. Conversely, seizures can be a cause of dementia

Temporal lobe seizures are suggested by an aura of fear, olfactory or gustatory hallucinations, and visceral or déjà vu sensations

Frontoparietal cortex seizures are suggested by contralateral focal sensory or motor phenomena

**generalized seizures**

- **absence (petit mal):** usually seen in children, unresponsive for 5-10 s with arrest of activity, staring, blinking or eye-rolling, no post-ictal confusion; 3 Hz spike and slow wave activity on EEG
- **clonic:** whole body repetitive rhythmic jerking movements
- **tonic:** whole body muscle rigidity in flexion or extension
- **tonic-clonic (grand mal)**
  - may have prodrome of unease or irritability hours to days before
  - tonic ictal phase: muscle rigidity
  - clonic ictal phase: repetitive violent jerking of face and limbs, tongue biting, cyanosis, frothing, incontinence
  - post-ictal phase: flaccid limbs, extensor plantar reflexes, headache, confusion, aching muscles, sore tongue, amnesia, elevated serum CK lasting hours, may have focal paralysis (Todd's paralysis)
- **myoclonic:** sporadic contractions localized to muscle groups of one or more extremities
- **atonic:** loss of muscle tone leading to drop attack

**Table 12. Classic Factors Differentiating Seizure, Syncope and Pseudoseizure**

Characteristic	Seizure	Syncope	Pseudoseizure* (Psychogenic non-epileptic seizure)
Timing	Day or night (especially from sleep)	Day	Day, other people present
Onset	Sudden, in any position	Gradual, upright position (not recumbent)	Provoked by emotional disturbance or suggestion
Early Symptoms or Signs	Possible specific aura	Lightheadedness, pallor, diaphoresis, tunnel vision	Variable
Duration	Brief or prolonged	Brief	Often prolonged
Incontinence	Common	Possible but rare	Rare
Post-ictal	Confusion, aphasia, Todd's paresis, fatigue	No	Variable, often none
Motor Activity	Synchronous, stereotypic, automatisms (common in complex partial), lateral tongue biting, eyes open or eyes rolled back	Occasional brief tonic stiffening, can have "convulsive syncope"	Prolonged episodes, opisthotonos, eye closure, irregular extremity movements, shaking head, pelvic thrust, crying, tongue biting at the tip
Injury	Common	Rare unless from fall	Rare
EEG	Usually abnormal + interictal discharges	Normal	Normal

\*Pseudoseizures do not rule out seizures (not uncommon to have both)

- alcoholic withdrawal seizures may occur up to 2 d from the last exposure to alcohol (see [Emergency Medicine, ER54](#))

**Investigations**

- CBC, electrolytes, Ca<sup>2+</sup>, Mg<sup>2+</sup>, PO<sub>4</sub><sup>3-</sup>, fasting blood glucose, Cr, liver enzymes, CK, prolactin
- toxicology screen, EtOH level, AED level (if applicable)
- CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)  
(Note: Neuroimaging may be normal in up to 90% of cases following the first unprovoked seizure)
- LP (if fever or meningismus)
- EEG (Note: EEG is specific but not sensitive)

**Treatment**

- avoid precipitating factors
- prognosis: risk of seizure recurrence increases with the number of unprovoked seizures at initial presentation, abnormal EEG, and presence of a neurological disorder
- indications for AED: EEG with epileptiform activity, remote symptomatic cause (organic brain disease, prior head injury, or CNS infection), abnormal neurologic examination or findings on neuroimaging, nocturnal seizure, recurrent unprovoked seizure
- psychosocial issues: stigma of seizures, education of patient and family, status of driver's license, pregnancy issues
- safety issues: driving, operating heavy machinery, bathing, swimming alone
- appropriate follow-up; refer for evaluation for possible surgical treatment if focal and refractory

**Antiepileptic Drug Monotherapy for Epilepsy: A Network Meta-Analysis of Individual Participant Data**

Cochrane DB Syst Rev 2017;CD011412

**Purpose:** To compare the time to withdrawal of treatment, time to remission, and time to first seizure of 10 antiepileptic drug treatments for adults and children with partial onset seizures

**Methods:** Articles were identified from Cochrane Epilepsy's Specialised Register, CENTRAL, MEDLINE, SCOPUS, and two clinical trial registers. Individual patient data was identified for network meta-analysis

**Results:** Carbamazepine and lamotrigine are suitable first-line treatments for partial onset seizures with levetiracetam as a suitable alternative. Evidence supports sodium valproate as first-line treatment for generalized tonic-clonic seizures with lamotrigine and levetiracetam as suitable alternatives, particularly for females of child-bearing age

**DDx of Convulsions**

Syncope, psychogenic non-epileptic seizures, hyperventilation, panic disorder, TIA, hypoglycemia, movement disorder, alcoholic blackouts, migraines (confusional, vertebrobasilar), narcolepsy (cataplexy)

Note that seizures originating in the frontal lobes may look like psychogenic non-epileptic spells due to an abundance of repetitive hyperkinetic movements; they often occur during sleep

By law, the Ministry of Transportation in most provinces must be contacted for all patients who have had a seizure, patients will have their license suspended until seizure free for 6 mo, commercial drivers face a longer wait

EEG findings suggestive of predisposition to epilepsy: spike and wave discharges, polyspike and wave discharges, spike-wave complex discharges

EEG has a 17% sensitivity and 95% specificity after first unprovoked seizure, sensitivity increases to 51% if EEG is performed within 24 h  
If the first routine EEG is normal, a sleep-deprived sleep EEG should be considered to increase the likelihood of detecting an abnormality

## Status Epilepticus

- **definition:** medical emergency involving unremitting seizure or successive seizures without return to baseline state of >5 min
- **complications:** anoxia, cerebral ischemia and cerebral edema, MI, arrhythmias, cardiac arrest, rhabdomyolysis and renal failure, aspiration pneumonia/pneumonitis, death (20%)
- **initial measures:** ABCs, vitals, monitors, capillary glucose (STAT), ECG, nasal O<sub>2</sub>, IV NS, IV glucose, IV thiamine, ABGs (if respiratory distress/cyanotic)
- **blood work:** electrolytes, Ca<sup>2+</sup>, Mg<sup>2+</sup>, PO<sub>4</sub><sup>3-</sup>, glucose, CBC, toxicology screen, EtOH level, AED levels
- **focused history:** onset, past history of seizures, drug and alcohol ingestion, past medical history, associated symptoms, witnesses/collateral history
- **physical exam (once seizures controlled):** LOC, vitals, HEENT (nuchal rigidity, head trauma, tongue biting, papilledema), complete neurological exam, signs of neurocutaneous disorders, decreased breath sounds, cardiac murmurs or arrhythmias, urinary incontinence, MSK exam (rule out injuries)
- **post-treatment stabilization:** CT head, EEG, Foley catheter to monitor urine output, urine toxicology screen, monitor for rhabdomyolysis, and IV fluids to maintain normal cerebral perfusion pressure

### Antiepileptic Drugs

- focal and most generalized seizures
  - valproate (Depakene<sup>®</sup>), lamotrigine (Lamictal<sup>®</sup>), levetiracetam (Keppra<sup>®</sup>), topiramate (Topamax<sup>®</sup>), phenobarbital (Phenobarb<sup>®</sup>), primidone, zonisamide, rufinamide (Banzel<sup>®</sup>), felbamate, benzodiazepines
- primarily focal seizures (± 2° generalization)
  - carbamazepine (Tegretol<sup>®</sup>), phenytoin (Dilantin<sup>®</sup>), gabapentin (Neurontin<sup>®</sup>), lacosamide (Vimpat<sup>®</sup>), oxcarbazepine (Trileptal<sup>®</sup>), eslicarbazepine acetate (Aptiom<sup>®</sup>), pregabalin (Lyrica<sup>®</sup>), tiagabine (Gabitril<sup>®</sup>), vigabatrin (Sabril<sup>®</sup>)
- absence seizure: ethosuximide (Zarontin<sup>®</sup>)

Medical Emergency: Status epilepticus can cause irreversible brain damage without treatment

The most common causes of status epilepticus in adults are failure to take AEDs, remote symptomatic causes, and stroke  
Despite being a common cause of seizures, EtOH withdrawal is a rare cause of status epilepticus

Consider non-convulsive status epilepticus in a patient who has a persistent decreased level of awareness >20 min after a generalized seizure; order an EEG if unsure

Complex partial status epilepticus can resemble schizophrenia or psychotic depression

Teratogenicity of anticonvulsants includes neural tube defects, cleft palate, urogenital malformations, and heart defects. Advise patient planning pregnancy to take 1-4 mg/d of folic acid. Optimize AEDs with lowest possible dose associated with good seizure control, preferably monotherapy if possible. The risk of fetal malformations with AEDs is 2x the general population; highest risk associated with valproic acid and/or 2+ concurrent AEDs. Consider pre-conception AED levels if patient is well-controlled, monthly serum levels during pregnancy, and titrate AED to maintain pre-conception serum levels. Refer to high-risk OB for intrapartum fetal screening

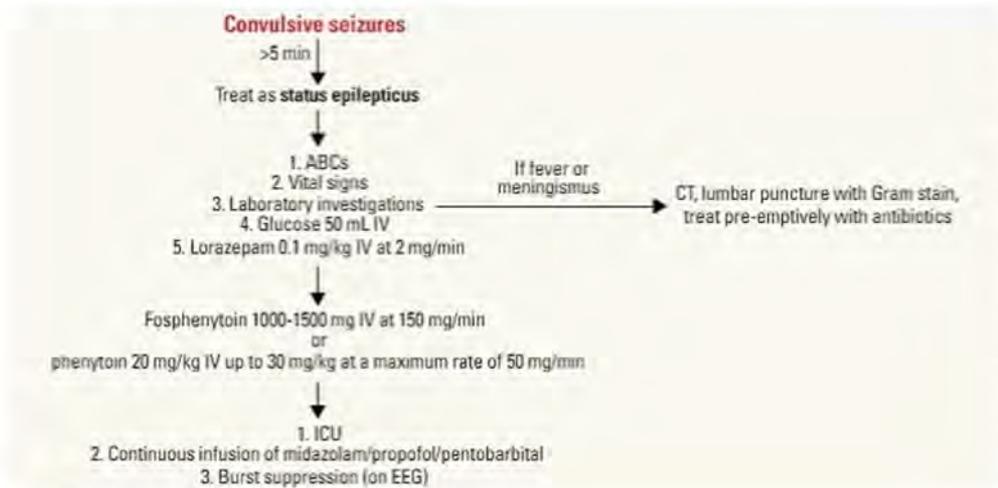

Figure 17. Status epilepticus treatment algorithm

# Behavioural Neurology

• see [Psychiatry](#), PS23

## Acute Confusional State/Delirium

**Table 13. Selected Causes of Acute Confusion**

	Etiology	Key Clinical Features	Investigations
Vascular	SAH	Thunderclap H/A, increased ICP, meningismus, loss of consciousness	CT, LP Angiography if CT and LP negative
	Stroke/TIA (ischemic or hemorrhagic)	Focal neurological signs	CT, MRI
Infectious	Meningitis	Fever, H/A, nausea, photophobia, meningismus	CT, LP
	Encephalitis	Fever, H/A, ± seizure Focal neurological signs	CT, LP MRI
	Abscess	Increased ICP Focal neurological signs	CT with contrast (often ring enhancing lesion)
Traumatic	Diffuse axonal shear, epidural hematoma, SDH	Trauma Hx Increased ICP Focal neurological signs	CT MRI
Autoimmune	Acute CNS vasculitis	Skin rash, active joints	ANA, ANCA, RF MRI Angiography
	Paraneoplastic or autoimmune encephalitis (anti-NMDA-R)	Onset: psychiatric features, memory loss, seizures Delayed: movement disorder, and changes in BP, HR, and temperature	Serum and CSF (test for presence of antibodies), search for primary neoplasm
Neoplastic	Primary or secondary CNS neoplasm	Increased ICP Focal neurological signs Papilledema	CT MRI Search for primary neoplasm if metastatic disease
Seizure	Focal seizure with impaired awareness, non-convulsive status epilepticus, post-ictal confusion	See <i>Seizure Disorders and Epilepsy, N18</i>	EEG CT or MRI Workup for seizure triggers
Primary Psychiatric	Psychotic, mood, and anxiety disorder	No organic signs or symptoms	No specific tests
Other	Illicit drug use (e.g. cocaine)	Chest pain, cough with black sputum, new-onset seizure, HTN, increased ICP, dyspnea	Vital signs Serum chemistry and electrolyte analysis Serum and urine toxicology screen
	Medications (e.g. anticholinergic side effects, benzodiazepines)	Flushing, dry skin and mucous membranes, mydriasis with loss of accommodation	Serum chemistry and electrolyte analysis
	Neuroleptic Malignant Syndrome	Antipsychotic medication use Muscle rigidity Hyperthermia Autonomic instability	Serum chemistry and electrolyte analysis

Delirium is a medical emergency carrying significant risk of morbidity and mortality. It is diagnosed when feature 1 AND 2 as well as feature 3 OR 4 are present:

- **Feature 1:** acute onset and fluctuating course
- **Feature 2:** inattention
- **Feature 3:** disorganized thinking
- **Feature 4:** altered LOC

It is often diagnosed using the Confusion Assessment Method

## Mild Neurocognitive Disorder (Mild Cognitive Impairment)

### Definition

- cognitive changes with measurable deficits in one or more cognitive domains
- preservation of independence or minimal impairment in ADLs and IADLs and not meeting criteria for major NCD
- amnesic (precursor to AD) vs. non-amnesic

### Epidemiology

- mild NCD: 2-10% at age 65 and 5-25% by age 85

### Risk Factors

- non-modifiable: age, history of stroke or heart disease, and apolipoprotein E (APOE) ε4 genotype
- modifiable: educational level and vascular risk factors (e.g. hypertension, diabetes mellitus, obesity)

### Clinical Features

- cognitive impairment with different subtypes
  - single domain vs. multiple domains (e.g. memory, visual spatial function, attention, executive function, language)

### Prevalence of Depression in Patients with Mild Cognitive Impairment: A Systematic Review and Meta-Analysis

JAMA Psychiatry 2017;74:58-67

**Purpose:** To estimate the prevalence of depression in individuals with mild cognitive impairment.

**Methods:** Review of articles with patients with mild cognitive impairment as a primary study group, reported depression/depressive symptoms using a validated tool, and reported the prevalence of depression in patients with mild cognitive impairment.

**Results:** Pooled prevalence of depression patients with mild cognitive impairment was 32% (95% CI 27-37%). Prevalence in community-based populations (25%, 95% CI 19-30) was significantly lower than clinic-based populations (40%, 95% CI 32-48).

**Conclusions:** Prevalence of depression in patients with mild cognitive impairment is high.

- amnesic (memory impairment) vs. nonamnesic (memory function preserved)
- amnesic subtype is the most common and most associated with AD pathology
- important to ascertain that memory complaints represent change from baseline
- neuropsychiatric symptoms: depression (50%), irritability, anxiety, aggression, and apathy

**Investigations**

- establish a baseline for follow-up
- clinical interview with patient and caregivers is the cornerstone of mild NCD evaluation, including detailed family history
- neuropsychological testing
  - MMSE (not sensitive to early cognitive change) or MoCA (more sensitive); should be done in conjunction with a history and neurological exam or with other neurocognitive tests
  - if abnormal, follow-up in one year to monitor cognitive and functional decline
- neuroimaging
  - role uncertain; a non-contrast brain CT is often ordered to evaluate for structural abnormalities (CVD, SDH, NPH, or mass lesion); a MRI is helpful to establish baseline and to look for other possible reversible causes of cognitive impairment
- other testing to exclude treatable conditions (e.g. B12 deficiency, hypothyroidism, seizures, autoimmune encephalitis) and underlying psychiatric conditions (e.g. depression)

**Treatment**

- non-pharmacologic management: exercise training for 6 mo is likely to improve cognition; insufficient evidence to support or refute cognitive intervention, it may improve outcome on select cognitive measures
- pharmacologic management: monitoring and management of hypertension and other vascular risk factors is recommended
- no evidence for cholinesterase inhibitors, anti-inflammatory agents

**Prognosis**

- development of major NCD for age ≥65 is 14.9% after 2 yr
- relative risk of major NCD is 3.3 after 2-5 yr

**Major Neurocognitive Disorder (formerly Dementia)**

- see [Psychiatry, PS24](#)

**Definition**

- acquired, generalized, and (usually) progressive impairment of cognitive function associated with impairment in ADLs/IADLs (e.g. shopping, food preparation, finances, medication management)
- diagnosis of major NCD requires presence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:
  - a) concern of the individual or a knowledgeable informant AND
  - b) substantial impairment in cognitive performance either documented by standardized neuropsychological testing or quantified clinical assessment
- see [Psychiatry, PS24](#)
- in comparison, mild NCD does not affect ADLs
  - mild NCD represents an intermediate stage between major NCD and normal aging

**Epidemiology**

- major NCD: 1-2% at age 65 and reaching as high as 30% by age 85
- major NCD due to AD is uncommon before age 60
- major NCD due to frontotemporal lobar degeneration has an earlier onset and represents a progressively smaller fraction of all NCDs with increasing age

**Etiology**

- see [Table 14, N23](#)
- reversible causes: alcohol (intoxication or withdrawal, Wernicke's encephalopathy), medication (benzodiazepines, anticholinergics), heavy metal toxicity, hepatic or renal failure, B12 deficiency, glucose, cortisol, thyroid dysfunction, NPH, depression (pseudodementia), intracranial tumour, SDH, and hypercalcemia
- must rule out delirium

**History**

- "geriatric giants"
  - confusion/incontinence/falls
  - memory and safety (wandering, leaving doors unlocked, leaving stove on, losing objects, driving)
  - behavioural (mood, anxiety, psychosis, suicidal ideation, personality changes, aggression)
  - polypharmacy and compliance (sedative hypnotics, antipsychotics, antidepressants, anticholinergics)
- ADLs and IADLs
- cardiovascular, endocrine, neoplastic, renal ROS, head trauma history

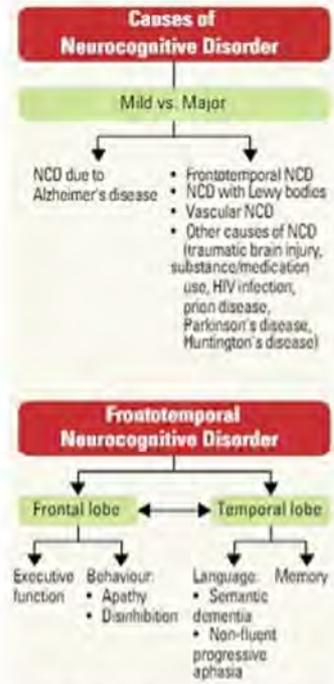

Figure 18. Major NCD classification

**Sensitivity and Specificity**

Tool	Sensitivity	Specificity
MMSE	87%	82%
Clinical Judgment	85%	82%
DSM IV	76%	80%

**Vitamin B12 Deficiency Symptoms**

- Macrocytic anemia, pallor, SOB, fatigue, chest pain, palpitations
- Confusion or change in mental status (if advanced)
- Decreased vibration sense
- Distal numbness and paresthesia
- Weakness with UMN findings
- Diarrhea, anorexia

**Major NCD Considerations for Management**

- ABCDs
- Affective disorders, ADLs
- Behavioural problems
- Caretaker, Cognitive medications and stimulation
- Directives, Driving
- Sensory enhancement (glasses/hearing aids)

Most common causes of rapidly progressive neurodegenerative dementia are CJD, frontotemporal lobar dementia, tauopathies, diffuse Lewy body disease, and AD

- alcohol, smoking
- collateral history
- family history

**Physical Exam**

- blood pressure
- hearing and vision
- neurological exam with attention to signs of parkinsonism, UMN findings
- general physical exam with focus on CVD, patient-specific risk factors, and history
- MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)

**Investigations**

- rule out reversible causes
  - CBC (note MCV for evidence of alcohol use and B12 deficiency), glucose, TSH, B12, RBC folate
  - electrolytes, LFTs, renal function, lipids, serum calcium
  - CT head, MRI as indicated, SPECT (optional)
  - as clinically indicated: VDRL, HIV, ANA, anti-dsDNA, ANCA, ceruloplasmin, copper, cortisol, toxicology, heavy metals
- issues to consider
  - failure to cope, fitness to drive, caregiver capacity and wellbeing, power of attorney, legal will, advanced medical directives, patient and caregiver safety

**Table 14. Selected Causes of Major NCD (Dementia)**

Etiology	Key Clinical Features	Investigations
<b>PRIMARY DEGENERATIVE</b>		
Alzheimer's disease	Memory impairment Aphasia, apraxia, agnosia	CT or MRI, FDG-PET or SPECT
Dementia with Lewy bodies	Visual hallucinations Parkinsonism Fluctuating cognition REM sleep behaviour disorder Severe neuroleptic sensitivity	CT or MRI, SPECT
Frontotemporal dementia (e.g. Pick's disease)	Behavioural presentation: disinhibition, perseveration, decreased social awareness, mental rigidity, memory relatively spared Language presentation: progressive non-fluent aphasia, semantic dementia	CT or MRI, SPECT
Huntington's disease	Chorea Neuropsychiatric symptoms	Genetic testing
<b>VASCULAR</b>		
Vascular cognitive impairment (previously Multi-infarct dementia)	Bradyphrenia without features of parkinsonism (slow thinking, slow rate of learning, slow gait) Dysexecutive syndrome May be abrupt onset Stepwise deterioration is classic but progressive deterioration is most common	CT or MRI, SPECT
CNS vasculitis	Systemic signs and symptoms of vasculitis	ANA; ANCA; RF CT or MRI Angiography
<b>INFECTIOUS</b>		
Chronic meningitis	Fever, HA, nausea (triad often absent in cases of chronic meningitis) Meningismus Localizing neurological deficits	CT, MRI, LP
Chronic encephalitis	Fever, HA	CT or MRI
Chronic abscess	Increased ICP Localizing neurological deficits	CT with contrast, MRI
HIV	See <i>Infectious Diseases</i> , 1027	HIV serology
Creutzfeldt-Jakob disease	Rapidly progressive, myoclonus, akinetic mutism, parkinsonism, or cortical symptoms	EEG, CT or MRI, LP
Syphilis	Ataxia, myoclonus, tabes dorsalis	LP, CT, or MRI VDRL
<b>TRAUMATIC</b>		
Diffuse axonal shear, epidural hematoma, subdural hematoma	Trauma Hx Increased ICP, papilloedema Localizing neurological signs	CT, MRI
<b>RHEUMATOLOGIC</b>		
SLE	See <i>Rheumatology</i> , R111	MRI ANA, anti-dsDNA
<b>NEOPLASTIC</b>		
Primary or secondary brain tumour (metastasis), paraneoplastic encephalitis	Increased ICP Localizing neurological signs Systemic symptoms of cancer	CT with contrast MRI Paraneoplastic antibodies
<b>OTHER</b>		
Normal pressure hydrocephalus	Gait disturbances Urinary incontinence See <i>Neurosurgery</i> , NS9	CT or MRI large volume LP

**Features of Early Major NCD vs. Normal Aging**

Early Signs of Major NCD	Normal Aging
Forgetting the names of close relations	Forgetting the names of acquaintances
Increased frequency of forgetting	Briefly forgetting part of an experience
Repeating phrases/stories in the same conversation	Not putting away things properly
Unpredictable mood changes	Mood changes in response to appropriate causes
Decreased interest in activities and difficulty making choices	Changes in usual interests

**Cholinesterase Inhibitors for Dementia with Lewy Bodies (DLB), Parkinson's Disease Dementia (PDD) and Cognitive Impairment in Parkinson's Disease (CIND-PD)**

Cochrane DB Syst Rev 2012;3:CD009504

**Purpose:** To assess the efficacy of treatment with cholinesterase inhibitors in DLB, PDD, and CIND-PD

**Methods:** Review of articles from databases including MEDLINE, EMBASE, PsycINFO, and CINAHL

**Results:** The six trials (n=1236) included demonstrated therapeutic benefit of cholinesterase inhibitors for global assessment, cognitive function, behavioural disturbance, and activities of daily living. Cholinesterase inhibitors were associated with increased adverse events (OR 1.64) and drop out (OR 1.94). Adverse events were more common with rivastigmine but not with donepezil. Fewer deaths occurred in the treatment group (OR 0.28)

**Conclusion:** Current evidence supports use of cholinesterase inhibitors for patients with PDD, but its role in DLB and CIND-PD is still unclear

## Major or Mild Neurocognitive Dementia due to Alzheimer's Disease

- see [Psychiatry](#), PS24

### Definition

- beyond criterion for NCD, the core features of AD include an insidious onset and gradual progression of cognitive and behavioural symptoms
- typical presentation: amnesic
  - mild phase: impairment in memory and learning sometimes accompanied with deficits in executive function
  - moderate-severe phase: visuoconstructional/perceptual-motor ability and language may also be impaired
  - social cognition tends to be preserved until late in the course of the disease
- atypical nonamnesic presentation (one of the following):
  1. language: aphasia, word-finding difficulty
  2. visuospatial: object agnosia, prosopagnosia, simultanagnosia, alexia, limb apraxia
  3. executive: reasoning, judgment, and problem-solving are affected

### Pathophysiology

- genetic factors
  - minority (<1%) of AD cases are familial (autosomal dominant), associated with early onset AD (<65 yr)
  - 3 major genes, responsible for 5-10% of early onset AD cases, for autosomal dominant AD have been identified:
    - ♦ amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
    - ♦ the  $\epsilon 4$  polymorphism of APOE is a susceptibility genotype ( $\epsilon 2$  is protective)
    - ♦ note: APOE cannot serve as a diagnostic marker because it is only a risk factor and neither necessary nor sufficient for disease occurrence
- pathology (not necessarily specific for AD)
  - gross pathology
    - ♦ diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)
  - microscopic pathology
    - ♦ senile  $\beta$ -amyloid plaques (extracellular deposits of amyloid in the grey matter of the brain)
    - ♦ loss of synapses
    - ♦ neurofibrillary tangles (intracytoplasmic paired helical filaments with amyloid and hyperphosphorylated tau protein)
    - ♦ loss of cholinergic neurons in the nucleus basalis of Meynert that project diffusely throughout the cortex
  - biochemical pathology
    - ♦ 50-90% reduction in action of choline acetyltransferase

### Epidemiology

- 1/12 of population 65-75 yr
- up to 1/3 population >85 yr
- very rare <65 yr
- accounts for 60-90% of all dementias (depending on setting and diagnostic criteria)

### Risk Factors

- age is the greatest risk factor
- genetic susceptibility polymorphism: APOE  $\epsilon 4$  increases risk and decreases age of onset
- other factors include: TBI, family history, Down syndrome, low education, and vascular risk factors (e.g. smoking, HTN, hypercholesterolemia, DM)

### Clinical Features

- cognitive impairment
  - memory impairment for newly acquired information (early)
  - deficits in language, abstract reasoning, and executive function
- behavioural and psychiatric manifestations (80% of those with major NCD)
  - mild NCD: major depressive disorder and/or apathy
  - major NCD: psychosis, irritability, agitation, combativeness, and wandering
- motor manifestations (late)
  - gait disturbance, dysphagia, incontinence, myoclonus, and seizures

### Investigations

- perform investigations to rule out other potentially reversible causes of dementia
- EEG: usually normal in mild-moderate stages, slow waves in moderate-advanced stages. May observe generalized slowing (nonspecific)
- MRI: preferential atrophy of the hippocampi and precuneus of the parietal lobe; dilatation of lateral ventricles; widening of cortical sulci

#### 4 As and one D of AD

Anterograde amnesia  
Aphasia  
Apraxia  
Agnosia  
Disturbance in executive function  
(Anterograde amnesia plus at least one of the other features is required for AD diagnosis)

Down syndrome predisposes to early onset of AD (i.e. age of ~40) due to three copies of the amyloid gene (amyloid precursor protein)

#### Vitamin E and Donepezil for the Treatment of Mild Cognitive Impairment

NEJM 2008;358:2379-88

**Purpose:** To investigate the efficacy of vitamin E or donepezil in slowing the progression of AD in patients with mild cognitive impairment

**Methods:** Patients with the amnesic subtype of mild cognitive impairment were randomly assigned to receive vitamin E (2000 IU daily), donepezil (10 mg daily), or placebo for 3 yr.

**Results:** Donepezil, but not vitamin E, reduced the likelihood of progression to AD during the first 12 mo ( $P=0.04$ ), but neither donepezil nor vitamin E significantly reduced the likelihood of progression to AD after 3 yr.

**Conclusion:** Although donepezil reduced the rate of progression to AD during the first 12 mo, it had no significant effect after 3 yr.

See Landmark Neurology trial table for more information on the CATIE-AD trial. The trial examined the effects of time and treatment on neuropsychological functioning during the Clinical Antipsychotic Trials of Intervention Effectiveness-Alzheimer's Disease study

- SPECT: hypoperfusion in temporal and parietal lobes
- PET imaging using Pittsburgh compound B (PIB) as a tracer enables imaging of  $\beta$ -amyloid plaque in neuronal tissue
  - FDG-PET can be used to identify regional patterns of cortical hypometabolism and can be helpful to distinguish AD from other causes of dementia (e.g. FTD, DLB)
- LP:  $\beta$ -amyloid protein can be measured in CSF
- **Note:** common investigations in a clinical setting include ruling out reversible causes with bloodwork, CSF studies, and MRI brain  $\pm$  EEG. The remainder of the tests are less frequently done or done so in a research setting

### Treatment

- acetylcholinesterase inhibitors (donepezil, rivastigmine, galantamine) slow the decline in cognitive function
- do not prolong life expectancy but reduce morbidity
- relative contraindications: bradycardia, heart block, arrhythmia, CHF, CAD, asthma, COPD, ulcers, or risk factors for ulcers and/or GI bleeding
- galantamine is contraindicated in patients with hepatic/renal impairment
- memantine is an NMDA-receptor antagonist that has some benefits in later stage AD (i.e. when MMSE <17)
- behavioural symptom management
  1. pharmacologic
    - low dose neuroleptics for agitation (neuroleptics may worsen cognitive decline)
    - trazodone for sleep disturbance
    - antidepressants (SSRIs)
  2. non-pharmacologic
    - redirection
    - explore inciting factors for behaviour and modify behaviour of patient or caregiver
    - family support and daycare facilities

### Prognosis

- mean duration of survival after diagnosis is approximately 10 yr, reflecting the advanced age of the majority of individuals rather than the course of the disease
- death commonly results from aspiration

## Major or Mild Neurocognitive Dementia with Lewy Bodies (formerly Dementia with Lewy Bodies)

### Definition

- NCD characterized by progressive cognitive impairment (with early changes in complex attention, executive, and visuospatial function) and recurrent complex visual hallucinations
- core diagnostic features (a diagnosis of probable DLB must have at least two core features, one is essential for possible DLB)
  - fluctuating cognition with pronounced variations in attention and alertness
  - recurrent visual hallucinations that are well formed and detailed
  - one or more spontaneous cardinal features of parkinsonism (bradykinesia, rest tremor, or rigidity) with onset subsequent to development of cognitive decline
  - REM sleep behaviour disorder
- suggestive/supportive features
  - severe sensitivity to neuroleptic medications (rigidity, neuroleptic malignant syndrome, extrapyramidal symptoms)
  - repeated falls, syncope, or transient episodes of unexplained loss of consciousness
  - auditory or other non-visual hallucinations, systematic delusions, and depression

### Etiology and Pathogenesis

- Lewy bodies (eosinophilic cytoplasmic inclusions) found in both cortical and subcortical structures
- mixed DLB and AD pathology is common

### Diagnostic Features

- indicative
  - low striatal dopamine transporter uptake on SPECT or PET
- supportive
  - relative preservation of medial temporal structures on CT/MRI
  - generalized low uptake on SPECT/PET perfusion scan with reduced occipital atrophy
  - abnormal (low uptake) 123-I-metaiodobenzylguanidine (MIBG) myocardial scintigraphy
  - prominent slow wave activity on EEG with temporal lobe transient sharp waves

### Epidemiology

- 0.1-5% of the general elderly population
- Lewy bodies are present in 20-35% of all dementia cases (more common in males)

**Treatment**

- only symptomatic treatments available
- cognitive symptoms: acetylcholinesterase inhibitors (e.g. donepezil and rivastigmine)
- REM sleep behaviour disorder: melatonin, clonazepam (use with caution in patients with cognitive impairment and gait disorders)

**Prognosis**

- average duration of survival 5-7 yr

## Major or Mild Frontotemporal Neurocognitive Dementia (formerly Frontotemporal Dementia)

**Definition**

- group of disorders caused by progressive cell degeneration in the brain's frontal or temporal lobes
  - deficits in executive function (e.g. poor mental flexibility, abstract reasoning, response inhibition, planning/organization, increased distractibility) with relative sparing of learning, memory, and perceptual-motor function
- "probable" is distinguished from "possible" frontotemporal NCD by:
  - evidence of causative frontotemporal NCD genetic mutation, from either family history or genetic testing
  - evidence of disproportionate frontal and/or anterior temporal atrophy on MRI or CT
  - evidence of frontal and/or anterior temporal hypoperfusion or hypometabolism on PET or SPECT

**Behavioural Variant FTD**

- most common variant
- insidious onset: must show progressive deterioration of behaviour and/or cognition by observation or history
- typically early symptom presentation (i.e. within the first 3 yr)
- at least 3/5 of the following symptoms must be present and persistent/recurrent:
  - behavioural disinhibition (socially inappropriate behaviour, impulsive, careless)
  - apathy or inertia (decreased initiation or continuation of behaviour, requiring cues/prompts, less likely to initiate or sustain conversations)
  - loss of sympathy or empathy (diminished response to others' needs/feelings, social interest)
  - preservative, stereotyped, or compulsive/ritualistic behaviour
  - hyperorality and dietary changes (binge eating, increased consumption of alcohol/cigarettes or inedible objects)

**Language Variants (Primary Progressive Aphasia)**

- prominent decline in language ability, in the form of speech production, word finding, object naming, grammar, or word comprehension
- three subtypes
  - nonfluent/agrammatic variant PPA (NFAV-PPA) or progressive nonfluent aphasia (PNFA): non-fluent, laboured articulation/speech, anomia, preserved single word comprehension, word-finding deficit, impaired repetition
  - semantic variant PPA (SV-PPA) or semantic dementia (SD): fluent, normal rate, anomia, impaired single word comprehension, intact repetition, use words of generalization ("thing") or supraordinate categories ("animal" for "dog")
  - logopenic progressive aphasia (LPA): naming difficulty and impaired repetition

**FTD Movement Disorders**

- corticobasal degeneration (CBD) (see *Parkinson's Disease, N33*)
- progressive supranuclear palsy (PSP) (see *Parkinson's Disease, N33*)

**Etiology and Pathogenesis**

- unknown, however there is likely a genetic/familial component (40% have family history of early onset NCD)
- genetic variants: MAPT gene (tau), PGRN gene (progranulin), VCP gene, TARDBP gene (TDP-43), CHMP2D gene, C9ORF72 gene (associated with FTD-ALS)
- unlike AD, FTD does not show amyloid plaques or neurofibrillary tangles, instead it is characterized by severe atrophy and specific neuronal inclusion bodies
- gross changes: atrophy in the frontal and anterior temporal lobes, cortical thinning, possible ventricular enlargement
- histological changes: gliosis, swollen neurons, microvacuolation, inclusion bodies in neurons/glia (Tau or TDP-43)

**Epidemiology**

- 4th most common cause of dementia (5% of all dementia cases)
- common cause of early-onset NCD in individuals <65 yr

**Prognosis**

- median survival being 6-11 yr after symptoms onset and 3-4 yr after diagnosis
- survival is shorter and decline is faster than in typical AD

## Major or Mild Vascular Neurocognitive Dementia

### Definition

- diagnosis of major or mild NCD with determination of CVD as the dominant if not exclusive pathology that accounts for the cognitive deficits
- vascular etiology suggested by one of the following:
  - onset of cognitive deficits is temporally related to one or more cerebrovascular events
  - evidence for decline is prominent in complex attention (including processing speed) and frontal-executive function
- neuroimaging evidence of CVD comprises one or more of the following:
  - one or more large vessel infarct or hemorrhage
  - a strategically placed single infarct or hemorrhage (e.g. angular gyrus, thalamus, basal forebrain)
  - two or more lacunar infarcts outside the brainstem
  - extensive and confluent white matter lesions
- for mild vascular NCD: history of a single stroke or extensive white matter disease is sufficient
- for major vascular NCD: history of two or more strokes, a strategically placed stroke, or a combination of white matter disease, and one or more lacunae is generally necessary
- associated features supporting diagnosis: personality and mood changes, abulia, depression, emotional lability, and psychomotor slowing

### Etiology and Pathogenesis

- major risk factors are the same as those for CVD (e.g. HTN, DM, smoking, obesity, high cholesterol levels, high homocysteine levels, other risk factors for atherosclerosis, atrial fibrillation, and conditions increasing risk of cerebral emboli)
- major or mild vascular NCD with gradual onset and slow progression is generally due to small vessel disease leading to lesions in white matter, basal ganglia, and/or thalamus
- cognitive deficits can be attributed to disruption of cortical-subcortical circuits

### Epidemiology

- second most common cause of NCD
- prevalence estimates for vascular dementia/NCD range from 0.2-13% (by age 70), 16% (ages  $\geq 80$ ) to 44.6% (ages  $\geq 90$ )
- higher prevalence in African Americans
- prevalence higher in males than in females

## Creutzfeldt-Jakob Disease

### Definition

- rare degenerative, fatal brain disorder caused by prion proteins causing spongiform changes, astrocytosis, and neuronal loss
  - rapidly progressive and common features include cognitive impairment, myoclonus, ataxia, akinetic mutism, weakness, visual changes, etc
- most common forms are sporadic (85%), hereditary (5-10%), and acquired (<1%)

### Investigations

- CSF analysis, MRI brain (cortical (i.e. cortical ribbon sign) and/or subcortical (i.e. hockey stick sign) FLAIR changes), EEG (periodic complexes)
- definitive diagnosis is by brain biopsy

### Treatment

- symptomatic management of seizures and movement disorders, and neuropsychiatric symptoms but there is no known cure for CJD

## Aphasia

### Definition

- an acquired disturbance of language characterized by errors in language production, writing, comprehension, or reading

### Neuroanatomy of Aphasia

- Broca's area (posterior inferior frontal lobe) is involved in language production (expressive)
- Wernicke's area (posterior superior temporal lobe) is involved in comprehension of language (receptive)
- angular gyrus is responsible for relaying written visual stimuli to Wernicke's area for reading comprehension
- arcuate fasciculus association bundle connects Wernicke's and Broca's areas

Prion proteins have a normal form and an infectious form, which results from conversion of the protein from  $\alpha$ -helix (normal) to  $\beta$ -pleated sheet (abnormal); these abnormally folded proteins aggregate leading to neuronal loss

>99% of right-handed people have left hemisphere language representation  
70% of left-handed people have left hemisphere language representation, 15% have right hemisphere representation, and 15% have bilateral representation

**Types of Paraphasias**  
Semantic (e.g. "chair" for "table")  
Phonemic (e.g. "clable" for "table")

**Assessment of Language**

- assessment of context
  - handedness (writing, drawing, toothbrush, scissors), education level, native language, learning difficulties
- assessment of aphasia
  - spontaneous speech (fluency, paraphasias, repetition, naming, writing, neologism, comprehension – auditory and reading)

Aphasia localizes the lesion to the dominant cerebral hemisphere

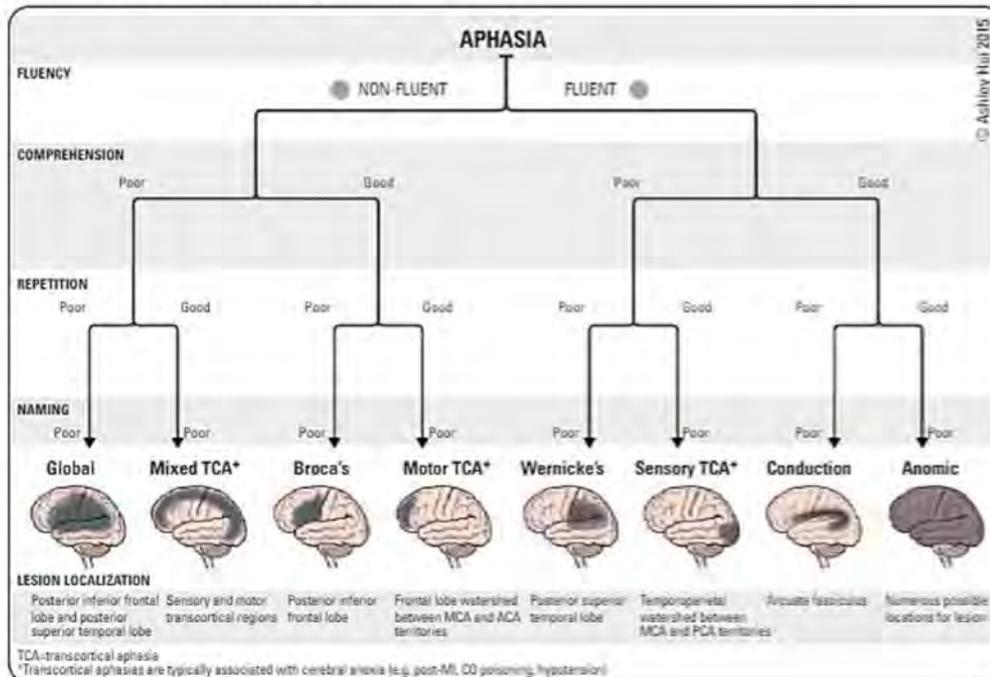

Figure 19. Aphasia classification

**Apraxia**

**Definition**

- inability to perform skilled voluntary motor sequences that cannot be accounted for by weakness, ataxia, sensory loss, impaired comprehension, or inattention

**Clinicopathological Correlations**

Table 15. Apraxia

	Description	Tests	Hemispheres
Ideomotor	Inability to perform skilled learned motor sequences	Blowing out a match, combing one's hair	Left
Ideational	Inability to sequence actions	Preparing and mailing an envelope	Right and left
Constructional*	Inability to draw or construct	Copying a figure	Right and left
Dressing*	Inability to dress	Dressing	Right

\*Refers specifically to the inability to carry out the learned movements involved in construction, drawing, or dressing; not merely the inability to construct, draw, or dress. Many skills aside from praxis are needed to carry out these tasks.

## Agnosia

### Definition

- inability to recognize the significance of sensory stimuli in the presence of intact sensation and naming

### Clinicopathological Correlations

Table 16. Agnosias

	Description	Lesion
Apperceptive Visual Agnosia	Bilateral temporo-occipital cortex Bilateral inferior temporo-occipital junction	Bilateral temporo-occipital cortex
Associative Visual Agnosia	Inability to name an object presented visually, 2° to disconnect between visual cortex and language areas Visual perception is intact as demonstrated by visual matching	Bilateral inferior temporo-occipital junction
Prosopagnosia	Inability to recognize familiar faces in the presence of intact visual perception and intact auditory recognition	Bilateral temporo-occipital areas or right inferior temporo-occipital region
Colour Agnosia	Inability to perceive colour	Bilateral inferior temporo-occipital lesions
Impaired Stereognosis	Inability to identify objects by touch	Anterior parietal lobe in the hemisphere opposite to the affected hand
Finger Agnosia	Inability to recognize, name, and point to individual fingers	Dominant hemisphere parietal-occipital lesions

### Parietal Lobe Lesions

- Lesions of the dominant parietal lobe are characterized by Gerstmann's syndrome: acalculia, agraphia, finger agnosia, and left-right disorientation
- Lesions of the non-dominant parietal lobe are characterized by neglect, anosognosia, and asomatognosia
- Cortical sensory loss (graphesthesia, astereognosis, impaired 2 point discrimination, and extinction) can be seen with left or right parietal lesions

## Mild Traumatic Brain Injury

### Definition

- mild TBI = concussion
- trauma-induced transient alteration in mental status that may involve loss of consciousness
- hallmark symptoms: confusion and amnesia, which may occur within minutes
- loss of consciousness (if present) less than 30 min, initial GCS between 13-15, post-traumatic amnesia <24 h

### Epidemiology

- 75% of TBIs are estimated to be mild; the remainder are moderate or severe (see [Neurosurgery, Brain Injury, NS37](#) and [Emergency Medicine, ER9](#))
- highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

### Clinical Features

- impairments following mild TBI
  - somatic: headache, sleep disturbance, nausea, vomiting, and blurred vision
  - cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
  - emotion and behaviour: impulsivity, irritability, depression
- severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
- associated conditions: brain contusion, diffuse axonal injury, C-spine injury

### Investigations

- neurological exam to identify focal neurologic deficits
- neurocognitive assessment
  - simple orientation questions are inadequate to detect cognitive changes
  - initial assessment of severity is determined by GCS
    - mild: 13-15, moderate: 9-12, severe: 3-8
  - sideline evaluation: Standardized Assessment of Concussion, Westmead Post-Traumatic Amnesia Scale, Sport Concussion Assessment Tool
- neuroimaging
  - x-ray skull: not indicated for routine evaluation of mild TBI
  - CT head as indicated by Canadian CT Head Rules
  - MRI not indicated in initial evaluation; consider if continued or worsening symptoms despite normal CT

Extent of retrograde amnesia correlates with severity of injury  
Regained from most distant to recent memories

**Treatment**

- observation for the first 24 h after mild TBI because of risk of intracranial complications
- emergency department for assessment if any loss of consciousness or persistent symptoms
- hospitalization with normal CT if GCS <15, seizures, or bleeding diathesis; or abnormal CT scan
- early rehabilitation to maximize outcomes
  - OT, PT, SLP, vestibular therapy, driving, therapeutic recreation
- pharmacological management of headaches, pain, depression
- CBT, relaxation therapy
- follow Return to Play guidelines ([www.thinkfirst.ca](http://www.thinkfirst.ca))

**Prognosis**

- most recover from mild TBI with minimal treatment, but some experience long-term consequences
- patients with a previous concussion are at increased risk of subsequent concussions and cumulative brain injury
- repeat TBI can lead to life threatening cerebral edema (controversially known as second impact syndrome) or permanent impairment
- sequelae include:
  - post-concussion syndrome: dizziness, headache, neuropsychiatric symptoms, cognitive impairment (usually resolves within weeks to months)
  - post-traumatic headaches: begin within 7 d of injury
  - post-traumatic epilepsy: approximately 2% risk post-mild TBI; prophylactic anticonvulsants are not effective
  - post-traumatic vertigo

## Neuro-Oncology

### Paraneoplastic Syndromes

- see [Endocrinology](#), E56

### Tumours of the Nervous System

- see [Neurosurgery](#), NS11

## Movement Disorders

### Function of the Basal Ganglia

- the cerebral cortex initiates movement via excitatory (glutamatergic) projections to the striatum, where they then activate two pathways: direct and indirect
  - direct: cortex activates the thalamus, allowing movement
  - indirect: cortex inhibits the thalamus, preventing movement

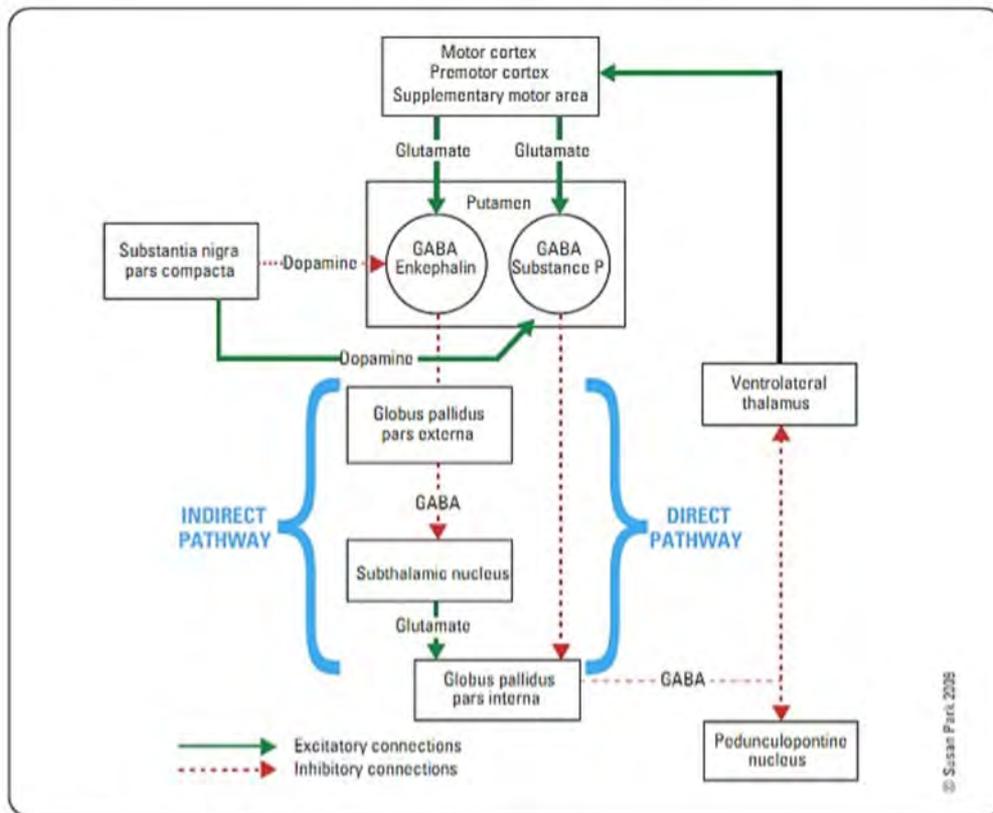

Figure 20. Neural connections of the basal ganglia

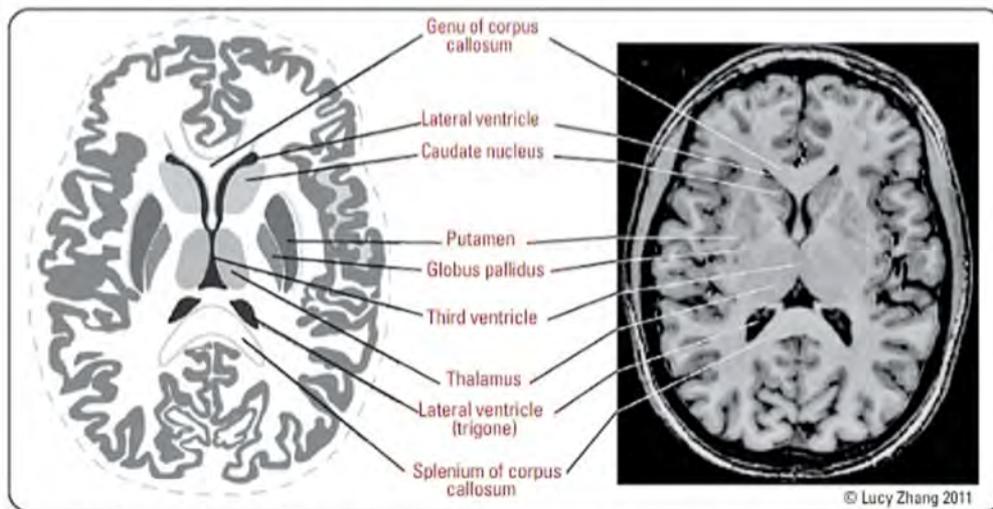

Figure 21. Horizontal section of basal ganglia

## Overview of Movement Disorders

**Table 17. Movement Disorder Definitions**

<b>Akathisia</b>	Subjective generalized restlessness relieved by voluntary stereotypic movements (e.g. squirming)
<b>Asterixis</b>	Transient loss of muscle tone (negative myoclonus)
<b>Athetosis</b>	Slow writhing movements, especially distally
<b>Ballism</b>	Large-amplitude, involuntary, flinging movements that are most commonly unilateral (hemiballism)
<b>Bradykinesia</b>	Slow, small amplitude movements
<b>Chorea</b>	Brief, unpredictable, irregular movements, flowing from one body part to another; can appear purposeful in milder forms
<b>Dysidiadochokinesia</b>	Inability to smoothly perform rapidly alternating movements
<b>Dyskinesia</b>	Any involuntary movement, but the term is often used to describe the stereotypical movements that come with long-term neuroleptic use ( tardive dyskinesia) or levodopa use (levodopa induced dyskinesia)
<b>Dystonia</b>	Co-contraction of agonist and antagonist muscles causing sustained twisting movements which can be tonic (dystonic postures) or phasic (dystonic movements)
<b>Freezing</b>	Episodes of halted motor action, especially during repetitive actions (e.g. walking)
<b>Myoclonus</b>	Brief muscle group contraction that is either focal, segmental, or generalized
<b>Myokymia</b>	Spontaneous, fine, fascicular contraction of muscle
<b>Stereotypies</b>	Predictable, repetitive, involuntary movements that do not appear to have any purpose (commonly associated with intellectual disability or autism)
<b>Tachykinesia</b>	Acceleration of movements e.g. accelerated walking (festination)
<b>Tics</b>	Stereotyped, nonrhythmic, and brief repetitive actions due to inner urge Can be phonic (vocal) or motor and can be suppressed
<b>Tremor</b>	Rhythmic and involuntary antagonistic muscle contractions

## Movement Disorders

### 1. Tremor

**Table 18. Approach to Tremors**

	<b>Resting Tremor</b>	<b>Action-Postural Tremor</b>	<b>Action-Intention Tremor</b>
<b>Affected Body Part</b>	UE>jaw>LE>head	UE>head>LE>tongue	UE>voice>LE
<b>Characteristics</b>	3-6 Hz pill-rolling	6-12 Hz fine tremor	<5 Hz coarse tremor
<b>Worse with Associated Sx</b>	Rest while concentrating "TRAP"	Sustained posture (outstretched arms) ± Autosomal dominant FHx	Finger to nose Cerebellar findings
<b>DDx</b>	PD, Parkinsonism, Wilson's disease, mercury poisoning, severe essential tremor	Physiologic, essential tremor, hyperthyroidism, hyperglycemia, heavy metal poisoning, CO poisoning, drug toxicity, sedative/alcohol withdrawal	Cerebellar disorders, Wilson's disease, MS, anticonvulsants, alcohol, sedatives
<b>Treatment</b>	Levodopa/carbidopa (Sinemet®), DBS	Propranolol, primidone, topiramate, and other anticonvulsants, surgery (thalamotomy, DBS)	Treat underlying cause

### 2. Chorea

- HD, HD-like syndromes, neuroacanthocytosis, SLE, APLA syndrome, Wilson's disease, CVD, tardive dyskinesia, senile chorea, Sydenham's chorea, pregnancy chorea (chorea gravidarum), levodopa induced dyskinesia

### 3. Dystonia

- **primary dystonia:** familial, sporadic (torticollis, blepharospasm, writer's cramp)
- **dystonia-plus syndromes:** dopa-responsive dystonia, myoclonus-dystonia
- **secondary dystonia:** stroke, CNS tumour, demyelination, drugs/toxins (L-dopa, neuroleptics, anticonvulsants, Mn, CO, cyanide, methanol)
- **heredodegenerative dystonias:** Parkinsonian disorders, Wilson's disease, HD

### 4. Myoclonus

- **physiologic myoclonus:** hiccups, nocturnal myoclonus
- **essential myoclonus:** myoclonus-dystonia with minimal or no occurrence of dystonia
- **epileptic myoclonus**
- **symptomatic myoclonus**

In some cases, dystonias may occur only during voluntary movements and sometimes only during specific activities, such as writing, chewing, or speaking (task-specific dystonia)

Hemiballismus is most often due to a vascular lesion

Myoclonus can be stimulus-sensitive (induced by sudden noise, movement, light, visual threat, or pinprick)

In a young patient (<45 yr) must do TSH (thyroid disease), ceruloplasmin (Wilson's disease), and CT/MRI (cerebellar disease) as indicated by type of tremor

Most of the time, essential tremor does not need treatment

#### Alcohol

- Dampens essential tremor
- Potentiates intention tremor during abstinence (delirium tremens)
- Does not improve resting tremor of PD

Most common cause of chorea is drug therapy for PD (levodopa induced dyskinesias)

Palatal tremor can result from lesion to the Dentato-Rubro-Olivary tract

- **degenerative disorders:** Wilson's disease, HD, corticobasal degeneration
- **infectious disorders:** CJD, viral encephalitis, AIDS-dementia complex
- **metabolic disorders:** drug intoxication/withdrawal, hypoglycemia, hyponatremia, hyperglycemic hyperosmolar syndrome, hepatic encephalopathy, uremia, hypoxia
- **focal brain damage:** head injury, stroke, mass

## Parkinson's Disease

### Etiology

- sporadic: combination of oxidative stress to dopaminergic neurons, environmental toxins (e.g. pesticides), accelerated aging, genetics
- familial (10%): autosomal dominant  $\alpha$ -synuclein or *LRRK2* mutations, autosomal recessive parkin, *PINK1*, or *DJ-1* mutation (juvenile onset)
- MPTP (neurotoxin)

### Epidemiology

- prevalence of 0.3% in industrialized countries, but rises with increased age
- second most common neurodegenerative disorder, after AD
- mean age of onset is 60 yr

### Associated Factors

- risk: family history, male, head injury, rural living, exposure to certain neurotoxins
- protective: coffee drinking, smoking, estrogen replacement in post-menopausal women

### Pathophysiology

- loss of dopaminergic neurons in pars compacta of substantia nigra  $\rightarrow$  decreased dopamine in striatum  $\rightarrow$  1. disinhibition of the indirect pathway, and 2. decreased activation of the direct pathway  $\rightarrow$  increased inhibition of cortical motor areas
- $\alpha$ -synucleinopathy:  $\alpha$ -synuclein accumulates in Lewy bodies and causes neurotoxicity in substantia nigra

### Clinical Features

- diagnosis is based on clinical features:

#### 1. Negative motor features

- bradykinesia: slow, small amplitude movements, fatigue from rapid alternating movements, difficulty initiating movement

#### 2. Positive motor features

- resting tremor: typically 4-6 Hz "pill-rolling" tremor, especially in hands
- rigidity: lead-pipe rigidity with cogwheeling due to superimposed tremor

#### 3. Asymmetric onset of tremor, rigidity, bradykinesia

#### 4. Progressive course

- related findings: hypomimia (reduced facial expression), hypophonia, aprosody (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
- freezing of gait: occurs with walking triggered by initiating stride or barriers/reaching destinations, lasting seconds
- postural instability: a late finding that presents as falls
- cognition: bradyphrenia (slow to think/respond), dementia (late finding)
- behavioural: decreased spontaneous speech, depression, sleep disturbances, anxiety
- autonomic: constipation, urinary dysfunction (nocturia, urgency, frequency), sexual dysfunction, orthostatic hypotension, clinostatic hypertension
- sleep: REM sleep behaviour disorder, insomnia, hypersomnolence

### Treatment

#### • pharmacologic

- mainstay of treatment: levodopa/carbidopa (Sinemet<sup>®</sup>) or levodopa/benserazide (Prolopa<sup>®</sup>)
- levodopa is a dopamine precursor. Both carbidopa and benserazide decrease levodopa peripheral metabolism, decreasing levodopa side effects and increasing its half-life
  - levodopa-related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration ("wearing-off"), random oscillations of on-off symptoms
  - major adverse effect of levodopa: dyskinesia
- treatment of early PD: levodopa, dopamine agonists, amantadine, MAOI
- adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), catechol-O-methyltransferase inhibitors

#### • surgical

- thalamotomy
- pallidotomy
- DBS (thalamic, pallidal, subthalamic)

#### • psychiatric

- SSRIs first line
- TCAs (beware fall risk, cognitive impairment, and worsening symptoms of PD)

#### Key Parkinsonian Features

##### TRAP

- Tremor (resting)
- Rigidity
- Akinesia/bradykinesia
- Postural instability

#### 2015 MDS Clinical Diagnostic Criteria for PD

- "Clinically Established PD" requires:
  - Cardinal Parkinsonism
    - Manifestations: Bradykinesia with either resting tremor or rigidity
  - 2 or more supportive criteria (clear and dramatic beneficial response to dopaminergic therapy, levodopa-induced dyskinesia, rest tremor of a limb, and/or olfactory loss/cardiac sympathetic denervation on MIBG scintigraphy)
- No absolute exclusion criteria and no red flags (see full diagnostic criteria - Mov Disord 2015;30:1591-601)

#### Consider an Alternative Diagnosis if Atypical Parkinsonism

- Poor response to levodopa
- Abrupt onset of symptoms
- Rapid progression
- Early falls
- Early autonomic dysfunction
- Symmetric symptoms at onset
- Early age of onset (<50 yr)
- Early cognitive impairment
- FHx of psychiatric disorders and/or dementia
- Recent diagnosis of psychiatric disease
- History of encephalitis
- Unusual toxin exposure
- Extensive travel history

## Other Parkinsonian Disorders

- NCD with Lewy bodies: see *Behavioural Neurology*, N21
- **progressive supranuclear palsy**: tauopathy with limited vertical gaze (downgaze more specific that can be overcome by the oculocephalic reflex), early falls, wide-based unsteady gait, axial rigidity, akinesia, dysarthria, and dysphagia
- **corticobasal syndrome**: tauopathy with varied presentations but classically presenting with unilateral parkinsonism, dystonia/myoclonus, and apraxia ± “alien limbs” phenomenon; ± progressive non-fluent aphasia
- **multiple system atrophy**: synucleinopathy presenting as either cerebellar predominant (MSA-C, previously olivopontocerebellar atrophy) or parkinsonism predominant (MSA-P, previously nigrostriatal degeneration); both are associated with early autonomic dysfunction (urinary incontinence or orthostatic hypotension, previously Shy-Drager syndrome)
- **vascular parkinsonism**: multi-infarct presentation with gait instability and lower body parkinsonism; step-wise decline over time; less likely associated with tremor

## Huntington's Disease

### Etiology and Pathogenesis

- genetics: autosomal dominant CAG repeats (with anticipation) in *HTT* on chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway, and decreased activity of the indirect pathway

### Epidemiology

- North American prevalence 4-8 in 100000
- mean age of onset 35-44 yr, but varies with degree of anticipation from 5-70 yr

### Clinical Features

- typical progression: insidious onset with clumsiness, fidgetiness, and irritability, progressing over 15 yr to major NCD, psychosis, and chorea
  - major NCD: progressive memory impairment and loss of intellectual capacity
  - chorea: begins as movement of eyebrows and forehead, shrugging of shoulders, and parakinesia (pseudo-purposeful movement to mask involuntary limb jerking)
  - progresses to dance-like or ballism, and in late stage is replaced by dystonia and rigidity
  - mood changes: irritability, depression, anhedonia, impulsivity, bouts of violence
- Juvenile-onset HD (Westphal variant) characterized by Parkinsonism, dystonia, rigidity, seizures

### Investigations

- MRI
  - enlarged ventricles, atrophy of cerebral cortex, and caudate nucleus
- genetic testing
  - cytosine-adenine-guanine (CAG) trinucleotide repeats within the *HTT* gene located on chromosome 4p16.3
  - CAG repeat sizes that result in: meiotic instability (27-35 repeats), reduced disease penetrance (36-39 repeats), and full disease penetrance ( $\geq 40$  repeats)

### Treatment

- no disease-modifying treatment
- psychiatric symptoms: antidepressants and antipsychotics
- chorea: tetrabenazine, amantadine, and neuroleptics
- dystonia: botulinum toxin (for focal dystonia)

## Wilson's Disease

- see *Gastroenterology*, G37

## Dystonia

### Epidemiology

- 3rd most common movement disorder after PD and essential tremor

### Clinical Features

- sustained or intermittent twitching movements caused by co-contraction of agonist and antagonist muscles
- symptoms exacerbated by fatigue, stress, and emotions; relieved by sleep or specific tactile/proprioceptive stimuli (“geste antagoniste,” e.g. place hand on face for cervical dystonia)
- more likely to be progressive and generalized if younger onset or leg dystonia

### Dopamine Agonist Therapy in Early Parkinson's Disease

Cochrane DB Syst Rev 2009;2:CD006564

**Study:** Meta-analysis of trials of dopamine agonists in early PD.

**Results:** Twenty-nine trials were included (n=5247). Dopamine agonists were found to have decreased motor side effects (dyskinesia (OR 0.51), dystonia (OR 0.64), motor fluctuations (OR 0.75), but provided poorer symptom control compared to levodopa. Also, other side effects were increased (constipation (OR 1.59), hallucinations (OR 1.69), dizziness (OR 1.45)).

**Conclusion:** Dopamine agonists have fewer motor side effects than levodopa, but provide worse symptom control and increased rate of other side effects.

**Treatment**

- local medical: botulinum toxin
- systemic medical: anticholinergics (trihexyphenidyl, benzotropine), muscle relaxants (baclofen), benzodiazepines, dopamine depletors (tetraabenazine), dopamine for dopa-responsive dystonia
- surgical: DBS, pallidotomy, or surgical denervation of affected muscle

## Tic Disorders

**Definition**

- a tic is a sudden, rapid, recurrent, nonrhythmic, stereotyped motor movement or vocalization
- common criteria
  - tics may wax and wane in frequency but have persisted for an extended period of time
  - onset is <18 yr
  - disturbance is not attributable to the physiological effects of a substance or another medical condition

**Clinical Classification**

- **Tourette's Syndrome:** multiple motor and  $\geq 1$  vocal tics that have persisted for >1 yr since onset
- **persistent (chronic) motor or vocal tic disorder:** single or multiple motor or vocal tics (but not both motor and vocal) that have persisted for >1 yr since onset
- **provisional tic disorder:** single or multiple motor and/or vocal tics present for <1 yr since first tic onset
- **other specified or unspecified tic disorder:** symptoms characteristic of a tic disorder but do not meet full criteria
- **secondary tic disorders:** encephalitis, CJD, Sydenham's chorea, head trauma, drugs (stimulants, levodopa), intellectual disability syndromes
- **neurodegenerative diseases:** neuroacanthocytosis, HD (see *Huntington's Disease, N34*)

**Tic Types**

- simple tics: short duration (msec)
- complex tics: longer (sec), more purposeful and often include a combination of simple tics
- motor tics
  - simple: blinking, head jerking, shoulder shrugging, extension of the extremities
  - dystonic: bruxism (grinding teeth), abdominal tension, sustained mouth opening
  - complex: copropraxia (obscene gestures), echopraxia (imitate gestures), throwing, touching
- vocal tics
  - simple: blowing, coughing, grunting, throat clearing
  - complex: coprolalia (shout obscenities), echolalia (repeat others' phrases), palilalia (repeat own phrases)

**Treatment**

- mild tics: education, counselling, supportive care, Comprehensive Behavioural Intervention for Tics
- debilitating tics:  $\alpha$ -2 adrenergic agonists (guanfacine, clonidine), antipsychotics (e.g. haloperidol, pimozide), botulinum toxin, topiramate

## Tourette's Syndrome (Gilles de la Tourette Syndrome)

**DSM-V Definition**

1. presence of both multiple motor and one or more vocal tics at some point during the illness, although not necessarily concurrently
2. tics may wax and wane in frequency but have persisted >1 yr since first tic onset (with no tic-free periods >3 mo)
3. onset is <18 yr
4. not due to effect of a substance or another medical condition

**Epidemiology**

- estimated prevalence among adolescents 3-8 in 1000 school-age children, M:F=2-4:1

**Signs and Symptoms**

- tics: wide variety that wax and wane in type and severity (see *Tic Disorders - Tic Types*)
  - can be associated with the presence of premonitory feelings or sensations that are relieved by carrying out the tic
  - can be voluntarily suppressed for some time
  - can be worsened by anxiety, excitement, and exhaustion; improved by calm, focused activities
- psychiatric: compulsive behaviour (associated with OCD and ADHD), hyperactive behaviour, "rages," sleep-wake disturbances, or learning disabilities

**Treatment**

- mild tics: (see *Tic Disorders - Treatment*)
- debilitating tics: DBS, (see *Tic Disorders - Treatment*)

**Prognosis**

- typically begins between ages 4-6
- peak severity occurs between ages 10-12, with a decline in severity during adolescence (50% are tic-free by age 18)
- tic symptoms, however, can manifest similarly in all age groups and across the lifespan

## Cerebellar Disorders

**Clinico-Anatomic Correlations**

- vermis: trunk/gait ataxia
- cerebellar lobe (i.e. lateral): rebound phenomenon, scanning dysarthria, dysdiadochokinesia, dysmetria, nystagmus

**Symptoms and Signs of Cerebellar Dysfunction**

- nystagmus: observe during EOM testing (most common is gaze-evoked nystagmus)
- dysarthria (ataxic): abnormal modulation of speech velocity and volume (elicit scanning/telegraphic/slurred speech on spontaneous speech)
- hypermetric saccades
- dysmetria: under/overshooting the target during voluntary movement of limb or eye
- dysdiadochokinesia: impairment of rapid alternating movements (e.g. pronation-supination task)
- rebound phenomenon: overcorrection after displacement of a limb
- intention tremor: typically orthogonal to intended movement, and increases as target is approached
- hypotonia: decreased resistance to passive muscular extension (occurs shortly after injury to lateral cerebellum)
- pendular patellar reflex: knee reflex causes pendular motion of leg (occurs after injury to cerebellar hemispheres), pendular reflexes at triceps
- truncal ataxia: on sitting, titubation (rhythmic rocking of trunk and head)
- ataxic gait: broad-based and lurching gait, difficulty with tandem gait

## Wernicke-Korsakoff Syndrome

- acute (Wernicke's encephalopathy) and chronic (Korsakoff's psychosis) disorders caused by thiamine (vitamin B1) deficiency, see *Psychiatry, PS29*
- etiology: alcohol use disorder, gastrointestinal disorders especially malabsorption, surgeries (e.g. gastric bypass), acquired immune deficiency syndrome, hemodialysis, malignancies
- note that alcohol can also cause a cerebellar ataxia separate from thiamine deficiency; this ataxia can be due to cerebellar atrophy or alcohol polyneuropathy

## Cerebellar Ataxias

**Congenital Ataxias**

- early onset non-progressive ataxias associated with various syndromes as well as developmental abnormalities (e.g. Arnold-Chiari malformation, Dandy-Walker cysts)

**Hereditary Ataxias**

- autosomal recessive: Friedrich's ataxia, ataxia with oculomotor apraxia, ataxia telangiectasia, ataxia with vitamin E deficiency
  - Friedrich's ataxia: prevalence 2 in 100000; typical onset between 8-15 yr
    - signs: gait and limb ataxia, weakness, areflexia, extensor plantar reflex, impaired proprioception and vibration, dysarthria
    - death in 10-20 yr from cardiomyopathy or kyphoscoliotic pulmonary restriction
- autosomal dominant: most commonly spinocerebellar ataxias (SCAs); 30+ types, most commonly due to CAG repeats
  - signs: ataxia and dysarthria, chorea, polyneuropathy, pyramidal and/or extrapyramidal features, dementia

**Acquired Ataxias**

- neurodegeneration: multiple system atrophy, SCAs
- systemic: alcohol, celiac sprue, hypothyroidism, Wilson's, thiamine deficiency, vitamin E deficiency
- toxins: CO, heavy metals, lithium, anticonvulsants, solvents
- vascular: infarct, bleed, basilar migraine
- autoimmune: MS, Miller-Fischer (GBS)
- primary and secondary neoplasm

## Vertigo

- see [Otolaryngology, OT12](#)

## Motor Neuron Disease

### Amiotrophic Lateral Sclerosis (Lou Gehrig's Disease)

#### Definition

- progressive neurodegenerative disease that causes UMN and LMN symptoms and is ultimately fatal

#### Etiology

- idiopathic (most common), genetic (5-10% familial, most commonly C9orf72 mutation, other mutations include: SOD1, TARDBP)

#### Pathology

- disorder of anterior horn cells of the spinal cord, cranial nerve nuclei, and corticospinal tract

#### Epidemiology

- 5 in 100000; incidence increases with age

#### Clinical Features

- limb motor symptoms: segmental and asymmetrical UMN and LMN symptoms
- bulbar findings: dysarthria (flaccid or spastic or mixed), dysphagia, tongue atrophy and fasciculations, facial weakness and atrophy
- pseudobulbar affect, FTD (up to 10%)
- sparing of sensation, ocular muscles, bowels, bladder, sphincters

#### Investigations

- EMG: active and chronic denervation and reinnervation, fasciculations
- NCS: to rule out peripheral neuropathy (e.g. multifocal motor neuropathy with conduction block)
- CT/MRI: to rule out spinal cord disease/compression

#### Treatment

- riluzole (modestly slows disease progression)
- symptomatic relief
  - spasticity/cramping: baclofen, tizanidine (Zanaflex<sup>®</sup>), regular exercise, and physical therapy
  - sialorrhea: TCA (e.g. amitriptyline), sublingual atropine drops, parotid and/or submandibular Botox<sup>®</sup> (rare)
  - pseudobulbar affect: dextromethorphan and quinidine, TCA, SSRI
- edaravone is FDA and Health Canada approved; reduces functional decline by 33% in early stage ALS
- non-pharmacologic: high caloric diet, ventilatory support (especially BiPAP), early nutritional support (e.g. percutaneous endoscopic gastrostomy tube), rehabilitation (PT, OT, SLP), and psychosocial support

#### Prognosis

- median survival is 3 yr; death is typically due to respiratory failure

### Other Motor Neuron Diseases

- degenerative
  - **progressive muscular atrophy (progressive bulbar palsy):** only LMN symptoms with asymmetric weakness, later onset than ALS, 5-10% of patients in ALS centres (considered the isolated LMN version of ALS)
  - **primary lateral sclerosis (progressive pseudobulbar palsy):** UMN symptoms, later onset, not fatal, variable disability, 5-10% of patients in ALS centres (considered the isolated UMN version of ALS)
- genetic
  - **spinal muscular atrophy:** paediatric or adult-onset disease with symmetric LMN symptoms (genetic disorder)
  - **spino-bulbar muscular atrophy (Kennedy disease):** speech and swallowing difficulty and limb weakness (X-linked genetic)
- infectious
  - **post-polio syndrome**
  - **West Nile infection:** residual asymmetric muscle weakness, atrophy

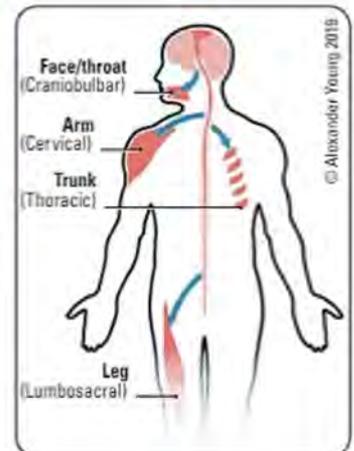

Figure 22. Regions affected by ALS

Adapted from: <https://www.mda.org/disease/amyotrophic-lateral-sclerosis/signs-and-symptoms> and labels: ALS and Other Motor Neuron Diseases (2017) Lecture by Dr. Aaron Izenberg

#### Safety and Efficacy of Edaravone in Well Defined Patients with Amyotrophic Lateral Sclerosis: A Randomised, Double-Blind, Placebo-Controlled Trial

Lancet Neurol 2017;16:505-12

**Purpose:** To assess the safety and efficacy of edaravone in patients with early-stage ALS

**Methods:** 137 early-stage ALS patients meeting stringent inclusion criteria were randomly assigned to receive 60 mg IV edaravone or IV saline placebo for 6 cycles (4 weeks/cycle with 2 weeks on, 2 weeks off) for a total treatment duration of 24 weeks

**Primary Outcome:** Difference in the Revised ALS Functional Rating Scale (ALSF<sup>®</sup>-R) score from baseline to 24 weeks

**Results:** The ALSFRS-R score change was -5.01 (SE 0.64) and -7.50 (0.66) in the edaravone group and placebo, respectively. The between-group least-squares mean difference was 2.49 (SE 0.36, 95% CI 0.99-3.98; P=0.0013), thus favouring edaravone. Adverse events were similar in both groups

**Conclusion:** In early-stage ALS patients identified in post-hoc analysis of a previous phase 3 study, edaravone significantly reduced the decline of ALSFRS-R scores

The only interventions shown to extend survival in ALS are riluzole and use of BiPAP. Edaravone in early ALS can decrease functional decline

**Red Flags Inconsistent with ALS**  
Sensory Sx, predominant pain, bowel or bladder incontinence, ocular muscle weakness

**Denervation on EMG**  
Fibrillations, positive sharp waves, complex repetitive discharges

**Reinnervation on EMG**  
Increased amplitude and duration of motor units

# Peripheral Neuropathies

## Diagnostic Approach to Peripheral Neuropathies

1. differentiate: motor vs. sensory vs. autonomic vs. mixed
2. pattern of deficit: symmetry; focal vs. diffuse; upper vs. lower limb; cranial nerve involvement
3. temporal pattern: acute vs. chronic; relapsing/remitting vs. constant vs. progressive
4. history: PMHx, detailed FHx, exposures (e.g. insects, toxins, sexual, travel), systemic symptoms
5. detailed peripheral neuro exam: LMN findings, differentiate between root and peripheral nerves, cranial nerves, respiratory status

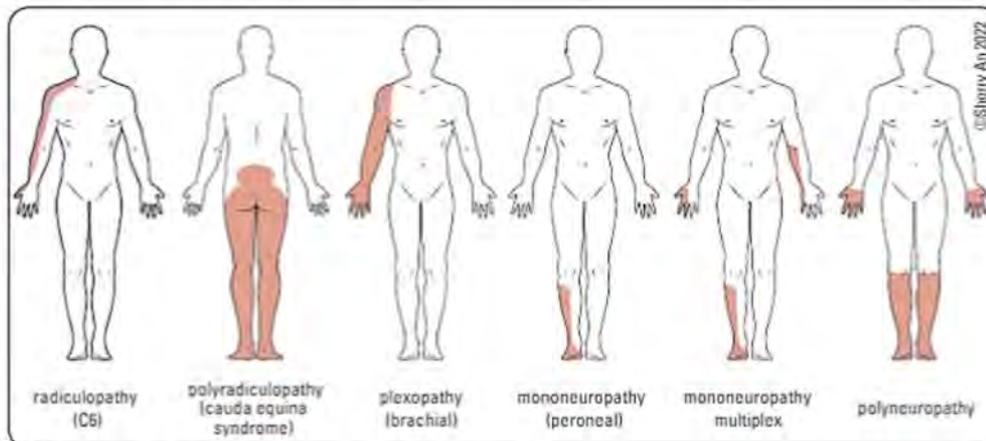

Figure 23. Pattern of distribution for peripheral neuropathies

## Classification

- **radiculopathy**: dermatomal sensory deficit and myotomal weakness in distribution of single nerve root (e.g. C7)
  - often due to disc herniation or root compression causing radicular pain
  - little tactile anesthesia, as dermatomes overlap
- **polyradiculopathy**: multiple dermatome sensory deficits and myotomal weakness
  - due to multiple nerve root lesions (e.g. cauda equina syndrome due to lumbosacral roots lesion)
- **plexopathy**: deficit matching distribution of a nerve plexus
  - due to lesion distal to nerve roots but proximal to origin of individual peripheral nerves
  - **brachial plexopathy**
    - upper (C5-C7): LMN Sx of shoulder and upper arm muscles (Erb's palsy)
    - lower (C8-T1): LMN Sx and sensory Sx of forearm and hand (Klumpke's palsy)
    - DDX: trauma, idiopathic neuritis, tumour infiltration, radiation, thoracic outlet syndrome (e.g. cervical rib)
  - **lumbosacral plexopathy** (rare, especially unilateral)
    - DDX: idiopathic neuritis, infarction (e.g. DM), compression
- **mononeuropathy**: single nerve deficit
  - **carpal tunnel syndrome (most common)**: compression of median nerve at wrist
    - symptoms: wrist pain, paresthesia first 3 and ½ digits, ± radiation to elbow, worse at night
    - signs: Tinel's sign, Phalen's test, thenar muscle wasting, sensory deficit
    - EMG/NCS: slowing at wrist (both motor and sensory)
    - etiology: entrapment, pregnancy, DM, gammopathy, rheumatoid arthritis, thyroid disease
  - **Bell's palsy (most common cranial neuropathy)**: see [Otolaryngology, O123](#)
  - **entrapment/compression**: ulnar (compression at elbow), median (at pronator teres), radial (at spiral groove of humerus), obturator (from childbirth), peroneal (due to crossing legs or surgical positioning), posterior tibial (tarsal canal)
- **mononeuropathy multiplex**: subacute involvement of multiple individual peripheral nerves in asymmetric, non-length-dependent manner; often painful
  - must rule out vasculitis or collagen vascular disease; consider MMN (multifocal motor neuropathy) or MADSAM (multifocal acquired demyelinating sensory and motor neuropathy), multiple compressive neuropathies
- **polyneuropathy**: chronic progressive involvement of multiple peripheral nerves in symmetrical, distal-predominant pattern
  - length-dependent, i.e. longest fibres affected first (stocking-glove distribution)
  - sensorimotor, with progression of dysesthesia earlier and weakness later
  - etiology: DM (most common), renal disease, substances, toxins, genetic, SLE, HIV, leprosy, alcohol, B12 deficiency

### Diabetic Neuropathies

- **Peripheral neuropathy**: pain or loss of sensation in a stocking-glove distribution (hands and feet affected before arms and legs)
- **Autonomic**: anhidrosis, orthostatic hypotension, impotence, gastroparesis, bowel, and bladder dysfunction
- **Mononeuropathy multiplex**: nerve infarct or compression
- **Cranial neuropathy**: CN III (pupil sparing) > IV > VI
- **Lumbosacral plexopathy** (i.e. diabetic amyotrophy)

**DDx of Demyelinating Neuropathy**  
 GBS, CIDP, paraproteinemia, diphtheria, amiodarone, Charcot-Marie-Tooth (including hereditary neuropathy with liability to pressure palsy), storage diseases, pressure palsy predisposition, paraneoplastic

### Tinel's Sign

Tap lightly over the median nerve at the wrist; the patient's symptoms of carpal tunnel will be elicited in a positive test

### Phalen's Test

Hold both wrists in forced flexion (with the dorsal surfaces of the hands pressed against each other) for 30-60 s; test is positive if symptoms of carpal tunnel are elicited

Axonal neuropathies have decreased amplitude on NCS; demyelinating neuropathies have decreased conduction velocity on NCS

Ototoxic drugs (e.g. aminoglycosides) should not be given to diabetics. Sensory neuropathy of the feet prevents them from adequately compensating for loss of vestibular function.

- **chronic inflammatory demyelinating polyneuropathy (CIDP)**
  - chronic relapsing sensorimotor polyneuropathy or polyradiculopathy with increased protein in CSF and demyelination (shown on EMG/NCS)
  - course is fluctuating, in contrast with the acute onset of GBS
  - treatment: first-line is prednisone; alternatives are plasmapheresis, IVIG, and azathioprine

**Table 19. Differential Diagnosis of Symmetric Polyneuropathy**

	Etiology	Mechanism	Course	Modalities	Investigations
<b>Vascular*</b>	PAN	Ischemic	Chronic	S/M	See <a href="#">Rheumatology, RH21</a>
	SLE	Ischemic	Chronic	S/M	See <a href="#">Rheumatology, RH11</a>
	RA	Ischemic	Chronic	S/M	See <a href="#">Rheumatology, RH8</a>
<b>Infectious</b>	HIV	Axonal	Chronic	S/A	HIV serology
	Leprosy	Infiltrative	Acute	S/A	Leprosy serology Nerve biopsy
	Lyme	Axonal	Chronic	M	Lyme serology
<b>Immune*</b>	GBS	Demyelination	Acute	M	LP (↑ protein, no ↑ cells) EMG
	CIDP	Demyelination	Chronic	S/M	LP (↑ protein) EMG
<b>Hereditary</b>	HMSN	Axonal/demyelination	Chronic	S/M	Genetic testing
<b>Neoplastic</b>	Paraneoplastic	Axonal/demyelination	Chronic	S/M	Paraneoplastic antibodies
	Myeloma	Axonal/demyelination	Chronic	S/M	SPEP Skeletal bone survey
	Lymphoma	Axonal	Chronic	M	SPEP Bone marrow biopsy
	Monoclonal gammopathy	Axonal/demyelination	Chronic	S/M	SPEP Bone marrow biopsy
<b>Toxin</b>	EtOH	Axonal	Sub-acute	S/M	GGT, MCV
	Heavy metals (e.g. lead)	Axonal	Sub-acute	S/M	Urine heavy metals
	Medications	Axonal	Sub-acute	S/M	Drug levels
<b>Metabolic</b>	DM	Ischemic/axonal	Chronic	S/A	Fasting glucose, HbA1c, 2h OGTT
	Hypothyroidism	Axonal	Chronic	S/M	TSH, T3, T4
	Renal failure	Axonal	Chronic	S/A	Electrolytes, Cr, BUN
<b>Nutritional</b>	B12 deficiency	Axonal	Sub-acute	S/M	Vitamin B 12
<b>Other</b>	Porphyria	Axonal	Sub-acute	M	Urine porphyrins
	Amyloid	Axonal	Sub-acute to chronic	S/M	SPEP Nerve biopsy

A = autonomic; CIDP = chronic inflammatory demyelinating polyneuropathy; GGT = gamma-glutamyl transferase; HMSN = hereditary motor sensory neuropathy;  
M = motor; OGTT = oral glucose tolerance test; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; S = sensory; SLE = systemic lupus erythematosus;  
SPEP = serum protein electrophoresis  
\* Neuropathies of vascular etiology usually present as mononeuropathy multiplex  
\* Neuropathies of immune etiology usually present as polyradiculopathy

**Evaluation of Distal Symmetric Polyneuropathy: Role of Laboratory and Genetic Testing**  
Neurology 2009;72:185-192  
**Screening Lab Tests:** Blood glucose, serum B<sub>12</sub> with metabolites, serum protein immunofixation-electrophoresis.  
**Genetic Testing:** Indicated for cryptogenic polyneuropathy exhibiting classic hereditary neuropathy phenotype. Screen for CM1A duplication/deletion and Cx32 mutations.

## Guillain-Barré Syndrome

### Definition

- acute (evolving over 4 wk or less) rapidly evolving demyelinating inflammatory polyradiculoneuropathy that often starts in the distal lower limbs and ascends

### Etiology

- autoimmune attack and damage to peripheral nerve myelin
- usually preceded by viral/bacterial infections

### Signs and Symptoms

- sensory: distal and symmetric paresthesias, loss of proprioception and vibration sense, neuropathic pain
- motor: weakness starting distally in legs and progressing proximally, areflexia
- autonomic: blood pressure dysregulation, arrhythmias, bladder dysfunction

In GBS, IVIG and plasmapheresis lead to more rapid improvement, less intensive care, and less ventilation, but do not change mortality or relapse rate

GBS is a neurological emergency due to risk of imminent respiratory failure

**Investigations**

- CSF: albuminocytologic dissociation (high protein, normal WBC)
- EMG/NCS: conduction block, differential or focal (motor>sensory) slowing, decreased F-wave, sural sparing

**Treatment**

- IVIG or plasmapheresis, pain management, monitor vitals and vital capacity

**Prognosis**

- peak of symptoms at 2-3 wk, plateau or resolution at 4-6 wk
- 5% mortality (higher if require ICU), up to 15% have permanent deficits

The most commonly identified antecedent infection in GBS is *Campylobacter jejuni*

**Miller-Fischer Variant of GBS – Triad**

- Ophthalmoplegia
- Ataxia
- Areflexia

# Neuromuscular Junction Diseases

## Clinical Approach to Disorders of the Neuromuscular Junction

**Table 20. Common Disorders of the Neuromuscular Junction**

	Myasthenia Gravis	Lambert-Eaton	Botulism
Ocular/Bulbar Paresis	+	-	++ (early)
Limb Weakness	+	+	+
Fatigability	+	+	+
Post-Exercise Enhancement	-	+	+
Reflexes	N	↓	↓
Anticholinergic Sx	-	-	++
Sensory Sx	-	-	-
Associated Conditions	Thymoma	Small cell carcinoma	GI S&S
Repetitive EMG Stimulation	Decremental response	Incremental response	↑ (rapid stimulation) ↓ (slow stimulation)

## Myasthenia Gravis

**Etiology and Pathophysiology**

- autoimmune disorder of the NMJ, commonly associated with anti-AChR or MuSK antibodies
- 15% of patients with MG have associated thymic neoplasia, 85% have thymic hyperplasia

**Epidemiology**

- bimodal age of onset, 20s (mostly women) and 60s (mostly men)

**Clinical Features**

- fatigable, symmetric, or asymmetric weakness without reflex changes, sensory changes, or coordination abnormalities
- ocular (diplopia/ptosis), bulbar (dysarthria/dysphagia), and/or proximal limb weakness
- symptoms may be exacerbated by infection, pregnancy, menses, and various drugs
- respiratory muscle weakness may lead to respiratory failure

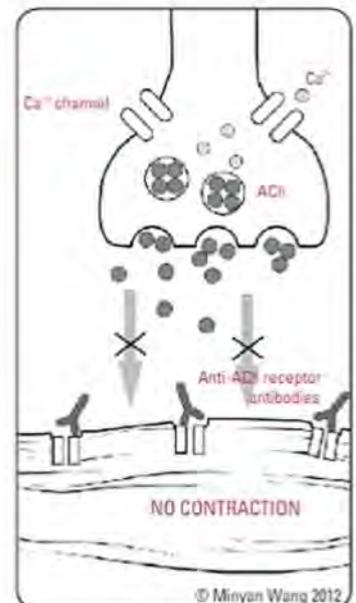

**Investigations**

- repetitive stimulation: decrement in amplitude >10%
- single fibre electromyography: shows increased jitter (80-100% sensitivity)
- spirometry: forced vital capacity may be used to monitor adequacy of respiratory effort over time
- AChR antibody assay (50-90% sensitivity); anti-MuSK antibody may be used if seronegative for anti-AChR antibody
- CT/MRI chest: screen for thymoma/thymic hyperplasia
- edrophonium (Tensilon®) test: assess for improvement over 2 min following edrophonium injection (no longer performed)

**Neuromuscular Junction Disease**

- Diseases of the NMJ typically feature prominent fatigability
- Fatigability can be tested by holding the arms out or by holding the gaze in the upward position (especially in MG)
- Muscle weakness due to fatigability will improve with rest and/or ice

**Figure 24. Myasthenia gravis**

Tensilon® is a drug that inhibits acetylcholinesterase. It improves muscle function immediately in MG, but not in a cholinergic crisis. This test is infrequently used as this drug is no longer available, but, if performed, a crash cart should be nearby as respiratory difficulty and/or bradycardia may occur

### Treatment

- acetylcholinesterase inhibitors (e.g. pyridostigmine): first line treatment
- corticosteroids (e.g. prednisone): mainstay of treatment if acetylcholinesterase inhibitors not effective
- short-term immunomodulation (e.g. IVIG and plasmapheresis): for crisis
- long-term immunosuppression (e.g. azathioprine, cyclophosphamide, mycophenolate): can be used as steroid-sparing therapy
- Newer medications that are more disease specific: Eculizumab (complement inhibitor), Efgartigimod (neonatal Fc receptor blocker)
- thymectomy: option in non-thymomatous AChR-antibody-positive generalized MG (85% remission rate)

### Prognosis

- 30% eventual spontaneous remission
- with treatment, life expectancy is equal to that of a person without MG, but quality of life may vary

## Lambert-Eaton Myasthenic Syndrome

### Etiology and Pathophysiology

- autoimmune disorder due to antibodies against presynaptic voltage-gated calcium channels, causing decreased ACh release at the NMJ
- 50-66% are associated with small cell carcinoma of the lung

### Clinical Features

- weakness of skeletal muscles without sensory or coordination abnormalities, proximal and lower muscles more affected
- reflexes are diminished or absent, but increase after active muscle contraction
- bulbar and ocular muscles affected in 25% (vs. 90% in MG)
- prominent anticholinergic autonomic symptoms (dry mouth > impotence > constipation > blurred vision)

### Investigations

- edrophonium test: no response
- rapid (>10 Hz) repetitive nerve stimulation: incremental response
- EMG: incremental response with exercise
- screen for malignancy, especially small cell lung cancer

### Treatment

- tumour removal
- ACh modulation
  - increased ACh release (3,4-diaminopyridine)
  - decreased ACh degradation (pyridostigmine)
- immunomodulation: steroids, plasmapheresis, IVIG

## Botulism

### Etiology and Pathophysiology

- caused by a toxin produced by spores of *Clostridium botulinum* bacteria, which can enter through wounds or by ingestion
- infantile botulism is the most common form and is usually from ingestion of honey or corn syrup

### Clinical Features

- occur 6-48 h after ingestion
- bilateral cranial neuropathies: ptosis, extraocular muscle weakness, dilated poorly reactive pupils, dysarthria, jaw weakness, dysphagia
- symmetric descending weakness with paralysis and absent/decreased reflexes
- autonomic dysfunction: nausea, orthostatic hypotension, constipation (paralytic ileus), bladder distension
- anticholinergic symptoms: dry mouth, constipation, urinary retention
- pattern of paresis often starts with GI symptoms → extraocular muscle weakness → dysphagia → limbs and respiratory involvement
- without prompt treatment, respiratory muscle weakness can lead to respiratory failure

### Investigations

- blood test for toxin, stool culture
- CT/MRI to rule out intracranial lesion (normal in botulism)

### Treatment

- botulinum anti-toxin: good prognosis with prompt treatment
- supportive therapy as required (monitor respiratory status and assess need for intubation)

### Randomized Trial of Thymectomy in Myasthenia Gravis

NEJM 2016;375:511-22

**Purpose:** To compare the efficacy of thymectomy plus prednisone vs. prednisone alone in the treatment of MG.

**Methods:** 126 patients with generalized nonthymomatous MG (clinical class II-IV disease <5 years duration and elevated acetylcholine-receptor antibody) received extended transsternal thymectomy plus alternate-day prednisone or alternate-day prednisone alone.

**Results:** Over 3 years, thymectomy was associated with a lower time-weighted average Quantitative MG score as compared to prednisone alone (6.15 vs. 8.99,  $P < 0.001$ ), and a lower average requirement for alternate-day prednisone (44 mg vs. 60 mg,  $P < 0.001$ ). Immunosuppression was required by fewer patients in the thymectomy group (17% vs. 48%,  $P < 0.001$ ); they were also hospitalized less frequently for exacerbations (9% vs. 37%,  $P < 0.001$ ).

**Conclusion:** In patients with nonthymomatous MG, thymectomy improved clinical outcomes.

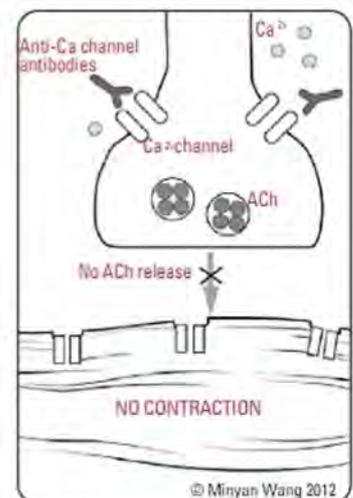

Figure 25. Lambert-Eaton myasthenic syndrome

# Myopathies

## Clinical Approach to Muscle Diseases

Table 21. Myopathies

	Etiology	Key Clinical Features	Key Investigations
Inflammatory	Polymyositis (see <a href="#">Rheumatology, RH16</a> )	Myalgias Pharyngeal involvement	↑ CK Biopsy: endomysial infiltrates, necrosis
	Dermatomyositis (see <a href="#">Rheumatology, RH16</a> )	Myalgias Characteristic rashes Can be paraneoplastic	↑ CK Biopsy: perifascicular atrophy
	Sarcoidosis	See <a href="#">Respirology, R15</a>	ACE level Biopsy: granulomas
	Inclusion body myositis	Weak quadriceps and deep finger flexors	↑ CK Biopsy: inclusion bodies
Endocrine	Thyroid (↑ or ↓) Cushing's syndrome Parathyroid (↑ or ↓)	See <a href="#">Endocrinology, E25</a>	TSH Serum cortisol Calcium panel
Toxic	Medication	Medication or toxin history	Toxicology screen
	Critical illness myopathy	ICU patient Hx steroids and nondepolarizing paralyzing agents Failure to wean from ventilation	Biopsy: selective loss of thick myosin filaments
Infectious	Parasitic, bacterial, or viral	Myalgias Inflammatory myopathy	↑ myoglobin
Hereditary Dystrophy	Duchenne (see <a href="#">Medical Genetics, M68</a> )	Early onset (Duchenne and Becker)	Dystrophin analysis: absent Genetic testing
	Becker	Progressive proximal muscle weakness Calf pseudohypertrophy	Dystrophin analysis: reduced Genetic testing
	Myotonic dystrophy	Distal myopathy Myotonia Genetic anticipation	Genetic testing
Hereditary Metabolic	McArdle's	Exercise-related myalgias, cramping, and myoglobinuria	↑ lactate ↑ serum/urinary myoglobin post-exercise
Hereditary Periodic Paralysis	"Channelopathy"	Episodic weakness Normal between attacks	Normal, ↑ or ↓ K <sup>+</sup>
Hereditary Mitochondrial	MERRF	Myoclonus, generalized seizures, dementia, myopathy	Biopsy: ragged red fibres Increased lactate
	MELAS	Paediatric onset, stroke-like symptoms, episodic vomiting, dementia	
	Kearns Sayre	Progressive ophthalmoplegia, retinal pigment degeneration, cardiac conduction abnormalities	

MELAS: mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes; MERRF: mitochondrial encephalomyopathy with ragged red fibres  
CK: creatine kinase

# Myotonic Dystrophy Type 1

### Etiology and Pathophysiology

- unstable trinucleotide (CTG) repeat in myotonic dystrophy kinase gene (protein kinase) at 19q13.3, number of repeats correlates with severity of symptoms, autosomal dominant

### Epidemiology

- most common adult muscular dystrophy, prevalence 3-5 in 100000

### Clinical Features

- appearance
  - ptosis, bifacial weakness, frontal baldness (including women), triangular face giving a drooping/dull appearance

- physical exam
  - distribution of weakness: distal weaker than proximal (in contrast to other myopathies), steppage gait
  - myotonia: delayed relaxation of muscles after exertion (elicit by tapping on thenar muscles with hammer)
  - cardiac: 90% have conduction defects (1° heart block; atrial arrhythmias)
  - respiratory: hypoventilation 2° to muscle weakness
  - ocular: subcapsular cataracts, retinal degeneration, decreased intraocular pressure
  - other: DM, infertility, testicular atrophy
  - EMG: electrical myotonia (waxing and waning discharges, sound like "dive-bomber")

#### Treatment

- management of myotonia: mexiletine, phenytoin

#### Prognosis

- no cure, progressive, death usually around 50 yr

## Pain Syndromes

### Approach to Pain Syndromes

#### Definitions

- nociceptive pain: pain arising from stimulus causing potential or actual non-neural tissue injury
- neuropathic pain: pain arising from lesion or disease affecting the somatosensory system
- spontaneous pain: unprovoked burning, shooting, or lancinating pain
- paresthesia: spontaneous abnormal non-painful sensation (e.g. tingling)
- dysesthesia: evoked pain with inappropriate quality or excessive quantity
- allodynia: pain response to a non-noxious stimulus
- hyperalgesia: exaggerated pain response to a noxious stimulus

#### Non-Pharmacological Management

- physical (PT, acupuncture, chiropractic manipulation, massage)
- psychoeducational (CBT, family therapy, education, psychotherapy)

#### Medical Pain Control

- combination multi-modal therapy is important
- primary analgesics: acetaminophen, NSAIDs (often used for soft tissue injuries, strains, sprains, headaches, and arthritis), opiates
- adjuvants: antidepressants (TCAs, SSRIs), anticonvulsants (gabapentin, carbamazepine, pregabalin), baclofen, sympatholytics (phenoxymethamine),  $\alpha_2$ -adrenergic agonists (clonidine)

#### Surgical Pain Control

- peripheral ablation: nerve blocks, facet joint denervation
- direct delivery: implantable morphine pump
- central ablation: stereotactic thalamotomy, spinal tractotomy, or dorsal root entry lesion
- DBS or dorsal column stimulation

### Neuropathic Pain

#### Epidemiology

- affects up to 6% of people (2 million Canadians)

#### Symptoms and Signs

- hyperalgesia, allodynia
- subjectively described as burning, heat/cold, pricking, electric shock, perception of swelling, numbness
- can be spontaneous or stimulus evoked, distribution may not fall along classical neuro-anatomical lines
- associated issues: sleep difficulty, anxiety/stress/mood alteration

#### Causes of Neuropathic Pain

- sympathetic: CRPS
- non-sympathetic: damage to peripheral nerves
  - systemic disease: DM, thyroid disease, renal disease, rheumatoid arthritis, MSA
  - nutritional/toxicity: alcoholism, pernicious anemia, chemotherapy
  - infectious: post-herpetic, HIV
  - trauma/compression: nerve entrapment, trigeminal neuralgia, post-surgical, nerve injury, cervical/lumbar radiculopathy, plexopathy

- Pinprick sensation mediated by A $\delta$  fibres
- Pain due to tissue damage is mediated by C fibres

#### WHO Pain Ladder

- Mild Pain:** Non-opioid (acetaminophen and/or NSAID)  $\pm$  adjuvant
- Moderate Pain:** Opioid for mild to moderate pain (codeine/oxycodone) + non-opioid  $\pm$  adjuvant
- Severe Pain:** Opioid for moderate to severe pain (morphine/hydromorphone) + non-opioid  $\pm$  adjuvant

Axonal regeneration is directed by intact nerve sheaths. If the nerve sheath is damaged, axons grow without direction, become tangled, and form a neuroma. This can result in ectopic electrical impulses and neuropathic pain

- **central:** abnormal CNS activity
  - phantom limb, post spinal cord injury, post stroke, MS

### Treatment

- identify/treat underlying cause
- **pharmacotherapy**
  - stepwise approach (Canadian Pain Society, 2014)
    - 1st line: gabapentinoids, TCA, SNRI
    - 2nd line: tramadol, opioid analgesics
    - 3rd line: cannabinoids
    - 4th line: methadone, anticonvulsants (lamotrigine, lacosamide), tapentadol, botulinum toxin
- **common non-pharmacologic therapies**
  - neuropsychiatry: CBT, psychotherapy
  - rehabilitation: physiotherapy
- **surgical therapies:** dorsal column neurostimulator, DBS (thalamus)

## Trigeminal Neuralgia

### Clinical Features

- recurrent episodes of sudden onset, excruciating, unilateral, paroxysmal, shooting "electric" pain in trigeminal root territory (V3>V2>>V1)
- may have normal sensory exam (if abnormal, think of secondary or structural cause)
- pain lasts seconds/minutes over days/weeks, may remit for weeks/months
- triggers: touching face, eating, talking, cold wind, shaving, applying make-up

### Etiology

- classic TN: compression of CN V by tortuous blood vessel (usually superior cerebellar artery)
- 2° TN: cerebellopontine angle tumour (5%), MS (5%)
- idiopathic TN

### Epidemiology

- F>M; usually middle-aged and elderly

### Diagnosis

- clinical diagnosis
- investigate for secondary causes, which are more likely if bilateral TN or associated sensory loss
  - MRI to rule out structural lesion, MS, or vascular lesion

### Treatment

- first line: carbamazepine or oxcarbazepine
- second line: baclofen or lamotrigine
- for medically-refractory classic TN, consider microvascular decompression
- other neurosurgical options for medically refractory TN: trigeminal ganglion percutaneous technique, gamma knife radiosurgery, invasive percutaneous denervation (radiofrequency/glycerol), percutaneous balloon microcompression, microvascular decompression
- narcotics not generally recommended

## Postherpetic Neuralgia

### Clinical Features

- pain persisting in the region of a cutaneous outbreak of herpes zoster
- constant deep ache or burning, intermittent spontaneous lancinating/jabbing pain, allodynia
- distribution: thoracic, trigeminal, cervical, lumbar, sacral
- associated symptoms: impaired sleep, decreased appetite, decreased libido

### Etiology and Pathogenesis

- destruction of the sensory ganglion neurons (e.g. dorsal root, trigeminal, or geniculate ganglia) secondary to reactivation of herpes zoster infection

### Epidemiology

- incidence in those with zoster increases with age (2% in <60 yr, 19% in >70 yr)
- risk factors: older age, greater acute pain, greater rash severity

### Prevention

- varicella zoster vaccine (Varivax<sup>®</sup>) in childhood reduces incidence of varicella zoster
- herpes zoster vaccine (Zostavax<sup>®</sup> or Shingrix<sup>®</sup>) reduces incidences of shingles, PHN, and other herpetic sequelae
  - Zostavax<sup>®</sup> is a live vaccine, recommended for patients ≥60 yr
  - Shingrix<sup>®</sup> is a recombinant vaccine, recommended for patients ≥50 yr (more efficacious than Zostavax<sup>®</sup>)

#### Herpes Zoster of Trigeminal Nerve

Typically involves V1 (ophthalmic division)

#### Hutchinson's Sign

Tip of nose involvement predicts corneal involvement

**Treatment**

- medical: TCA (e.g. amitriptyline), anticonvulsants (e.g. pregabalin, gabapentin), analgesia (e.g. opiates, lidocaine patch), intrathecal methylprednisolone, topical capsaicin
  - early treatment of acute herpes zoster with antivirals (longer-acting famciclovir and valacyclovir more effective)
  - treatment of herpes zoster with corticosteroids does not decrease PHN
- surgical: spinal tractotomy, dorsal root entry zone lesion, DBS of thalamus

**Painful Diabetic Neuropathy**

- see [Endocrinology](#), E16

**Approach**

- determine if pain is neuropathic or vascular
- more likely neuropathic if pain is present at rest and improves with walking, pain is sharp/tingling, more in feet → calves

**Treatment**

- level A: pregabalin
- level B: venlafaxine, duloxetine, amitriptyline, gabapentin, valproate, rarely opioids, capsaicin

**Complex Regional Pain Syndromes****Definition**

- regional pain disproportionate to an inciting event (e.g. fracture, stroke), typically lasting 4-6 wk

**Diagnosis**

- clinical diagnosis consistent with the Budapest Criteria:
  1. continuing regional pain disproportionate to an inciting event
  2. patient must have symptoms in 3 of the 4 categories, and must have signs in 2 of the 4 categories (a sign must be observed at the time of diagnosis):
    - sensory: hyperesthesia and/or allodynia
    - vasomotor: temperature and/or skin colour asymmetry
    - sudomotor/edema: edema, sweating changes, and/or sweating asymmetry
    - motor/trophic: decreased range of motion, motor dysfunction (weakness, tremor, dystonia) and/or trophic changes (hair, skin, nail)
  3. absence of any other diagnosis that would better explain the signs or symptoms
- bone scintigraphy ≤5 mo of symptom onset may support diagnosis (negative test does not rule it out)
- MRI may help rule out other causes of regional pain if indicated

**Classification**

- CRPS type I (reflex sympathetic dystrophy): minor injuries of limb or lesions in remote body areas precede onset of symptoms
- CRPS type II (causalgia): injury of peripheral nerves precedes the onset of symptoms

**Prevention**

- early mobilization after injury/infarction

**Treatment**

- goal of treatment is to facilitate function
- conservative treatment: education, support groups, PT, OT, smoking cessation
- medical: topical capsaicin; TCA; NSAID; tender point injections with corticosteroid/lidocaine; gabapentin/pregabalin/lamotrigine; calcitonin or bisphosphonates; oral corticosteroids
- surgical: paravertebral sympathetic ganglion blockade
- refer to pain management clinic

# Headache

• see [Emergency Medicine](#), ER23 and [Family Medicine](#), FM36

## Clinical Approach

### • history

- pain characteristics: onset, frequency, duration, intensity, location, radiation, other specific features (e.g. worse in AM, worse with bending/coughing/Valsalva)
- associated symptoms: visual changes, change in mental status, N/V, fever, meningismus, photophobia, phonophobia, temporomandibular popping/clicking, jaw claudication, neurological symptoms
- precipitating/alleviating factors (triggering factors, analgesics), medications (especially nitrates, calcium channel blockers, NSAIDs, anticoagulants), PMHx, FHx
- red flags (possible indications for CT scan/further investigation) "SNOOP4": Systemic symptoms or 2° risk factors (fever, weight change, immunocompromised); Any focal neurological symptoms on history or exam;; Onset sudden ('thunderclap'); Older age (new-onset headache >50 yr); Pattern change; Positional; Progressive; Precipitated by Valsalva; Pregnancy-CSVT/IH/Preeclampsia

### • physical exam

- vitals (including BP and temperature), Jolt accentuation/Kernig's/Brudzinski's, MSK examination of head and neck
- HEENT: fundi (papilledema, retinal hemorrhages), red eye, temporal artery tenderness, sinus palpation, TMJ
- full neurological exam (including LOC, orientation, pupils (symmetry), and focal neurological deficits)
- red flags: papilledema, altered LOC, fever, meningismus, focal neurological deficits, signs of head trauma

## Classification

### • primary

- tension, migraine, cluster, autonomic cephalgias, short-lasting unilateral neuralgiform headache with conjunctival injection and tearing (SUNCT)

### • secondary

- cervical OA, TMJ syndrome, SAH, ICH, stroke, venous sinus thrombosis, meningitis/encephalitis, trauma, increased ICP (space-occupying lesion, malignant HTN, or IIH), temporal arteritis, sinusitis, acute-angle closure glaucoma, pre-eclampsia, post LP, drugs/toxins (e.g. nitroglycerin use and analgesia withdrawal); all can be associated with serious morbidity or mortality

**Table 22. Headaches – Selected Primary Types**

	Tension-Type	Migraine	Cluster
<b>Prevalence</b>	30-40%	~10-20%	~1%
<b>Age of Onset</b>	15-40	10-30	20-40
<b>Sex Bias</b>	F>M	F>M	M>F
<b>Family History</b>	None	+++	+
<b>Location</b>	Bilateral frontal Nuchal-occipital	Unilateral = bilateral (in adults especially) Fronto-temporal	Retro-orbital Supra-orbital Temporal
<b>Duration</b>	Minutes-days	Hours-days	10 min-2 h
<b>Onset/Course</b>	Gradual, worse in PM Episodic or chronic	Gradual, worse in PM; can also be acute	Daily attacks for weeks to months; more common early AM or late PM
<b>Quality</b>	Band-like, constant	Pulsating, throbbing	Constant, aching, stabbing
<b>Severity</b>	Mild-moderate (does not wake you up from sleep)	Moderate-severe	Severe (wakes from sleep)
<b>Triggers/Provoking</b>	Depression Anxiety Noise Hunger Sleep deprivation	Noise/light Caffeine/alcohol Hunger Stress Sleep deprivation	Light EtOH
<b>Palliating</b>	Rest	Rest	Walking around
<b>Associated Symptoms</b>	No vomiting No photophobia	N/V Photo/phonophobia/osmophobia ± Aura	Red watery eye Eyelid, forehead swelling Nasal congestion or rhinorrhea Unilateral Horner's
<b>Management</b>	Non-pharmacological: Eliminating known triggers Healthy lifestyle: sleep, diet (protein for breakfast), exercise, hydration, be aware of technology use, vitamin/minerals Psychological counseling Physical modalities (e.g. heat, massage) Pharmacological Vitamins/minerals - Magnesium citrate, Riboflavin (Vitamin B2), Coenzyme Q10, Melatonin if insomnia or difficulty falling asleep Simple analgesics: Tylenol, NSAIDs	Acute Rx/Abortive: NSAIDs Triptans Ergotamine Valproate Anti-emetics CGRP Antagonists  Prophylaxis/Preventive: TCA CCB Anticonvulsants β-Blockers  Botox	Acute Rx Oz Sumatriptan (nasal or injection) Prophylaxis Verapamil Lithium Methysergide Prednisolone Valproate CGRP antibody

If CT is negative but clinically there is suspicion of SAH or meningitis, perform an LP

### Headache DDx

#### ER VISIT

- Eye (acute angle closure glaucoma, sinusitis)
- Recurrent/Chronic (migraine, tension, cluster, temporomandibular joint disease, cervical OA)
- Vascular (SAH, ICH, temporal arteritis)
- Infectious (meningitis, encephalitis)
- Systemic (anemia, anoxia, CO, pre-eclampsia)
- ICP (mass/abscess, HTN encephalopathy, IIH)
- Trauma (concussion, SDH, epidural headache)

### Trial of Galcanezumab in Prevention of Episodic Cluster Headache

NEJM 2019;381:132-41

**Purpose:** To investigate the efficacy and safety of galcanezumab as a preventive treatment for cluster headache.

**Methods:** 106 patients who had min. one attack every other day, min. four total attacks, and max. eight attacks/d, plus a history of cluster headache periods lasting min. 6 weeks, received 300 mg galcanezumab or placebo, administered SC at baseline and 1 month.

**Results:** After 3 weeks, the mean reduction in the weekly frequency of cluster headache attacks was 8.7 attacks in the galcanezumab group vs. 5.2 in the placebo group (difference: 3.5/wk; 95% CI, 0.2-6.7; P=0.04), and the proportion of patients who had a reduction of >50% in headache frequency was 71% and 53%, respectively (P=0.046). Incidence of adverse events were similar in both groups.

**Conclusion:** Galcanezumab reduced the weekly frequency of attacks of episodic cluster headache.

### Antiepileptics in Migraine Prophylaxis: An Updated Cochrane Review

Cephalalgia 2015;35:51-62

**Purpose:** To review the evidence for anticonvulsants in migraine prophylaxis.

**Study:** Systematic meta-analysis of 37 published and 3 unpublished prospective, controlled trials of regular use of anticonvulsants to prevent migraines and/or improve quality of life related to migraines.

**Results:** Sodium valproate and topiramate were associated with a reduction of 4 d and 1 d of headache per month, respectively, and patients taking either drug were more than 2 times as likely to experience greater than 50% reduction in headache frequency, vs. placebo. Neither drug was associated with undue rates of adverse events, though higher doses of topiramate were associated with increased adverse events. There is insufficient evidence of efficacy with other antiepileptic drugs, including gabapentin, for migraine prophylaxis.

**Conclusions:** Daily sodium valproate 400 mg and topiramate 50 mg are well tolerated and effective in prophylactic treatment of migraine headache in adults.

**Table 23. Prophylactic Management of Migraine Headaches**

Class	Drug	Evidence	Contraindications	Side Effects
β-blockers	Propranolol	A	Asthma, DM (mask hypoglycemia)	Fatigue
	Timolol	A	CHF	Depression
	Metoprolol	B		Light-headedness
TCA	Amitriptyline	A	Heart disease, glaucoma	Sedation
	Nortriptyline	C	Avoid in elderly	Dry mouth Weight gain Light-headedness
CCBs	Flunarizine	A	Depression, obesity	Weight gain, depression, PD (rare)
	Verapamil	B	Heart disease	Weight gain (4.5-9 kg), constipation
AED	Valproate	A	Liver, pancreatic disease	Weight gain, elevated liver enzymes/hyperammonemia, tremor, alopecia, teratogenic: neural tube defect
	Topiramate	A	Renal disease	Paresthesia, acute angle-closure glaucoma, weight loss, cognitive: memory loss, difficulty concentrating, renal stone (rare)

**Table 24. Headaches – Selected Serious but Rare Secondary Types**

	Meningeal Irritation	Increased ICP	Temporal Arteritis
Age of Onset	Any age	Any age	>60 yr
Location	Generalized	Any location	Temporal
Onset/Course	Meningitis: hours-days SAH: thunderclap onset	Gradual; worse nocturnal and AM	Variable
Severity	Severe	Severe	Variable, can be severe
Provoking	Head movement	Lying down Valsalva Head low Exertion	Jaw claudication
Associated Symptoms	Neck stiffness Photophobia Focal deficits (e.g. CN palsies)	N/V Focal neurological symptoms Decreased LOC	Polymyalgia rheumatica Visual loss
Physical Signs	Kernig's sign Brudzinski's sign Meningismus	Focal neurological symptoms Papilloedema	Temporal artery changes: firm, nodular, incompressible, tender
Management	CT/MRI with gadolinium, LP, antibiotics for bacterial meningitis	CT/MRI and treatment to reduce pressure See <a href="#">Neurosurgery</a> , NS6 and NS8	Prednisone See <a href="#">Rheumatology</a> , RH22
Etiology	Meningitis, SAH	Tumour, CSVT, IHH, malignant HTN	Vasculitis (GCA)

## Migraine Headaches

### Definition (Common Migraine)

- ≥5 attacks fulfilling each of the following criteria
  - 4-72 h in duration
  - 2 of the following: unilateral, pulsating, moderate-severe (interferes with daily activity), aggravated by routine physical activity
  - 1 of the following: N/V, photophobia/phonophobia/osmophobia
  - not better accounted for by another diagnosis

### Epidemiology

- 18% females, 6% males; frequency decreases with age (especially at menopause)
- in pre-pubertal children, more commonly seen in males; post-pubertal, more commonly seen in females

### Etiology and Pathophysiology

- theories of migraine etiology
  - depolarizing wave of "cortical spreading depression" across the cerebral cortex that may cause an aura (e.g. visual symptoms due to wave through occipital cortex) and activate trigeminal nerve afferent fibres
  - possible association with vasoconstriction/dilation
- significant genetic contribution
- triggers: stress, sleep excess/deprivation, drugs (estrogen, nitroglycerin), hormonal changes, caffeine withdrawal, chocolate, tyramines (e.g. red wine), nitrites (e.g. processed meats)

Migraine auras can mimic other causes of transient neurological deficits (e.g. TIAs and seizures)

"Menstrual Migraine" Subtype  
Migraine headache that is associated with the onset of menstruation – usually 2 d before to 3 d after the onset of menstrual bleeding

**Signs and Symptoms**

- stages of uncomplicated migraine
  1. prodrome (hours to days before headache onset)
  2. aura
  3. headache
  4. postdrome
- aura
  - self-resolving symptom of focal cerebral dysfunction lasting <60 min
  - e.g.: visual disturbance (fortification spectra – zigzags; scintillating scotomata – spots), unilateral paresthesia and numbness or weakness, aphasia
- prodrome/postdrome: appetite change, autonomic symptoms, altered mood, psychomotor agitation/retardation
- classification of migraines
  - common migraine: no aura
  - classic migraine: with aura (headache follows reversible aura within 60 min)
  - complicated migraine: with severe/persistent sensorimotor deficits
    - ♦ examples: basilar-type migraine (occipital headache with diplopia, vertigo, ataxia, and altered LOC), hemiplegic/hemisensory migraine, ophthalmoplegic migraine
  - acephalgic migraine (i.e. migraine equivalent): aura without headache
  - status migrainosus: single attack lasting longer than 72 h

**Treatment**

- avoid triggers
- mild to moderate migraine
  - 1st line: NSAIDs (ibuprofen, naproxen)
- moderate to severe migraine
  - triptans (most effective), ergots (dihydroergotamine, dihydroergotamine mesylate (DHE))
- migraine prophylaxis: anticonvulsants (valproate, topiramate, TCA (amitriptyline, nortriptyline), propranolol, calcium channel blocker (verapamil)
- medication overuse (use of triptans/opioids/comboanalgesics for ≥10 d/mo, or use of NSAIDs for ≥15 d/mo) can lead to medication-overuse headaches

The oral contraceptive pill is contraindicated with complicated migraine due to risk of stroke

- Can still use non-estrogen based forms of birth control (e.g. copper IUD, Depo-provera shot)

If patient presents to ED with severe migraine and NV – consider treating with IV fluids and anti-emetics (chlorpromazine, prochlorperazine)

**Elements of Sleep History**

Initiation of sleep  
 Events prior to bed  
 Lights  
 Latency (estimated)  
 Restless legs  
 Hallucinations  
 Maintaining sleep  
 Number of nighttime awakenings  
 Sleep walking/talking  
 Snoring/gasping  
 Dreams/nightmares  
 Consequences of sleep  
 Restorative  
 Morning headache  
 Falling asleep in inappropriate setting

**Drug Effects on Wakefulness and Sleep**

- Antihistamines increase sleepiness
- Stimulants increase arousal
- Caffeine (an adenosine antagonist) increases wakefulness
- Benzodiazepines reduce amount of slow wave sleep and cause sleepiness
- Antidepressants (TCA/MAOI/SSRI) reduce amount of REM sleep and prolong REM latency
- Alcohol may hasten sleep onset but is associated with increased nighttime arousals and poor sleep efficiency

Avoid sleep medications (especially in elderly patients) due to increased risk of falls, pseudodepression, and memory loss

**Sleep Disorders**

**Overview of Sleep**

**Recommendations**

- newborn: 18 h sleep (50% REM), adolescents: 10 h, adults: 7-9 h but most get insufficient amounts
- many older patients have reduced sleep as a consequence of underlying sleep disorders

**Sleep Architecture**

- PSG measures: EEG, eye movements (electro-oculogram – EOG), EMG, respiratory effort, oxygenation, ECG

Table 25. Sleep Stage Characteristics

	EEG	EOG	Muscle Tone	Other Characteristics
<b>Waking State</b>	Alpha waves: high frequency (8-12 Hz), moderate amplitude Beta waves: frequency >13 Hz, low amplitude	Rapid, blinking	High	
<b>Stage N1 (~5%)</b>	~50% Alpha waves (see above), mixed with slow wave activity (theta, 4-7 Hz)	Slow, roving eye movements	High, but gradually dropping	Marker for very light quality sleep or sleep disruption
<b>Stage N2 (~50%)</b>	K complexes (high voltage negative and positive discharges) with sleep spindles (12-14 Hz) are central and midline	Still	High	
<b>Stage N3 (previously 3 and 4)/Slow Wave/Delta Sleep (~20%)</b>	Delta waves: low frequency (<2 Hz), high voltage (>75 µV)	Still	Low	Homeostatic sleep Reduced BP, HR, cardiac output, RR Growth hormone release
<b>Rapid Eye Movement Sleep (~25%)</b>	Sawtooth waves, mixed frequency, low voltage	Rapid eye movements	Very low	Irregular respiration HR variation Classical dreaming state

## Coma

- see [Neurosurgery, NS40](#)

## Insomnia

### Definition

- difficulty initiating or maintaining sleep, or waking up earlier than desired (leading to sleep that is chronically non-restorative/poor quality) despite adequate opportunity and circumstances for sleep

### Types

- sleep state misperception, psychophysiologic insomnia (learned sleep-preventing associations – i.e. clock watching), idiopathic (lifelong difficulty)
- secondary causes
  - psychiatric disorders (80% of psychiatric patients): i.e. depression and anxiety (see [Psychiatry, PS12 and PS15](#))
  - neurologic disorders: i.e. neurodegenerative disease, epilepsy, neuromuscular disorders
  - sleep disorders: i.e. RLS (sleep initiation difficulties), sleep apnea (sleep maintenance difficulties)
  - medical conditions: i.e. pregnancy, cardiorespiratory (COPD/heart failure), gastroesophageal reflux disease, pain (arthritis, fibromyalgia, cancer)
  - drugs/toxins: i.e. caffeine, alcohol, stimulants, antidepressants, steroids, sedative withdrawal
  - fatal familial insomnia: i.e. rare genetic prion protein mutation causing autonomic dysfunction

### Treatment

- sleep log, sleep hygiene, stimulus control, sleep restriction, relaxation response, CBT, melatonin

## Sleep Apnea

- see [Respirology, R29](#)

### Definition

- disorder of breathing in sleep associated with sleep disruption and consequent excessive somnolence (or drowsiness)

### Epidemiology

- >6% of the Canadian population
- correlated with obesity
- significant morbidity: HTN, stroke, heart failure, sleepiness, mortality (accidents)

### Types

- obstructive sleep apnea; etiology: collapse of airway due to low muscle tone in deep and REM sleep
- central sleep apnea: no effort to breathe >10 s; etiology: heart failure, opiates, brainstem pathology, myotonic dystrophy
- mixed apnea: combination of both central and obstructive sleep apnea

### Diagnosis

- PSG or ambulatory sleep monitoring device-apnea hypopnea index (AHI) or respiratory disturbance index (RDI)  $\geq 5$

### Treatment

- weight loss, positional therapy, dental devices, CPAP (common), surgery (rare), ensure driving safety

## Restless Legs Syndrome and Periodic Limb Movement in Sleep

- RLS: urge to move legs accompanied by uncomfortable sensations that begin or worsen with rest, is partially or totally relieved with movement, and is worse in evening/night; these features cannot be accounted for by another medical/behavioural condition
- PLMS: involuntary, jerking movements of the legs during sleep, diagnosed with PSG
- epidemiology: 10% North Americans, 90% of RLS have PLMS, 50% of patients with PLMS have RLS
- associated conditions: peripheral nervous system (radiculopathy, neuropathy), pregnancy, iron deficiency, alcohol use, PD, uremia/renal failure

### Treatment

- underlying contributors (iron and B<sub>12</sub> supplementation), dopaminergic agonists (first line), clonazepam (causes tachyphylaxis), gabapentin, opioids (only exceptional circumstances)
- NOT recommended: levodopa/carbidopa (Sinemet®) which causes augmentation

## Narcolepsy

### Definition

- excessive daytime sleepiness (all narcolepsy), cataplexy (loss of muscle tone with emotional stimuli, pathognomonic), sleep paralysis (unable to move upon waking), hypnagogic and hypnopompic hallucinations (vivid hallucinations while falling asleep or waking up, respectively)

### Epidemiology

- prevalence 1 in 2000, onset in adolescence/early adulthood; life-long disorder

### Etiology

- presumed autoimmune attack on orexin/hypocretin system, post head injury, MS, hypothalamic tumours; rarely familial

### Diagnosis

- based on clinical history and multiple sleep latency test findings of short sleep latency <8 min and REM within 15 min of sleep onset on 2/4 naps

### Treatment

- sleep hygiene and scheduled brief naps, restricted driving
- alerting agents: modafinil (non-amphetamine stimulant), stimulant (i.e. methylphenidate)
- anticataplectic: TCAs, SSRIs, sodium oxybate

## Parasomnias

### Definition

- unusual behaviours in sleep with clinical features appropriate to stage of sleep

### Etiology

- in elderly, REM sleep behaviour disorder may be associated with PD; in children, slow wave sleep arousals (sleep walking) may be associated with sleep-disordered breathing

### Diagnosis

- clinical history in children, polysomnography in adults to exclude nocturnal seizures

### Treatment

- behavioural management (safety, adequate sleep), clonazepam for REM sleep behaviour, tonsillectomy if appropriate in children

## Central Nervous System Infections

- see [Infectious Diseases, ID17](#)

## Spinal Cord Syndromes

- see [Neurosurgery, NS34](#)

## Stroke

### Terminology

- stroke: focal cerebral, spinal, or retinal infarction in a defined vascular distribution
  - infarction is permanent tissue injury (confirmed by neuroimaging)
- TIA: transient (<24 h), episode of neurological dysfunction caused by focal brain, spinal cord or retinal ischemia without acute infarction on CT or MRI
  - may present with amaurosis fugax (transient monocular painless vision loss)

### Pathophysiology

- two major types: ischemic (~80%) and hemorrhagic (~20%)

#### 1. ischemic

- arterial thrombosis: thrombus formation in artery (*local/in situ*)
  - large vessel: stenosis or occlusion of the internal carotid artery, vertebral artery, basilar artery, or middle/anterior/posterior cerebral arteries
    - mechanism: insufficient blood flow beyond lesion (hemodynamic stroke)
    - underlying processes: atherosclerosis (most common cause), dissection, and vasculitis
  - small vessel/lacunar
    - mechanism: chronic HTN and DM cause vessel wall thickening and decreased luminal diameter
    - affects mainly small penetrating arteries (primarily basal ganglia, internal capsule, and thalamus)
- cardioembolic: blockage of cerebral arterial blood flow due to thrombus originating from a cardiac source
  - atrial fibrillation (most common), rheumatic valve disease, prosthetic heart valves, recent MI, fibrous and infectious endocarditis
- systemic hypoperfusion (global cerebral ischemia)
  - inadequate blood flow to brain, usually secondary to cardiac pump failure (e.g. cardiac arrest, arrhythmia, or MI)
  - primarily affects watershed areas (between the major cerebral arterial territories)

#### 2. hemorrhagic

- intracerebral hemorrhage
  - hypertensive (most common): due to chronic arteriosclerosis which predisposes vessels to focal necrosis and pseudoaneurysm formation eventually leading to intraparenchymal hemorrhage; most common sites are putamen, caudate nucleus, thalamus, cerebellum, and pons
  - other: trauma, amyloid angiopathy (associated with lobar hemorrhage), vascular malformations, aneurysms, vasculitis, drug use (cocaine or amphetamines)
- SAH, see [Neurosurgery, NS22](#)

#### Stroke Syndromes According to Vascular Territory

- ACA: contralateral leg paresis, sensory loss, cognitive deficits (e.g. apathy, confusion, and poor judgment)
- MCA: proximal occlusion involves
  - contralateral weakness and sensory loss of face and arm
  - cortical sensory loss
  - may have contralateral homonymous hemianopia or quadrantanopia
  - if dominant (usually left) hemisphere: aphasia
  - if non-dominant (usually right) hemisphere: neglect
  - eye deviation towards the side of the lesion (away from the weak side)

#### Hypertension Encephalopathy

Acute severe HTN (typically dBp >130 or sBP >200) can cause hypertensive encephalopathy. Abnormal fundoscopic exam (papilledema, hemorrhages, exudates, cotton-wool spots), focal neurologic symptoms, N/V, visual disturbances, seizures, and change in LOC

Consider transfer of acute stroke patient to a designated stroke centre for neuroprotective or thrombolytic therapy, and endovascular therapy (EVT) if the patient is seen in first few hours

Early seizure activity occurs in 5-25% of patients after ICH

Cerebral venous sinus thrombosis should be considered in the differential diagnosis of stroke and headache. It is an uncommon cause of either, but is associated with high morbidity and mortality. Patients often present with headache alone, but can have seizures, focal neurological deficits, or cranial nerve palsies. This is diagnosed with MRV or CTV. Treatment is typically anticoagulation with heparin initially, then warfarin eventually

20-40% of patients with ischemic stroke may develop hemorrhagic transformation within 1 wk after the initial infarction  
Can be exacerbated by reperfusion injury (distal migration of clot as it dissolves) naturally or by use of thrombolytic therapy, endovascular therapy or anticoagulation

Blood work should only delay treatment if patient is on anticoagulants, low platelet count suspected, abnormal electrolytes suspected, or any bleeding abnormality suspected

Suspect an alternate diagnosis if fever, decreased LOC, fluctuating symptoms, gradual onset, no focal neurological symptoms, and/or positive symptoms

Infarcted area of brain tissue can often appear normal on CT during the first several hours after stroke onset, especially if in posterior circulation

- **PCA**
  - contralateral hemianopia or quadrantanopia
  - midbrain findings: CN III and IV palsy/pupillary changes, hemiparesis
  - thalamic findings: sensory loss, amnesia, decreased LOC
  - if bilateral: cortical blindness or prosopagnosia
  - hemiballismus
- **basilar artery**
  - proximal (usually thrombosis): impaired EOM, vertical nystagmus, reactive miosis, hemi- or quadriplegia, dysarthria, ataxia, locked-in syndrome, coma
  - distal (usually embolic, i.e. top of the basilar syndrome): somnolence, memory and behaviour abnormalities, oculomotor deficit
- **PICA (lateral medullary or Wallenberg syndrome):** ipsilateral ataxia, ipsilateral Horner's, ipsilateral facial sensory loss, contralateral limb impairment of pain and temperature sensation, nystagmus, vertigo, N/V, dysphagia, dysarthria, hiccups
- **medial medullary infarct (anterior spinal artery, which can be associated with anterior cord infarct):** contralateral hemiparesis (facial sparing), contralateral impaired proprioception and vibration sensation, ipsilateral tongue weakness
- **lacunar infarcts (deep hemispheric white matter; involving deep penetrating arteries of MCA, circle of Willis, basilar and vertebral arteries):** contralateral face, arm, leg hemiparesis
- **Common lacunar syndromes:**
  - sensorimotor stroke: weakness and numbness of the face/arm/leg without other cortical signs (i.e. aphasia, apraxia, visual loss)
  - pure motor hemiparesis (posterior limb of internal capsule or ventral pons): contralateral arm, leg, and face
  - pure sensory loss (ventral thalamic): hemisensory loss
  - ataxic hemiparesis (ventral pons or internal capsule): ipsilateral ataxia and leg paresis
  - dysarthria-clumsy hand syndrome (ventral pons or genu of internal capsule): dysarthria, facial weakness, dysphagia, mild hand weakness, and clumsiness

See Landmark Neurology Trials for more information on the ARISTOTLE trial. It details the efficacy of a pixaban, an oral direct factor Xa inhibitor, in reducing the risk of stroke, as compared to warfarin.

**The National Institute of Health Stroke Scale (NIHSS)** is a standardized clinical examination that determines the severity of an acute stroke; it can also be used to monitor response to treatment over time

The scale uses 11 items that evaluate:

- LOC
- Visual system
- Motor system
- Sensory system
- Language abilities

Scoring (x/42):

- 0=no stroke
- 1-4=mild stroke
- 5-15=moderate stroke
- 16-20=moderate to severe stroke
- 21-42=severe stroke

**Aspect Score: 10-Point Quantitative Score to Assess Ischemic Changes on CT Scan**

- 10/10 is normal and <4/10 signifies high-risk of bleed with rtPA
- Subtract 1 point for each of following structures if abnormal within the ischemic hemisphere; caudate, lentiform, insula, internal capsule, MCA 1, 2, 3, 4, 5, 6 regions

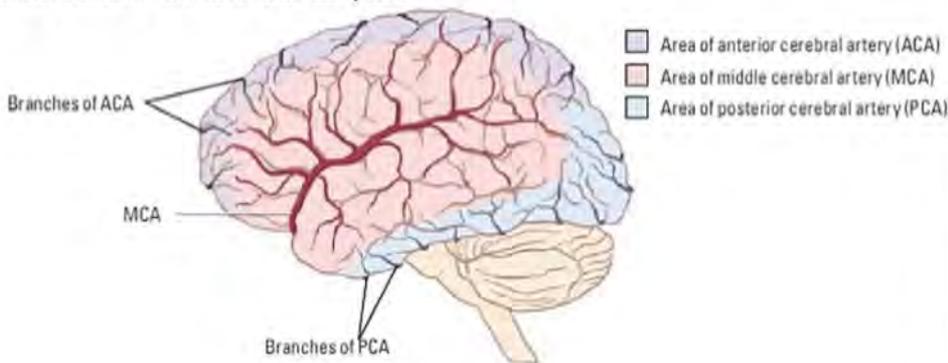

If rtPA is given at stroke onset, delay acute antiplatelet/anticoagulation treatment by 24 h

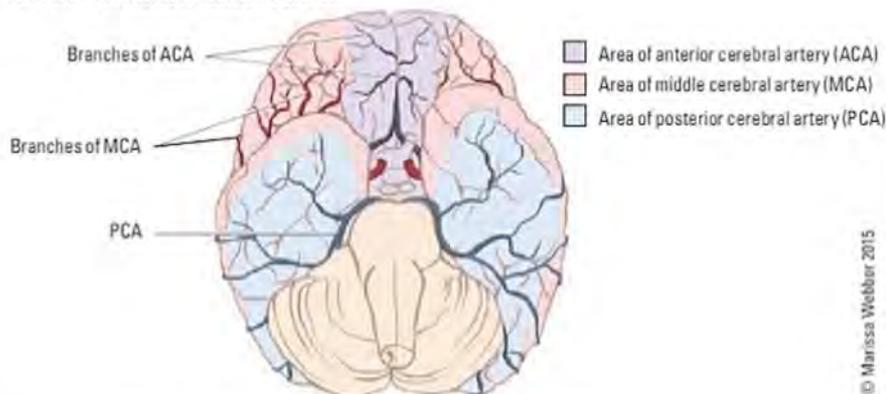

**Absolute Contraindications to rtPA**  
Any source of active hemorrhage, any hemorrhage on brain imaging, any condition that could increase the risk of major hemorrhage after rtPA administration

**Cortical Vascular Territories: Left Hemisphere**

**Cortical Vascular Territories: Ventral Surface**

© Marissa Webber 2015

Figure 26. Vascular territories

## Assessment of Acute Ischemic Stroke

### General Assessment

- ABCs, full vital sign monitoring, capillary glucose (Accu-Chek<sup>®</sup>), urgent CODE STROKE if <4.5 h from symptom onset (for possible thrombolysis), NIHSS
- LOC (knows age, month; obeys commands), dysarthria, dysnomia (cannot name objects)
- gaze preference, visual fields, facial palsy
- arm drift, leg weakness, ataxia
- sensation to pinprick, extinction/neglect
- history
  - onset: time when last known to be awake and symptom free
  - mimics to rule out: seizure/post-ictal, hypoglycemia, migraine, conversion disorder
- investigations
  - neuroimaging: non-contrast CT head (STAT) to rule out hemorrhage, MRI
  - vascular imaging: CT angiogram (STAT), carotid dopplers ultrasound, MRA ECG
  - ECG, Holter monitor, transthoracic echocardiogram: to rule out cardioembolic causes such as atrial fibrillation
  - CBC, electrolytes, creatinine, partial thromboplastin time (PTT)/INR, blood glucose, lipid profile
- imaging (i.e. CT ± MR or CT angiography) signs of stroke
  - loss of cortical white-grey differentiation
  - sulcal effacement (i.e. mass effect decreases visualization of sulci)
  - hypodensity of parenchyma
  - insular ribbon sign
  - hyperdense MCA sign
  - calculate ASPECTS score for CT

## Treatment of Acute Ischemic Stroke

### 1. Neuroprotective strategies

- BP, glucose, temperature control (exact targets will depend on clinical scenario)

### 2. Thrombolysis

- rtPA should be given within 4.5 h of acute ischemic stroke onset provided there are clinical indications and no contraindications to use (see sidebar)

### 3. Intra-Arterial Mechanical Thrombectomy

- early endovascular treatment of proximal anterior circulation occlusion has significant benefit on outcomes
  - ≤6 hours: with small-to-moderate ischemic core on CT
  - 6-24h: CT perfusion used to select patients with large mismatch volume
  - For basilar occlusions: weigh risks and benefits
- current standard of care is IV tPA + mechanical thrombectomy

### 4. Anti-Platelet Therapy

- loading dose of antiplatelets at presentation of TIA or stroke if rtPA not received
  - loading dose of ASA: recommended dose 160 mg chewed
  - if patient intolerant to ASA, use another antiplatelet agent (e.g. clopidogrel 300 mg)
  - if TIA or minor stroke (NIHSS ≤4), load with ASA and clopidogrel and treat with dual antiplatelet therapy for 21 d / 3 wk (ASA 81 mg and clopidogrel 75 mg)
- ASA 81 mg or clopidogrel 75 mg daily should be continued indefinitely for secondary prevention
  - Dual antiplatelets should not be continued for >90 d as risk of hemorrhage is significantly increased beyond this point

### 5. Acute Anti-Coagulant Therapy

- delay initiation/hold oral anticoagulation depending on size of infarct and presence of petechial/frank hemorrhage

### Other Acute Management Issues

- avoid hyperglycemia which can increase the infarct size
- lower temperature if febrile (febrile stroke: think septic emboli from endocarditis)
- prevent complications
  - NPO if dysphagia (to be reassessed by SLP)
  - DVT prophylaxis if bed-bound
  - initiate rehabilitation early

#### Relative Contraindications to rtPA

**Historical:** history of ICH, stroke or serious head/spinal trauma in the preceding 3 mo, major surgery in the preceding 14 d (risk varies by procedure), arterial puncture at a non-compressible site in the previous 7 d  
**Clinical:** suspicious for SAH, suspicious for another non-ischemic acute neurological condition (e.g. post-ictal Todd's paralysis, focal neurological signs due to severe hypo- or hyperglycemia), elevated BP (sBP ≥180 mmHg, dBP ≥105 mmHg) refractory to treatment, current use of direct oral anticoagulant  
**Imaging:** early signs of extensive infarction  
**Laboratory:** blood glucose <2.7 mmol/L or >22.2 mmol/L, elevated aPTT, INR >1.7, platelet count <100 x 10<sup>3</sup>/mm<sup>3</sup>

See Landmark Neurology Trials for more information on the DAWN trial. It details the efficacy and safety of endovascular thrombectomy performed more than 6 hours after the onset of ischemic stroke in patients who were well 6-24 h earlier with a mismatch between clinical deficit and infarct.

See Landmark Neurology Trials for more information on the SPARCL trial. It details whether statins reduce the risk of stroke after a recent stroke or TIA.

#### Evaluating for Occult Atrial Fibrillation – CRYSTAL AF Trial

NEJM 2014;370:2478-86

**Purpose:** To investigate optimal methods for using ECG to detect AFib after cryptogenic stroke.  
**Methods:** 441 patients ≥40 yr with no evidence of AFib during ≥24 h ECG monitoring received long-term monitoring with an insertable cardiac monitor (ICM) or conventional follow-up (control).  
**Results:** Incidence of AFib detection in the ICM group vs. the control group was 8.9% vs. 1.4% at 6 mo (hazard ratio, 6.4; 95% CI, 1.9-21.7; P=0.001), and 12.4% vs. 2.0% at 12 mo (7.3 (2.6-20.8); P<0.001), respectively.  
**Conclusion:** Following cryptogenic stroke, ECG monitoring with ICM was more effective than conventional follow-up for detecting AFib.

Carotid endarterectomy needs to be done within 2 wk of the ischemic event for the most benefit.

### Blood Pressure Control

- do not lower the blood pressure unless the HTN is severe
- antihypertensive therapy is withheld for 48-72 h (permissive hypertension) after non-thrombolysed ischemic stroke unless sBP >220 mmHg or dBP >120 mmHg, or in the setting of acute MI, renal failure, aortic dissection (IV labetalol first-line if needed)
  - if patient receives tPA, target BP  $\leq$  180/105 mmHg
- acutely elevated BP is necessary to maintain brain perfusion to the ischemic penumbra
- most patients with an acute cerebral infarct are initially hypertensive but their BP will improve within 1-2 d

### Stroke Rehabilitation

- individualized based on severity and nature of impairment; may require inpatient program and continuation through home care or outpatient services
- multidisciplinary approach includes dysphagia assessment and dietary modifications, communication rehabilitation, cognitive and psychological assessments including screen for depression, therapeutic exercise programs, assessment of ambulation and evaluation of need for assistive devices, splints or braces, vocational rehabilitation

## Primary and Secondary Prevention of Ischemic Stroke

### Anti-Platelet Therapy

- primary prevention
  - no firm evidence of a protective role for antiplatelet agents in low-risk patients without a prior stroke/TIA
- secondary prevention
  - initial choice: ASA, but other antiplatelet agents reasonable alternatives (clopidogrel or ASA/dipyridamole)
  - longer-term use of combined ASA and clopidogrel not recommended for secondary prevention unless there is an alternate indication (e.g. coronary drug-eluting stent requiring dual antiplatelet therapy), due to increased risk of bleeding and mortality

### Carotid Stenosis

- primary prevention (asymptomatic)
  - carotid endarterectomy is controversial; if stenosis >60%, risk of stroke is 2% per yr; carotid endarterectomy reduces the risk of stroke by 1% per yr (but 5% risk of complications)
- secondary prevention (previous stroke/TIA in carotid territory)
  - carotid endarterectomy clearly benefits those with symptomatic severe stenosis (70-99%), as well as those with moderate stenosis (50-69%) but to a lesser degree (NASCET trial), see [Vascular Surgery, VS9](#)
- according to the CREST trial, endarterectomy and carotid stenting have similar benefits in a composite endpoint of reduction of stroke, MI, and death; however, in the periprocedural period, stenting results in a higher rate of stroke, while endarterectomy results in a higher rate of MI

### Atrial Fibrillation

- primary and secondary prevention with anticoagulation
  - classical risk stratification used CHADS2 score (0-6), but Stroke 2014 guidelines recommend that virtually all patients with atrial fibrillation without contraindication be anticoagulated
    - 0 (low-risk, 1.9% annual stroke risk): antiplatelet
    - 1 (intermediate risk, 2.8% annual stroke risk): anticoagulant or antiplatelet – patient specific decision
    - >2 (high-risk, 4-18.2% annual stroke risk): anticoagulant
  - anticoagulation therapy
    - warfarin (titrate to INR 2-3)
    - direct oral anticoagulants (DOAC): dabigatran (110 or 150 mg PO BID), apixaban (2.5 or 5 mg PO BID), rivaroxaban (15 or 20 mg PO once daily), or edoxaban (30 or 60 mg once daily) may be alternatives to warfarin and generally have a lower risk of ICH
      - Praxbind® reversal agent for dabigatran if necessary
      - Andexanet® reversal agent for apixaban and rivaroxaban if necessary
      - do not use DOAC in patients with mechanical heart valves or Af with valvular heart disease

### Hypertension

- primary prevention
  - targets: BP <140/90 mmHg (sBP <120 mmHg for high-risk without diabetes (SPRINT trial) or <130/80 mmHg for diabetics or renal disease)
  - ACEI: ramipril 10 mg PO once daily is effective in patients at high-risk for cardiovascular disease (HOPE trial)
- secondary prevention
  - combination of ACEI and thiazide diuretics are recommended in patients with previous stroke/TIA (PROGRESS trial)

#### CHADS2

Stroke risk stratification for patients with atrial fibrillation  
 CHF (1 point)  
 HTN sBP >160 mmHg/treated HTN (1 point)  
 Age >75 yr (1 point)  
 DM (1 point)  
 Prior Stroke or TIA (2 points)

#### ABCD<sup>2</sup> Score

To predict/identify individuals at high-risk of stroke following TIA  
 Age: 1 point for age >60 yr  
 Blood pressure (at presentation): 1 point for HTN (>140/90 mmHg at initial evaluation)  
 Clinical features: 2 points for unilateral weakness, 1 point for speech disturbance without weakness  
 Duration of symptoms: 1 point for 10-59 min, 2 points for >60 min  
 DM: 1 point  
 Stroke risk: 0-3: low-risk, 4-5: moderate risk, 6-7: high-risk

See Landmark Neurology Trials for more information on the SAMMPRIS trial. It compares the efficacy of percutaneous transluminal angioplasty and stenting (PTAS) to aggressive medical management in intracranial arterial stenosis.

#### Endovascular Thrombectomy after Large-Vessel Ischemic Stroke: A Meta-Analysis of Individual Patient Data from Five Randomized Trials

Lancet 2016;387:1723-1731

**Purpose:** To compare the efficacy of endovascular thrombectomy to standard medical care in patients with acute ischemic stroke due to occlusion of the proximal anterior circulation.  
**Study:** A meta-analysis of individual patient data from 5 RCTs (MR CLEAN, ESCAPE, REVASCAL, SWIFT PRIME, and EXTEND IA).  
**Results:** Data from 1287 individual patients (634 assigned to endovascular thrombectomy and 653 assigned to control) were analyzed. The number needed to treat to reduce disability for one patient by at least one level on the modified Rankin Scale, which measures disability and dependence in activities of daily living, was 2.6. Mortality at 90 d and risk of parenchymal hemorrhage and symptomatic ICH did not differ between the endovascular thrombectomy and control groups.  
**Conclusion:** Most patients—irrespective of patient characteristics or geographical location—with acute ischemic stroke caused by occlusion of the proximal anterior circulation benefit from endovascular thrombectomy.

**Hypercholesterolemia**

- primary prevention
  - statins in patients with CAD or at high-risk for cardiovascular events, even with normal cholesterol (CARE trial)
- secondary prevention
  - target LDL <2 mmol/L (or 50% reduction in LDL); high dose atorvastatin (SPARCL trial) but lower doses may be adequate if intolerable

**Type 1 and Type 2 Diabetes**

- HbA1c <7%, fasting blood glucose 4-7 mmol/L, 2 h postprandial plasma glucose target 5-10 mmol/L

**Smoking**

- primary prevention: smoking increases risk of stroke in a dose-dependent manner
- secondary prevention: combination of pharmacological therapy and behavioural therapy should be considered in all smoking cessation programs; after smoking cessation, the risk of stroke decreases to baseline within 2-5 yr

**Physical Activity**

- beneficial effect of regular physical activity has a dose-related response in terms of intensity and duration of activity

**Cerebral Hemorrhage**

- definition: intracranial bleeding into brain parenchyma or epidural, subdural or subarachnoid spaces
- etiology: head trauma, aneurysm, AVM, cavernous malformation, brain tumour, hemorrhagic stroke

**Investigations**

- general investigations: see *Assessment and Treatment of Acute Ischemic Stroke, N53*
- further investigations, when clinically indicated:
  - LP (if suspect SAH despite negative CT)
  - may require cerebral angiogram if suspecting aneurysm or AVM
  - if typical location for hypertensive hemorrhage, repeat CT head in 4-6 wk after hemorrhage has resolved to rule out an underlying lesion

**Treatment**

- medical
  - anti-hypertensives: no conclusive BP target ranges for managing ICH exist; 2020 Canadian Stroke Best Practice Guidelines suggest that sBP<140-160 mmHg for the first 24-48h post-ICH is reasonable
  - ICP lowering medical management (if necessary): see *Neurosurgery, NS8*
- surgical: see *Neurosurgery, NS25*

**Neurocutaneous Syndromes**

- see *Paediatrics, P89*

**Multiple Sclerosis**

**Definition**

- a chronic inflammatory disease of the CNS characterized by relapsing-remitting or progressive neurologic symptoms due to inflammation, demyelination, and axonal degeneration

**Epidemiology**

- global prevalence ~2.8 million
- onset 17-35 yr; F:M=3:1
- genetic
  - polygenetic: the HLA-DRB1 gene has been demonstrated to be a genetically susceptible area
  - 30% concordance for monozygotic twins, 2-4% risk in offspring of affected mother or father
- environmental
  - MS is more common in regions with less sun exposure and lower stores of vitamin D (Europe, Canada, US, New Zealand, Southeast Australia)
  - MS has also been linked to certain viruses (e.g. EBV)

**Clinical Patterns**

- clinically isolated syndrome (CIS): first clinical episode that is suggestive of MS
- relapsing-remitting (RRMS) 85%, primary progressive (PPMS) 10%, progressive relapsing (PRMS) 5%, secondary progressive (SPMS)
- most RRMS goes on to become SPMS

**ACE Inhibitor in Stroke Prevention – HOPE Trial**  
NEJM 2000;342:145-153

**Study:** Randomized, blinded, placebo-controlled trial. Mean follow-up 5 yr.

**Patients:** 9297 patients >55 yr (mean age 66 yr, 73% men) who had evidence of vascular disease or DM plus one other cardiovascular risk factor and who were not known to have a low ejection fraction or heart failure. Intervention: Ramipril 10 mg PO once daily vs. matching placebo.

**Main Outcomes:** Stroke, MI, or death from cardiovascular causes.

**Results:**

Outcome	RRR (95%CI)	NNT (CI)
Stroke	32% (16-44)	67 (43-145)
MI, stroke, or CV mortality	26 (19-43)	22% (14-30)
All-cause mortality	16% (5-25)	56 (32-195)

Treatment with ramipril reduced the risk of stroke (3.4% vs. 4.9%; RR 0.68; P<0.001).

Conclusions: In adults at high-risk for cardiovascular events, ramipril reduced the risk of stroke, as well as other vascular events and overall mortality. In addition, ACEI reduce risk of stroke beyond their hypertensive effect.

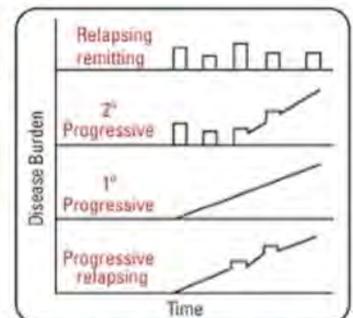

Figure 27. Clinical patterns of MS

Most symptoms in MS are due to cord, brainstem, and optic nerve lesions

**Chronic Cerebrospinal Venous Insufficiency (CCSVI)**

A theory proposed in 2008 described abnormal venous blood flow in patients with MS; while some RCTs are still underway, recent studies have largely discredited this highly controversial theory. That is, studies indicate no connection between CCSVI and MS

### Clinical Features

- an MS relapse/attack/exacerbation is characterized by the onset of new neurological symptoms lasting more than 24 h, in the absence of fever or infection
  - symptoms typically peak over days to weeks, followed by variable improvement over weeks to months
  - in RRMS, average 0.4-0.6 relapses per yr, but higher disease activity in first yr of disease
- symptoms include numbness, visual disturbance (optic neuritis), weakness, spasticity, diplopia (e.g. INO), impaired gait, vertigo, bladder dysfunction
- Lhermitte's sign: flexion of neck causes electric shock sensation down back into limbs suggestive of a dorsal cervical cord lesion
- Uhthoff's phenomenon: worsening of symptoms in heat
- SPMS: classically presents with progressive weakness and gait dysfunction with cerebellar findings of arms (i.e. intention tremor); associated features: fatigue, depression, subtle cognitive dysfunction, autonomic dysfunction
- symptoms not commonly found in MS: visual field defects, aphasia, apraxia, progressive hemiparesis
- negative prognostic factors include age >40 at onset, male sex, non-White ethnicity, frequent relapses, moderate or severe relapse, multi-system relapse (motor, sensory, cerebellar, brainstem, etc.), incomplete recovery, high MRI lesion burden, presence of brainstem and/or spinal cord lesions

### Diagnosis

- demonstration of both dissemination in time and space based on the revised McDonald criteria (2017)
  - dissemination in time:  $\geq 2$  attacks (lasting at least 24 h with 30 d between the 2 attacks), simultaneous presence of gadolinium enhancing and non-enhancing MRI lesions at any time, or a new T2 and/or gadolinium-enhancing lesion(s) on follow-up MRI, presence of CSF oligoclonal bands
  - dissemination in space:  $\geq 1$  T2 lesions on MRI in at least 2 of the 4 CNS regions (periventricular, cortical/juxtacortical, infratentorial, or spinal cord) or developing a second attack that implicates a different CNS region

### MS Variants

- Devic's = neuromyelitis optica (NMO): severe optic neuritis and longitudinally extensive transverse myelitis extending >3 vertebral segments (aquaporin-4 antibody positive)
- tumefactive MS: solitary lesion >2 cm mimicking neoplasms on MRI
- fulminant MS (Marburg): rapidly progressive and fatal MS associated with severe axonal damage, inflammation, and necrosis
- paediatric MS: onset of MS before the age of 18
  - epidemiology: rare (1.35-2.5 in 100000 children)
  - presentation: more likely to present with isolated optic neuritis, isolated brainstem syndrome, or symptoms of encephalopathy compared to adults
  - course: 98% have RRMS
  - diagnosis and treatment similar to adult MS
  - differential diagnosis: in the setting of nonspecific CSF abnormalities and MRI evidence of white matter lesion, rule out ADEM (acute disseminated encephalomyelitis), optic neuritis, transverse myelitis, neuromyelitis optica, CNS malignancies, stroke, leukodystrophies, and mitochondrial disease
- ADEM: monophasic demyelinating disorder with multifocal neurologic symptoms with encephalopathy seen mainly in children, often following infection

### Investigations

- MRI: demyelinating plaques appear as hyperintense lesions on T2-weighted MRI, with active lesions sometimes showing enhancement with gadolinium
  - typical locations: periventricular, corpus callosum, cerebellar peduncles, brainstem, juxtacortical region, and dorsolateral spinal cord
  - Dawson's fingers: periventricular lesions extending into corpus callosum
  - T1 "black holes"
  - cranial MRI is more sensitive than spinal MRI
- CSF: oligoclonal bands in 90%, increased IgG concentration
- evoked potentials (visual/auditory/somatosensory): delayed but well-preserved wave forms

### Treatment

- acute treatment: methylprednisolone 1000 mg IV daily x 3-7 d (no taper required) or prednisone 1000-1250 mg PO daily x 3-7 d (no taper required); if poor response to corticosteroids, may consider plasma exchange
- long-term treatment: vitamin D 4000 units/d
- disease modifying therapy (DMT)
  - goals: decrease relapse rate, decrease progression of disability, slow accumulation of MRI lesions
  - first line: teriflunomide, interferon- $\beta$  (injection: Betaseron<sup>®</sup>, Avonex<sup>®</sup>, Rebif<sup>®</sup>), glatiramer acetate (injection: Copaxone<sup>®</sup>), dimethyl fumarate (Tecfidera<sup>®</sup>)
  - second line: natalizumab (Tysabri<sup>®</sup>) (monthly IV infusion), fingolimod (Gilenya<sup>®</sup>), ocrelizumab (Ocrevus<sup>®</sup>), alemtuzumab (Lemtrada<sup>®</sup>), cladribine (Mavenclad<sup>®</sup>), ofatumumab (Kesimpta<sup>®</sup>)
  - increased risk of PML associated with natalizumab; PML may also described with fingolimod, dimethyl fumarate, and ocrelizumab, but to a lesser degree

**The Expanded Disability Status Scale (EDSS)** is used as a measure of disability progression and is scored from 0 to 10 based on the neurologic exam and ambulation

#### Fingolimod for Relapsing-Remitting Multiple Sclerosis

Cochrane DB Syst Rev 2016;4:CD009371

**Purpose:** Systematic literature review of the evidence for fingolimod in treatment of relapsing-remitting MS.

**Study:** Meta-analysis of six RCTs (n=55152) investigating the benefits and harms of fingolimod and other disease modifying drugs in the treatment of relapsing-remitting MS.

**Results:** Compared to placebo and interferon  $\beta$ -1a, fingolimod increases the probability of being relapse free at 24 mo (RR 1.44 vs. placebo, RR 1.18 vs. interferon  $\beta$ -1a) but has little to no effect on disability progression (RR 1.07 vs. placebo, RR 1.02 vs. interferon  $\beta$ -1a). Fingolimod use was associated with a higher incidence of adverse events and discontinuation within 6 mo.

**Conclusions:** Fingolimod significantly reduces disease activity in relapse-remitting MS compared to placebo but does not prevent disability. Its use is associated with adverse events and requires close patient monitoring, particularly within the first 6 mo. Further study is needed to assess the benefits of fingolimod vs. other disease-modifying drugs.

#### Recombinant Interferon $\beta$ or Glatiramer Acetate for Delaying Conversion of the First Demyelinating Event to Multiple Sclerosis

Cochrane DB Syst Rev 2008;2:CD005278

**Study:** Meta-analysis of RCTs investigating clinically isolated syndrome (CIS) patients treated with immunomodulatory drugs.

**Primary Outcomes:** Proportion of patients converting to clinically definite MS and adverse effects.

**Results:** Three trials (n=1160) tested the efficacy of interferon beta (IFN) and no trial tested glatiramer acetate (GA). The pooled odds ratio (OR) for patients on IFN vs. placebo at 1 yr was 0.53 (95% CI 0.40-0.71, P=0.0001). The 2 yr follow-up OR was 0.52 (95% CI 0.38-0.70, P=0.0001). There was no significant increase in adverse events for those on IFN.

**Conclusions:** IFN treatment can delay progression to clinically definite MS in patients with CIS over 2 yr.

See Landmark Neurology Trials for more information on the PreCISE trial. It details the efficacy of early treatment with glatiramer acetate in delaying onset of clinically definite multiple sclerosis (MS).

- CIS: early treatment may delay potential second attack; glatiramer acetate, interferons, and teriflunomide all with RCT data
- RRMS: first-line DMT reduces rate of relapse by about 30%; second-line by 50-90%
- PPMS: ocrelizumab infusion (ORATORIO trial 2017)
- SPMS: siponimod (Mayzent<sup>®</sup>)
- symptomatic treatment
  - spasticity: baclofen, tizanidine, dantrolene, benzodiazepine, botulinum toxin
  - bladder dysfunction: oxybutynin, mirabegron
  - pain: TCA, carbamazepine, gabapentin
  - fatigue: amantadine, modafinil, methylphenidate
  - depression: antidepressant, lithium
  - constipation: high fibre intake, stool softener, laxatives
  - sexual dysfunction: sildenafil (Viagra<sup>®</sup>), tadalafil (Cialis<sup>®</sup>), vardenafil (Levitra<sup>®</sup>, Staxyn<sup>®</sup>)
- education and counselling: MS Society, support groups, psychosocial issues

**Prognosis**

- good prognostic indicators: female, young, RRMS, presenting with optic neuritis, low burden of disease on initial MRI, low rate of relapse early in disease
- PPMS: poor prognosis, higher rates of disability, poor response to therapy

## Common Medications

**Table 26. Common Medications – Major Issues**

Indications	Mechanism of Action/Class	Generic Name	Trade Name	Dosing	Contraindications	Side Effects
Parkinson's Disease	Dopamine precursor	levodopa + carbidopa	Sinemet <sup>®</sup>	Carbidopa 25 mg/levodopa 100 mg PO TID Maximum 200 mg carbidopa and 2000 mg levodopa/d	Use of MAO inhibitor in last 14 d	Nausea, hypotension, hallucinations, dyskinesias
	Dopamine agonist	pramipexole ropinirole rotigotine	Mirpaex <sup>®</sup> Requip <sup>®</sup> Neupro <sup>®</sup>	Initial: 0.125 mg TID Maximum: 4.5 mg/d Initial: 0.25 mg TID Maximum: 8 mg	Hypersensitivity	Hallucinations, nausea, dizziness, headache, insomnia, somnolence, application site reactions (rotigotine)
	MAOB inhibitor	MAOB inhibitor	Eldepryl <sup>®</sup> Azilect <sup>®</sup>	5 mg PO BID 1 mg PO once daily	Concomitant use of meperidine or tricyclic antidepressants	H/A, insomnia, dizziness, nausea, dry mouth, hallucinations, confusion, orthostatic hypotension, increased akinesia, risk of hypertensive crisis with tyramine-containing foods
Myasthenia Gravis	Acetylcholinesterase inhibitor	pyridostigmine	Mestinon <sup>®</sup>	600 mg/d PO divided in 5-6 doses Range 60-1500 mg/d	GI or GU obstruction	N/V, diarrhea, abdominal cramps, increased peristalsis, increased salivation, increased bronchial secretions, miosis, diaphoresis, muscle cramps, fasciculations, muscle weakness, bradycardia
Acute Migraine	Triptan (selective 5-hydroxytryptamine receptor agonist)	sumatriptan	Imitrex <sup>®</sup>	25-100 mg PO PRN, maximum 200 mg/d	Hemiplegic/basilar migraine, ischemic heart disease, CVD, uncontrolled HTN, use of ergotamine/5-HT1 agonist in past 24 h, use of MAO inhibitor in last 14 d, severe hepatic disease	Vertigo, chest pain, flushing, sensation of heat, hypertensive crisis, peripheral vascular disease, coronary artery vasospasm, cardiac arrest, nausea, vomiting, H/A, hyposalivation, fatigue
	Ergot (5-HT1D receptor agonist)	dihydroergotamine	Migranal <sup>®</sup>	Nasal spray 0.5 mg/spray, maximum 4 sprays/d	Hemiplegic/basilar migraine, high-dose ASA therapy, uncontrolled HTN, ischemic heart disease, peripheral vascular disease, severe hepatic or renal dysfunction, use of triptans in last 24 h, use of MAO inhibitors in last 14 d	Coronary artery vasospasm, transient myocardial ischemia, MI, ventricular tachycardia, ventricular fibrillation; may cause significant rebound H/A
Migraine Prophylaxis	Anticonvulsant	topiramate	Topamax <sup>®</sup>	25 mg PO (in evening); may increase weekly by 25 mg/d to a max 50 mg BID	Nephrolithiasis	Sedation, mood disturbance, cognitive dysfunction, anorexia, nausea, diarrhea, paresthesias, metabolic acidosis, glaucoma, SJS/TEN
	β-blocker	propranolol	Inderal <sup>®</sup>	80 mg/d divided every 6-8 h; increase by 20-40 mg/dose every 3-4 wk to max 160-240 mg/d in divided doses q6-8 h	Uncompensated CHF, severe bradycardia or heart block, severe COPD or asthma	Fatigue, cognitive dysfunction, disturbed sleep, rashes, dyspepsia, dry eyes, heart failure, bronchospasm, risk of acute tachycardia and HTN if withdrawal

SJS: Stevens-Johnson Syndrome, TES: toxic epidermal necrolysis

Table 26. Common Medications – Major Issues

Indications	Mechanism of Action/Class	Generic Name	Trade Name	Dosing	Contraindications	Side Effects
Epilepsy	Anticonvulsant for partial ± 2° generalization, generalized tonic-clonic	carbamazepine	Tegretol®	Start at 100-200 mg PO once daily to TID, increase by 200 mg/d up to 800-1200 mg/d	History of bone marrow depression, hepatic disease, hypersensitivity to the drug, use of MAO inhibitor in last 14 d	Drowsiness, H/A, unsteadiness, dizziness, N/V, skin rash, agranulocytosis/aplastic anemia (rare)
	Anticonvulsant for partial, tonic-clonic, status epilepticus	phenytoin	Dilantin®	100 mg PO TID, maintenance dose up to 200 mg PO TID SE: 10-15 mg/kg IV loading dose then maintenance doses of 100 mg PO or IV q6-8 h	Hypersensitivity, pregnancy, breastfeeding; caution with P-450 interactions	Hypotension, SJS/TEN, SLE-type symptoms, gingival hypertrophy, peripheral neuropathy, H/A, blood dyscrasias, nystagmus, N/V, constipation, sedation, teratogenic
	Anticonvulsant for partial or generalized, absence seizures	valproic acid	Depakene® Apo-Valproic®	10-15 mg/kg/d PO in divided doses, increase incrementally until therapeutic dose to max of 60 mg/kg/d	Hypersensitivity, hepatic disease, urea cycle disorders	Hepatic failure, H/A, somnolence, alopecia, N/V, diarrhea, tremor, diplopia, thrombocytopenia, hypothermia, pancreatitis, encephalopathy, most teratogenic AED (dose-dependent)
	Anticonvulsant for absence seizures	ethosuximide	Zarontin®	500 mg/d PO, increase by 250 mg every 4-7 d to max 1.5 g/d in divided doses	Hypersensitivity (succinimides)	CNS depression, blood dyscrasias, SLE, SJS, GI symptoms
Stroke Prevention in Atrial Fibrillation	Anticoagulant (direct thrombin inhibitor)	dabigatran	Pradaxa®	110 mg PO BID or 150 mg PO BID	CrCl <30 mL/min, significant hemostatic impairment, or CNS lesions within 6 mo with high-risk of bleeding	Dyspepsia, gastritis, bleeding
	Anticoagulant (Factor Xa inhibitor)	rivaroxaban	Xarelto®	15 mg PO once daily or 20 mg PO once daily	Concomitant anticoagulant, hepatic disease, pregnancy, strong CYP3A4 and P-glycoprotein inhibitors e.g. itraconazole, ritonavir	Bleeding
	Anticoagulant (Factor Xa inhibitor)	apixaban	Eliquis®	2.5 mg PO BID or 5 mg PO BID	Active bleeding, gastrointestinal bleeding, recent cerebral infarction, active peptic ulcer disease with recent bleeding, hepatic disease with coagulopathy	Bleeding (conjunctival, gastrointestinal, gingival, contusion, hematoma, epistaxis, hematuria)
	Anticoagulant (Factor Xa inhibitor)	edoxaban	Savaysa®	30 mg PO or 60 mg PO once daily	Active bleeding, hepatic disease, CrCl <30 mL/min	Bleeding
Mild to Moderate Alzheimer's Disease or Dementia with Lewy Bodies	Cholinesterase Inhibitor	donepezil	Aricept®	5 mg PO once daily, may increase to 10 mg PO once daily after 4-6 wk	Hypersensitivity to donepezil or to piperidine derivatives	Diarrhea, N/V, insomnia, muscle cramps, fatigue, anorexia, HTN, syncope, AV block
Multiple Sclerosis	MS Disease Modifying Therapy	interferon-β-1b interferon-β-1a SC interferon-β-1a IM	Betaseron® Rebif® Avonex®	0.25 mg (8 MU) SC every other day 44 µg SC 3 times/wk 30 µg IM once weekly	Pregnancy, hypersensitivity to natural or recombinant interferon-β	Injection site reactions, injection site necrosis, flu-like symptoms (fever, chills, myalgia; tend to decrease over time)
	MS Disease Modifying Therapy	glatiramer acetate	Copaxone®	20 mg SC once daily	Hypersensitivity to glatiramer or mannitol	Injection site reactions, nausea, transient chest pain, vasodilation
	MS Disease Modifying Therapy	natalizumab	Tysabri®	300 mg IV given over 1 h, every 4 wk	Hypersensitivity to natalizumab, progressive multifocal leukoencephalopathy (PML)	Rash, nausea, arthralgia, H/A, infections, rare risk of PML and melanoma
	MS Disease Modifying Therapy	fingolimod	Gilenya®	0.5 mg PO once daily	Not available	Diarrhea, transaminitis, H/A, bradyarrhythmia, lymphopenia
Spasticity (i.e. MS)	Muscle Relaxant – Antispastic	baclofen	Lioresal®	5 mg PO TID, increase by 15 mg/d q3d to max dose 80 mg/d in three divided doses	Hypersensitivity to baclofen	Transient drowsiness, daytime sedation, dizziness, weakness, fatigue, convulsions, constipation, nausea

SJS: Stevens-Johnson Syndrome, TEN: toxic epidermal necrolysis

# Landmark Neurology Trials

Trial Name	Reference	Clinical Trial Details
<b>Stroke</b>		
NASCET	NEJM 1991;7:445-53	<p><b>Title:</b> Beneficial Effect of Carotid Endarterectomy in Symptomatic Patients with High-Grade Carotid Stenosis</p> <p><b>Purpose:</b> To assess the efficacy of carotid endarterectomy for reducing stroke risk in patients with a recent adverse cerebrovascular event and ipsilateral carotid stenosis.</p> <p><b>Methods:</b> 659 patients with recent (<math>\leq 120</math>d) hemispheric or retinal TIA or nondisabling stroke with 70-99% stenosis received optimal medical care. Those assigned to surgical treatment underwent carotid endarterectomy.</p> <p><b>Results:</b> Estimated cumulative risk of any ipsilateral stroke at 2yr was 26% in medical patients and 9% in surgical patients (absolute risk reduction, 17%; <math>P &lt; 0.001</math>), and 13.1% and 2.5%, respectively, for major or fatal ipsilateral stroke (10.6%; <math>P &lt; 0.001</math>).</p> <p><b>Conclusion:</b> Carotid endarterectomy effectively reduces stroke risk in patients with a recent adverse cerebrovascular event and ipsilateral carotid stenosis.</p>
NINDS rtPA	NEJM 1995;333:1581-87	<p><b>Title:</b> Tissue Plasminogen Activator for Acute Ischemic Stroke</p> <p><b>Purpose:</b> To investigate the clinical efficacy of IV rtPA in acute ischemic stroke.</p> <p><b>Methods:</b> Patients with acute ischemic stroke randomly assigned to receive rtPA or placebo.</p> <p><b>Results:</b> At 24hr, there was no significant differences in neurologic improvement between rtPA and placebo. Clinical benefit of rtPA was observed at 3 mo for all outcome measures. Patients treated with rtPA were 30% less likely to be disabled at 3mo. rtPA was associated with significantly more symptomatic intracerebral hemorrhage within 36 h after stroke.</p> <p><b>Conclusion:</b> When administered within 3 h of ischemic stroke, rtPA improved clinical outcomes despite a greater risk of symptomatic intracerebral hemorrhage.</p>
WASID	NEJM 2005;352:1305-16	<p><b>Title:</b> Comparison of Warfarin and Aspirin for Symptomatic Intracranial Arterial Stenosis</p> <p><b>Purpose:</b> To compare the safety and efficacy of warfarin and aspirin in the treatment of stroke caused by atherosclerotic intracranial arterial stenosis.</p> <p><b>Methods:</b> 569 patients with TIA or stroke caused by 50-99% stenosis were randomized to receive warfarin (target international normalized ratio, 2.0-3.0) or aspirin (1300 mg/d).</p> <p><b>Results:</b> Study stopped early due to safety concerns. Adverse events included death (4.3% on aspirin vs. 9.7% on warfarin; <math>P = 0.02</math>), major hemorrhage (3.2% vs. 8.3%; <math>P = 0.01</math>), and MI or sudden death (2.9% vs. 7.3%; <math>P = 0.02</math>) during 1.8 yr mean follow-up.</p> <p><b>Discussion:</b> In patients with intracranial arterial stenosis, warfarin afforded no clinical benefit and was associated with more adverse events. Aspirin is thus preferable.</p>
SPARCL	NEJM 2006;355:549-59	<p><b>Title:</b> High-Dose Atorvastatin after Stroke or Transient Ischemic Attack</p> <p><b>Purpose:</b> To investigate whether statins reduce the risk of stroke after a recent stroke or TIA.</p> <p><b>Method:</b> 4731 patients with stroke or TIA within 1-6 mo and LDL-<math>2.6-4.9</math> mmol/L and without coronary disease were randomly assigned to receive 80 mg atorvastatin daily or placebo.</p> <p><b>Results:</b> Fatal or nonfatal stroke occurred in 11.2% of patients receiving atorvastatin and 13.1% receiving placebo (5-yr absolute reduction in risk, 2.2%; adjusted hazard ratio, 0.84; 95% CI, 0.71 to 0.99; <math>P = 0.03</math>). The atorvastatin group experienced relatively more hemorrhagic strokes (hazard ratio 1.66 [1.08-2.55]).</p> <p><b>Conclusion:</b> Atorvastatin reduced the overall incidence of strokes in patients with recent stroke or TIA, despite an increase in rates of hemorrhagic stroke</p>
ECASS 3	NEJM 2008;359:1317-29	<p><b>Title:</b> Thrombolysis With Alteplase 3 to 4.5 Hours After Acute Ischemic Stroke</p> <p><b>Purpose:</b> To investigate the efficacy and safety of alteplase administered 3-4.5 h following stroke onset.</p> <p><b>Methods:</b> Randomly assigned 821 patients with acute ischemic stroke to receive IV alteplase (0.9 mg/kg) or placebo. Primary outcome was disability at 90d (favorable outcome: 0-1 on modified Rankin scale) or unfavorable outcome (2-6).</p> <p><b>Results:</b> Alteplase was associated with more favourable outcomes than placebo (52.4% vs. 45.2%; OR, 1.34; 95% CI, 1.02-1.76; <math>P = 0.04</math>). Intracranial hemorrhage was more frequent on alteplase vs. placebo (27.0% vs. 17.6%; <math>P = 0.001</math>). No significant difference in mortality or adverse events.</p> <p><b>Conclusion:</b> In patients with acute ischemic stroke, IV alteplase administered 3-4.5 h after symptom onset significantly improved clinical outcomes but also increased the frequency of ICH.</p>
RELY	NEJM 2009;361:1139-51	<p><b>Title:</b> Dabigatran Versus Warfarin in Patients with Atrial Fibrillation</p> <p><b>Purpose:</b> To investigate the efficacy and safety of dabigatran vs. warfarin in preventing stroke or systemic embolism in patients with AFib.</p> <p><b>Methods:</b> 18,113 patients with AFib and risk of stroke were randomly assigned to receive dabigatran 110-150 mg BID or adjusted-dose warfarin.</p> <p><b>Results:</b> Rates of stroke or systemic embolism were 1.69%/yr on warfarin and 1.53%/yr on 110 mg dabigatran (relative risk with dabigatran, 0.91; 95% CI, 0.74-1.11) and 1.11%/yr on 150 mg dabigatran (0.66 [0.53-0.82]). Frequency of major bleeding was 3.36%/yr on warfarin and 2.71%/yr on 110 mg of dabigatran (<math>P = 0.003</math>) and 3.11%/yr on 150 mg dabigatran (<math>P = 0.31</math>).</p> <p><b>Conclusion:</b> When compared to warfarin, dabigatran has potential to lower stroke rates or major hemorrhage depending on dose.</p>
CREST	NEJM 2010;363:11-23	<p><b>Title:</b> Stenting Versus Endarterectomy for Treatment of Carotid-Artery Stenosis</p> <p><b>Purpose:</b> To investigate the efficacy and safety of carotid-artery stenting vs. carotid endarterectomy for treating carotid-artery stenosis.</p> <p><b>Methods:</b> 2502 patients with carotid stenosis were randomly assigned to carotid-artery stenting or carotid endarterectomy. Primary composite outcome was MI, stroke, or death from any cause or any ipsilateral stroke within 4yr.</p> <p><b>Results:</b> Estimated 4-year rates of the primary outcome did not significantly differ between stenting and endarterectomy (7.2% vs. 6.8%; hazard ratio with stenting, 1.11 [0.81-1.5]); <math>P = 0.51</math>). Rates of individual endpoint components for stenting vs. endarterectomy were 0.7% vs. 0.3%, <math>P = 0.18</math> for death; 4.1% vs. 2.3%, <math>P = 0.01</math> for stroke; and 1.1% vs. 2.3%, <math>P = 0.03</math> for MI.</p> <p><b>Conclusion:</b> Composite primary outcome risk did not differ significantly between stenting and endarterectomy in patients with carotid stenosis.</p>
ARISTOTLE	NEJM 2011;365:981-92	<p><b>Title:</b> Apixaban Versus Warfarin in Patients With Atrial Fibrillation</p> <p><b>Purpose:</b> To assess the efficacy of apixaban in reducing the risk of stroke as compared to warfarin.</p> <p><b>Methods:</b> 18,201 patients with AFib and one additional risk factor for stroke were randomized to receive either apixaban or warfarin. The primary outcome was stroke or systemic embolism.</p> <p><b>Results:</b> The rate of stroke or systemic embolism was lower in the apixaban group than in the warfarin group (1.27% vs. 1.60%; <math>P = 0.001</math> for noninferiority, <math>P = 0.01</math> for superiority). The rates of major bleeding (2.13% vs. 3.09%; <math>P &lt; 0.001</math>) and death (3.52% vs. 3.94%; <math>P = 0.047</math>) were lower in the apixaban group than in the warfarin group.</p> <p><b>Conclusion:</b> In patients with AFib, apixaban was superior to warfarin for preventing stroke or systemic embolism with lower rates of major bleeding and death.</p>
AVERROES	NEJM 2011;364:806-17	<p><b>Title:</b> Apixaban in Patients with Atrial Fibrillation</p> <p><b>Purpose:</b> To investigate the efficacy and safety of apixaban in preventing stroke in patients with AFib.</p> <p><b>Methods:</b> 5599 patients with AFib at increased risk for stroke and who were unsuitable for vitamin K antagonist therapy were randomly assigned to receive 5 mg apixaban BID or aspirin (81-324 mg daily).</p> <p><b>Results:</b> Study terminated early due to clear apixaban benefit. Rates of stroke or systemic embolism were 1.6%/yr on apixaban and 3.7%/yr on aspirin (hazard ratio with apixaban, 0.45 [0.32 to 0.62]; <math>P &lt; 0.001</math>). There were no significant differences in rates of major bleeding or intracranial bleeding.</p> <p><b>Conclusion:</b> Apixaban reduced the risk of stroke or systemic embolism without increasing bleeding or hemorrhage risk in patients with AFib unsuitable for vitamin K antagonists.</p>
ROCKET AF	NEJM 2011;365:883-91	<p><b>Title:</b> Rivaroxaban Versus Warfarin in Nonvalvular Atrial Fibrillation</p> <p><b>Purpose:</b> To investigate if rivaroxaban is noninferior to warfarin in preventing stroke or systemic embolism in AFib.</p> <p><b>Methods:</b> 14,264 patients with nonvalvular AFib at increased risk for stroke were randomly assigned to receive either rivaroxaban (20 mg/d) or dose-adjusted warfarin.</p> <p><b>Results:</b> Rates of stroke or systemic embolism were 1.7%/yr on rivaroxaban and 2.2%/yr on warfarin (hazard ratio, 0.79 [0.66 to 0.96]; <math>P &lt; 0.001</math> for noninferiority). Significant reductions in ICH (0.5% vs. 0.7%, <math>P = 0.02</math>) and fatal bleeding (0.2% vs. 0.5%, <math>P = 0.003</math>) were seen in the rivaroxaban group.</p> <p><b>Conclusion:</b> Rivaroxaban was noninferior to warfarin in patients with AFib for preventing stroke or systemic embolism with lower risks of ICH and fatal bleeding.</p>

Trial Name	Reference	Clinical Trial Details
SAMMPRIS	NEJM 2011;365:993-1003	<b>Title:</b> Stenting Versus Aggressive Medical Therapy for Intracranial Arterial Stenosis <b>Purpose:</b> To compare the efficacy of percutaneous transluminal angioplasty and stenting (PTAS) vs. medical management in intracranial arterial stenosis. <b>Methods:</b> 451 patients with recent TIA or stroke attributed to 70-99% stenosis were randomly assigned to aggressive medical management plus PTAS or aggressive medical management alone. <b>Results:</b> 30-day stroke or death rate was 14.7% and 5.8% in the PTAS and medical-management group, respectively (P=0.002). 1-yr rates of the primary end point (stroke or death within 30 d or after a revascularization during follow-up or stroke in the territory of the qualifying artery beyond 30d) were 20.0% in PTAS and 12.2% in medical-management (P=0.009). <b>Conclusion:</b> Aggressive medical management in patients with intracranial arterial stenosis was superior to PTAS.
INTERACT2	NEJM 2013;368:2355-65	<b>Title:</b> Rapid Blood-Pressure Lowering in Patients with Acute Intracerebral Hemorrhage <b>Purpose:</b> To investigate the efficacy of rapid lowering of elevated BP for improving outcomes in patients with intracerebral hemorrhage. <b>Methods:</b> 2839 patients with spontaneous intracerebral hemorrhage and elevated sBP were randomly assigned to receive intensive treatment (target sBP<140 mmHg within 1 hr) or guideline-based treatment (target sBP<180 mmHg). <b>Results:</b> 52.0% receiving intensive treatment vs. 55.6% receiving guideline-based treatment experienced a primary outcome event (death or major disability) (OR, 0.87 (0.75-1.01); P=0.06). Intensive treatment was associated with significantly lower modified Rankin scores (OR for greater disability, 0.87 (0.77-1.00); P=0.04). <b>Conclusion:</b> Intensive BP lowering in intracerebral hemorrhage did not significantly reduce rates of death or severe disability but may improve functional outcomes.
ESCAPE	NEJM 2015;372:1019-30	<b>Title:</b> Randomized Assessment of Rapid Endovascular Treatment of Ischemic Stroke <b>Purpose:</b> To investigate rapid endovascular treatment plus standard care in acute ischemic stroke with a proximal intracranial arterial occlusion, small infarct core, and moderate-good collateral circulation. <b>Methods:</b> 316 patients randomly assigned to receive endovascular treatment with the use of available thrombectomy devices plus standard of care (intervention group) or standard care alone (control group). <b>Results:</b> The intervention reduced mortality (10.4%, vs. 19.0% in controls; P=0.04) and was associated with improved scores on the modified Rankin scale at 90 days (common OR, 2.6; 95% CI, 1.7 to 3.8; P<0.001). <b>Conclusion:</b> Rapid endovascular treatment improved functional outcomes and reduced mortality in select patients with acute ischemic stroke.
MR CLEAN	NEJM 2015;372:11-20	<b>Title:</b> A Randomized Trial of Intraarterial Treatment for Acute Ischemic Stroke <b>Purpose:</b> To investigate functional outcomes of intraarterial treatment for emergency revascularization in patients with acute ischemic stroke caused by a proximal intracranial arterial occlusion. <b>Methods:</b> 500 patients that could be treated intraarterially within 6h after symptom onset were randomly assigned to either intraarterial treatment plus standard care or standard care alone. <b>Results:</b> The rate of functional independence (modified Rankin score, 0 to 2) was higher in the intervention group (32.6% vs. 19.1%; absolute difference, 13.5%, 95% CI, 5.9 to 21.2). Rates of mortality or symptomatic intracerebral hemorrhage were not significantly different between groups. <b>Conclusion:</b> Intraarterial treatment within 6 h following stroke onset was safe and effective in acute ischemic stroke caused by intracranial, proximal arterial occlusion of the anterior circulation.
DAWN	NEJM 2018;378:11-21	<b>Title:</b> Thrombectomy 6 to 24 Hours after Stroke with a Mismatch between Deficit and Infarct <b>Purpose:</b> To investigate the efficacy and safety of endovascular thrombectomy performed > 6 h following ischemic stroke onset. <b>Methods:</b> 206 patients with acute stroke who were well 6-24 hours earlier with mismatch between clinical deficit and infarct were randomly assigned to thrombectomy plus standard care or standard care alone (control). <b>Results:</b> At 90 d, mean scores on a modified Rankin scale were 5.5 in thrombectomy and 3.4 in controls (adjusted difference, 2.0 points (1.1-3.0); posterior probability of superiority, >0.999), and the rate of functional independence were 49% and 13%, respectively (adjusted difference, 33% (24-44); posterior probability of superiority, >0.999). <b>Conclusion:</b> Adding thrombectomy to standard of care improved disability outcomes in patients with acute stroke who were well 6-24 hours earlier with clinical deficit and infarct mismatch.
POINT	NEJM 18;379:215-25	<b>Title:</b> Clopidogrel and Aspirin in Acute Ischemic Stroke and High-Risk TIA <b>Purpose:</b> To investigate the efficacy of clopidogrel plus aspirin to reduce the rate of stroke recurrence during the first 3 months following a minor ischemic stroke or TIA. <b>Methods:</b> 4881 patients with minor ischemic stroke or high-risk TIA were randomly assigned to clopidogrel plus aspirin or aspirin plus placebo. <b>Results:</b> Fewer major ischemic events were observed in those receiving clopidogrel plus aspirin (5%) vs. aspirin plus placebo (6.5%) (hazard ratio, 0.75 (0.59-0.95); P=0.02). Risk of major hemorrhage was greater in those receiving clopidogrel plus aspirin (0.9%) vs. those receiving aspirin plus placebo (0.4%) (2.32 (1.10-4.87); P=0.02). <b>Conclusion:</b> Clopidogrel plus aspirin lowers risk of major ischemic events but increases risk of major hemorrhage in patients with minor ischemic stroke or high-risk TIA.

## Multiple Sclerosis

Interferon-β-1b is effective in relapsing-remitting multiple sclerosis. I. Clinical results of a multicenter, randomized, double-blind, placebo-controlled trial. The IFNB Multiple Sclerosis Study Group	Neurology 1993;43:655-61	<b>Title:</b> Interferon-β-1b is effective in relapsing-remitting multiple sclerosis. I. Clinical results of a multicenter, randomized, double-blind, placebo-controlled trial. The IFNB Multiple Sclerosis Study Group <b>Purpose:</b> To investigate the efficacy of Interferon-β-1b (IFNB) in relapsing-remitting MS. <b>Methods:</b> 372 ambulatory patients with relapsing-remitting MS self-administered either placebo, 1.6 million international units (MIU) of IFNB, or 8 MIU of IFNB. <b>Results:</b> After 2 yr, rates of annual clinical exacerbation for patients on placebo were 1.27; 1.17 for 1.6 MIU IFNB; and 0.84 for 8 MIU IFNB, indicating both treatment groups performed significantly better than placebo. In the 8 MIU group, there was a twofold reduction in the frequency of moderate-severe attacks. <b>Conclusion:</b> Interferon-β-1b reduces relapse rate and severity of relapses in relapsing-remitting MS.
PreCISe	Lancet 2009;374:1503-11	<b>Title:</b> Effect of Glatiramer Acetate on Conversion to Clinically Definite Multiple Sclerosis in Patients with Clinically Isolated Syndrome (Precise Study): A Randomised, Double-Blind, Placebo-Controlled Trial <b>Purpose:</b> To assess the efficacy of early treatment with glatiramer acetate in delaying onset of clinically definite MS. <b>Methods:</b> 481 patients with clinically isolated syndrome with unifocal manifestation, and ≥2 T2-weighted brain lesions >6 mm, received SC glatiramer acetate (20 mg/d) or placebo for up to 36 months. <b>Results:</b> Relative to placebo, the risk of developing clinically definite MS was reduced by 45% with glatiramer acetate (hazard ratio 0.55, 95% CI 0.40-0.77; P=0.0005). It prolonged the time for 25% of patients to convert to clinically definite disease by 115%. Injection-site reactions and immediate post-injection reactions were the most common adverse events. <b>Conclusion:</b> In patients presenting with clinically isolated syndrome and brain lesions, conversion to clinically definite MS can be delayed by early treatment with glatiramer acetate.

<b>Seizure Disorders and Epilepsy</b>		
MESS	Lancet 2005;365:2007-13	<b>Title:</b> Immediate Versus Deferred Antiepileptic Drug Treatment for Early Epilepsy and Single Seizures: A Randomised Controlled Trial <b>Purpose:</b> To investigate the relative benefits and risks of initiating or withholding antiepileptic drug treatment in patients with few or infrequent seizures. <b>Methods:</b> 1443 patients with single seizures or early epilepsy were randomly assigned to receive either immediate or deferred antiepileptic drug treatment. <b>Results:</b> Immediate treatment prolonged time to 1st seizure (hazard ratio 1.4; (95% CI 1.2-1.7)), 2nd seizure (1.3 (1.1-1.6)), and first tonic-clonic seizure (1.5 (1.2-1.8)). Time to 2-yr remission of seizures was reduced by immediate treatment (P=0.023). The proportion of patients that were seizure-free between years 3-5 were 76% on immediate treatment and 77% on deferred treatment. <b>Conclusion:</b> In individuals with single or infrequent seizures, seizure occurrence in the first 1-2 yr is reduced by immediate antiepileptic drug treatment, but long-term remission is not affected.
SANAD	Lancet 2007;369:1016-26	<b>Title:</b> The SANAD Study of Effectiveness of Valproate, Lamotrigine, or Topiramate for Generalised and Unclassifiable Epilepsy: An Unblinded Randomised Controlled Trial <b>Purpose:</b> To investigate the long-term effects of valproate, lamotrigine, and topiramate in patients with generalized onset seizures or seizures that are not easily classified. <b>Methods:</b> Between 1999-2004 during the initial trial, patients were randomly assigned to receive valproate, lamotrigine, or topiramate, and follow-up data were obtained up to 2006. <b>Results:</b> Valproate was significantly better than topiramate for time to treatment failure (hazard ratio 1.57 (95% CI 1.19-2.08)), and significantly better than lamotrigine for time to 12-mo remission (0.76 (0.62-0.94)). <b>Conclusion:</b> Valproate should remain the first line therapy for generalised and unclassified epilepsies due to superior efficacy and safety profiles.
<b>Alzheimer's Disorder</b>		
CATIE-AD	Am J Psychiatry 2011;168:831-839	<b>Title:</b> Cognitive Effects of Atypical Antipsychotic Medications in Patients with Alzheimer's Disease: Outcomes from CATIE-AD <b>Purpose:</b> To examine the effects of time and treatment on neuropsychological functioning during the Clinical Antipsychotic Trials of the Intervention Effectiveness-Alzheimer's Disease study. <b>Methods:</b> 421 outpatients with Alzheimer's disease and psychosis or agitated/aggressive behaviour were randomized to receive olanzapine, quetiapine, risperidone, or placebo in a multicentre double-blinded RCT. MMSE and Alzheimer's Disease Assessment Scale (ADAS) scores were measured at 36 wk. <b>Results:</b> Patients receiving atypical antipsychotics exhibited a faster rate of cognitive decline as measured by MMSE scores (-0.067/wk vs. -0.007/wk). They also had a significantly faster decline compared to placebo on a composite measure of ADAS, MMSE, and various other cognitive tests (-0.011/wk vs. -0.001/wk). <b>Conclusions:</b> Long-term use of atypical antipsychotics for behavioural symptoms and psychosis in dementia patients is associated with greater rates of cognitive decline.
<b>Neuropathic Pain</b>		
A Vaccine to Prevent Herpes Zoster and Postherpetic Neuralgia in Older Adults. Oxman et al. 2005	NEJM 2005;352:2271-84	<b>Title:</b> A Vaccine to Prevent Herpes Zoster and Postherpetic Neuralgia in Older Adults <b>Purpose:</b> To investigate whether vaccination against herpes zoster would decrease the incidence and/or severity of infection and/or PHN in older adults. <b>Methods:</b> 38,546 adults aged ≥ 60 yr were randomized to receive live attenuated Oka/Merck VZV vaccine (zoster vaccine) or placebo. <b>Results:</b> Vaccination reduced herpes zoster illness burden by 61.1% (P<0.001), incidence of infection by 51.3% (P<0.001), and incidence of PHN by 66.5% (P<0.001). <b>Conclusion:</b> Among older adults, the zoster vaccine significantly reduced morbidity from herpes zoster and postherpetic neuralgia.

**Figure 3. Relationship of nerve roots to vertebral level in the cervical and lumbar spine**  
 Note: AP (anterior-posterior) views depict left-sided C4-5 and L4-5 disc herniation, and correlating nerve root impingement

**Figure 4. Vascular supply of the brain**  
 Please see legend for artery names. 4A. Circle of Willis, most common variant. 4B. Vascular supply to subcortical structures, axial view. 4C. Vascular territories of the brain, sagittal view, seen laterally. 4D. Vascular territories of the brain, sagittal view, seen medially

# Differential Diagnoses of Common Presentations

**Table 1. Differential Diagnoses of Common Presentations**

Intracranial Mass Lesions	Disorders of the Spine	Peripheral Nerve Lesions
<b>Tumour</b> Metastasis Glioma Meningioma Vestibular schwannoma (acoustic neuroma) Pituitary adenoma Primary CNS lymphoma  <b>Pus/Inflammation</b> Cerebral abscess, extradural abscess, subdural empyema Encephalitis, e.g. Herpes Simplex Virus (see <a href="#">Infectious Diseases</a> , ID18) Tumefactive multiple sclerosis (MS) Sarcoidosis  <b>Blood</b> Extradural (epidural) hematoma SDH Ischemic stroke Hemorrhage: SAH, ICH, IVH  <b>Cyst</b> Arachnoid cyst Dermoid cyst Epidermoid cyst Colloid cyst (3rd ventricle)	<b>Extradural</b> Degenerative: disc herniation, canal stenosis, spondylolisthesis/spondylolysis Infection/inflammation: osteomyelitis, discitis Ligamentous: OPLL Trauma: mechanical compression/instability, hematoma Tumours (55% of all spinal tumours): lymphoma, metastases (lymphoma, lung, breast, prostate), neurofibroma  <b>Intradural Extradural</b> Vascular: dural AVF, SDH (especially if on anticoagulants) Tumours (40% of all spinal tumours): meningioma, schwannoma, neurofibroma  <b>Intradural Intramedullary</b> Tumours (5% of all spinal tumours): gliomas, ependymomas, hemangioblastomas, and dermoids Syringomyelia: trauma, congenital, idiopathic Infectious/inflammatory: TB, sarcoid, transverse myelitis Vascular: AVM, ischemia	<b>Neuropathies</b> Traumatic Entrapments Iatrogenic Inflammatory Tumours

## INTRACRANIAL PATHOLOGY

### Intracranial Pressure Dynamics

**Table 2. Approach to Intracranial Pathology**

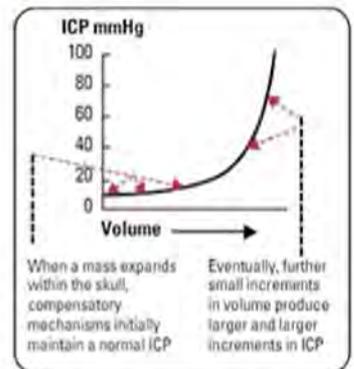

Issue	Time Frame	Features
Vascular	Sudden	No H/A = occlusive H/A = hemorrhagic
Metabolic	Hours to days	Affects entire CNS
Infectious	Days to weeks	Often a source of infection or immunodeficiency on history
Tumour	Months	Increased ICP: Initially → H/A Constant Progressive Severe Worse in morning and/or wakes from sleep As ICP increases: Blurry vision Projectile vomiting (may initially present without nausea) Severely raised ICP: Cushing's triad 1. Bradycardia 2. HTN 3. Respiratory irregularity

**Table 3. Consequences of Common Brain Lesions**

Location of Lesion	Consequence
<b>Frontal Lobe</b> Usually large lesions produce symptoms	Abulia, disinhibition, apathy, executive dysfunction, deficits in orientation and judgment, $\pm$ primitive reflex re-emergence, $\pm$ contralateral UMN signs (upgoing Babinski reflex and pronator drift)
<b>Frontal Eye Fields</b>	Gaze deviation toward side of a destructive lesion Gaze deviation away from irritative lesion (i.e. seizure)
<b>Broca's Area</b> Posterior inferior frontal gyrus of dominant hemisphere	Non-fluent, dysarthric, aphasia Repetition impaired Comprehension spared
<b>Occipital Lobe</b>	Contralateral homonymous hemianopia
<b>Parietal Lobe</b> Either side Dominant side (left) Non-dominant side (right)	Dressing apraxia, cortical sensory loss, lower homonymous quadrantanopia Inattention or extinction of non-dominant side Aphasias, Gerstmann's syndrome Hemispatial neglect, apraxias, agnosias (if temporal involvement)
<b>Temporal Lobe</b>	Hippocampus: anterograde amnesia Upper homonymous hemianopia Wernicke's aphasia (if left/dominant side)
<b>Wernicke's Area</b> Posterior superior temporal gyrus of dominant hemisphere	Fluent aphasia Repetition impaired Comprehension impaired
<b>Basal Ganglia</b>	Resting tremor Chorea Athetosis Hemiplegia if IC involved
<b>Subthalamic Nucleus</b>	Contralateral hemiballismus
<b>Brainstem</b>	Absent brainstem reflexes: oculocephalic, oculovestibular, corneal, gag, and cough Dorsal midbrain/pineal gland: Parinaud's syndrome (supranuclear upward gaze palsy) Pons: locked-in syndrome Below red nucleus: decerebrate posture Above red nucleus: decorticate posture Reticular activating system (midbrain): reduced level of arousal CPA: disequilibrium, ataxia, and CN V, VII, VIII deficits
<b>Cerebellar Hemisphere</b>	Intention tremor Ipsilateral limb ataxia Fall towards side of lesion
<b>Cerebellar Vermis</b>	Truncal ataxia Dysarthria

### ICP/Volume Relationship

- **Monro-Kellie doctrine:** the brain is encased in a rigid skull with constant intracranial volume
  - the intracranial space contains CSF, blood, and brain
- the increase in one constituent will: 1) necessitate the redistribution of CSF, blood, and/or brain; and 2) increase ICP
- compensatory mechanisms initially maintain a normal ICP
- **compensatory reserve (spatial compensation):** 60-80 mL in young people, 100-140 mL in elderly (largely due to cerebral atrophy)
  - immediate: egress of CSF through foramen magnum to spinal canal, displacement of venous blood from sinuses into jugular veins
- once compensation is exhausted, ICP rises exponentially:
  - late: displacement of arterial blood (decreased CPP) eventually leading to ischemia, increasing brain edema, or expanding mass displaces parenchyma into compartments under less pressure (see Table 4, NS7)
  - end: cessation of cerebral perfusion when  $ICP > MAP$ , cerebral herniation down into foramen magnum

**Figure 5. ICP volume curve**  
Adapted from: Lindsay KW, Bone I, Fuller G. Neurology and Neurosurgery illustrated. © 2004. With permission from Elsevier

## Cerebral Blood Flow

- brain receives about 15% of cardiac output (~750 mL/min)
- CBF is the vital parameter for brain function, it depends on CPP and CVR
- CPP is the difference between MAP and ICP (normal CPP >50 mmHg)
- cerebral autoregulation: mechanism that maintains constant CBF despite changes in CPP, unless:
  - high ICP such that CPP <40 mmHg
  - MAP >150 mmHg or MAP <50 mmHg (these setpoints can be higher in hypertensives, thus important to avoid hypotension)
  - increased CO<sub>2</sub> = increased CBF via vasodilation
  - O<sub>2</sub> <50 mmHg = increased CBF via vasodilation
  - brain injury: e.g. SAH, severe trauma

## ICP Measurement

- normal ICP 10-15 mmHg for adult, 3-7 mmHg for child, 1.5-6 mmHg for infant; varies with patient position
- ICP >25 mmHg → end-organ damage possible, treatment should be initiated
- ICP >40 mmHg → life-threatening emergency, urgent pressure reduction required
  - ICP measurements should be considered in the context of underlying pathology when evaluating severity

### Acute Monitoring

- indications include: severe TBI (GCS <8T) + abnormal CT; or severe TBI and normal CT if two or more of: age >40, BP <90 mmHg, or abnormal motor posturing
- methods:
  - intraventricular catheter (EVD) is the "gold standard"; most accurate method and allows therapeutic drainage of CSF
  - parenchymal ICP monitor
  - non-invasive methods (e.g. transcranial Doppler, CT/MRI, funduscopy, etc.) fail to measure ICP accurately enough to be used as routine measurement techniques

### Chronic Monitoring

- Licox monitor (intraventricular, intraparenchymal, subdural), subarachnoid bolt (Richmond screw), and epidural monitor

## Elevated ICP

### Etiology

- **pathologic structure**
  - intracranial mass (tumour, cyst)
  - cerebral edema
    - vasogenic: BBB compromised (meningitis, hypertensive encephalopathy, tumour, late ischemia)
    - cytotoxic: BBB intact (cell death in: early ischemia, brain injury, encephalitis, status epilepticus)
    - interstitial: transudation of CSF into periventricular white matter in hydrocephalus
    - osmotic: osmotic gradient increases intracellular free H<sub>2</sub>O (acute hyponatremia, hepatic encephalopathy)
  - other space occupying lesions: depressed skull fracture, foreign body, pus/empyema
- **increased intracranial blood volume**
  - space occupying blood: epidural and subdural hematomas, intraparenchymal and subarachnoid hemorrhages
  - venous obstruction (venous sinus thrombosis, superior vena cava syndrome, cor pulmonale, venous sinus compression)
  - impaired autoregulation (hypotension, HTN, brain injury, status epilepticus)
  - vasodilation (increased pCO<sub>2</sub>/decreased pO<sub>2</sub>/decreased extracellular pH)
- **increased intracranial CSF volume** (see *Hydrocephalus, Table 7, NS9*)
  - non-obstructive: increased production (rare, choroid plexus papilloma, secretory vestibular schwannoma), decreased absorption (e.g. post-traumatic, post-SAH/IVH, post-meningitis)
  - obstructive: blockage in CSF pathway
- **idiopathic intracranial HTN** (pseudotumour cerebri; see *Idiopathic Intracranial Hypertension, NS8*)

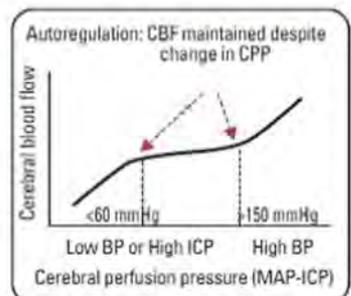

CBF = CPP / CVR  
CPP = MAP - ICP

### MAP Targets in Trauma

TBI: MAP >80 mmHg  
SCI: MAP between 85-90 mmHg in first 7 d post injury

**Figure 6. Cerebral autoregulation curve**

Adapted from: Lindsay KW, Bone I, Fuller G. Neurology and Neurosurgery Illustrated. © 2004. With permission from Elsevier

LP can be used for ICP monitoring, although it is not the most accurate. LP can precipitate tonsillar and uncal herniation with elevated ICP. This procedure is absolutely contraindicated in the setting of suspected acutely raised ICP or obstructive hydrocephalus, and relatively contraindicated with known/suspected intracranial mass

### Consider Monitoring ICP in the Following Situations

- Patients with an abnormal head CT (SAH, hematoma, contusion, basal cistern compression, swelling, and herniation), and GCS score ≤8 after CPR
- OR
- Patients with a normal head CT and GCS score of ≤8 AND the presence of two or more of the following:
  - >40 yr
  - Unilateral or bilateral motor posturing
  - sBP <90 mmHg
  - Postoperative monitoring
  - Investigation of NPH

### Cautioned Medication Use in Elevated ICP

- Nitroprusside: can raise ICP in patients with intracranial mass lesions due to direct vasodilation (arterial > venous)
- Nitroglycerine: can raise ICP via vasodilation but less so than nitroprusside because venous > arterial
- Succinylcholine: induced fasciculations may increase ICP

Clinical Features

Table 4. Clinical Features of Elevated ICP

Clinical Features	Acutely Elevated ICP	Chronic Progressive ICP Elevation
Headache	Both aggravated by stooping, coughing, and straining (Valsalva) Morning H/A: vasodilation due to increased CO <sub>2</sub> with recumbency	
Nausea and Vomiting	Present in both, though greater predilection in acutely elevated ICP	
LOC	Lethargy if ICP = dBP or midbrain compression	Irritability, inattentiveness. Normal or modestly reduced LOC, confusion
GCS	Significant decline in GCS Best index to monitor progress and predict outcome of acute intracranial process (see <i>Neurotrauma, NS35</i> )	Can be unchanged or modestly decreased
Optic Disc Changes	Subtle changes suggesting papilledema (subtle elevations in disc margin, mild disc hyperemia) ± retinal hemorrhages (may take 24-48 h to develop)	Obvious papilledema
Visual Changes	Less common. Often not affected initially; however, visual obscurations, flickering, or blurring can occur	Optic atrophy/blindness due to chronic papilledema Enlarged blind spot, if advanced → episodic constrictions of visual fields ("grey-outs" lasting ~20 min) Differentiate from papillitis (usually unilateral with decreased visual acuity)
Extraocular Movements	Less common. CN VI palsy: due to long intracranial course, more sensitive to ICP changes and thus earlier sign of acutely increased ICP Often falsely localizing (causative lesion remote to nerve) Upward gaze palsy and sunset eyes (especially in children with obstructive hydrocephalus due to pressure on tectal plate)	Often full extraocular movement
Herniation Syndromes	Often occur	Present if acute-on-chronic presentation
Neurologic Deficits	Focal deficits present	Focal deficits can be present

Blood-Brain Barrier (BBB)

Glucose and amino acids cross slowly  
Non-polar/lipids cross fast

Infarction/neoplasm → destroy tight junctions → vasogenic edema

Cushing's Triad of Acute Raised ICP

(Full triad seen in 1/3 of cases)

- Bradycardia (late finding)
- HTN
- Irregular respiratory pattern

Papilledema

- Optic disc swelling with blurred margins (most commonly bilateral)
- Larger blind spot

Investigations

- patients with suspected elevated ICP require an urgent CT/MRI to identify etiology, assess for MLS/herniation
- ICP monitoring where appropriate

Herniation Syndromes

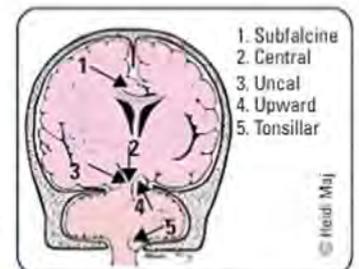

Figure 7. Herniation types

Table 5. Herniation Syndromes

Herniation Syndrome	Definition	Etiology	Clinical Features
1. Subfalcine	Cingulate gyrus herniates under falx	Lateral supratentorial lesion	Usually asymptomatic Warns of impending transtentorial herniation Risk of anterior cerebral artery (ACA) compression
2. Central Tentorial (Axial)	Displacement of diencephalon through tentorial notch	Supratentorial midline lesion Diffuse cerebral swelling Late uncal herniation	Small pupils, moderately dilated, fixed (rostral to caudal deterioration), sequential failure of diencephalon, medulla Decreased LOC (midbrain compression), extraocular movement (EOM)/upward gaze impairment ("sunset eyes"): compression of pretectum and superior colliculi (Parinaud's syndrome) Risk of posterior cerebral artery (PCA) compression Brainstem (Duret) hemorrhage: secondary to shearing of basilar artery perforating vessels DI (traction on pituitary stalk and hypothalamus), end-stage sign
3. Lateral Tentoria (Uncal)	Uncus of temporal lobe herniates down through tentorial notch	Lateral supratentorial lesion (often rapidly expanding traumatic hematoma)	Ipsilateral non-reactive dilated pupil (earliest, most reliable sign) + ipsilateral EOM paralysis, ptosis (CN III compression) Decreased LOC (midbrain compression) Risk of PCA compression Contralateral hemiplegia ± extensor (upgoing) plantar response ± ipsilateral hemiplegia ("Kernohan's notch" – a false localizing sign resulting from pressure from the edge of the tentorium on the contralateral cerebral peduncle)
4. Upward	Cerebellar vermis herniates through tentorial incisura	Posterior fossa mass, brainstem or cerebellar infarction, exacerbated by ventriculostomy or ventriculoperitoneal (VP) shunt	Cerebellar infarct (superior cerebellar artery (SCA) compression) Hydrocephalus (cerebral aqueduct of Sylvius compression)
5. Tonsillar	Cerebellar tonsils herniate through foramen magnum	Infratentorial lesion Following central tentorial herniation Following LP in presence of intracranial mass lesion	Neck stiffness and head tilt (tonsillar impaction) Decreased LOC (midbrain compression) Flaccid paralysis Respiratory irregularities, respiratory arrest (compression of medullary respiratory centres) Blood pressure instability (compression of medullary cardiovascular centres)

## Treatment of Elevated ICP

- treatment principle: treat primary etiology (i.e. remove mass lesions, ensure adequate ventilation e.g. in acute respiratory distress syndrome (ARDS))
- if elevated ICP persists following treatment of primary cause, consider therapy when ICP >20 mmHg
- targets: ICP <20 mmHg, CPP 60-70 mmHg, sBP >100 (ages 50-69) or >110 (age <50 or >70) mmHg (individualize targets based on patient's clinical picture and progression)

**Table 6. Management of Elevated ICP**

Consideration	Intervention	Rationale
<b>Conservative Measures</b>		
Position	Elevate head of bed at 30° Maintain neck in neutral position	Increases 1. Jugular venous patency 2. Intracranial venous outflow with minimal effect on MAP
Fever Management	Acetaminophen or mechanical cooling	Decrease basal metabolic and oxygen demands in order to minimize brain injury
Prevent Hypotension	PRN: fluid, vasopressors, dopamine, norepinephrine	Maintains CBF
Normocarbida	Ventilate to pCO <sub>2</sub> 35-40 mmHg	Prevents vasodilation
Adequate O <sub>2</sub>	Target pO <sub>2</sub> >60 mmHg	Prevents hypoxic brain injury
Osmolar Diuresis	Mannitol 20% IV solution 1-1.5 g/kg, then 0.25 g/kg q6 h to serum osmolality of 315-320 mOsm/kg Acts in 15-30 min, maintain sBP >100 mmHg Hypertonic saline 3% comparable to mannitol	Increases serum tonicity → osmotically drives fluid out of brain
Corticosteroids	Dexamethasone	Decrease vasogenic edema over subsequent days around brain tumour, abscess, blood No proven value in head injury or stroke
<b>Aggressive Measures</b>		
Sedation	Usually propofol Others: barbiturates/codeine, or fentanyl/MgSO <sub>4</sub> Light = barbiturates/codeine Heavy = fentanyl/MgSO <sub>4</sub>	Reduces sympathetic tone Reduces HTN induced by muscle contraction
Paralysis	Vecuronium	Reduces sympathetic tone Reduces HTN induced by muscle contraction
Barbiturate-Induced Coma (refractory ICP)	Phenobarbital 10 mg/kg over 30 min, then 1 mg/kg q1h continuous infusion	Reduce CBF and metabolism Decreases mortality, but no effect on neurologic outcome No role for the use of hypothermia in head injury
Hyperventilate	Target pCO <sub>2</sub> 30-35 mmHg Avoid within 24 h following trauma	Decreases CBF and thus ICP, but use for brief periods only
Drain CSF	Insert EVD (if acute) or shunt Drain 3-5 mL CSF	Reduces intracranial volume
Decompression	Decompressive craniectomy	Allows brain to swell while reducing risk of herniation

### Treatment of Elevated ICP

- ICP HEAD**  
 Intubate  
 Calm (sedate)/Coma  
 Place drain/Paralysis  
 Hyperventilate  
 Elevate head  
 Adequate BP  
 Diuretic (mannitol)

### Trial of Decompressive Craniectomy for Traumatic Intracranial Hypertension

NEJM 2016;375:1119-1130

**Purpose:** To compare the effect of decompressive craniectomy on clinical outcomes to that of medical management in patients with traumatic brain injury (TBI) and refractory intracranial hypertension (HTN).

**Methods:** Patients with TBI and refractory intracranial HTN >25 mmHg were randomized to undergo decompressive craniectomy or receive ongoing medical care. Primary outcome was Extended Glasgow Outcome Scale at 6 mo.

**Results:** Patients treated with decompressive craniectomy had lower mortality rates (26.9% vs. 48.9%) but higher rates of disability (8.5% vs. 2.1% lower severe disability, 21.9% vs. 14.4% upper severe disability, 15.4% vs. 8.0% moderate disability).

**Conclusion:** Compared to medical care, decompressive craniectomy in patients with TBI and refractory intracranial HTN results in lower mortality but higher rates of vegetative state and severe disability.

## Idiopathic Intracranial Hypertension (Pseudotumour Cerebri)

### Definition

- raised ICP with papilledema, but without: mass, hydrocephalus, infection, or hypertensive encephalopathy (diagnosis of exclusion)
- diagnosed by modified Dandy's criteria

### Etiology

- unknown (majority), but associated with:
  - vascular: dural venous sinus thrombosis
  - habitus/diet: obesity, hypervitaminosis A
  - endocrine: reproductive age, menstrual irregularities, Addison's/Cushing's disease
  - hematologic: iron deficiency anemia, polycythemia vera
  - drugs: steroid withdrawal, tetracycline, amiodarone, lithium, nalidixic acid, oral contraceptive, growth hormone, retinoids
- risk factors overlap with those of venous sinus thrombosis; similar to those for gallstones ("fat, female, fertile, forties")

### Epidemiology

- incidence: general population ~1-2 in 100000 per yr; women of childbearing age with obesity 19-21 in 100000 per yr

### Modified Dandy's Criteria

1. Symptoms of raised ICP
2. No localizing signs except CN VI palsy
3. Patient awake and alert
4. Normal neuroimaging without evidence of thrombosis
5. LP opening pressure >25 cm H<sub>2</sub>O, normal CSF
6. No better explanation for raised ICP

**Clinical Features**

- symptoms: H/A in >90%, nausea, transient visual obscurations, pulsatile tinnitus, diplopia can occur with CN VI palsy, neck/back pain
- signs: CN VI palsy can occur (otherwise no neurologic deficits), visual acuity and field deficits, papilledema, optic atrophy
- morbidity: risk of blindness and severe visual impairment (6-24% risk) are the major morbidity of idiopathic intracranial hypertension (IIH), but are not reliably correlated to duration, symptoms, or clinical course
- clinical course: usually self-limited, recurrence in 10%, chronic in some

**Investigations**

- MRI brain (with and without contrast): slit-like ventricles and distended perioptic subarachnoid space, but otherwise normal
  - rule out: venous sinus thrombosis, mass, infection, hydrocephalus
- LP findings
  - opening pressure >25 cmH<sub>2</sub>O
  - normal CSF analysis
- ophthalmologic: fields, acuity, papilledema

**Treatment**

- lifestyle change: encourage weight loss, fluid/salt restriction
- pharmacotherapy: acetazolamide (decreases CSF production), thiazide diuretic, or furosemide; discontinue offending medications
- surgery: if above fail, serial LPs (temporizing), optic nerve sheath fenestration (if progressive impairment of visual acuity), shunt placement (ventriculo-peritoneal, lumbo-peritoneal)
- long term: 2 yr follow-up, repeat imaging to rule out occult tumour, ophthalmology follow-up

**Hydrocephalus**

• for hydrocephalus in children, see *Paediatric Neurosurgery, NS42*

**Definition**

- accumulation of excess CSF in the brain, functionally divided into obstructive and communicating
  - flow of CSF: produced by choroid plexus, lateral ventricles → foramen of Monro → 3rd ventricle → cerebral aqueduct of Sylvius → 4th ventricle → foramen of Luschka (lateral) and Magendie (medial) → subarachnoid space where CSF is reabsorbed by arachnoid villi/granulations into dural venous sinuses

**Classification**

**Table 7. Classification of Hydrocephalus**

Disorder	Definition	Etiology	Findings on CT/MRI
<b>Obstructive (Non-Communicating) Hydrocephalus</b>	CSF circulation blocked within ventricular system proximal to the arachnoid granulations	<p><b>Acquired</b></p> <p><b>Aqueductal stenosis:</b> adhesions after infection, hemorrhage; gliosis, tumour (e.g. medulloblastoma)</p> <p><b>Intraventricular lesions:</b> tumours, e.g. 3rd ventricle colloid cyst, hematoma</p> <p>Mass causing tentorial herniation causing aqueduct/4th ventricle compression</p> <p><b>Others:</b> neurosarcooidosis, abscess/granulomas, arachnoid cysts</p> <p><b>Congenital</b></p> <p>Primary aqueductal stenosis, Dandy-Walker malformation, Arnold-Chiari malformation, myelomeningocele, encephalocele (see <i>Paediatric Neurosurgery, NS42</i>)</p>	<p>Ventricular enlargement proximal to block (enlarged temporal horns, ballooning frontal and/or occipital horns, enlarged 3rd &amp; 4th ventricles)</p> <p>Periventricular hypodensity/lucency (transependymal migration of CSF forced into extracellular space)</p> <p>Sulcal effacement, reduced visibility of Sylvian and interhemispheric fissures</p>
<b>Non-Obstructive (Communicating) Hydrocephalus</b>	Most commonly CSF absorption blocked at extraventricular site = arachnoid granulations, rarely CSF absorption is overwhelmed by increased production	<p>Post-infectious (#1 cause) = meningitis, abscess, cysticercosis</p> <p>Post-hemorrhagic (#2 cause) = SAH, IVH, traumatic</p> <p>Leptomeningeal carcinomatosis – metastatic meningitis</p> <p>Choroid plexus papilloma</p> <p>Idiopathic → NPH</p>	All ventricles dilated
<b>Normal Pressure Hydrocephalus (NPH)</b>	Persistent ventricular dilation in the context of normal CSF pressure	<p>Idiopathic (50%)</p> <p>Others: SAH, meningitis, trauma, radiation-induced</p>	Enlarged ventricles without increased prominence of cerebral sulci
<b>Hydrocephalus Ex Vacuo</b>	Ventricular enlargement resulting from atrophy of surrounding brain tissue	<p>Normal aging</p> <p>Degenerative dementias: Alzheimer's, frontotemporal, Creutzfeldt-Jakob disease (see <i>Neurology, N27</i>)</p>	Enlarged ventricles and sulci Cerebral atrophy

**Effect of Acetazolamide on Visual Function in Patients with Idiopathic Intracranial Hypertension and Mild Visual Loss (IHHT)**  
JAMA 2014;311(16):1641-1651

**Purpose:** To determine whether acetazolamide and a low-sodium weight reduction diet is beneficial in improving vision compared to diet alone in patients with IHH and mild visual loss.

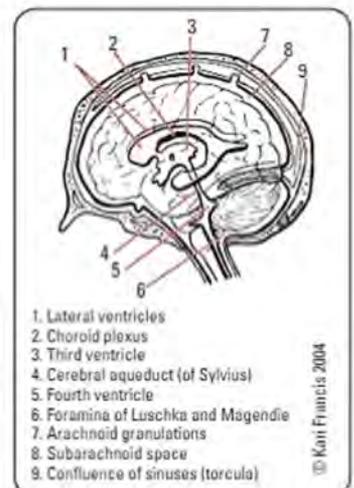

**Methods:** 165 patients were randomized to either a low-sodium weight-reduction diet plus the maximally tolerated dosage of acetazolamide or placebo for 6 mo.

**Results:** Acetazolamide was superior to placebo with regards to perimetric mean deviation improvement (P<0.05), papilledema grade improvement (P<0.001), vision-related quality of life (P<0.003), and weight reduction (P<0.001).

**Conclusion:** Acetazolamide with low-sodium weight-reduction diet resulted in improvement in visual field function in patients with IHH and mild visual loss.

CSF production = CSF reabsorption = ~ 500 mL/d in normal adults  
Normal CSF volume ~150 mL (50% spinal, 50% intracranial = 25 mL intraventricular, 50 mL subarachnoid)

**Figure 8. The flow of CSF**

### Etiology

- impaired CSF dynamics
  - obstruction of CSF flow
  - decreased CSF absorption
  - increased CSF production (rarely in choroid plexus papilloma 0.4-1% of intracranial tumours)
- congenital and acquired causes

### Epidemiology

- estimated prevalence 1-1.5%; incidence of congenital hydrocephalus ~1-2 in 1000 live births

### Clinical Features

- acute hydrocephalus: signs and symptoms of acutely elevated ICP (see Table 4, NS7)
- chronic/gradual onset hydrocephalus: (wk to mo; i.e. NPH) presents with a classic triad (Hakim's triad)
  - Ataxia (magnetic gait) + apraxia (pressure of ventricle on lower extremity motor fibres → gait disturbance)
  - Incontinence (pressure on cortical bowel/bladder centre)
  - Dementia (subcortical)

### Investigations

- imaging
  - CT/MRI findings (see Table 7, NS9)
  - ultrasound (through anterior fontanelle in infants): ventriculomegaly, size and location of lesions (e.g. IVH)
  - mantle radionuclide cisternography can test CSF flow and absorption rate (unreliable)
- ICP monitoring (e.g. LP, EVD) may be used to investigate NPH and test response to shunting (lumbar tap test)

### Treatment

- EVD (acute hydrocephalus, intraventricular hemorrhage)
- intermittent LPs for transient communicating hydrocephalus (SAH, IVH in premature infants)
- eliminating obstruction (i.e. excision of mass, posterior fossa decompression for Chiari malformation)
- endoscopic
  - endoscopic third ventriculostomy (ETV) ± choroid plexus cauterization (for obstructive hydrocephalus)
  - endoscopic placement of aqueductal stent
- shunt
  - VP: most common shunt
  - ventriculopleural
  - ventriculoatrial (VA)
  - lumboperitoneal: for communicating hydrocephalus and pseudotumour cerebri

#### Classic (Hakim's) Triad of NPH

##### Progression

"Wet, wacky, wobbly": Incontinence, dementia, ataxia

#### Important Features to Note on CT and MRI (± contrast enhancement)

- Lesions (± edema, necrosis, hemorrhage)
- MLS and herniations
- Effacement of ventricles and sulci (often ipsilateral), basal cisterns
- Single or multiple (multiple implies metastasis)

#### Complications of Specific Hydrocephalus Treatments

- VP Shunt: intra-abdominal cysts, adhesions, ascites
- VA Shunt: greater infection risk, septicemia, emboli
- Ventriculopleural Shunt: pleural effusion, hydrothorax, respiratory distress
- LP Shunt: radiculopathy, CSF leaks, adhesions, arachnoiditis
- ETV: 56% success rate, hypothalamic injury, iatrogenic basilar aneurysm

### Shunt Complications

Table 8. Shunt Complications

Complication	Etiology	Clinical Features	Investigations
<b>Obstruction</b> (most common)	Obstruction by choroid plexus Buildup of proteinaceous accretions, blood, cells (inflammatory or tumour)	Acute hydrocephalus signs and symptoms of increased ICP	"Shunt series" (plain x-rays of entire shunt that only rule-out disconnection, break, tip migration)
Proximal Catheter	Infection		CT
Valve	Disconnection or damage		Radionuclide "shuntogram"
Distal Catheter			
<b>Infection</b> (3-6%)	<i>S. epidermidis</i> <i>S. aureus</i> <i>P. acnes</i> Gram-negative bacilli	Fever, N/V, anorexia, irritability Meningitis Peritonitis Signs and symptoms of shunt obstruction Shunt nephritis (VA shunt)	CBC Blood culture Tap shunt for C&S (LP usually NOT recommended)
<b>Overshunting</b> (10% over 6.5 yr)	Slit ventricle syndrome, collapse of ventricles leading to occlusion of shunt ports by ependymal lining  SDH Collapsing brain tears bridging veins (especially common in NPH patients)	Chronic or recurring H/A often relieved when lying down  Asymptomatic H/A, vomiting, somnolence	CT/MRI Slit-like ventricles on imaging  CT
	Secondary craniosynostosis (children): apposition and overlapping of the cranial sutures in an infant following decompression of hydrocephalus	Abnormal head shape	Clinical CT
<b>Seizures</b> (5.5% risk in 1st yr, 1.1% after 3rd yr)	Ventricular shunts only		EEG
<b>Inguinal hernia</b> (13-15% incidence when shunt inserted in childhood)	Increased intraperitoneal pressure/fluid results in hernia becoming apparent	Inguinal swelling, discomfort	U/S

## Spontaneous Intracranial Hypotension

### Definition

- low CSF pressure + postural headache secondary to CSF leak
- symptoms not attributable to another disorder, no recent history of dural puncture

### Etiology

- CSF leakage from the thecal sac within or along the spinal canal

### Epidemiology

- incidence: ~2-5 in 100000 per yr, but likely underdiagnosed; M:F=1:2
  - can occur at any age, but most frequently in 4th or 5th decade

### Clinical Features

- **symptoms:** orthostatic H/A in 75-80%, tinnitus or auditory disturbance ("underwater feeling") in 50%, dizziness in 50%, nausea, vomiting, photophobia, meningismus
- **signs:** CN III, CN IV, CN VI palsy in <10%
- **morbidity:** misdiagnosis and underdiagnosis are common, leading to delays in treatment and inappropriate treatment for mimickers of intracranial hypotension
- **clinical course:** usually self-limited, recurrence in 10%, chronic in some

### Investigations

- MRI brain with contrast: sagging of the brain (e.g. low cerebellar tonsils), pachymeningeal enhancement, subdural hematoma or hygroma, pituitary hyperemia
- MRI spine with contrast: extrathecal fluid collections/extrathecal contrast accumulation and/or meningeal diverticula
- CT myelogram with contrast: preferred method to diagnose and localize CSF leak
  - digital subtraction myelogram (DSM): combines fluoroscopy and ability to subtract background images to visualize small CSF leaks by contrast extravasation
- LP: opening pressure <6 cmH<sub>2</sub>O; xanthochromia, elevated protein, lymphocytic pleocytosis

### Treatment

- conservative management: bed rest, hydration, caffeine, possibly theophylline
- epidural blood patch: mainstay treatment; autologous blood (10-20 mL) injected into epidural space
- surgery: indicated if epidural blood patches are ineffective and site of leak has been localized

## CNS Tumours

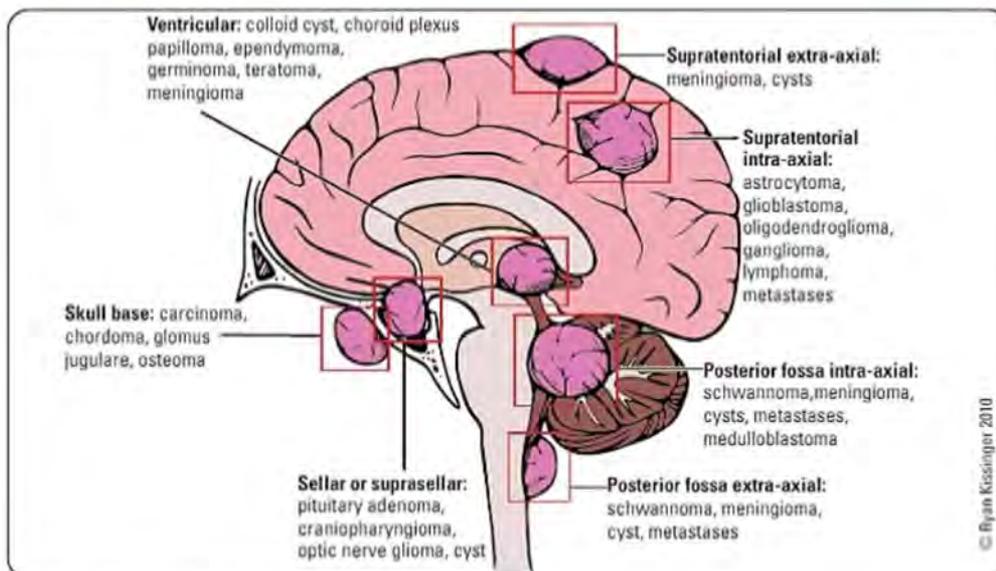

Figure 9. Tumours of the CNS

### Classification

- benign vs. malignant, primary vs. metastatic (e.g. primary in breast, lung), intra-axial (parenchymal) vs. extra-axial, supratentorial vs. infratentorial, adult vs. paediatric
- benign: non-invasive, but can be devastating due to mass effect in fixed volume of skull (e.g. most meningiomas)
- malignant: implies rapid growth, invasiveness, possibly drop-metastases to spinal cord from a primary CNS tumour (rare)

DDx for Ring Enhancing Lesion on CT with Contrast

MAGICAL DR  
Metastases\*  
Abscess\*  
Glioblastoma (high-grade glioma)\*  
Infarct  
Contusion  
AIDS (toxoplasmosis)  
Lymphoma  
Demyelination  
Resolving hematoma, Radiation Necrosis  
(\*3 most common diagnoses)

Ring Enhancing Lesions in Patients with HIV

DDx: Toxoplasmosis or CNS lymphoma  
Treatment: Empiric treatment with pyrimethamine and sulfadiazine; brain biopsy if no resolution with antimicrobial therapy  
Primary CNS lymphoma reported in 6-20% of HIV infected patients!

Primary Brain Tumours  
Rarely undergo metastasis  
Adults = mostly supratentorial  
Children = mostly infratentorial

- Based on the 2021 WHO Classification of Tumours of the CNS guideline which integrates molecular diagnostics with other diagnostic approaches (i.e. immunohistochemistry, histology)

**Table 9. WHO 2021 Classification of Tumours of the CNS****Gliomas, Glioneuronal Tumours, Neuronal Tumours**

Adult-type diffuse gliomas	Astrocytoma, IDH-mutant Oligodendroglioma, IDH-mutant, and 1p/19q-codeleted Glioblastoma, IDH-wildtype
Paediatric-type diffuse low-grade gliomas	Diffuse astrocytoma, <i>MYB</i> - or <i>MYBL1</i> -altered Angiocentric glioma Polymorphous low-grade neuroepithelial tumour of the young Diffuse low-grade glioma, MAPK pathway-altered
Paediatric-type diffuse high-grade gliomas	Diffuse midline glioma, H3K27-altered Diffuse hemispheric glioma, H3G34-mutant Diffuse paediatric-type high-grade glioma, H3-wildtype and IDH-wildtype Infant-type hemispheric glioma
Circumscribed astrocytic gliomas	Pilocytic astrocytoma High-grade astrocytoma with piloid features Pleomorphic xanthoastrocytoma Subependymal giant cell astrocytoma Chordoid glioma Astroblastoma, <i>MNF</i> -altered
Glioneuronal and neuronal tumours	Ganglioglioma Desmoplastic infantile ganglioglioma/desmoplastic infantile astrocytoma Dysembryoplastic neuroepithelial tumour Diffuse glioneuronal tumour with oligodendroglioma-like features and nuclear clusters Papillary glioneuronal tumour Rosette-forming glioneuronal tumour Myxoid glioneuronal tumour Diffuse leptomeningeal glioneuronal tumour Gangliocytoma Multinodular and vacuolating neuronal tumour Dysplastic cerebellar gangliocytoma (Lhermitte-Duclos disease) Central neurocytoma Extraventricular neurocytoma Cerebellar liponeurocytoma
Ependymal tumours	Supratentorial ependymoma (including <i>ZFTA</i> fusion-positive or <i>YAP1</i> fusion-positive) Posterior fossa ependymoma (including group PFA and PFB) Spinal ependymoma (including <i>MYCN</i> -amplified) Myxopapillary ependymoma Subependymoma

**Choroid Plexus Tumours**

Choroid plexus papilloma  
Atypical choroid plexus papilloma  
Choroid plexus carcinoma

**Embryonal Tumours**

Medulloblastoma	Medulloblastomas, molecularly defined: WNT-activated, SHH-activated and <i>TP53</i> -wildtype, SHH-activated and <i>TP53</i> -mutant, non-WNT/non-SHH Medulloblastomas, histologically defined
Other CNS embryonal tumours	Atypical teratoid/rhabdoid tumour Cribriform neuroepithelial tumour Embryonal tumour with multilayered rosettes CNS neuroblastoma, <i>FOXR2</i> -activated CNS tumour with <i>BCOR</i> internal tandem duplication CNS embryonal tumour

**Pineal Tumours**

Pineocytoma  
Pineal parenchymal tumour of intermediate differentiation  
Pineoblastoma  
Papillary tumour of the pineal region  
Desmoplastic myxoid tumour of the pineal region, *SMARCB1*-mutant

**Cranial and Paraspinal Nerve Tumours**

Schwannoma  
Neurofibroma  
Perineurioma  
Hybrid nerve sheath tumour  
Malignant melanotic nerve sheath tumour  
Malignant peripheral nerve sheath tumour  
Paraganglioma

**Meningiomas**

**Table 9. WHO 2021 Classification of Tumours of the CNS**

<b>Mesenchymal, Non-Meningothelial Tumours</b>	
Soft tissue tumours	Fibroblastic and myofibroblastic tumours: solitary fibrous tumour Vascular tumours: haemangiomas and vascular malformations, hemangioblastomas Skeletal muscle tumours: rhabdomyosarcoma Uncertain differentiation: intracranial mesenchymal tumour, <i>FET-CREB</i> mutation positive, <i>CIC</i> -rearranged sarcoma, primary intracranial sarcoma, <i>DICER1</i> -mutant, Ewing sarcoma
Chondro-osseous tumours	Chondrogenic tumours: mesenchymal chondrosarcoma, chondrosarcoma Notochordal tumours: chordoma (including poorly differentiated chordoma)
<b>Melanocytic Tumours</b>	
Diffuse meningeal melanocytic neoplasms	Meningeal melanocytosis Meningeal melanomatosis
Circumscribed meningeal melanocytic neoplasms	Meningeal melanocytoma Meningeal melanoma
<b>Hematolymphoid Tumours</b>	
Lymphomas	CNS lymphomas: primary diffuse large B-cell lymphoma of the CNS, immunodeficiency-associated CNS lymphoma, lymphomatoid granulomatosis, intravascular large B-cell lymphoma Miscellaneous rare lymphomas in the CNS: MALT lymphoma of the dura, other low-grade B-cell lymphomas of the CNS, anaplastic large cell lymphoma ( <i>ALK+</i> / <i>ALK-</i> ), T-cell and NK/T-cell lymphomas
Histiocytic tumours	Erdheim-Chester disease Rosai-Dorfman disease Juvenile xanthogranuloma Langerhans cell histiocytosis Histiocytic sarcoma
<b>Germ Cell Tumours</b>	
Teratoma: mature, immature, somatic-type malignancy Germinoma Embryonal carcinoma Yolk sac tumour Choriocarcinoma Mixed germ cell tumour	
<b>Tumours of the Sellar Region</b>	
Adamantinomatous craniopharyngioma Papillary craniopharyngioma Pituitary, granular cell tumour of the sellar region, and spindle cell oncocytoma Pituitary adenoma/PitNET Pituitary blastoma	
<b>Metastases to the CNS</b>	
Metastases to the brain and spinal cord parenchyma Metastases to the meninges	

**Familial Syndromes Associated with CNS Tumours**

- ataxia telangiectasia
- Cowden syndrome
- familial adenomatous polyposis
- hereditary non-polyposis-related colorectal cancer
- Li-Fraumeni syndrome
- Gorlin syndrome
- neurofibromatosis types 1 & 2
- multiple endocrine neoplasia type 1
- tuberous sclerosis complex
- von Hippel-Lindau disease
- Turcot syndrome
- Lynch syndrome

**Investigations**

- CT, MRI with contrast, stereotactic biopsy (tissue diagnosis and molecular markers for prognosis), tumour resection (often performed as initial step rather than biopsy), metastatic workup, tumour markers (i.e. germ cell tumours)

**Treatment**

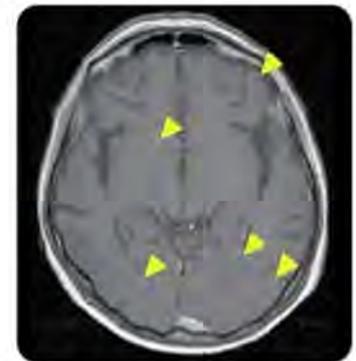

- conservative: serial history, physical, imaging for slow growing/benign lesions
- medical: corticosteroids to reduce ICP, cytotoxic cerebral edema; pharmacologic (i.e. pituitary adenoma)
- surgical: total or partial excision (decompressive, palliative)
- radiotherapy: conventional fractionated XRT, hypofractionated XRT, SRS (e.g. Gamma Knife®)
- chemotherapy: e.g. alkylating agents (i.e. temozolomide, vincristine, cyclophosphamide, etc.)
- targeted therapy: e.g. trastuzumab for HER2-positive breast cancer and brain metastases, osimertinib for EGFR-mutant lung cancer and brain metastases

New onset communicating hydrocephalus in a patient with cancer should raise the suspicion of leptomeningeal carcinomatosis

**Table 10. Tumour Location: Etiology and Clinical Features**

	Supratentorial	Infratentorial (Posterior Fossa)
<b>Epidemiology</b>		
<b>Age &lt;15 yr</b> Incidence: 2-5 in 100000 per yr 60% infratentorial	Glioma (all grades) (50%) Craniopharyngioma (2-5%) Others: pineal region tumours, choroid plexus tumours, ganglioglioma, dysembryoplastic neuroepithelial tumours (DNET)	Medulloblastoma (15-20%) Cerebellar astrocytoma (15%) Ependymoma (9%) Brainstem astrocytoma
<b>Age &gt;15 yr</b> 80% supratentorial	High-grade glioma (12-15%, e.g. GBM) Metastasis (15-30%, includes infratentorial) Meningioma (15-20%) Low-grade astrocytoma (8%) Pituitary adenoma (5-8%) Oligodendroglioma (5%) Other: colloid cyst, CNS lymphoma, dermoid/epidermoid cysts	Metastasis Acoustic neuroma (schwannoma) (5-10%) Hemangioblastoma (2%) Meningioma
<b>Clinical Features</b>		
<b>Shared Features (from elevated ICP)</b>	H/A: usually worse in AM and made worse with straining, coughing N/V Papilledema Diplopia - CN VI palsy	
<b>Distinguishing Features</b>	<b>Seizure:</b> commonly the first symptom <b>Progressive neurological deficits (70%)</b> <b>Frontal lobe:</b> hemiparesis, dysphasia, personality changes, cognitive changes <b>Temporal lobe:</b> auditory/olfactory hallucinations, memory deficits, contralateral superior quadrantanopia <b>Mental status change:</b> depression, apathy, confusion, lethargy "Tumour TIA" (transient ischemic attack) stroke like symptoms caused by a) occlusion of vessel by tumour cells b) hemorrhage c) 2° to "steal phenomenon" - blood is shunted from ischemic regions to non-ischemic regions Endocrine disturbance: pituitary tumours (see <a href="#">Endocrinology, E22</a> )	<b>Brainstem involvement:</b> CN deficits and long tract signs <b>N/V:</b> compression on vagal nucleus/area postrema <b>Diplopia:</b> direct compression CN VI <b>Vertigo</b> <b>Nystagmus</b> <b>Truncal ataxia + titubation:</b> cerebellar vermis lesions <b>Limb ataxia, dysmetria, intention tremor:</b> cerebellar hemisphere lesions <b>Obstructive hydrocephalus</b> more common than supratentorial lesions

**Figure 10. Multiple brain metastases (see arrows)**

## Metastatic Tumours

### Brain Metastasis

- most common intracranial tumour in adults (~50% of all brain tumours)
- afflict ~25% of patients with any cancer
- hematogenous spread most common
- 80% are hemispheric, often at grey-white matter junction or temporal-parietal-occipital lobe junction
  - likely emboli spreading to terminal middle cerebral artery (MCA) branches

### Investigations

- identify primary tumour
  - full metastatic workup CXR, CT chest/abdomen, abdominal U/S, nuclear medicine scan/PET, mammogram)
- CT with contrast → round, well-circumscribed, often ring enhancing, ++ edema, often multiple
- contrast-enhanced MRI more sensitive, especially for posterior fossa
- consider biopsy in unusual cases or if no primary tumour identified

### Treatment

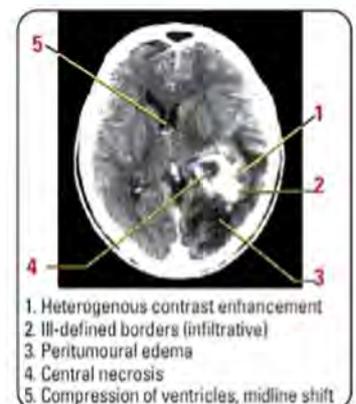

- medical
  - phenytoin (or levetiracetam) for seizure prophylaxis if patient presents with seizure
  - dexamethasone to reduce edema given with H2 blocker
  - role of chemotherapy limited because of poor penetration across BBB
  - targeted therapies are currently being investigated (e.g. EGFR (epidermal growth factor receptor) inhibitors in patients with EGFR-mutant lung cancer and brain metastases)
- radiation
  - SRS (highly focused fraction of radiation targeted to tumour): for discrete, deep-seated/inoperable tumours
  - multiple lesions: use WBRT (upwards of 10 lesions); consider SRS if <4-10 lesions
  - postoperative adjuvant radiotherapy consideration: SRS to surgical cavity following resection
  - emerging evidence supports avoidance of WBRT and use of focal radiation to spare cognitive functions (refer to Brown et al., 2016)
- surgical
  - single/solitary lesions or dominant lesion with significant mass effect or symptoms: surgical resection and radiation in carefully selected patients

**Most Common Cancers that Metastasize to the CNS**

Site of Primary	Frequency of CNS metastasis
Lung	44%
Breast	10%
Kidney (RCC)*	7%
GI	6%
Melanoma	3%

\*RCC=renal cell carcinoma

**Figure 11. High-grade glioma on CT**

### Prognosis

- median survival without treatment once symptomatic is ~1 mo, with optimal treatment 6-9 mo; may be prolonged survival in some patient subgroups (e.g. HER2/neu breast cancer, EGFR-mutant lung cancer)
- the disease-specific Graded Prognostic Assessment (DS-GPA) is a useful prognostic index
- depending on primary tumour type, prognosis may depend on a combination of patient age, Karnofsky score, extent of extracranial metastatic disease, number of intracranial lesions, and molecular disease subtype

## Adult Diffuse Gliomas

- most common primary intra-axial brain tumour, common in 4th-6th decades

**Table 11. WHO 2021 Diffuse Gliomas Classification**

Type	WHO Grade*	Typical CT/MRI Findings	Altered Molecular Profiles	Prognosis
Oligodendroglioma	2, 3	Low grade: areas of calcification on CT, ± enhancement  High grade: enhancement	Defining: IDH-mutant  Other: TERT promoter, CIC, FUBP1, NOTCH1	Low grade: ~10 yr  High grade: 5 yr
Astrocytoma	2, 3, 4	Low grade: mass effect, no enhancement  High grade: complex enhancement	Defining: IDH mutant and 1p/19q codeleted  Other: ATRX, TP53, CDKN2A/B	Low grade: 3 yr  High grade: 1.5-2 yr
Glioblastoma	4	Necrosis (ring enhancement)	Defining: IDH-wildtype  Other: TERT promoter, chromosomes 7/10, EGFR	15 mo

\*grade based on natural history

### Clinical Features

- sites: cerebral hemispheres >> cerebellum, brainstem, spinal cord
- symptoms: recent onset of new/worsening H/A, N/V, seizure, ± focal deficits or symptoms of increased ICP

### Investigations

- CT/MRI with contrast: variable appearance depending on grade
  - hypodense on CT, hypointense on T1 MRI, hyperintense on T2 MRI
  - low-grade: most do not enhance and have calcification on CT
  - high-grade: most enhance with CT contrast dye/gadolinium, possibly with central necrosis (especially if IDH wildtype)
  - histology during surgical resection or biopsy

### Treatment

- **low-grade diffuse gliomas**
  - close follow-up, radiation, chemotherapy, and surgery are all valid options
  - dedifferentiation to more malignant grade; typically occurs faster when diagnosed after age 45
  - surgery: maximal safe resection, not curative, trend towards better outcomes, provides tissue sample for histologic/molecular characterization
  - XRT alone or postoperative prolongs survival (retrospective evidence)
  - chemotherapy: initial therapy in all patients with high-risk low-grade glioma
- **high-grade diffuse gliomas**
  - goal is to prolong "quality" survival
  - surgery
    - gross total resection: maximal safe resection + fractionated radiation with 2 cm margin + concomitant and adjuvant temozolomide
      - except: nearing end-of-life; or extensive brainstem, bilateral, or dominant lobe GBM involvement
    - awake craniotomy for tumours in "eloquent" regions (e.g. speech and language regions or near motor strip)
    - stereotactic biopsy if resection not possible, followed by fractionated radiation with 2 cm margin
      - expectant: based on functional impairment Karnofsky score <70; patient's/family's wishes
    - chemotherapy: temozolomide (agent of choice); better response to temozolomide predicted by MGMT gene methylation
- **multicentric gliomas**
  - WBRT ± chemotherapy

#### Surgical Resection vs. Watchful Waiting in Low-Grade Gliomas

Ann Oncol 2017;28:1942-1948

**Purpose:** This study examined the effect of up-front surgery vs. watchful waiting for treatment of low-grade gliomas on long term survival.

**Methods:** The study was designed as a population-based parallel cohort study that compared outcomes from a hospital favouring watchful waiting (n=66 patients) and one favouring early resection (n=87 patients). Follow-up was between 7 and 18 yr post-diagnosis. The two groups were equivalent in terms of baseline parameters.

**Results:** Overall, survival was significantly better with early surgical resection. Patients from the centre favouring watchful waiting had a median survival of 5.8 yr (95% CI 4.5-7.2) whereas patients from the centre favouring early resection had a median survival of 14.4 yr (95% CI 10.4-18.5). The enhanced survival benefit remained after adjusting for molecular markers.

**Conclusions:** Early surgical resection of low-grade gliomas is associated with significantly improved overall survival compared to watchful waiting.

#### Comparison of a Strategy Favouring Early Surgical Resection vs. a Strategy Favouring Watchful Waiting in Low-Grade Gliomas

JAMA 2012;308(18):1881-1888

**Purpose:** To examine "watchful waiting" vs. early surgical resection of low-grade gliomas.

**Study:** A population-based parallel cohort study was undertaken between two hospitals that each favoured different management approaches for low-grade gliomas (biopsy and watchful waiting vs. early surgical resection).

**Results:** 66 patients were included from the watchful waiting hospital and 87 patients from the early resection centre. Median follow-up was 7.0 and 7.1 yr at each centre. The two groups were equivalent in terms of baseline parameters. Overall, survival was significantly better with early surgical resection (watchful waiting: median survival of 5.9 yr 95% CI, 4.5-7.3 vs. early resection: median survival was not reached due to prolonged length of life, P<0.01).

**Conclusions:** Early surgical resection of low-grade gliomas is associated with better overall survival as compared to watchful waiting.

#### Bevacizumab Plus Radiotherapy-Temozolomide for Newly Diagnosed Glioblastoma

NEJM 2014;370:709-722

**Purpose:** To evaluate the effect of combined bevacizumab and XRT-temozolomide in the treatment of newly diagnosed glioblastoma.

**Methods:** Patients with supratentorial GBM were randomly assigned to receive IV bevacizumab (n=458) or placebo plus XRT and oral temozolomide (n=463) for 30 wk total in cycles, followed by bevacizumab or placebo monotherapy. Outcomes were progression-free survival and overall survival.

**Results:** The median progression-free survival was longer in the bevacizumab group compared with placebo (10.6 mo vs. 6.2 mo, HR 0.64, 95% CI 0.55-0.74), although overall survival did not differ significantly between groups (HR 0.88, 95% CI 0.76-1.02). Baseline health-related quality-of-life and performance status were maintained longer in the bevacizumab group although there was a higher frequency of adverse events.

**Conclusions:** The addition of bevacizumab to XRT-temozolomide improves progression-free survival but not overall survival in patients with glioblastoma.

## Primary Central Nervous System Lymphoma

- highly aggressive, non-Hodgkin lymphoma confined to the CNS; ~95% are large B-lymphocyte
- brain + spinal cord, leptomeningeal, CSF, and ocular manifestations possible
- intracranial lesions predominantly supratentorial

### Clinical Features

- occurs in both immunocompetent and immunocompromised populations (multifocal lesions in 20-40% of immunocompetent patients, and in 30-80% of immunocompromised patients)
- epidemiology: 0.47 in 100000 per yr; M:F=1.35:1; age of onset 50-70 (30-40 in immunocompromised individuals)
- symptoms: focal neurological deficit, cognitive/behavioural symptoms ± increased ICP or seizures or CN palsies
  - blurred vision + floaters if ocular involvement
- high association with Epstein-Barr virus in patients with HIV

### Investigations

- CT: hyper- or iso-attenuated lesions; significant enhancement with contrast
- MRI with contrast (imaging of choice): intensely enhancing lesions, often localized to periventricular space
  - immunocompetent → homogenous enhancement ± minimal edema
  - immunocompromised → heterogenous or ring enhancement, necrosis, edema ± hemorrhage
  - restriction on diffusion imaging due to hypercellularity helpful to distinguish from other brain tumours
- confirmation by stereotactic biopsy and histopathology
  - corticosteroids may prevent histopathological diagnosis → avoid until biopsy complete when clinically possible

### Treatment

- chemotherapy: first-line treatment; induction therapy using MATRix regimen (high-dose methotrexate (HDMTX) + cytarabine + thiotepa + rituximab) preferred
- surgery: generally reserved for stereotactic biopsy; resection discouraged
- radiation: WBRT used in consolidation therapy and for palliation; consider as second-line induction therapy in HDMTX-ineligible patients
  - significant risk of neurotoxicity when combined with HDMTX

### Prognosis

- age and performance status are key prognostic factors
- median survival: 26 mo across all age groups; <7 mo for patients ≥70 yr old

## Meningioma

- most common **primary** intracranial tumour, arising from arachnoid cap cells
- sometimes calcified, often causes hyperostosis of adjacent bone (detectable on imaging)
- classically see Psammoma bodies ("meningocytic whorls") on histology
- location: 70% occur along the parasagittal convexity, falx cerebri, and sphenoid bone; other locations: tuberculum sellae, foramen magnum, olfactory groove, and CPA

### Clinical Features

- middle aged, slight female predominance (M:F=1:1.8), many express the progesterone receptor (increase in size with pregnancy)
- many are asymptomatic and can be an incidental finding; when symptoms occur focal neurologic deficits specific to location, ± seizures, symptoms of increased ICP
- molecular changes: between 40-80% of meningiomas contain mutations in chromosome 22 (involved in suppressing tumour growth); some have extra copies of *PDGFR* and *EGFR*; some are associated with mutations in the *NF2* gene

### Investigations

- CT with contrast: homogeneous, densely enhancing, along dural border ("dural tail"), well circumscribed, usually solitary (10% multiple, likely with loss of *NF2* gene/22q12 deletion)
- MRI with contrast: characterization of mass and provides a better assessment of the patency of dural venous sinuses
- angiography
  - most are supplied by external carotid feeders (meningeal vessels)
  - can assess venous sinus involvement, "tumour blush" commonly seen (prolonged contrast image)

### Treatment

- conservative management: asymptomatic and/or non-progressive on CT/MRI serial monitoring for interval growth changes
- surgery: often curative if complete resection and indicated when symptomatic and/or documented growth on serial CT/MRI

**Interim Results from the CATNON trial (EORTC study 26053-22054) of Treatment with Concurrent and Adjuvant Temozolomide for 1p/19q Non-co-deleted Anaplastic Glioma: a phase 3, randomised, open-label intergroup study**  
Lancet 2017;390(10103):1645-53

**Purpose:** To assess the use of radiotherapy with concurrent and adjuvant temozolomide in adults with non-co-deleted anaplastic gliomas.

**Methods:** Patients with newly diagnosed non-co-deleted anaplastic glioma were randomized to receive radiotherapy alone or with adjuvant temozolomide; or to receive radiotherapy with concurrent temozolomide 75 mg/m<sup>2</sup> per day, with or without adjuvant temozolomide. The primary endpoint was overall survival.

**Results:** Overall survival at 5 years was 55.9% (95% CI 47.2-63.8) with and 44.1% (36.3-51.6) without adjuvant temozolomide. Grade 3-4 adverse events were seen in 8-12% of 549 patients assigned temozolomide, and were mainly haematological and reversible.

**Conclusions:** Adjuvant temozolomide chemotherapy was associated with a significant survival benefit in patients with newly diagnosed non-co-deleted anaplastic glioma.

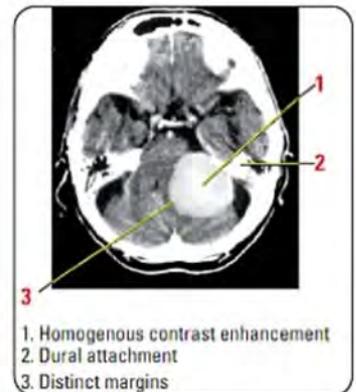

Figure 12. Meningioma on CT

**WHO Classification of Meningioma (by histology)**

- Grade 1: low-risk of recurrence
- Grade 2: intermediate risk of recurrence
- Grade 3: high-risk of recurrence

**Recommendations for Management of Meningiomas**

Lancet Oncol 2016;17(9):e383-391  
European Association of Neuro-Oncology assessed available literature, rated scientific evidence, and graded recommendation levels.

#### Key recommendations:

1. First standard therapy is gross total surgical resection (including involved dura).
2. Alternative treatments include radiosurgery for small tumours and fractionated XRT in larger previously treated tumours.
3. New treatment concepts combining surgery and radiosurgery/fractionated XRT to treat complete tumour volume are being developed.
4. Although pharmacological treatments are still experimental, antiangiogenic drugs, peptide receptor radionuclide therapy, and targeted agents are candidates for future pharmacological approaches to treat refractory meningioma of all WHO grades.

Activate Windows

Go to Settings to activate Windows.

- endovascular: embolization for highly vascularized, likely bloody, tumours to facilitate surgery
- radiation: SRS may be an option for lesions <3 cm partially occluding the superior sagittal sinus; SRS or XRT for non-resectable, recurrent atypical/malignant meningiomas

### Prognosis

- 5 yr survival is >85% for Grade I, 60-90% for Grade II, and 35-65% for Grade III
- depends on extent of resection
- Simpson's classification: degree of surgical resection completeness with symptomatic recurrence

**Table 12. Simpson Grade of Meningioma Resection**

Grade	Criteria
I	Macroscopically complete removal of tumour, with excision of its dural attachment and of any abnormal bone
II	Macroscopically complete removal of tumour, with coagulation of its dural attachment
III	Macroscopically complete removal of tumour without resection or coagulation of dural attachment or extradural extensions
IV	Partial removal of tumour
V	Simple decompression with or without biopsy

Progressive unilateral or asymmetrical sensorineural hearing loss = vestibular schwannoma until proven otherwise

## Vestibular Schwannoma (Acoustic Neuroma)

- slow-growing (60% show no growth over 1 yr; average rate for growing tumours 1-2 mm/yr), benign posterior fossa tumour (8-10% of tumours)
- arises from vestibular nerve of CN VIII in internal auditory canal, expanding into bony canal and CPA
- if bilateral, diagnostic of NF2
- epidemiology: 1.5 in 100000; all age groups affected, peaks at 4th-6th decades

### Clinical Features

- early clinical triad: (tumour <2 cm) unilateral progressive hearing loss 98%, tinnitus, and disequilibrium (compression of CN VIII)
- later clinical features
  - tumour usually >2 cm: otalgia, facial numbness + weakness, changes to taste (due to CN V and VII compression, respectively)
  - tumour usually >4 cm: ataxia, H/A, N/V, diplopia, cerebellar signs (due to brainstem compression; ± obstructive hydrocephalus)

### Investigations

- MRI with gadolinium or T2 fast imaging employing steady-state acquisition (FIESTA) sequence (>98% sensitive/specific); CT with contrast 2nd choice
- audiogram, brainstem auditory evoked potentials, caloric tests

### Treatment

- expectant: serial imaging (CT/MRI q6 mo) and audiometry if tumour is small, hearing is still preserved, high perioperative risk, or elderly patient
- radiation: SRS
- surgery: if lesion >3 cm, brainstem compression, edema, hydrocephalus
- curable if complete resection (almost always possible)
- operative complications: CSF leak, meningitis, required shunt; CN V, VII, VIII dysfunction (proportional to tumour size; only significant CN VIII disability if bilateral)
- implications for testing of family members of NF2 mutation carrier

**Figure 13. Vestibular schwannoma (tumour in CPA)**

## Pituitary Adenoma

- primarily from anterior pituitary, 3rd-4th decades, M=F, associated with multiple endocrine neoplasia type 1 (MEN-1) syndrome
- incidence in autopsy studies approximately 20%
- classification
  - microadenoma <1 cm; macroadenoma ≥1 cm
  - endocrine active (functional/secretory) vs. inactive (non-functional)
  - most common functional: prolactinomas, adrenocorticotropic, GH-producing
  - differential diagnosis: parasellar tumours (e.g. craniopharyngioma, tuberculum sellae meningioma), carotid aneurysm

### Clinical Features

- mass effects
- H/A
- bitemporal hemianopia (compression of optic chiasm); hydrocephalus (3rd ventricle compression)
- invasive adenomas: CN III, IV, V1, V2, VI palsy (cavernous sinus compression); proptosis and chemosis (cavernous sinus occlusion)

Go Look For The Adenoma Please – GH, LH, FSH, TSH, ACTH, Prolactin  
A compressive adenoma in the pituitary will impair hormone production in this order (i.e. GH-secreting cells are most sensitive to compression)

- endocrine effects (see [Endocrinology](#), E22)
  - hyperprolactinemia (prolactinoma): infertility, amenorrhea, galactorrhea, decreased libido
  - ACTH production: Cushing's disease, hyperpigmentation
  - GH production: acromegaly/gigantism
  - panhypopituitarism: due to compression of pituitary (hypothyroidism, hypoadrenalism, hypogonadism)
  - DI – rare, except in apoplexy
- pituitary apoplexy (sudden expansion of mass due to hemorrhage or necrosis)
  - abrupt onset H/A, visual disturbances, ophthalmoplegia, reduced mental status, panhypopituitarism and DI
  - CSF rhinorrhea and seizures (rare)
  - signs and symptoms of SAH (rare)

### Investigations

- formal visual fields, CN testing
- endocrine tests (prolactin level, TSH, 8 AM cortisol, fasting glucose, FSH/LH, insulin-like growth factor I (IGF-1)), electrolytes, urine electrolytes, and osmolality
- imaging (MRI with and without contrast)

### Treatment

- medical
  - for apoplexy: rapid corticosteroid administration ± surgical decompression
  - for prolactinoma: dopamine agonists (e.g. bromocriptine)
  - for Cushing's: serotonin antagonist (cyproheptadine), inhibition of cortisol production (ketoconazole)
  - for acromegaly: somatostatin analogue (octreotide) ± bromocriptine
  - endocrine replacement therapy
- surgical
  - endoscopic endonasal trans-sphenoidal, and less commonly trans-cranial approaches (i.e. for significant suprasellar extension)
- postoperative concerns: DI, adrenal insufficiency (AI), CSF leak
  - DI and AI: AM cortisol, serum sodium and osmolality, urine output and specific gravity (treatment - AI: glucocorticoids; DI: desmopressin/DDAVP™)
  - CSF rhinorrhea: test for β-transferrin

### Genetic Associations

- sellar masses have known associations with several classic oncogene mutations, including:
  - MEN1: loss-of-function mutations are common
  - GNSA1: activating mutations found in ~40% of somatotroph adenomas
  - AIP: mutations associated with familial pituitary adenomas

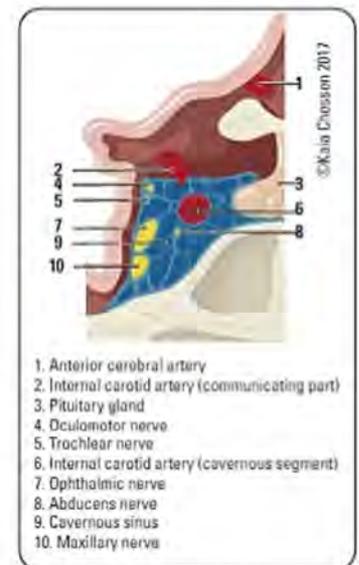

Figure 14. Cavernous sinus

## Cerebral Abscess

### Definition

- pus in brain substance, surrounded by tissue reaction (capsule formation)

### Etiology

- modes of spread: 10-60% of patients have no identifiable cause
- pathogens
  - *Streptococcus* (most common), often anaerobic or microaerophilic
  - *Staphylococcus* (penetrating injury)
  - Gram-negatives, anaerobes (*Bacteroides*, *Fusobacterium*)
  - in neonates: *Proteus* and *Citrobacter* (exclusively)
  - immunocompromised: *Toxoplasma*, *Nocardia*, *Candida albicans*, *Listeria monocytogenes*, *Mycobacterium*, and *Aspergillus*

### Sources of Pus/Infection

- four routes of microbial access to CNS
  1. hematogenous spread: arterial and retrograde venous
    - adults: chest is most common source (lung abscess, bronchiectasis, empyema)
    - children: congenital cyanotic heart disease with R-to-L shunt
    - immunosuppression (AIDS toxoplasmosis)
  2. direct implantation (dural disruption)
    - trauma
    - iatrogenic (e.g. following LP, postoperative)
    - congenital defect (e.g. dermal sinus)
  3. contiguous spread (adjacent infection): from air sinus, naso/oropharynx, surgical site (e.g. otitis media, mastoiditis, sinusitis, osteomyelitis, dental abscess)
  4. spread from peripheral nervous system (PNS) (e.g. viruses: rabies, herpes zoster)

- common examples
  - epidural abscess: in cranial and spinal epidural space, associated with osteomyelitis
    - treatment: immediate drainage and antibiotics, surgical emergency if cord compression
  - subdural empyema: bacterial/fungal infection, due to contiguous spread from bone or air sinus, progresses rapidly
    - treatment: surgical drainage and antibiotics, 20% mortality
  - meningitis, encephalitis (see [Infectious Diseases, ID17](#))
  - cerebral abscess

**Risk Factors**

- lung abnormalities (infection, AVFs; especially Osler-Weber-Rendu syndrome/hereditary hemorrhagic telangiectasia)
- congenital coronary heart disease: R-to-L shunt bypasses pulmonary filtration of microorganisms
- bacterial endocarditis
- penetrating head trauma
- immunosuppression (e.g. AIDS)
- dental abscess, poor dentition

**Clinical Features**

- focal neurological signs and symptoms
  - H/A, decreased LOC
- mass effect, increased ICP and sequelae (cranial enlargement in children)
- hemiparesis and seizures in 50% of cases
- ± signs and symptoms of systemic infection (low-grade fever, leukocytosis)

**Complications**

- with abscess rupture: ventriculitis, meningitis, venous sinus thrombosis
- CSF obstruction
- transtentorial herniation

**Investigations**

- CT scan often first test in emergency department
- MRI
  - imaging of choice
  - restriction on diffusion imaging (also seen in lymphoma)
  - apparent diffusion coefficient (ADC) used to differentiate abscess (black) from tumour (white)
